Motivated forgetting is the active process of forgetting memories that are unpleasant, painful, or generally threatening to the self-image that individuals strive to maintain (Tajfel and Turner, 1986; Thompson et al., 1997). Research in cognitive psychology demonstrates that people can intentionally down-prioritize unwanted memories from entering consciousness via control processes. For instance, studies using the think-no-think paradigm (Anderson and Green, 2001; Anderson and Levy, 2009) demonstrate that individuals are capable of intentionally forgetting memories for words that were previously encoded. The think-no-think paradigm begins by requiring students to first learn a list of cue-target pairs (e.g., Ordeal-Roach). After this initial learning phase, individuals are presented with a previously studied cue (i.e., Ordeal) and are instructed to either remember the associated target word (i.e., Think of Roach) or to suppress the associated target word (i.e., No-think; Roach). During a memory test at the end, individuals are again presented with the same cues and asked to try their best to recall the correct target memory words. These studies consistently reveal that individuals have more difficulty recalling words that they were previously instructed to suppress relative to words they were instructed to remember. Additionally, individuals are also worse at recalling suppressed words relative to baseline words which were previously studied but were not paired with either “remember” or “suppress” instructions.

THREAT BASED MODEL OF MOTIVATED FORGETTING

The cognitive literature on intentional forgetting provides compelling evidence that forgetting previously encoded information is possible, yet it has not provided an account for why individuals engage in intentional forgetting outside of the laboratory. Recent social psychological investigations have advanced the motivated forgetting literature by developing a framework to predict the social and intrapersonal circumstances that elicit motivated forgetting.

A growing body of research draws on threat-based theories to argue that motivated forgetting arises as a possible coping mechanism to defend against memories that threaten the integrity of the self (Tajfel and Turner, 1986; Aronson et al., 1999; Sherman and Cohen, 2006). Threat-based theories begin with the premise that people are motivated to see themselves in an overly positive light and will fundamentally alter their behaviors, attention, and even memory processes to maintain this positive internal representation (Greenwald, 1980; Taylor and Brown, 1994).

MOTIVATED FORGETTING AND ACADEMIC BREAK PERIODS

A recent study examined the consequences of motivated forgetting within the context of education, where students are generally motivated to remember. Ramirez et al. (2017) asked whether we can draw on the basic premises underlying the research on psychological threat and motivated

forgetting to predict the circumstances under which students forget course content once the class is over. To test this, students enrolled in a multivariable calculus course were asked to report their math self-perceptions and course relevant stress. At the end of the quarter, students completed their final exam per usual which served as a baseline measure of acquired knowledge. The authors measured how much content students forgot by asking them to re-take some items from their final exam 2 weeks into the summer break.

CURRENT STUDY

To summarize, memory research suggests that people are capable of intentional forgetting. Threat-based theories identify self-perceptions and experiences that threaten self-perceptions as key ingredients in creating a defensive memory reaction that leads to a motivation to forget. Recent neuro investigations of threat suggests that brain activity during rest periods is associated with activation in areas involved in defensive memory adaptations. The aim of the current proof-of-concept study is to address whether children at risk for motivated forgetting may be forgetting important course relevant content during academic break periods.

LIMITATIONS

The current study holds several limitations which warrant attention. For instance, the data collection timeline makes it difficult to make a strong case that the winter break period was responsible for allowing students to engage in motivated forgetting; all of the students in the study underwent a winter break period. Future research should examine achievement immediately prior to and after the winter break period using assessments that measure what children are learning in their specific class. The reliability for my measure of math self-perceptions could have been higher if children had been presented with more items, as well. The correlational research design also did not allow me to manipulate extensive rest periods or identity threat, which could have provided causal evidence for the account I put forth. Lastly, I was also not able to assess perceived threat, intention to forget, or suppression-avoidance processes, which limited my ability to provide greater evidence for the mechanism of motivated forgetting.

IMPLICATIONS AND FUTURE DIRECTIONS

The work reported here extends research on motivated forgetting to an educational context where students typically exert a great deal of effort to avoid forgetting. This work also makes a novel contribution by providing evidence that even young children are capable of experiencing threat-based motivated forgetting. If motivated forgetting is indeed a factor reducing children's accessibility of memories for important course content, then ensuring that children begin and leave the classroom with a restored sense of self (Walton, 2014) could be quite useful in reducing motivated forgetting.

CONCLUSION

Taken together, the promising findings of this proof-of-concept study suggests that children may deal with threatening classroom experiences by forgetting important course relevant knowledge. Although there has been a recent interest in using a motivated forgetting framework to understand defensive adaptations in the social psychology literature (Shu et al., 2011; Dalton and Huang, 2014; Kouchaki and Gino, 2016), the work reported here and elsewhere (Ramirez et al., 2017) is the first to extend research on motivated forgetting to the classroom. These findings lead to a novel conception of the defensive adaptations that students engage in when they are "at rest" from schooling.

MULTIPLE CHOICE QUESTION

1. When an object is moved farther away, we tend to see it as more or less invariant in size. This is due to:

- a) Shape Constancy
- b) Colour Constancy
- c) Size Constancy
- d) Brightness Constancy
- e) None of the above

Answer: C

2. Reversible goblet is a favoured demonstration of:

- a) A figure-ground reversal
- b) A focus-margin reversal
- c) A shape-size reversal
- d) A size-contour reversal
- e) None of the above

Answer: A

3. A simpler form of stroboscopic motion is :

- a) Psychokinesis
- b) Autokinetic Effect
- c) Phi-Phenomenon
- d) Illusion
- e) Hallucination

Answer: C

4. Empiricists (Barkeley, Locke) maintained that we learn our ways of perceiving through :

- a) Eyes
- b) Motivation
- c) Experience
- d) Learning
- e) None of the above

Answer: C

5. William James characterised the perception of an infant as a :

- a) Blooming buzzing confusion
- b) Haphazard Stimulation of nerve cells
- c) Stimulation of nerve cells in the eyes
- d) Stimulation of rods and cones
- e) None of the above

Answer: A

6. Behaviourists have:

- (a)** No theory of learning
- (b)** No theory of thinking
- (c)** No theory of memory
- (d)** No theory of perception
- (e)** None of the above

Answer: D

7. The process by which the eyes get prepared to see very dim light is known as:

- a)** Light Adaptation
- b)** Dark Adaptation
- c)** Brightness Adaptation
- d)** Colour Adaptation
- e)** None of the above

Answer: B

8. The partially colour blind people are known as:

- a)** Blind
- b)** Colour-blind
- c)** Achromats
- d)** Dichromats
- e)** None of the above

Answer: D

9. Totally colour blind people are otherwise known as :

- a)** Colour-blind
- b)** Achromats
- c)** Monochromats
- d)** Dichromats
- e)** None of the above

Answer: C

10. The phenomenon of shifting from one picture to another is known as :

- a)** Retina Rivalry
- b)** Eyes Rivalry
- c)** Attention Rivalry
- d)** Perception Rivalry
- e)** None of the above

Answer: A

11. When the lens cannot bulge out to the extent necessary due to muscular defects, the individual suffers from:

- a)** Double Vision
- b)** Astigmatism
- c)** Myopia
- d)** Farsightedness

e) None of the above

Answer: D

12. Due to the irregularities in the formation of the lens or the cornea, the object viewed will be partly clear and partly blurred. This occurs when the individual suffers from:

a) Astigmatism

b) Colour-blindness

c) Distraction

d) Retinal Disparity

e) None of the above

Answer: A

13. The length of car number has reference to:

a) Shifting of Attention

b) Distraction

c) Span of Attention

d) Focus and Margin

e) Focus of Consciousness

Answer: C

14. Sensations of movement from inside our bodies are called:

(a) Proprioception

(b) Perception

(c) Interoception

(d) Sensation

(e) Attention

Answer: A

15. Sensation increases by a constant amount each time the stimulus is doubled. This is called:

(a) Lewin-Zeigamik Effect

(b) Lewin-Prentice Effect

(c) Mallinoswki Law

(d) Webber-Fechner Law

(e) None of the above

Answer: D

16. The experiments which tell us about the relationship between the intensity of stimulus and the consequent changes in the intensity of sensation are included in :

a) Psychoanalysis

b) Gestalt Psychology

c) Parapsychology

d) Psychophysics

e) None of the above

Answer: D

17. The study on the Zulu tribes of Africa revealed that the Zulu individuals would be less susceptible to the:

- a) Figure-Ground Phenomenon
- b) Zollner Illusion
- c) Ponzo illusion
- d) Muller-Lyer Illusion
- e) None of the above

Answer: D

18. A complete change of vitreous humour occurs approximately once in:

- a) Every four hours
- b) Every three hours
- c) Every two hours
- d) Every one hour
- e) None of the above

Answer: A

19. The theory of colour perception which seems to be the most acceptable one today is called the:

- a) Retinex Theory
- b) Perspective Theory
- c) Confusion Theory
- d) Young-Helmholtz Theory
- e) None of the above

Answer: A

20. Who developed the 'Retinex Theory' of colour perception?

- a) Thomas Young
- b) Hermann Von Helmholtz
- c) Edward Herring
- d) Edwin Land
- e) None of the above

Answer: D

21. Who received Nobel Prize for his research on the mechanisms of the cochlea?

- a) Snyder
- b) Pronko
- c) VonBekesy
- d) Stratton
- e) Turnbull

Answer: C

22. The condition of night-blindness is a consequence of:

- (a) Rhodopsin deficiency in rods

- (b)** Defective rods
- (c)** Defective Cones
- (d)** Defective Retina
- (e)** None of the above

Answer: A

23. As compared with cones, rods appear to be more sensitive to:

- a)** Longer Wavelengths
- b)** Any wavelengths
- c)** Both shorter and longer wavelengths
- d)** Shorter wavelengths
- e)** None of the above

Answer: D

24. The alteration in the comparative sensitivity of the retinal apparatus which accompanies change in the level of light energy is known as:

- a)** Purkinje Effect
- b)** Dark Adaptation
- c)** Scotopic Vision
- d)** Visual Acuity
- e)** None of the above

Answer: A

25. An increase in sensitivity of retina owing to absence of stimulation in darkness is known as:

- a)** Dark Adaptation
- b)** Scotopic Vision
- c)** Visual Acuity
- d)** Photopic Vision
- e)** None of the above

Answer: A

26. The decrease in sensitivity of the eye which occurs on account of its stronger stimulation is known as:

- a)** Light Adaptation
- b)** Photopic Vision
- c)** Scotopic Vision
- d)** Visual Acuity
- e)** None of the above

Answer: A

27. In cone adaptation experiment, test field is strictly limited to the:

- (a)** Cone-free fovea
- (b)** Cornea
- (c)** Retina

- (d)** Rod-free fovea
- (e)** None of the above

Answer: D

28. Reaction to powerful light, primarily by cones, is called:

- a)** Photopic Vision
- b)** Scotopic Vision
- c)** Colourless Vision
- d)** Visual Acuity
- e)** None of the above

Answer: A

29. Visual reaction of the dark adapted eye to very feeble light is called :

- a)** Photopic Vision
- b)** Scotopic vision
- c)** Visual Acuity
- d)** Colourless Vision
- e)** None of the above

Answer: B

30. Visual angle varies inversely with:

- a)** Acuity
- b)** Light
- c)** Brightness
- d)** Length of cones
- e)** Length of rods

Answer: A

31. Ability to discriminate fine differences in visual detail or visual sharpness is otherwise known as:

- a)** Photopic Vision
- b)** Scotopic Vision
- c)** Visual Acuity
- d)** Colourless Vision
- e)** None of the above

Answer: C

32. Intensity multiplied by its duration brings about a constant perceptual effect. Let "I" stands for light intensity and "T" for time or duration, then $I \times T = C$, where "C" is constant perceptual effectiveness. This above principle is called:

- a)** Roscoe-Bunsen Law
- b)** Hess and Polt Law
- c)** Evans Principle
- d)** Landis Principle

e) None of the above

Answer: A

33. Cases of yellow-blue colourblindness are:

a) Maximum

b) Exceedingly Rare

c) Mostly found in children

d) Mostly found in women

e) Mostly found in men

Answer: B

34. "Interest is latent attention and attention is interest in action." This statement deals with the:

a) Objective determinants of attention

b) Span of attention

c) Subjective determinants of attention

d) Shifting of attention

e) None of the above

Answer: C

35. "It is not a different process; it is just attention to irrelevant stimuli that are not a part of the main assigned task." Then what is it?

a) Distraction

b) Shifting of Attention

c) Span of attention

d) Involuntary Attention

e) Voluntary Attention

Answer: A

36. Simultaneous focussing on two separate activities is otherwise known as:

a) Span of attention

b) Shifting of attention

c) Division of attention

d) Distraction

e) None of the above

Answer: C

37. When familiar large objects look smaller than they are known to be, they are regarded as being at a distance. This is an instance of what is called:

(a) Visual Acuity

(b) Monocular Parallax

(c) Linear Perspective

(d) Scotopic Vision

(e) Pliotopic Vision

Answer: C

38. Movement Parallax is a monocular cue of distance or depth and for this reason it is also called:

- a)** Visual Acuity
- b)** Monocular parallax
- c)** Linear Perspective
- d)** Scotopic vision
- e)** Photopic Vision

Answer: B

39. Certain alterations in the colour of objects occur depending upon their relative distances from the observer. For this reason, distant hills look blue on account of the light rays travelling through haze. This illustrates:

- (a)** Linear Perspective
- (b)** Monocular Parallax
- (c)** Aerial Perspective
- (d)** Visual Acuity
- (e)** Scotopic Vision

Answer: C

40. A set of depth cues of the nature of some sort of arrangement of proportional rise and fall in compactness of designs which is related to perspectives is called:

- (a)** Rods
- (b)** Cones
- (c)** Gradients
- (d)** Perspectives
- (e)** None of the above

Answer: C

41. The apparent displacement of an object resulting from an actual change of observer's position is known as:

- (a)** Parallax
- (b)** Acuity
- (c)** Scotopic Vision
- (d)** Photopic Vision
- (e)** None of the above

Answer: A

42. The phenomenon of "induced movement" occurs when there is some real movement which is attributed to:

- (a)** A right object
- (b)** A real object
- (c)** A wrong object
- (d)** A substitute object
- (e)** None of the above

Answer: C

43. “It has been said that beauty is in the eye of the beholder” – With what factors of perception this statement deals?

- (a) Objective Factors
- (b) Figure and Ground
- (c) Phi-phenomenon
- (d) Functional Factors
- (e) None of the above

Answer: D

44. According to Woodworth (1938), the first systematic experiment that attempted to measure the span of apprehension was carried out by:

- (a) Jevons
- (b) Paulham
- (c) Jastrow
- (d) Cairnes
- (e) Hersey

Answer: A

45. The first experiment to measure span of attention (apprehension) was designed by:

- (a) Coren and Porac in 1979
- (b) Coren and Girgus in 1978
- (c) Jevons in 1871
- (d) Watkins in 1973
- (e) None of the above

Answer: C

46. Who was/were the Subject (S) in Jevon’s first experiment on span of apprehension?

- (a) Boys from different SES
- (b) Girls from different SES
- (c) A friend of Jevons
- (d) Jevons himself
- (e) The wife of Jevons

Answer: D

47. The first person to document the existence of the sensory register and to explore its properties was:

- (a) George Sperling (1960)
- (b) Paulham (1887)
- (c) Cairnes (1891)
- (d) Hersey (1936)
- (e) O’comer (1958)

Answer: A

48. From his experiments of sensory register, Sperling suggested that there is some visual trace available to the Subject that prolongs the life of the image. He calls this visual trace as the:

- (a) Sensory Information Centre
- (b) Perceptual Information Centre
- (c) Attending Information Centre
- (d) Apprehension Information Centre
- (e) None of the above

Answer: A

49. In 1976, Neisser introduced a term for "Sensory Information Store." That term is called as:

- (a) Focus
- (b) Margin
- (c) Prepotency
- (d) Icon
- (e) Extensity

Answer: D

50. When tachistoscope exposures are short and there is no post exposure masking field, we can be fairly sure that the Subject is actually reading the stimulus:

- (a) From the icon rather than from the visual image itself
- (b) From the image
- (c) From the short-term memory storage
- (d) From the long-term memory storage
- (e) None of the above

Answer: A

51. A basis on which one stream of information can be segregated and attended to while others can be ignored is known as:

- (a) Basilar Membrane
- (b) Cochlea
- (c) Tympanic Membrane
- (d) Channel
- (e) Eustachian tube

Answer: D

52. The most important school of psychology which has contributed a lot toward perception is:

- (a) Psychoanalysis
- (b) Behaviouristic School
- (c) Structuralistic School
- (d) Gestalt Psychology
- (e) Functionalistic School

Answer: D

53. Autokinetic movement does not occur if there is a fixed:

- (a) Frame of Reference
- (b) Illusion
- (c) Vision
- (d) Distance between stimulus and the eye
- (e) None of the above

Answer: A

54. A stimulus is any change in external energy that activates:

- (a) An effector organ
- (b) A sense organ and its receptors
- (c) A cell
- (d) A neuron
- (e) Any cell of the sense organs

Answer: B

55. Hue, saturation and brightness are the conventional terms which are used to characterise the attributes of:

- (a) Brightness
- (b) Colours
- (c) Light
- (d) Darkness
- (e) None of the above

Answer: B

56. Vision in the ordinary ranges of daylight from fairly faint twilight up to the brightest blaze of the sun is called:

- (a) Photopic Vision
- (b) Scotopic Vision
- (c) Autokinetic Effect
- (d) Phi-phenomenon
- (e) Illusion

Answer: A

57. The important part of the inner ear for hearing is the snail-shaped:

- (a) Cochlea
- (b) Round Window
- (c) Oval Window
- (d) Semicircular Canals
- (e) Auditory Nerve

Answer: A

58. The most primitive and oldest feature of music is:

- (a) Harmony
- (b) Melody

- (c) Rhythm
- (d) Song
- (e) None of the above

Answer: C

59. Phi-phenomenon is a form of:

- (a) Stroboscopic Motion
- (b) Photopic Vision
- (c) Scotopic Vision
- (d) Autokinetic Effect
- (e) Illusion

Answer: A

60. Which one of the following is not a principle of Organization of Perception?

- (a) The Law of Proximity
- (b) The Law of Similarity
- (c) The Law of Pragnaz
- (d) The Law of Contrast
- (e) None of the above

Answer: D

61. Alcohol is/an:

- (a) Stimulant
- (b) Sensory Stimulus
- (c) Effective Stimulus
- (d) Depressant
- (e) None of the above

Answer: D

62. The name given to the cone pigments is:

- (a) Idopsin
- (b) Bipolar Cells
- (c) Ganglian Cells
- (d) Rhodopsin
- (e) None of the above

Answer: A

63. Ishihara test is meant for testing:

- (a) Visual Experience
- (b) Principal complementary Colour
- (c) Wavelengths
- (d) Colour-blindness
- (e) None of the above

Answer: D

64. Young-Helmholtz theory of colour vision can otherwise be called:

- (a)** Trichromatic Theory
- (b)** Opponent Process Theory
- (c)** Ladd-Franklin Theory
- (d)** Scientific Validity Theory
- (e)** None of the above

Answer: A

65. A continuous small tremor of the eyes is known as:

- (a)** Rod-Cone breaks
- (b)** Purkinje Effect
- (c)** Physiological Nystagmus
- (d)** Acuity
- (e)** None of the above

Answer: C

66. The eye is sensitive to wavelengths of light that range from about:

- (a)** 380 to about 760 nm
- (b)** 300 to about 500 nm
- (c)** 200 to about 300 nm
- (d)** 160 to about 200 nm
- (e)** None of the above

Answer: A

67. Different wavelengths produce the experience of different:

- (a)** Colours
- (b)** Brightness
- (c)** Hues
- (d)** Lights
- (e)** None of the above

Answer: C

68. The Scottish Philosopher Thomas Reid (1710- 1796) has first developed the distinction between:

- (a)** Sensation and Attention
- (b)** Attention and Perception
- (c)** Audition and Vision
- (d)** Sensation and Perception
- (e)** Vision and Recurrent Inhibition

Answer: D

69. Helmholtz's theory of space perception centred around the concept of:

- (a) Unconscious inference
- (b) Conscious inference
- (c) Recurrent Inhibition
- (d) Mechanism of Vision
- (e) The Static sense

Answer: A

70. Rudolf Lotze (1817-1881) assumed that mind is inherently capable of:

- (a) Perceiving Space
- (b) Perceiving Size
- (c) Perceiving Depth
- (d) Perceiving Colour
- (e) Perceiving Brightness

Answer: A

71. Helmholtz's treatment of perception is the extension of:

- (a) Hering's opponent-process theory
- (b) Ladd-Franklin Theory
- (c) Lotze's local-sign theory
- (d) Recurrent inhibition theory
- (e) None of the above

Answer: C

72. Who defined apperception as the awareness of any conscious content that is clearly comprehended or grasped?

- (a) Ratliff
- (b) E. B. Titchener
- (c) J.B. Watson
- (d) Wilhelm Wundt
- (e) Kurt Lewin

Answer: D

73. Harvey Carr defined perception as the cognition of a present object in relation to:

- (a) Recurrent Inhibition
- (b) Some acts of adjustment
- (c) Some acts of stimulation
- (d) Simultaneous Contrast
- (e) None of the above

Answer: B

74. Gestalt Psychology looks upon the world as:

- (a) Psychophysical
- (b) Psychological
- (c) Physical

(d) Neuro-physiological

(e) Neurological

Answer: A

75. Which principle states that because Gestalten are isomorphic to stimulus patterns, they may undergo extensive changes without losing their identities?

(a) Simultaneous Contrast

(b) Recurrent Inhibition

(c) Transposition

(d) Phi-phenomenon

(e) Autokinetic Effect

Answer: C

76. "Memory is a dynamic process in which traces undergo progressive changes according to some principles of organization that govern original perception." This definition of memory was given by:

(a) Behaviourists

(b) Structuralists

(c) Functionalists

(d) Gestalt Psychologists

(e) Psychoanalysts

Answer: D

77. Who defined 'perception' as the process of maintaining contact with the world?

(a) Helmholtz

(b) Lorrin A. Riggs

(c) Herring

(d) Gibson

(e) None of the above

Answer: D

78. When the sense organs are oriented towards the environment and are actively seeking information, we call it—

(a) Obtained Perception

(b) Illusion

(c) Hallucination

(d) Attention

(e) Distraction

Answer: A

79. The perception which arises from the skin, nose, ears, eyes or other organs is called:

(a) Obtained Perception

(b) Illusion

(c) Hallucination

- (d) Imposed Perception
- (e) None of the above

Answer: D

80. The distinction between "Obtained and Imposed Perception" was brought out by:

- (a) Helmholtz
- (b) Herring
- (c) Franklin
- (d) Gibson
- (e) Riggs

Answer: D

81. The gestalt concept of equilibrium is expressed by the law of:

- (a) Similarity
- (b) Proximity
- (c) Continuity
- (d) Pragnaz
- (e) Good Figure

Answer: D

82. In 1915; Edgar Rubin introduced the idea of:

- (a) Figure and Ground
- (b) Phi-phenomenon
- (c) Physiological Nystagmus
- (d) Illusion
- (e) Hallucination

Answer: A

83. The 'Law of Closure' reflects the idea of striving for:

- (a) Good figure
- (b) Continuity
- (c) Completion
- (d) Good Contour
- (e) None of the above

Answer: C

84. Which law of organization in perception has become a principle of temporal contiguity in the learning theory?

- (a) The Law of Similarity
- (b) The Law of Pragnaz
- (c) The Law of Proximity
- (d) The Law of Good Figure
- (e) None of the above

Answer: C

85. The contrast between a dynamic field and a machine was brought out by:

- (a) Kurt Koffka
- (b) Wertheimer
- (c) Kurt Lewin
- (d) W. G. Kohler
- (e) Helmholtz

Answer: D

86. The Gestalt Psychologists learned their "Principles of Organization" from the study of:

- (a) Perception
- (b) Sensory Experience
- (c) Attention
- (d) Consciousness
- (e) Insightful Learning

Answer: B

87. Reinforcing factors in perceptual organization are analogous to the:

- (a) Reinforcement of a conditioned response
- (b) The Law of Effect
- (c) Both (a) and (b)
- (d) The Law of Exercise
- (e) None of the above

Answer: C

88. Wavelength is obtained by dividing the speed of the light by the:

- (a) Frequency
- (b) Brightness
- (c) Illumination
- (d) Colour
- (e) None of the above

Answer: A

89. For constancy to operate in the world of normal objects, the more distant features must be:

- (a) Perceptually expanded
- (b) Clearly Visualised
- (c) Projected in sufficient light
- (d) Clearly Spaced
- (e) None of the above

Answer: A

90. Outline or boundary of an object is called:

- (a) Contour
- (b) Figure

- (c) Ground
- (d) Brightness
- (e) None of the above

Answer: A

91. Prolongation or renewal of sensory experience after the stimulus has ceased to affect the sense organ is called:

- a) After image
- b) Illusion
- c) Hallucination
- d) Autokinetic Effect
- e) Stroboscopic Motion

Answer: A

92. A famous study on perception which has shown that the poor children overestimated the size of coins to a greater degree than wealthy children, was done by:

- (a) Bruner and Goodman
- (b) Osgood
- (c) DeBono
- (d) Murray
- (e) McGinnis

Answer: A

93. Camouflage is the deliberate confusion of:

- (a) Illusion and Hallucination
- (b) Stroboscopic Motion
- (c) Figure and Ground
- (d) Autokinetic Effect
- (e) Phi-phenomenon

Answer: C

94. The protective colouration of many animals is an example of:

- (a) Figure and Ground
- (b) Camouflage
- (c) Reversible Figures
- (d) Phi-phenomenon
- (e) Autokinetic Effect

Answer: B

95. Sense Organs in the muscles, tendons and joints tell us about the position of our limbs and the state of tension in the muscles. They serve the sense called:

- (a) Kinesthesia
- (b) Transduction
- (c) Vision
- (d) Auditory Sense

(e) None of the above

Answer: A

96. The process of converting physical energy into nervous system activity is called:

(a) Transmission

(b) Nerve Impulse

(c) Inhibition

(d) Transduction

(e) None of the above

Answer: D

97. Receptor cells convert physical energy into an electric voltage or potential called:

(a) Receptor Potential

(b) Generator Potential

(c) Vestibular Sense

(d) Spike Potential

(e) None of the above

Answer: A

98. Whether it is the receptor potential itself or some other voltage, the electrical event that triggers nerve impulses is known as the:

(a) Spike Potential

(b) Generator Potential

(c) Receptor Potential

(d) Nerve Impulse

(e) None of the above

Answer: B

99. The entire range of wavelengths is called the:

(a) Electromagnetic Spectrum

(b) Visible Spectrum

(c) Photosensitive Area

(d) Blind Spot

(e) None of the above

Answer: A

100. The tendency to perceive a line that starts in one way as continuing in the same way is called the principle of:

(a) Proximity

(b) Similarity

(c) Closure

(d) Continuation

(e) None of the above

Answer: D

101. The idea that we may be 'ready' and 'primed for' certain kinds of sensory input is known as:

- (a) Set
- (b) Cognitive Style
- (c) Sensory System
- (d) Mood
- (e) None of the above

Answer: A

102. The spatial-frequency theory maintains that form vision depends on the firing pattern of brain cells that respond to variations in the rates of change in brightness from:

- (a) One part of a visual scene to another
- (b) Temporal lobe to Frontal lobe
- (c) One part of the brain to another
- (d) Spinal cord to brain
- (e) None of the above

Answer: A

103. The receptors for taste are specialized cells grouped together in little clusters known as:

- (a) Tongue
- (b) Taste Buds
- (c) Taste Nerves
- (d) Sweet Glands
- (e) None of the above

Answer: B

104. The audible range for human beings is from about:

- (a) 20 hertz to about 20,000 hertz
- (b) 200 hertz to about 2000 hertz
- (c) 400 hertz to about 4000 hertz
- (d) 300 hertz to about 3000 hertz
- (e) 600 hertz to about 6000 hertz

Answer: A

105. On a dark night, we may hear the footsteps of a thief outside the house, whereas in reality, a cat may be passing by. This is an example of:

- (a) Hallucination
- (b) Illusion
- (c) Linear perspective
- (d) Law of Pragnaz
- (e) None of the above

Answer: B

106. In a study on the Zulu tribes of Africa, the Experimenters reasoned that the Zulu individuals

would be less susceptible to the Muller- Lyer illusion than the European people in Africa. This illustration states that:

- (a) Perception of illusions depends on the culture of the perceiver
- (b) Perception of illusion depends on the Socio-economic Status
- (c) Perception of illusions depends on the educational qualification of the individuals
- (d) Perception of illusion depends on the colour of the individuals
- (e) None of the above

Answer: A

107. Sometimes it is very difficult to find an empty seat in a dark cinema hall. We bump against people and sometimes try to sit on them after entering to the dark hall in a sunny afternoon. After a brief span of time, we may adapt to darkness and see. This is an example of:

- (a) Dark Adaptation
- (b) Perceptual Constancy
- (c) Depth Perception
- (d) Brightness Constancy
- (e) Colour Constancy

Answer: A

108. One psychologist has developed a theory of colour vision as well as a theory of hearing. Who is he?

- (a) Von Bekesy
- (b) Helmholtz
- (c) Hubel
- (d) Wiesel
- (e) N.R. Carlson

Answer: B

109. From the following, who won the Nobel Prize for his research on the mechanisms of the cochlea?

- (a) Helmholtz
- (b) Von Bekesy
- (c) E. Gardner
- (d) Schiffman
- (e) Leiman

Answer: B

110. When your friend is at a distance, certainly he looks smaller than when he is standing close to you. But you do not think that really he is smaller or shorter. The size of familiar objects does not change with distance. As your friend comes closer to you from a distance, you do not think that he is getting larger and larger. This is an illustration of:

- (a) Size Constancy
- (b) Object Constancy
- (c) Height Constancy

- (d) Depth Constancy
- (e) Binocular Vision

Answer: A

111. The mechanism of reflex action is called:

- (a) Reflexology
- (b) Reflex Path
- (c) Reflex Arc
- (d) Reflexon
- (e) None of the above

Answer: C

112. Figure-ground relationship was first established by:

- (a) Gestalt Psychologists
- (b) Behaviourists
- (c) Structuralists
- (d) Functionalists
- (e) None of the above

Answer: A

113. Closure is a basic principle of:

- (a) Perceptual defence
- (b) Perceptual Organization
- (c) Depth Perception
- (d) Phi-phenomenon
- (e) None of the above

Answer: B

114. Personal factors in perception are otherwise known as:

- (a) Functional factors in perception
- (b) Motivational factors in perception
- (c) Social factors in perception
- (d) Cultural factors in perception
- (e) None of the above

Answer: A

115. The gap between Cornea and lens is filled with:

- (a) Amino Acid
- (b) Vitreous Humour
- (c) Unknown Fluid
- (d) Aqueous Humour
- (e) None of the above

Answer: D

116. The image of an object falling on the blind spot of the eye :

- (a) Will be visible
- (b) Will not be visible
- (c) Automatically vanishes
- (d) Is not clear
- (e) None of the above

Answer: B

117. The gap between cornea and lens is known as:

- (a) Posterior Chamber
- (b) Anterior Chamber
- (c) Inner Chamber
- (d) Secular Chamber
- (e) None of the above

Answer: B

118. The innermost layer of the eye is called:

- (a) Cornea
- (b) Retina
- (c) Blind Spot
- (d) Fovea
- (e) None of the above

Answer: B

119. The point at which the optic nerve gets out of the retina is called the:

- (a) Light Spot
- (b) Fovea
- (c) Blind Spot
- (d) Yellow Spot
- (e) None of the above

Answer: C

120. A person who has no cones at the fovea:

- (a) Is a colour blind
- (b) Is very often a colour blind
- (c) Is not able to see yellow colour at all
- (d) Is deprived of black and white vision
- (e) None of the above

Answer: A

121. Perception without sensory stimulus is called:

- (a) Illusion
- (b) Phi-phenomenon
- (c) Hallucination

- (d) Perceptual Defence
- (e) Perceptual Constancy

Answer: C

122. As the eyes become adapted to dark at one particular point, red colours begin to darken and the green and blues become brighter. This change is known as:

- (a) Duplicity theory of Colour Vision
- (b) Herring's theory of Colour Vision
- (c) Purkinje Effect
- (d) Perceptual Constancy
- (e) None of the above

Answer: C

123. The classic example of perceiving a coil of rope in darkness as a snake depicts about:

- (a) Hallucination
- (b) Illusion
- (c) Phi-phenomenon
- (d) Autokinetic Effect
- (e) Perceptual Constancy

Answer: B

124. Meaningful sensation is otherwise known as:

- (a) Attention
- (b) Sensation
- (c) Emotion
- (d) Perception
- (e) None of the above

Answer: D

125. Size judgement is based on:

- (a) Retinal Image
- (b) Clarity of Object
- (c) Object Size
- (d) Distance Information
- (e) None of the above

Answer: D

126. "Perceived Size" approaches "physical size" when:

- (a) Depth and Distance Cues are available
- (b) Object is small
- (c) Information is Minimum
- (d) Object is Old
- (e) None of the above

Answer: A

127. Which one of the following happens to be an important factor in selectivity of attention?

- (a) Attitude
- (b) Interest
- (c) Boredom
- (d) Concentration
- (e) None of the above

Answer: B

128. An incorrect interpretation of the stimulus input is called:

- (a) Illusion
- (b) Hallucination
- (c) Sensation
- (d) Perception
- (e) Attention

Answer: A

129. Each receptor requires some minimum level of energy to excite it. That minimum energy is called:

- (a) Minimum Threshold
- (b) Absolute Threshold
- (c) Boundary Threshold
- (d) Contour Threshold
- (e) None of the above

Answer: B

130. A general principle of perception of form is the law of Prägnanz which was termed by:

- (a) Behaviourists
- (b) Structuralists
- (c) Functionalists
- (d) Gestalt Psychologists
- (e) None of the above

Answer: D

131. Which one of the following is a stimulus variable in the determination of attending?

- (a) Interest
- (b) Attitude
- (c) Size
- (d) Aptitude
- (e) None of the above

Answer: C

132. The perception of the whiteness of the snow even though the night is dark can be explained on the basis of:

- (a) Purkinje Effect
- (b) Dark Adaptation
- (c) Brightness Constancy
- (d) Perceptual Defence
- (e) None of the above

Answer: C

133. Perception of "Figure and Ground" results from:

- (a) Experience
- (b) Sensation Pattern
- (c) Trial and Error
- (d) The structure of Nervous System
- (e) None of the above

Answer: B

134. An one-eyed person would lose precision in the perception of:

- (a) Height
- (b) Weight
- (c) Colour
- (d) Depth
- (e) None of the above

Answer: D

135. The perceptual principle of 'proximity' states that:

- (a) When stimuli are close together they tend to be grouped
- (b) The nearer an object is, the more likely it is to be perceived
- (c) The closer a stimulus is, the more likely it is to be attended
- (d) Stimuli coming from equal distance are perceived as part of the same figure
- (e) None of the above

Answer: A

136. Even though parallel, the rails appear to be meeting at a distance. This is a bright illustration of:

- (a) Linear Perspective
- (b) Distance Perception
- (c) Visual Illusion
- (d) Aerial perspective
- (e) None of the above

Answer: C

137. In a normal waking state, if an individual gets certain sensation with particular stimulus which is not available to others, this person is said to have:

- (a) An illusion
- (b) A phi-phenomenon

- (c) A sensation
- (d) A hallucination
- (e) None of the above

Answer: D

138. Figure and Ground perception results from:

- (a) Attention Pattern
- (b) Sensation pattern
- (c) Perception Pattern
- (d) Emotional pattern
- (e) None of the above

Answer: B

139. Perception is a:

- (a) Psychological Process
- (b) Physiological Process
- (c) Physical Process
- (d) Psycho-physiological Process
- (e) None of the above

Answer: D

140. We perceive a square as a square in whatever position it is held, this constancy in perception relates to:

- (a) Size
- (b) Depth
- (c) Shape
- (d) Height
- (e) Weight

Answer: C

141. Illusion is the:

- (a) False perception
- (b) Right perception
- (c) Wrong perception
- (d) Delayed Perception
- (e) None of the above

Answer: C

142. Hallucinations occur to individuals suffering from:

- (a) Hysteria
- (b) Epilepsy
- (c) Peptic Ulcer
- (d) Schizophrenia
- (e) Asthma

Answer: D

143. A normal individual may experience hallucinations after taking drugs like:

- (a) Heroin
- (b) Morphine
- (c) Seconel
- (d) Pethidine
- (e) None of the above

Answer: A

144. The tendency to see the immobility of objects when they move about is called:

- (a) Location Constancy
- (b) Size Constancy
- (c) Shape Constancy
- (d) Depth Constancy
- (e) None of the above

Answer: A

145. A contour is the boundary between:

- (a) A figure and its ground
- (b) A figure and another figure's ground
- (c) Two similar figures
- (d) Two dissimilar figures
- (e) None of the above

Answer: A

146. An object that has been constituted perceptually as a permanent and stable thing continues to be perceived as such, regardless of illumination, position, distance etc. This kind of stability of the environment experienced by human beings is termed as:

- (a) Depth Constancy
- (b) Perceptual Constancy
- (c) Size Constancy
- (d) Shape constancy
- (e) None of the above

Answer: B

147. Whenever an object appears to maintain its shape despite marked changes in the retinal image, it is known as:

- (a) Size Constancy
- (b) Depth Constancy
- (c) Shape Constancy
- (d) Height Constancy
- (e) None of the above

Answer: C

148. A red ball looks red in broad daylight as well as in dark night. This is due to:

- (a) Light Constancy
- (b) Brightness Constancy
- (c) Size Constancy
- (d) Colour Constancy
- (e) None of the above

Answer: A

149. Soldiers dressed in colours of uniform that merge with the background is called:

- (a) Colour Matching
- (b) Colour Constancy
- (c) Brightness Constancy
- (d) Camouflage
- (e) None of the above

Answer: D

150. When there is a deliberate confusion of figure and ground and it is difficult to organise form and distinguish objects from one another, it is called:

- (a) Camouflage
- (b) Phi-phenomenon
- (c) Colour Constancy
- (d) Brightness Constancy
- (e) None of the above

Answer: A

151. Which principle/law of organization in perception states that there is a tendency to organize stimuli to make a balanced or symmetrical figure that includes all parts?

- (a) Law of Similarity
- (b) Law of Symmetry
- (c) Law of Proximity
- (d) Law of Closure
- (e) Law of Prägnanz

Answer: B

152. Stimuli that make the fewest interruptions in contour also tend to be grouped together. The tendency to organize the fragmentary stimuli into a familiar pattern is called the principle of:

- (a) Similarity
- (b) Proximity
- (c) Closure
- (d) Continuation
- (e) Prägnanz

Answer: D

153. "Why do things look the way they do"? – This question was asked by the Gestalt Psychologist:

- (a) W. G. Kohler
- (b) M. Wertheimer
- (c) Kurt Lewin
- (d) K. Koffka
- (e) None of the above

Answer: D

154. An illusion is not a trick or misperception. It is a/an:

- (a) Attention
- (b) Sensation
- (c) Perception
- (d) Emotion
- (e) Motive

Answer: C

155. "The whole (perception) is more than the sum of its parts (Sensory inputs)". This statement was given by:

- (a) Behaviourists
- (b) Gestalt Psychologists
- (c) Functionalists
- (d) Psychoanalysts
- (e) Structuralists

Answer: B

156. The events, we perceive clearly, are at the:

- (a) Margin
- (b) Centre
- (c) Side
- (d) Focus
- (e) None of the above

Answer: D

157. Attention is the term given to the processes that select certain inputs for inclusion in the focus of:

- (a) Sensation
- (b) Consciousness
- (c) Unconsciousness
- (d) Experience
- (e) None of the above

Answer: B

158. The most fundamental process in form perception is the recognition of:

- (a) A figure on a ground
- (b) A picture without background

- (c) A figure without ground
- (d) The contour of a figure
- (e) None of the above

Answer: A

159. Which principle of perceptual organization makes our perceived world of form more complete than the sensory stimulation that is presented?

- (a) The Law of Pragnaz
- (b) The Law of Closure
- (c) The Law of Similarity
- (d) The Law of Proximity
- (e) The Law of Continuity

Answer: B

160. The device which is used in perceptual experiments for the very brief presentation of stimuli is known as:

- (a) Psycho galvanometer
- (b) Tachistoscope
- (c) Aesthesiometer
- (d) Electroencephalograph
- (e) Polygraph

Answer: B

161. Coal looks black even in very bright sunlight, while snow continues to look white even at night. This is due to:

- (a) Colour Constancy
- (b) Size Constancy
- (c) Shape Constancy
- (d) Constancy of Brightness
- (e) Colour Reflection

Answer: D

162. Monocular Cues are those which can operate when:

- (a) Two eyes are looking
- (b) Both eyes are invalid
- (c) Only one eye is looking
- (d) Only one eye is invalid
- (e) None of the above

Answer: C

163. A gradient is a continuous change:

- (a) Without abrupt transitions
- (b) With abrupt transitions
- (c) With highest stimulating agent

(d) With lowest stimulating agent

(e) None of the above

Answer: A

164. Retinal disparity is the difference in the images falling on:

(a) The retinas of the two eyes

(b) The foveas of the two eyes

(c) The blind spots of the two eyes

(d) The corneas of the two eyes

(e) None of the above

Answer: A

165. Who conducted a pioneering experiment to show that "Value" has a considerable effect on perception?

(a) Bruner and Goodman

(b) Osgood

(c) Dember

(d) Carter

(e) Postman

Answer: A

166. Which one of the following is a term given to the processes that select certain inputs for inclusion in the focus of experience?

(a) Sensation

(b) Emotion

(c) Affection

(d) Attention

(e) Conation

Answer: D

167. Which are the well known examples of the transformations and elaborations of sensory input that occur in the process of perceiving the world?

(a) Hallucinations

(b) Sensations

(c) Illusions

(d) Conation

(e) Attention

Answer: C

168. Who has first pointed out that the 'Whole' is more than the sum total of its parts?

(a) Kohler

(b) Wertheimer

(c) Kurt Lewin

(d) Kurt Koffka

(e) Otto Rank

Answer: D

169. Which one of the following is formed whenever a marked difference occurs in the brightness or colour of the background?

(a) Sizes

(b) Shapes

(c) Contours

(d) Sets

(e) None of the above

Answer: C

170. Perceived motion also occurs without any energy movement across the receptor surface. This type of motion is called:

(a) Constant Motion

(b) Retinal Disparity

(c) Real motion

(d) Apparent Motion

(e) None of the above

Answer: D

171. Which one of the following is an increase in the activity to extract information from the environment as a result of experience or practice with the stimulation coming from it?

(a) Convergence

(b) Divergence

(c) Perceptual Learning

(d) Plasticity of Perception

(e) None of the above

Answer: C

172. The ability to read other people's thoughts is called

(a) Precognition

(b) Telepathy

(c) Psychokinesis

(d) Clairvoyance

(e) None of the above

Answer: B

173. "We perceive things as we are". This statement emphasises upon:

(a) Functional Factors in Perception

(b) Objective Patterns in Perception

(c) Organizational factors in perception

(d) Voluntary Attention

(e) Involuntary Attention

Answer: A

174. The fact that the moon looks larger near the horizon than high in the sky is called the:

- (a) Muller-Lyer Illusion
- (b) Jastrow Illusion
- (c) Ponzo illusion
- (d) Moon Illusion
- (e) Height-Width Illusion

Answer: D

175. One of the causes of the mental set is:

- (a) Mood
- (b) Emotion
- (c) Sensation
- (d) Habit
- (e) Span

Answer: D

176. The old saying "Seeing is believing" does not hold good in case of:

- (a) Hallucination
- (b) Illusion
- (c) Affection
- (d) Conation
- (e) Stimulation

Answer: B

177. The stimulus is explicit in:

- (a) Hallucination
- (b) Illusion
- (c) Affection
- (d) Conation
- (e) Stimulation

Answer: B

178. In illusion, the stimulation is usually external, while the stimulations in hallucinations are:

- (a) In the person himself
- (b) In the stimulus itself
- (c) Both in stimulus and perceiver
- (d) In the external world
- (e) None of the above

Answer: A

179. Muller-Lyer illusion is:

- (a) Also a hallucination Jastrow illusion
- (b) An individual illusion
- (c) Otherwise called as
- (d) An optical illusion
- (e) None of the above

Answer: D

180. We are able to separate forms from the general ground in our visual perception only because we can perceive:

- (a) Size
- (b) Shape
- (c) Side
- (d) Contours
- (e) Colours

Answer: D

181. The thought perception without any known means of communication is known as:

- (a) Preognition
- (b) Psychokinesis (PK)
- (c) Clairvoyance
- (d) Telepathy
- (e) None of the above

Answer: D

182. The perception of future events or happenings through dreams or hallucinations is known as:

- (a) Psychokinesis (PK)
- (b) Clairvoyance
- (c) Precognition
- (d) Telepathy
- (e) None of the above

Answer: C

183. Attention divides our perceived world into:

- (a) Focus and Margin
- (b) Margin and Centre
- (c) Nucleus and Focus
- (d) Focus and centre
- (e) None of the above

Answer: A

184. The tendency to see the colour of a familiar object as the same, regardless of the actual light conditions is called:

- (a) Colour Constancy
- (b) Brightness Constancy

- (c) Light Constancy
- (d) Dark Constancy
- (e) None of the above

Answer: A

185. By comparing experimental outcomes, which model provides more accurate predictions?

- (a) Averaging Model
- (b) Additive Model
- (c) Self-attribution Model
- (d) Personal-attribution Model
- (e) None of the above

Answer: A

186. Experimental evidences suggest that people use a weighted averaging model to combine:

- (a) Type information
- (b) Attribute information
- (c) Non-common Effects
- (d) Trait information
- (e) None of the above

Answer: D

187. The way in which individuals focus on specific traits to form an overall impression of others is known as:

- (a) Social perception
- (b) Perceptual organization
- (c) Person Perception
- (d) Phi-phenomenon
- (e) Perceptual Constancy

Answer: C

188. Averaging models suggest that the mean of the information is:

- (a) Most appropriate
- (b) Not most appropriate
- (c) Predictable
- (d) Unpredictable
- (e) None of the above

Answer: A

189. "Schemas" are organized bodies of information stored in:

- (a) Perceptual Field
- (b) Cognitive Field
- (c) Emotion field
- (d) Memory
- (e) Sensation

Answer: D

190. In case of personality traits, we organize information into schemas called:

- (a) Common Effects
- (b) Non-common Effects
- (c) Prototypes
- (d) Somatotypes
- (e) Stereotypes

Answer: C

191. Prototypes are schemas that organize a group of personality traits into a/an:

- (a) Meaningful Personality Type
- (b) Meaningless Personality Type
- (c) Emotional Trauma
- (d) Avoidance conflicting situation
- (e) None of the above

Answer: A

192. The personality types that we derive in the case of person perception are organized into schemas known as:

- (a) Prototypes
- (b) Stereotypes
- (c) Somatotypes
- (d) Phi-phenomenon
- (e) None of the above

Answer: A

193. Nancy Cantor and Walter Mischel suggest a frequently held prototype concerns a person labelled on a general level as:

- (a) "Permitted"
- (b) "Submitted"
- (c) "Dedicated"
- (d) "Committed"
- (e) None of the above

Answer: D

194. At what level, the prototype consists of different types of committed individuals like monks, nuns and activists?

- (a) Personal Level
- (b) Environmental Level
- (c) Subordinate Level
- (d) Secondary Level
- (e) Primary Level

Answer: C

195. Information processing capabilities are enhanced through the use of:

- (a) Stereotypes
- (b) Prototypes
- (c) Prejudices
- (d) Attitudes
- (e) None of the above

Answer: B

196. With any schema, prototypes help us to organize:

- (a) The social world around us
- (b) The psychological world around us
- (c) The psychophysical world around us
- (d) The physical world around us
- (e) None of the above

Answer: A

197. Covariation principle suggests that we try to analyse the relationships among a multitude of possible cause-and-effect variables inherent in a situation:

- (a) To pin point a cause of behaviour
- (b) To find out the cause of perceptual errors
- (c) To find out cause of sensation errors
- (d) To find out the cause of social perception
- (e) None of the above

Answer: A

198. The Covariation Principle" states that the cause that will be chosen to explain an effect a cause that is present when the effect is also absent. This principle was introduced by:

- (a) T. D. Wilson
- (b) Keith Davis
- (c) Harold Kelley
- (d) E.E. Jones
- (e) I.J. Stone

Answer: C

199. Consensus is the degree to which other people react similarly in the:

- (a) Same situation
- (b) Different situation
- (c) Different emotional setup
- (d) Different sensational setup
- (e) None of the above

Answer: A

200. Consistency refers to the degree to which the actor behaves the same way in :

- (a) Different situations

- (b) Similar situations
- (c) Both similar and dissimilar situations
- (d) Other situations
- (e) None of the above

Answer: D

201. "A goal refers to some substance, objects or environmental condition capable of reducing or temporarily eliminating the complex of internal conditions which initiated action." This definition of "goal" was given by:

- (a) Janis & Mann (1977)
- (b) Ruch (1970)
- (c) Solomon and Corbit (1974)
- (d) Neal Miller (1959)
- (e) None of the above

Answer: B

202. Cannon called the concept of internal equilibrium and function as:

- (a) Imprinting
- (b) Instinct
- (c) Homeostasis
- (d) Substitute Behaviour
- (e) None of the above

Answer: C

203. The expectations or goal that one sets to achieve in future keeping in view his past performance is called:

- (a) Valence
- (b) Vector
- (c) Vigilance
- (d) Level of Aspiration
- (e) None of the above

Answer: D

204. "The need for achievement" was first defined largely on the basis of clinical studies done by:

- (a) Murray (1938)
- (b) Janis and Mann (1977)
- (c) Solomon (1974)
- (d) Corbit (1974)
- (e) None of the above

Answer: A

205. The achievement motivation theory of McClelland is explained in terms of:

- (a) "Affective Arousal model of motivation"
- (b) Action Specific energy

- (c) Innate Releasing Mechanism
- (d) Displacement Behaviour
- (e) Opponent Process Theory

Answer: A

206. Intrinsic Motivational Theory was propounded by:

- (a) Mc Clelland
- (b) Maslow
- (c) Harry Harlow
- (d) Solomon
- (e) Corbit

Answer: C

207. Psychoanalytic theory of motivation was developed by:

- (a) Sigmund Freud
- (b) Maslow
- (c) Harry Harlow
- (d) McClelland
- (e) None of the above

Answer: A

208. The goals which the person tries to escape are called:

- (a) Positive goals
- (b) Vectors
- (c) Valences
- (d) Negative goals
- (e) None of the above

Answer: D

209. A person's need for feeling competent and self-determining in dealing with his environment is called:

- (a) Intrinsic Motivation
- (b) Instinct
- (c) Imprinting
- (d) Coolidge Effect
- (e) None of the above

Answer: A

210. When the motive is directed towards goals external to the person such as money or grade, it is called:

- (a) Extrinsic Motivation
- (b) Intrinsic Motivation
- (c) Imprinting
- (d) Instinct

(e) None of the above

Answer: A

211. Steers and Porter (1975) in their text entitled "Motivation and work behaviour" identified:

- (a)** Two major components of motivation
- (b)** Four major components of motivation
- (c)** Five major components of motivation
- (d)** Three major components of motivation
- (e)** None of the above

Answer: D

212. The conditions which influence the arousal, direction and maintenance of behaviours relevant in work settings are called:

- (a)** Work Motivation
- (b)** Drive stimuli
- (c)** Substitute behaviour
- (d)** Consummatory behaviour
- (e)** None of the above

Answer: A

213. Intrinsic motivation as currently conceived is championed by:

- (a)** Janis (1977)
- (b)** Solomon (1974)
- (c)** Deci (1975)
- (d)** Mann (1977)
- (e)** Corbit (1974)

Answer: C

214. Most of the research on intrinsic motivation has concentrated on the interaction between:

- (a)** Intrinsic and extrinsic rewards
- (b)** Instinct and imprinting
- (c)** Action specific energy and balance sheet grid
- (d)** Substitute behaviour and consummatory behaviour
- (e)** None of the above

Answer: A

215. An individual's affective orientation towards particular outcomes is called the:

- (a)** Vector of the outcome
- (b)** Approach gradient of the outcome
- (c)** Valence of the outcome
- (d)** Avoidance gradient of the outcome
- (e)** None of the above

Answer: C

216. Dipboye (1977) distinguished between the strong and weak version of:

- (a) Achievement theory
- (b) Two-factor theory
- (c) Valence theory
- (d) Consistency theory
- (e) None of the above

Answer: D

217. Motives are:

- (a) Internal sources of behaviour
- (b) External sources of behaviour
- (c) Natural sources of behaviour
- (d) Both subjective and objective sources of behaviour
- (e) None of the above

Answer: A

218. Motives move a person from:

- (a) Within
- (b) Outside
- (c) Beginning
- (d) Birth
- (e) Death

Answer: A

219. Literally, motivation means the process of inducing:

- (a) Movement
- (b) Excitement
- (c) Tension
- (d) Conflict
- (e) None of the above

Answer: A

220. Motivation is defined as a state of the organism in which bodily energy is mobilised and selectively directed towards parts of the:

- (a) Stimulus
- (b) Response
- (c) World
- (d) Environment
- (e) None of the above

Answer: D

221. "Mobilisation of bodily energy" is otherwise known as:

- (a) Drive
- (b) Need

- (c) Motive
- (d) Incentive
- (e) None of the above

Answer: A

222. The selected part of environment refers to the end results of behaviour sequence which are known as:

- (a) Aims
- (b) Objectives
- (c) Goals
- (d) Destinations
- (e) None of the above

Answer: C

223. Goal refers to:

- (a) Directional aspects of behaviour
- (b) End result of instrumental behaviour
- (c) Destination after conscious activities
- (d) Occasional halts
- (e) None of the above

Answer: A

224. When a motive is aroused and the organism is driven to a goal, a condition is produced within the organism called:

- (a) Conflict
- (b) Tension
- (c) Anxiety
- (d) Jealousy
- (e) None of the above

Answer: B

225. The tension increases when the goal is:

- (a) Free
- (b) Easy to achieve
- (c) Obstructed
- (d) Static
- (e) None of the above

Answer: C

226. Those internal mechanisms of the body which, by controlling numerous highly complicated physiological processes, keep it in a state of equilibrium are known as:

- (a) Homeostases
- (b) Nervous System
- (c) Nutrition

(d) None of the above

Answer: A

227. Homeostasis is the overall term for equilibrium preserving tendencies with an organism by which:

(a) Neurophysiological condition is maintained

(b) Psychological condition is maintained

(c) Physiological condition is maintained

(d) Psychophysical condition is maintained

(e) None of the above

Answer: A

228. Curiosity comes under:

(a) Social Motives

(b) Personal motives

(c) Non-homeostatic motives

(d) Both (b) and (c)

(e) None of the above

Answer: B

229. Sex is a:

(a) Biological motive

(b) Physiological motive

(c) Both (a) and (b)

(d) Psychological motive

(e) None of the above

Answer: C

230. Maslow's idea about the structure of needs is known as:

(a) Self-actualisation theory of motivation

(b) Physiological theory of motivation

(c) Psychological theory of motivation

(d) Psychophysical theory of motivation

(e) None of the above

Answer: A

231. "Intrinsic motivation theory" was developed by:

(a) Halow (1950)

(b) Sigmund Freud (1902)

(c) Mark and Ervin (1970)

(d) Dollard (1939)

(e) Bandura (1973)

Answer: A

232. A person who is motivated displays:

- (a) Unconscious Behaviour
- (b) Conscious Behaviour
- (c) Hapazard Behaviour
- (d) Goal-directed Behaviour
- (e) Erratic Behaviour

Answer: D

233. The process of maintaining the biochemical balance or equilibrium throughout human body is referred as:

- (a) Osmosis
- (b) Circulation
- (c) Homeostasis
- (d) Nervous System
- (e) Diffusion

Answer: C

234. Which one of the following is not a psychological motive?

- (a) Need for achievement
- (b) Need for affection
- (c) Need for belonging
- (d) Need for Oxygen
- (e) None of the above

Answer: D

235. 'The competition of two or more contradictory impulses, usually accompanied by emotional tension is called a/an:

- (a) Conflict
- (b) Anxiety
- (c) Neurosis
- (d) Psychosis
- (e) Phobia

Answer: A

236. An object or thing which directs or stimulates behaviour:

- (a) Instinct
- (b) Incentive
- (c) Need
- (d) Motive
- (e) Drive

Answer: B

237. A pituitary hormone associated with the secretion of milk is known as:

- (a) Prolactin
- (b) Adrenalin

- (c) Estrogens
- (d) Progesterones
- (e) Insulin

Answer: A

238. A motive that is primarily learned rather than based on biological needs is known as:

- (a) Physical Motive
- (b) Psychological Motive
- (c) Neurophysiological Motive
- (d) Psychological Motive
- (e) None of these

Answer: D

239. During 1950s, psychologists began to be disenchanted with the drive reduction theory of motivation as an explanation of:

- (a) All types of behaviour
- (b) Only certain types of physiological behaviour
- (c) Only certain types of psychological behaviour
- (d) Both physiological and psychological behaviour
- (e) Social behaviour

Answer: A

240. The hypothalamus plays an important role in the regulation of:

- (a) Food intake
- (b) Water intake
- (c) Alcohol intake
- (d) Both food and water intake
- (e) None of the above

Answer: A

241. Lateral hypothalamus (LH) is otherwise known as:

- (a) Stimulating centre
- (b) Circulatory Centre
- (c) Feeding Centre
- (d) Water centre
- (e) None of the above

Answer: C

242. Research evidence indicated that ventromedial hypothalamus (VMH):

- (a) Facilitates eating
- (b) Expedites eating
- (c) Both facilitates and
- (d) Inhibits eating expedites eating
- (e) None of the above

Answer: D

243. Electrical stimulation of ventromedial hypothalamus (VMH) cells:

- (a) Inhibits eating
- (b) Facilitates eating
- (c) Expedites eating
- (d) Both expedites and inhibits eating
- (e) None of the above

Answer: A

244. Injections of glucose (which raise blood sugar level):

- (a) Facilitate eating
- (b) Expedite eating
- (c) Both expedite and facilitate eating
- (d) Inhibit eating
- (e) None of the above

Answer: D

245. Injections of insulin (which lower blood sugar level):

- (a) Increase food intake
- (b) Decrease food intake
- (c) Expedite food intake
- (d) Facilitate food intake
- (e) None of the above

Answer: A

246. Studies indicated that the hypothalamus contains cells (glucoreceptors) sensitive to the rate of which:

- (a) Glucose passes through them
- (b) Glucose stimulates them
- (c) Glucose inhibits them
- (d) Glucose both stimulates and inhibits them
- (e) None of the above

Answer: A

247. An empty stomach produces the periodic contractions of muscles in the stomach wall which we identify as:

- (a) Stomach ache
- (b) Stomach pain
- (c) Stomach ailment
- (d) Hunger Pangs
- (e) None of these

Answer: D

248. Obesity is thought to stem from disturbances during the:

- (a) Phallic stage of psychosexual development
- (b) Oral and Anal stages of psychosexual development
- (c) Genital stage of psychosexual development
- (d) Latency period of psychosexual development
- (e) None of these

Answer: B

249. Dehydration of the osmoreceptors can be produced by depriving the organism of:

- (a) Food
- (b) Water
- (c) Blood
- (d) Sugar
- (e) Alcohol

Answer: B

250. Water deficit in the body increases the concentration of:

- (a) Potassium
- (b) Insulin
- (c) Sugar
- (d) Sodium
- (e) Glucose

Answer: D

251. Realistic anxiety is otherwise known as:

- (a) Objective anxiety
- (b) Subjective anxiety
- (c) Psychic anxiety
- (d) Ego defenses

Answer: A

252. In "moral anxiety", ego's dependence upon:

- (a) Superego is found
- (b) Id is found
- (c) Sex is found
- (d) Unconscious is found

Answer: A

253. Neurotic anxiety is one in which there occurs emotional response to a threat to ego that the impulses may break through into:

- (a) Consciousness
- (b) Unconsciousness
- (c) Subconsciousness
- (d) Super ego

Answer: A

254. Sometimes the superego gives threats to punish the ego. This causes an emotional response called:

- (a) Moral Anxiety
- (b) Realistic Anxiety
- (c) Objective Anxiety
- (d) Neurotic Anxiety

Answer: A

255. Always we want to protect ego from the ensuring anxiety. For doing this, ego adopts some strategies which are called:

- (a) Defense mechanisms
- (b) Sex energy
- (c) Instincts
- (d) Dreams

Answer: A

256. Defense mechanisms help the person in protecting ego from open expression of id impulses and opposing:

- (a) Superego directives
- (b) Death Instinct
- (c) Lie Instinct
- (d) Unconscious mind

Answer: A

257. Defense mechanisms operate at unconscious level. They occur without awareness of the individual. Hence they are:

- (a) Self-explanatory
- (b) Self-deceptive
- (c) Self-expressive
- (d) Self-dependant

Answer: B

258. A child scolded by his father may hit his younger siblings. This is an example of:

- (a) Displacement
- (b) Rationalization
- (c) Regression
- (d) Repression

Answer: A

259. "A young woman after fighting with her husband returned to her parent's home only to allow her parents to "baby" her and fulfil her every wish like that of a child". This is an illustration of:

- (a) Repression
- (b) Regression
- (c) Fixation
- (d) Reaction Formation

Answer: B

260. The last stage of psychosexual development is:

- (a) Phallic Stage
- (b) Genital Stage
- (c) Oral Stage
- (d) Anal Stage

Answer: B

261. Sigmund Freud has regarded the first three stages of psychosexual development i.e., the period of 5 or 6 years of life, to be decisive for the formation of:

- (a) Intelligence
- (b) Personality
- (c) Emotion
- (d) Ego

Answer: B

262. In the book "Group Psychology and the Analysis of the Ego", Freud has explained the formation of:

- (a) Personality
- (b) Group
- (c) Society
- (d) Gang

Answer: B

263. Freud had published a book "Totem and Taboo" in 1913. By publishing this book, he has shown his concern for:

- (a) Social Psychology
- (b) Abnormal Psychology
- (c) Industrial Psychology
- (d) Child Psychology

Answer: A

264. Who viewed, "A person is born with sex, lives in sex and finally dies in sex" ?

- (a) J. Herbart
- (b) Sigmund Freud
- (c) Alfred Adler
- (d) C.G. Jung

Answer: B

265. Who said that after birth, the child has a strong frustrating experience?

- (a) Sigmund Freud (1917)
- (b) Otto Rank (1929)
- (c) Alfred Adler (1920)
- (d) C.G. Jung (1919)

Answer: B

266. "Penis envy" is found in girls in:

- (a) Oral Stage
- (b) Anal Stage
- (c) Genital Stage
- (d) Phallic Stage

Answer: D

267. Homosexuality is a derivative of:

- (a) Electra Complex
- (b) Oedipus Complex
- (c) Libido
- (d) Death Instinct

Answer: B

268. The Oral, Anal and Phallic stages of Psychosexual Development are called:

- (a) Preenatal Period
- (b) Sexual Genesis
- (c) Life Instinct
- (d) Latency Period

Answer: A

269. The genital stage is generally characterized by object choices rather than by:

- (a) Libido
- (b) Narcissism
- (c) Personality
- (d) Superego

Answer: B

270. In Anal Stage of Psychosexual Development, pleasure is derived from:

- (a) Thinking
- (b) Libido
- (c) Emotion
- (d) Expulsion and Retention

Answer: D

271. The "Super ego" is the equivalent of what is more commonly known as the:

- (a) Conscience

- (b)** Personality
- (c)** Libido
- (d)** Narcissism

Answer: A

272. The psychoanalysis performed in a controlled setting is known as:

- (a)** Psychotherapy
- (b)** Chemotherapy
- (c)** Hypoanalysis
- (d)** Hyperanalysis

Answer: C

273. A state of deep unconsciousness, with non-responsiveness to stimulation, is known as:

- (a)** Coma
- (b)** Fixation
- (c)** Hypnotism
- (d)** Trauma

Answer: A

274. In 1895, Freud and Breuer published a book entitled:

- (a)** Studies in Hysteria
- (b)** Interpretation of Dreams
- (c)** Moses and Menotheism
- (d)** Psychopathology of Everyday Life

Answer: A

275. Studies of Freud and Breuer reported successful treatment of hysterical symptoms by a method called:

- (a)** Hypnosis
- (b)** Free Association
- (c)** Catharsis
- (d)** Dream Analysis

Answer: C

276. The success of the cathartic method was regarded by Freud as evidence of the:

- (a)** Unconscious
- (b)** Conscious
- (c)** Subconscious
- (d)** Libido

Answer: A

277. From the experiences in hypnotism and catharsis, Freud's theory of:

- (a)** Unconscious was derived
- (b)** Conscious was derived

- (c) Narcissism was derived
- (d) Dream was derived

Answer: A

278. Dreams represent demands or wishes stemming from the:

- (a) Unconscious
- (b) Conscious
- (c) Preconscious
- (d) Death Instinct

Answer: A

279. In a special book, Freud analyzed the psychology of error and found the source of errors in the conflict between:

- (a) Ego and Super ego
- (b) Unconscious wish and conscious censorship
- (c) Conscious wish and unconscious censorship
- (d) Ego and Preconscious

Answer: B

280. The parts of the body that are capable of reacting to sexual stimuli are called:

- (a) Erogenic Zones
- (b) Abnormal Zones
- (c) Sensitive Zones
- (d) Secular Zones

Answer: A

281. The main erogenic zone of our body is:

- (a) Mouth
- (b) Genitals
- (c) Anal Zones
- (d) Lips

Answer: B

282. According to Freud, the entire activity of men is bent upon procuring pleasure and avoiding pain. This activity is controlled by:

- (a) Reality Principle
- (b) Pleasure Principle
- (c) Primary Narcissism
- (d) Secondary Narcissism

Answer: B

283. The urethral development stage is an introductory period to the:

- (a) Oral Stage
- (b) Phallic Stage

- (c) Genital Stage
- (d) Latency Stage

Answer: B

284. The very term “Phallic” is derived from “Phallos”, which means:

- (a) Penis in erection
- (b) Sexual urge
- (c) Ego-conflict
- (d) Self-Love

Answer: A

285. Urethral eroticism is mainly:

- (a) Autoerotic
- (b) Conscious
- (c) Unconscious
- (d) Egocentric

Answer: A

286. According to Freud, the negative Oedipus complex may lead to:

- (a) Heterosexuality
- (b) Homosexuality
- (c) Narcissism
- (d) Castration

Answer: B

287. The idea of developmental stages was borrowed by Freud from:

- (a) Biology
- (b) Sociology
- (c) Anthropology
- (d) Physics

Answer: A

288. The diversion of a part of the sexual energy into non-sexual activities is called:

- (a) Repression
- (b) Regression
- (c) Rationalization
- (d) Sublimation

Answer: D

289. The term “defense mechanism” was introduced by:

- (a) Freud in 1894
- (b) Jung in 1902
- (c) Alfred Adler in 1905
- (d) Sullivan in 1935

Answer: A

290. Moving away from the reality is called the mechanism of:

- (a) Withdrawal
- (b) Denial
- (c) Daydream
- (d) Introjection

Answer: B

291. The stimulation of a muscle fibre by a motor neuron occurs at the

- (a) myofibril
- (b) transverse tubules
- (c) neuromuscular junction
- (d) sarcoplasmic reticulum

Answer: (c)

292. An injury sustained by the hypothalamus is most likely to interrupt

- (a) coordination during locomotion
- (b) short term memory
- (c) regulation of body temperature
- (d) executive function like decisionmaking

Answer: (c)

293. In humans, the Alzheimer disease is linked with the deficiency of

- (a) acetylcholine
- (b) dopamine
- (c) glutamic acid
- (d) Gamma Amino Butyric Acid (GABA)

Answer: (a)

294. What is the person with these symptoms suffering from? Outbursts of emotions, unpredictable moods, quarrelsome behaviour, conflicts with others

- (a) Mood disorders
- (b) Addictive disorders
- (c) Schizophrenia
- (d) Borderline personality disorder (BPD)

Answer: (d)

295. Even after the brain of a frog has been crushed, it still responds to a pinch on the leg by drawing it away. This act is an example of

- (a) Conditioned reflex
- (b) Simple reflex
- (c) Automated motor response
- (d) Neurotransmitter induced response

Answer: (b)

296. Which of these functions will be affected if the medulla oblongata is damaged?

- (a) Vision
- (b) Thermoregulation
- (c) Memory
- (d) Tactile sensation – response when pricked with a needle

Answer: (d)

297. This part of the human brain is also known as the emotional brain

- (a) Epithalamus
- (b) Limbic system
- (c) Broca's area
- (d) Corpus callosum

Answer: (b)

298. This is the outermost cranial appendage

- (a) Dura mater
- (b) Pia mater
- (c) Skull
- (d) Arachnoid

Answer: (a)

299. This cranial meninges is in close proximity of the brain tissue

- (a) Dura mater
- (b) Pia mater
- (c) Arachnoid
- (d) Skull tissue

Answer: (b)

300. This statement is not associated with midbrain

- a) the ventral portion of the midbrain is composed of mainly four, round swellings known as corpora quadrigemina
- b) located between thalamus of the forebrain and pons of the hindbrain
- c) the canal called cerebral aqueduct passes through the midbrain
- d) hindbrain and midbrain constitute the brain stem

Answer: (a)

301. This hormone is produced under condition of stress which stimulates glycogenolysis in the liver of human beings

- (a) Insulin
- (b) Thyroxin
- (c) Estradiol
- (d) Adrenaline

Answer: (d)

302. Fight or flight reactions cause the activation of
(a) the parathyroid glands, leading to increased metabolic rate
(b) adrenal medulla leading to increased secretion of epinephrine and norepinephrine
(c) pancreas leading to a reduction in the blood sugar levels
(d) the kidney, causing suppression of the renin-angiotensin-aldosterone pathway
Answer: (b)

303. After trying for several years, a couple finally learnt that they are going to have a baby. They are experiencing this type of stress
(a) Strain
(b) Anxiety
(c) Distress
(d) Eustress
Answer: (d)

304. This part of the autonomic nervous system provides the body with energy for the fight-or-flight response
(a) Central nervous system
(b) Sympathetic nervous system
(c) Peripheral nervous system
(d) Parasympathetic nervous system
Answer: (b)

305. A real or perceived challenge or threat which causes the body to produce a response is a(n)
(a) injury
(b) phobia
(c) stressor
(d) frustration
Answer: (c)

306. The hormone released by the adrenal glands allows the body to make energy more readily available from the stored nutrients
(a) ACTH
(b) Cortisol
(c) Epinephrine
(d) Norepinephrine
Answer: (b)

307. When danger or stress is perceived/experienced, this response occurs in the body
(a) Exhaustion
(b) Adaption
(c) Fight-or-flight
(d) Resistance

Answer: (c)

308. This branch of science investigates the relationship between stress and the nervous and immune systems

- (a) Neurolinguistics
- (b) Sociology
- (c) Adaptive immunology
- (d) Psychoneuroimmunology

Answer: (d)

309. All of the following is true about the hormone epinephrine except that it

- (a) is released by the pituitary gland
- (b) is also known as adrenaline
- (c) is secreted by the adrenal gland
- (d) prepares the body for action

Answer: (a)

310. The primary hormone responsible for stress-related physiological responses, such as an increase in heart rate is

- (a) insulin
- (b) cortisol
- (c) epinephrine
- (d) thyroxin

Answer: (c)

UNIT – 6

THINKING, INTELLIGENCE AND CREATIVITY

THINKING, INTELLIGENCE AND CREATIVITY

What is Theoretical perspectives on thought processes: Associationism, Gestalt, Information processing, Feature integration model Concept formation: Rules, Types, and Strategies; Role of concepts in thinking Types of Reasoning Language and thought?

THEORETICAL PERSPECTIVES ON THOUGHT PROCESSES: ASSOCIATIONISM, GESTALT, INFORMATION PROCESSING, FEATURE INTEGRATION MODEL CONCEPT FORMATION: RULES, TYPES, AND STRATEGIES; ROLE OF CONCEPTS IN THINKING TYPES OF REASONING LANGUAGE AND THOUGHT

Theoretical perspectives on thought processes: Associationism, Gestalt, Information processing, Feature

ASSOCIATIONISM

Associationism is a theory that connects learning to thought based on principles of the organism's causal history. Since its early roots, associationists have sought to use the history of an organism's experience as the main sculptor of cognitive architecture. In its most basic form, associationism has claimed that pairs of thoughts become associated based on the organism's past experience.

So, **for example**, a basic form of associationism (such as Hume's) might claim that the frequency with which an organism has come into contact with Xs and Ys in one's environment determines the frequency with which thoughts about Xs and thoughts about Ys will arise together in the organism's future.

Associationism's popularity is in part due to how many different masters it can serve. In particular, associationism can be used as a theory of learning (e.g., as in behaviorist theorizing), a theory of thinking (as in Jamesian "streams of thought"), a theory of mental structures (e.g., as in concept pairs), and a theory of the implementation of thought (e.g., as in connectionism).

All these theories are separable, but share a related, empiricist-friendly core. As used here, a "pure associationist" will refer to one who holds associationist theories of learning, thinking, mental structure, and implementation.

The "pure associationist" is a somewhat idealized position, one that no particular theorist may have ever held, but many have approximated to differing degrees (e.g., Locke 1690/1975; Hume 1738/1975; Thorndike 1911; Skinner 1953; Hull 1943; Churchland 1986, 1989; Churchland and Sejnowski 1990; Smolensky 1988; Elman 1991; Elman et al. 1996; McClelland et al. 2010; Rydell and McConnell 2006; Fazio 2007).

Outside of these core uses of associationism the movement has also been closely aligned with a

number of different doctrines over the years: empiricism, behaviorism, anti-representationalism (i.e., skepticism about the necessity of representational realism in psychological explanation), gradual learning, and domain-general learning. All of these theses are dissociable from core associationist thought (see section 7).

While one can be an associationist without holding those theses, some of those theses imply associationism to differing degrees. These extra theses' historical and sociological ties to associationism are strong, and so will be intermittently discussed below.

1) **ASSOCIATIONISM AS A THEORY OF MENTAL PROCESSES: THE EMPIRICIST CONNECTION:** Empiricism is a general theoretical outlook, which tends to offer a theory of learning to explain as much of our mental life as possible. From the British empiricists through Skinner and the behaviorists (see the entry on behaviorism) the main focus has been arguing for the acquisition of concepts (for the empiricists' "ideas", for the behaviorists "responses") through learning.

However, the mental processes that underwrite such learning are almost never themselves posited to be learned. So winnowing down the amount of mental processes one has to posit limits the amount of innate machinery with which the theorist is saddled. Associationism, in its original form as in Hume (1738/1975), was put forward as a theory of mental processes.

Associationists' attempt to answer the question of how many mental processes there are by positing only a single mental process: the ability to associate ideas. Of course, thinkers execute many different types of cognitive acts, so if there is only one mental process, the ability to associate, that process must be flexible enough to accomplish a wide range of cognitive work. In particular, it must be able to account for learning and thinking.

Accordingly, associationism has been utilized on both fronts. We will first discuss the theory of learning and then, after analyzing that theory and seeing what is putatively learned, we will return to the associationist theory of thinking.

2) **ASSOCIATIONISM AS A THEORY OF LEARNING:** In one of its senses, "associationism" refers to a theory of how organisms acquire concepts, associative structures, response biases, and even propositional knowledge. It is commonly acknowledged that associationism took hold after the publishing of John Locke's essay concerning human understanding (1690/1975).

However, Locke's comments on associationism were terse (though fertile), and did not address learning to any great degree. The first serious attempt to detail associationism as a theory of learning was given by Hume in the *Treatise of Human Nature* (1738/1975). Hume's associationism was, first and foremost, a theory connecting how perceptions ("Impressions") determined trains of thought (successions of "Ideas").

Hume's empiricism, as enshrined in the Copy Principle demanded that there were no Ideas in the mind that were not first given in experience. For Hume, the principles of association constrained the functional role of Ideas once they were copied from Impressions: if Impressions IM1 and IM2 were associated in perception, then their corresponding Ideas, ID1 and ID2 would also become associated.

In other words, the ordering of Ideas was determined by the ordering of the Impressions that caused the Ideas to arise. Hume's theory then needs to analyze what types of associative relations between Impressions mattered for determining the ordering of Ideas. Hume's analysis consisted of three types of associative relations: cause and effect, contiguity, and resemblance.

If two Impressions instantiated one of these associative relations, then their corresponding Ideas would mimic the same instantiation. For instance, if Impression IM1 was cotemporaneous with Impression IM2, then (*ceteris paribus*) their corresponding Ideas, ID1 and ID2, would become associated.

As stated, Hume's associationism was mostly a way of determining the functional profile of Ideas. But we have not yet said what it is for two Ideas to be associated (for that see section 4). Instead, one can see Hume's contribution as introducing a very influential type of learning—associative learning—for Hume's theory purports to explain how we learn to associate certain Ideas.

We can abstract away from Hume's framework of ideas and his account of the specific relations that underlie associative learning, and state the theory of associative learning more generally: if two contents of experiences, X and Y, instantiate some associative relation, R, then those contents will become associated, so that future activations of X will tend to bring about activations of Y.

The associationist then has to explain what relation R amounts to. The Human form of associative learning (where R is equated with cause and effect, contiguity, or resemblance) has been hugely influential, informing the accounts of those such as Jeremy Bentham, J.S. Mill, and Alexander Bain (see, e.g., the entries on John Stuart Mill and 19th Century Scottish Philosophy).

Associative learning didn't hit its stride until the work of Ivan Pavlov, which spurred the subsequent rise of the behaviorist movement in psychology. Pavlov introduced the concept of classical conditioning as a modernized version of associative learning.

For Pavlov, classical conditioning was in part an experimental paradigm for teaching animals to learn new associations between stimuli. The general method of learning was to pair an unconditioned stimulus (US) with a novel stimulus. An unconditioned stimulus is just a

stimulus that instinctively, without training, provokes a response in an organism. Since this response is not itself learned, the response is referred to as an “unconditioned response” (UR). In Pavlov’s canonical experiment, the US was a meat powder, as the smell of meat automatically brought about salivation (UR) in his canine subjects. The US is then paired with a neutral stimulus, such as a bell.

Over time, the contiguity between the US and the neutral stimulus causes the neutral stimulus to provoke the same response as the US. Once the bell starts to provoke salivation, the bell has become a “conditioned stimulus” (CS) and the salivating, when prompted by the bell alone, a “conditioned response” (CR).

The associative learning here is learning to form new stimulus-response pairs between the bell and the salivation. Classical conditioning is a fairly circumscribed process. It is a “stimulus substitution” paradigm where one stimulus can be swapped for another to provoke a response. However, the responses that are provoked are supposed to remain unchanged; all that changes is the stimulus that gets associated with the response.

Thus, classical conditioning seemed to some to be too restrictive to explain the panoply of novel behavior organisms appear to execute. Edward Thorndike’s research with cats in puzzle boxes broadened the theory of associative learning by introducing the notion of consequences to associative learning.

Thorndike expanded the notion of associative learning beyond instinctual behaviors and sensory substitution to genuinely novel behaviors. Thorndike’s experiments initially probed, e.g., how cats learned to lift a lever to escape the “puzzle boxes” (the forerunner to “Skinner boxes”) that they were trapped in. The cats’ behaviors, such as attempting to lift a lever, were not themselves instinctual behaviors like the URs of Pavlov’s experiments.

Additionally, the cats’ behaviors were shaped by the consequences that they brought on. For Thorndike it was because lifting the lever caused the door to open that the cats learned the connection between the lever and the door. This new view of learning, operant conditioning (for the organism is “operating” on its environment), was not merely the passive learning of Pavlov, but a species-nonspecific, general, active theory of learning.

This research culminated in Thorndike’s famous “Law of Effect” (1911), the first canonical psychological law of associationist learning. It asserted that responses that are accompanied by the organism feeling satisfied will, *ceteris paribus*, be more likely to be associated with the situation in which the behavior was executed, whereas responses that are accompanied with a feeling of discomfort to the animal will, *ceteris paribus*, make the response less likely to occur when the organism encounters the same situation.

The greater the positive or negative feelings produced, the greater the likelihood that the behavior will be evinced. To this Thorndike added the “Law of Exercise”, that responses to situations will, *ceteris paribus*, be more connected to those situations in proportion to the frequency of past pairings between situation and response. Thorndike’s paradigm was popularized and extended by B.F. Skinner (see, e.g., Skinner 1953) who stressed the notion not just of consequences but of reinforcement as the basis of forming associations.

For Skinner, a behavior would get associated with a situation according to the frequency and strength of reinforcement that would arise as a consequence of the behavior. Since the days of Skinner, associative learning has come in many different variations. But what all varieties should share with their historical predecessors is that associative learning is supposed to mirror the contingencies in the world without adding additional structure to them (see section 9 for some examples of when supposedly associative theories smuggle in extra structure).

The question of what contingencies associative learning detects (that is, one’s preferred analysis of what the associative relation R is), is up for debate and changes between theorists. The final widely shared, though less central, property of associative learning concerns the domain generality of associative learning.

Domain generality’s prevalence among associationists is due in large part to their traditional empiricist allegiances: excising domain-specific learning mechanisms constrains the amount of innate mental processes one has to posit. Thus it is no surprise to find that both Hume and Pavlov assumed that associative learning could be used to acquire associations between any contents, regardless of the types of contents they were. For example, Pavlov writes,

3) ASSOCIATIONISM AS A THEORY OF MENTAL STRUCTURE: Associative learning amounts to a constellation of related views that interprets learning as associating stimuli with responses (in operant conditioning), or stimuli with other stimuli (in classical conditioning), or stimuli with valences (in evaluative conditioning).

Associative learning accounts raise the question: when one learns to associate contents x and y because, e.g., previous experiences with x s and y s instantiated r , how does one store the information that x and y are associated? A highly contrived sample answer to this question would be that a thinker learns an explicitly represented unconscious conditional rule that states “when a token of x is activated, then also activate a token of y ”.

Instead of such a highly intellectualized response, associationists have found a natural (though by no means necessary, see section 4.2) complementary view that the information is stored in an associative structure. An associative structure describes the type of bond that connects two distinct mental states. An example of such a structure is the associative pair salt/pepper.

The associative structure is defined, in the first instance, functionally:

If X and Y form an associative structure, then, *ceteris paribus*, activations of mental state X bring about mental state Y and viceversa without the mediation of any other psychological states (such as an explicitly represented rule telling the system to activate a concept because its associate has been activated).

In other words, saying that two concepts are associated amounts to saying that there is a reliable, psychologically basic causal relation that holds between them—the activation of one of the concepts causes the activation of the other. So, saying that someone harbors the structure salt/pepper amounts to saying that activations of salt will cause activations of pepper (and vice versa) without the aid of any other cognitive states.

Associative structures are most naturally contrasted with propositional structures. A pure associationist is opposed to propositional structures—strings of mental representations that express a proposition—because propositionally structured mental representations have structure over and above the mere associative bond between two concepts.

Take, for example, the associative structure green/toucan. This structure does not predicate green onto toucan. If we know that a mind has an associative bond between green and toucan, then we know that activating one of those concepts leads to the activation of the other.

A pure associative theory rules out predication, for propositional structures aren't just strings of associations. "Association" (in associative structures) just denotes a causal relation among mental representations, whereas predication (roughly) expresses a relation between things in the world (or intentional contents that specify external relations).

Saying that someone has an associative thought green/toucan tells you something about the causal and temporal sequences of the activation of concepts in one's mind; saying that someone has the thought there is a green toucan tells you that a person is predicating greenness of a particular toucan (see Fodor 2003: 91–94, for an expansion of this point).

Associative structures needn't just hold between simple concepts. One might have reason to posit associative structures between propositional elements (see section 5) or between concepts and valences (see section 8). But none of the preceding is meant to imply that all structures are associative or propositional—there are other representational formats that the mind might harbor (e.g., analog magnitudes or iconic structures; see Camp 2007; Quilty-Dunn forthcoming).

For instance, not all semantically related concepts are harbored in associative structures. Semantically related concepts may in fact also be directly associated (as in doctor/nurse) or they may not (as in horse/zebra; see Perea and Rosa 2002).

The difference in structure is not just a theoretical possibility, as these different structures have different functional profiles: for example, conditioned associations appear to last longer than semantic associations do in subjects with dementia (Glosser and Friedman 1991).

4) ASSOCIATIONISM IN SOCIAL PSYCHOLOGY: Since the cognitive revolution, associationism's influence has mostly died out in cognitive psychology and psycholinguistics. This is not to say that all aspects of associative theorizing are dead in these areas; rather, they have just taken on much smaller, more peripheral roles (for example, it has often been suggested that mental lexicons are structured, in part, associatively, which is why lexical decision tasks are taken to be facilitation maps of one's lexicon).

In other areas of cognitive psychology (for example, the study of causal cognition), associationism is no longer the dominant theoretical paradigm, but vestiges of associationism still persist (see Shanks 2010 for an overview of associationism in causal cognition). Associationism is also still alive in the connectionist literature, as well as in the animal cognition tradition.

But the biggest contemporary stronghold of associationist theorizing resides in social psychology, an area which has traditionally been hostile to associationism (see, e.g., Asch 1962, 1969). The ascendance of associationism in social psychology has been a fairly modern development, and has caused a revival of associationist theories in philosophy (e.g., Madva and Brownstein 2019).

The two areas of social psychology that have seen the greatest renaissance of associationism are the implicit attitude and dual-process theory literature. However, in the late 2010s social psychology has begun to take a critical look at associationist theories (e.g., Mann et al. 2019).

CRITICISMS OF ASSOCIATIONISM

Associationism has been a dominant theme in mental theorizing for centuries. As such, it has garnered an appreciable amount of criticism.

LEARNING CURVES

The basic associative learning theories imply, either explicitly or implicitly, slow, gradual learning of associations (Baeyens et al. 1995). The learning process can be summarized in a learning curve which plots the frequency (or magnitude) of the conditioned response as a function of the number of reinforcements (Gallistel et al. 2004: 13124). Mappings between CRs and USs are gradually built up over numerous trials (in the lab) or experiences (in the world). Gradual, slow learning has come under fire from a variety of areas (see sections 9.3 and 9.4.1).

However, here we just focus on the behavioral data. In a series of works re-analyzing animal

behavior, Gallistel (Gallistel et al. 2004; Gallistel and King 2009) has argued that although group-level learning curves do display the properties of being negatively accelerated and gradually developing, these curves are misleading because no individual's learning curve has these properties.

Gallistel has argued that learning for individuals is generally step-like, rapid, and abrupt. An individual's learning from a low-level of responding to asymptotic responding is very quick. Sometimes, the learning is so quick that it is literally one-shot learning. For example, after analyzing multiple experiments of animal learning of spatial location Gallistel writes.

THE PROBLEM OF PREDICATION

The problem of predication is, at its core, a problem of how an associative mechanism can result in the acquisition of subject/predicate structures, structures which many theorists believe appear in language, thought, and judgment.

The first major discussion of the problem appears in Kant (1781/1787), but variants of the basic Kantian criticism can be seen across the contemporary literature (see, e.g., Chomsky 1959; Fodor and Pylyshyn 1988; Fodor 2003; Mandelbaum 2013a; for the details of the Kantian argument see the entry on Kant's Transcendental Argument).

For a pure associationist, association is "semantically transparent" (see Fodor 2003), in that it purports to add no additional structure to thoughts. When a simple concept, X and a simple concept Y, become associated one acquires the associative structure X/Y. But X/Y has no additional structure on top of their contents.

Knowing that X and Y are associated amounts to knowing a causal fact: that activating Xs will bring about the activation of Ys and vice versa. However, so the argument goes, some of our thoughts appear to have more structure than this: the thought birds fly predicates the property of flying onto birds.

The task for the associationist is to explain how associative structures can distinguish a thinker who has a single (complex) thought birds fly from a thinker who conjoins two simple thoughts in an associative structure where one thought, birds, is immediately followed by another, fly.

As long as the two simple thoughts are reliably causally correlated so that, for a thinker, activations of birds regularly brings about fly, then that thinker has the associative structure birds/fly. Yet it appears that thinker hasn't yet had the thought birds fly.

The problem of predication is explaining how a purely associative mechanism could eventuate in complex thoughts. In Fodor's terms the problem boils down to how association, a causal relation among mental representations, can affect predication, a relation among intentional contents (Fodor

2003).

AGAINST THE CONTIGUITY ANALYSIS OF ASSOCIATIONISM

Contiguity has been a central part of associationist analyses since the British Empiricists. In the experimental literature, the problem of figuring out the parameters needed for acquiring an association due to the contiguity of its relata has sometimes been termed the problem of the "Window of Association" (e.g., Gallistel and King 2009).

Every associationist theory has to specify what temporal window two properties must instantiate in order for those properties to be associated. A related problem for contiguity theorists is that if the domain generality of associative learning is desired, then the window needs to be homogenous across content domains. The late 1960s saw persuasive attacks on domain generality, as well as the necessity and sufficiency of the contiguity criterion in general.

AGAINST THE NECESSITY OF CONTIGUITY

Research on "taste aversions" and "bait-shyness" provided a variety of problems with contiguity in the associative learning tradition of classical conditioning. Garcia observed that a gustatory stimulus (e.g., drinking water or eating a hot dog) but not an audiovisual stimulus (a light and a sound) would naturally become associated with feeling nauseated.

For instance, Garcia and Koelling (1966) paired an audiovisual stimulus (a light and a sound) with a gustatory stimulus (flavored water). The two stimuli were then paired with the rats receiving radiation, which made the rats feel nauseated. The rats associated the feeling of nausea with the water and not with the sound, even though the sound was contiguous with the water.

Moreover, the delay between ingesting the gustatory stimulus and feeling nauseated could be quite long, with the feeling not coming on until 12 hours later (Roll and Smith 1972), and the organism needn't even be conscious when the negative feeling arises. (For a review, see Seligman 1970; Garcia et al. 1974).

The temporal delay shows that the CS (the flavored water) needn't be contiguous with the US (the feeling of nausea) in order for learning to occur, thus showing that contiguity isn't necessary for associative learning.

GESTALT PERSPECTIVES ON THOUGHT PROCESSES

Gestalt psychology is a school of thought that looks at the human mind and behavior as a whole. When trying to make sense of the world around us, Gestalt psychology suggests that we do not simply focus on every small component.

Instead, our minds tend to perceive objects as part of a greater whole and as elements of more complex systems. This school of psychology played a major role in the modern development of the study of human sensation and perception.

Originating in the work of Max Wertheimer, Gestalt psychology formed partially as a response to the structuralism of Wilhelm Wundt. While Wundt was interested in breaking down psychological matters into their smallest possible part, the Gestalt psychologists were instead interested in looking at the totality of the mind and behavior. The guiding principle behind the Gestalt movement was that the whole was greater than the sum of its parts.

The development of this area of psychology was influenced by a number of thinkers, including Immanuel Kant, Ernst Mach, and Johann Wolfgang von Goethe. The development of Gestalt psychology was influenced in part by Wertheimer's observations one day at a train station. He purchased a toy stroboscope which displayed pictures in a rapid sequence to mimic the appearing movement.

He later proposed the concept of the Phi phenomenon in which flashing lights in sequence can lead to what is known as apparent motion. In other words, we perceive movement where there is none. Movies are one example of apparent motion. Through a sequence of still frames, the illusion of movement is created.

"The fundamental 'formula' of Gestalt theory might be expressed in this way," Max Wertheimer wrote. "There are wholes, the behavior of which is not determined by that of their individual elements, but where the part-processes are themselves determined by the intrinsic nature of the whole. It is the hope of Gestalt theory to determine the nature of such wholes."

Gestalt is a decisive trend in psychology history. It was born in Germany at the beginning of the 20th century. It was Christian von Ehrenfels, an Austrian philosopher, who gave this movement its name in *The Attributes of Form*, his most important work. There is no perfect English translation of the term "gestalt". But we can interpret it as "totality", "figure", "structure", "configuration" or "organized unity".

"The whole is more than the sum of its parts" is its maximum. The main authors of Gestalt proposed alternatives to the dominant psychological paradigms and made great contributions to cognitive psychology.

This particular focus was a breath of fresh air and allowed people who did not feel represented by the main currents of psychology to find an alternative.

GESTALT THEORY: CHARACTERISTICS

- **Its main predecessors of gestalt theory are philosophers:** Thinkers such as Kant, Descartes or Husserl developed the theoretic basis on which this school developed. The psychologists belonging to this current were able to take their ideas to the laboratory and obtain amazing results.
- **We must treat people as a whole:** We cannot explore the different dimensions that shape us in isolation. A holistic approach is needed when speaking about mental health.

- **The complexity of the human mind cannot be reduced.** Gestalt theory explores the dynamic relationships that connect the various elements of reality. Gestalt theory does not conceive separating processes such as learning from memory.
- **We are active in understanding reality:** We do not all perceive reality, in the same way, we have our own vision. Each one structures the information they receive according to their previous experiences. **Our mental representations do not correspond completely with those that exist in reality, we construct them ourselves.** We are also able to adapt our mental processes and contents as new situations arise.
- **They opposed the predominant schools in their time:** Gestalt theory psychologists did not agree with approaches such as behaviorism, which limits human behavior to associations between stimuli and responses. This perspective leaves mental processes aside and does not contemplate the potential of human intelligence. On the other hand, they did not adhere to psychoanalysts either, seeing people as passive agents without willpower.
- **Gestalt theory's main study area is perception:** Gestalt theorists focused especially on seeking simple and natural explanations that could be adapted to our natural way of perceiving reality.

Through perception, we are able to acquire knowledge of the world, interact with it and connect with others. Our senses and mental processes interact to allow us to perform tasks as varied as removing the hand from a burning surface or notice that the person speaking to us is upset by their frowning. **Gestalt theory focuses on visual perception.** However, their ideas have been adapted to fields such as music.

Gestalt psychologists are known for their contributions to the study of the learning process and problem-solving. However, their most relevant contribution, which was stated by Wertheimer, is the elaboration of some basic laws that govern our perception.

INFORMATION PROCESSING, FEATURE INTEGRATION MODEL

Basic Assumptions

The information processing approach is based on a number of assumptions, including:

- 1) information made available by the environment is processed by a series of processing systems (e.g. attention, perception, short-term memory);
- 2) these processing systems transform or alter the information in systematic ways;
- 3) the aim of research is to specify the processes and structures that underlie cognitive performance;
- 4) information processing in humans resembles that in computers.

The development of the computer in the 1950s and 1960s had an important influence on psychology and was, in part, responsible for the cognitive approach becoming the dominant approach in modern psychology (taking over from Behaviorism). The computer gave cognitive psychologists a metaphor, or analogy, to which they could compare human mental processing.

The use of the computer as a tool for thinking how the human mind handles information is known

as the computer analogy. Essentially, a computer codes (i.e., changes) information, stores information, uses information, and produces an output (retrieves info). The idea of information processing was adopted by cognitive psychologists as a model of how human thought works.

For example, the eye receives visual information and codes information into electric neural activity which is fed back to the brain where it is “stored” and “coded”. This information can be used by other parts of the brain relating to mental activities such as memory, perception and attention. The output (i.e. behavior) might be, for example, to read what you can see on a printed page. Hence the information processing approach characterizes thinking as the environment providing input of data, which is then transformed by our senses.

The information can be stored, retrieved and transformed using “mental programs”, with the results being behavioral responses. Cognitive psychology has influenced and integrated with many other approaches and areas of study to produce, for example, social learning theory, cognitive neuropsychology and artificial intelligence (AI).

Information Processing and Selective Attention

When we are selectively attending to one activity, we tend to ignore other stimulation, although our attention can be distracted by something else, like the telephone ringing or someone using our name.

Psychologists are interested in what makes us attend to one thing rather than another (selective attention); why we sometimes switch our attention to something that was previously unattended (e.g. Cocktail Party Syndrome), and how many things we can attend to at the same time (attentional capacity).

One way of conceptualizing attention is to think of humans as information processors who can only process a limited amount of information at a time without becoming overloaded. Broadbent and others in the 1950s adopted a model of the brain as a limited capacity information processing system, through which external input is transmitted.

Information processing models consist of a series of stages, or boxes, which represent stages of processing. Arrows indicate the flow of information from one stage to the next.

- **Input** processes are concerned with the analysis of the stimuli.
- **Storage** processes cover everything that happens to stimuli internally in the brain and can include coding and manipulation of the stimuli.
- **Output** processes are responsible for preparing an appropriate response to a stimulus.

Critical Evaluation

A number of models of attention within the Information Processing framework have been proposed including:

Broadbent's Filter Model (1958), Treisman's Attenuation Model (1964) and Deutsch and Deutsch's Late Selection Model (1963).

However, there are a number of evaluative points to bear in mind when studying these models, and the information processing approach in general. These include:

- 1) The information processing models assume serial processing of stimulus inputs.
 - **Serial processing** effectively means one process has to be completed before the next starts.
 - **Parallel processing** assumes some or all processes involved in a cognitive task(s) occur at the same time.

There is evidence from dual-task experiments that parallel processing is possible. It is difficult to determine whether a particular task is processed in a serial or parallel fashion as it probably depends (a) on the processes required to solve a task, and (b) the amount of practice on a task.

Parallel processing is probably more frequent when someone is highly skilled; for example a skilled typist thinks several letters ahead, a novice focuses on just 1 letter at a time.

- 2) The analogy between human cognition and computer functioning adopted by the information processing approach is limited.

Computers can be regarded as information processing systems insofar as they:

- i. combine information presented with stored information to provide solutions to a variety of problems, and
- ii. Most computers have a central processor of limited capacity and it is usually assumed that capacity limitations affect the human attentional system.

BUT -

- i. the human brain has the capacity for extensive parallel processing and computers often rely on serial processing;
 - ii. humans are influenced in their cognitions by a number of conflicting emotional and motivational factors.
- 3) The evidence for the theories/models of attention which come under the information processing approach is largely based on experiments under controlled, scientific conditions. Most laboratory studies are artificial and could be said to lack ecological validity.

In everyday life, cognitive processes are often linked to a goal (e.g. you pay attention in class because you want to pass the examination), whereas in the laboratory the experiments are carried out in isolation from other cognitive and motivational factors. Although these laboratory experiments are easy to interpret, the data may not be applicable to the real world outside the laboratory.

More recent ecologically valid approaches to cognition have been proposed (e.g. the Perceptual Cycle, Neisser, 1976). Attention has been studied largely in isolation from other cognitive processes, although clearly it operates as an interdependent system with the related cognitive processes of perception and memory.

The more successful we become at examining part of the cognitive system in isolation, the less our data are likely to tell us about cognition in everyday life.

FEATURE INTEGRATION THEORY

Feature Integration Theory was parent to a family of subsequent models. Many of these include the concept of guided search. In guided search, the information gathered about basic features can be used to guide attention toward likely targets.

Thus, if an observer is looking for a red letter T, attention will be guided to red letters and not wasted on letters that could never be the target (Wolfe, J. M., 1994). In two-stage modeling, critical questions include the nature of the stimulus attributes that can be processed prior to attentional selection as discussed earlier.

Some attributes, like color and orientation clearly fall into the preattentive category. The more interesting and problematic cases are complex and/or learned classes of stimuli like faces and letters. All models must resolve issues about the nature of selection.

What is selected? If objects are selected, how are objects parsed from the background prior to selection? What are the limits on selection? Can more than one item be selected at one time? What does selection do? Does it enhance processing? Does it enable different types of processing?

BINDING BY ATTENTION

Anne Treisman's Feature Integration Theory (FIT), developed in the context of visual search tasks, postulates that the correct binding of object features requires visual attention. Treisman starts from the assumption that the visual system is equipped with a set of 'feature maps,' with a different map for every conceivable feature (e.g., 'red,' 'green,' 'square,' 'circular').

These feature maps are connected to a 'master map of locations,' which encodes the exact positions of objects in visual space (**Figure 4**). When the search target is defined by a single feature, for example, 'red,' one only has to monitor the respective feature map and trace its activation to the target's position on the master map. This is what occurs in parallel search when the target seems to 'pop out' of the display (see 'Empirical evidence for binding problems in visual perception' section).

However, when the target is defined by a conjunction of features, it is necessary to employ visual

attention. Each object location on the master map has to be scanned by a 'spotlight' of attention, and for each of these positions the single features have to be collected from the feature maps and bound into an 'object file' that can be compared with a target template stored in working memory.

As soon as the current object file matches the target template, the object has been found, and the search is terminated. Because the sequential scanning of object positions is a time-consuming process that depends on the number of positions to be covered, this model can explain serial search.

FEATURE INTEGRATION THEORY

Anne Treisman's Feature Integration Theory (FIT), first proposed in 1980, holds that attention is critical to the formation of bound representations of objects and, by extension, it proposes that attention is critical to our conscious experience of those bound representations. In FIT, following the understanding of visual neurophysiology given above, the visual system first decomposes the visual scene into its composite features, arrayed in a set of "feature maps."

The pre-attentive description of a scene or object comprises a list of such features. The term "pre-attentive" has been controversial but it can be operationally defined here as the representation of a stimulus before selective attention is directed to that stimulus.

In FIT, the approximate position of each feature is recorded on its pre-attentive feature map. For example, if the visual scene contains two red objects, the feature map corresponding to redness would be activated at two points roughly corresponding to the locations of the red objects. If each feature were associated with a precise region in space, this might solve the binding problem.

Features that correspond to the same region in space could be automatically conjoined thus guaranteeing veridical perception. Unfortunately, the location of many features is measured in an imprecise fashion. For example, the smallest receptive fields in IT, the region whose activity correlates well with shape perception, have a spatial extent of a few degrees of visual angle. Within this region, the cell will respond to an object in an approximately translation invariant manner.

Thus, a neuron in IT cannot signal the location of a particular shape with a precision of better than a few degrees, while the perception of coherent objects requires a much finer resolution. Because of the poor resolution of these feature maps, if two objects are close together, then there is the potential that the features from one object may become conjoined with the features of the other object thus creating a percept of an object that did not in fact exist.

For example, if the visual scene contains a red vertical bar and a blue horizontal bar then one might see a blue vertical bar and a red horizontal bar. Such inappropriate combinations of features are known as illusory conjunctions. FIT suggests that attention hinders the formation of illusory conjunctions.

Supporting this assertion is a series of classic experiments by Treisman and her colleagues showing that, if attention is occupied elsewhere, illusory conjunctions are, in fact, reported. In one version of the experiment, observers viewed a display of five characters aligned horizontally. The outer two characters were always digits and the inner three characters were always letters. While the digits were always black, the letters were colored.

The observer's primary task was to name the digits. After doing that, the observer reported the letters and their associated colors. When the display was presented sufficiently rapidly, observers would often report seeing an incorrect conjunction of a color and a letter. For example, if the display contained a red X and a green T, they might report seeing a red T.

Crucially, these illusory conjunctions occurred at a much higher rate than could be attributed to the observer simply misperceiving a given feature. Generally, the observer correctly perceived the features present in the display. It was the conjoining of features that proved to be problematic. When asked to report how confident they were that they had actually seen an object, observers were just as confident when they reported seeing an illusory conjunction as they were when they correctly reported the features of an object.

Indeed, although all observers were told that the digits would always be black (and in fact always were) about half the observers spontaneously reported that the digits sometimes appeared to be colored, sometimes even going as far as to argue with the experimenter about the issue! This raises an interesting problem in the study of attention and awareness. In tasks of this sort, one can only ask about what was seen, after the fact.

If one asks about the current status of a visible object, the observer will attend to it in order to answer the question and will be unable to give an accurate report of the unattended state. Nevertheless, the phenomenology of illusory conjunctions does show that, within a fraction of a second of the disappearance of a display, observers can be quite convinced that they have seen something that was not, in fact, present.

Subsequent studies have shown that illusory conjunctions can be perceived even when the subject attends to the objects, especially if the objects are perceptually grouped. Clearly, attention does not always succeed in solving the binding problem. There is neuropsychological evidence, from studies of patients with Balint's syndrome, which supports the idea that attention can inhibit the formation of illusory conjunctions.

This syndrome occurs when both the left and right parietal lobes are damaged. As these areas help govern the deployment of attention, such patients have great difficulty in directing their attention to a given object, resulting in the inability to perceive more than one object at a time. As would be expected, they are also prone to suffer from illusory conjunctions, experiencing them even when the

image is displayed for several seconds.

Neurophysiological support also comes from work by Robert Desimone and colleagues. They performed a series of extracellular studies in area V4 of the macaque monkey that have shown that attention can help solve the binding problem. First they would find a stimulus that, when presented on its own, would elicit a strong response from the neuron in question (the preferred stimulus), and another that would elicit only a weak response (the non-preferred stimulus).

They would then present both stimuli simultaneously so that they both were within the neuron's receptive field. In the absence of attention, the cell would simultaneously respond to both stimuli, with its response (spike rate) lying between that generated by each stimulus when presented on its own. In other words, the response reflected contributions from both stimuli, meaning that the cell could not distinguish between the two.

However, when the monkey attended to one of the stimuli, the situation changed and the cell responded primarily to the attended stimulus. Specifically, when the monkey attended to the preferred stimulus, the cell would respond strongly, but when the non-preferred stimulus was attended, only a weak response was elicited.

In this case, attention was able to solve the binding problem, at least at the neuronal level, by shrinking the receptive field of the cell to include just the selected item, thereby removing the influence of the unattended item. This constriction of the receptive field does not explain how signals about one feature analyzed in one cortical area can be bound to signals about another feature from another area.

Other mechanisms have been suggested to account for this aspect of binding. Several of these are based on the idea that neurons in different cortical areas that respond to the same object synchronize their activity, so that they create action potentials at the same time. Consequently, a third brain area could determine whether two neurons in two different parts of the brain are responding to different features of the same object by being sensitive to this synchrony.

As attention is known to increase neural synchrony, theories based on synchrony are consistent with the notion that attention is needed to solve the binding problem. An alternative theory put forward by Edward Vul and Anina Rich suggests that features are not directly bound together but rather are unconsciously perceived as being bound when they are perceived to share a location in space and time.

Attending to a feature allows it to be more precisely localized, thereby increasing the chances that the correct features are perceived together and decreasing the chances of illusory conjunctions forming. Thus they propose that attention solves the binding problem only in an indirect fashion by increasing the precision by which features can be localized in space and time.

CONCEPT FORMATION: RULES, TYPES

Concept formation, process by which a person learns to sort specific experiences into general rules or classes. With regard to action, a person picks up a particular stone or drives a specific car. With regard to thought, however, a person appears to deal with classes. For instance, one knows that stones (in general) sink and automobiles (as a class) are powered by engines.

In other words, these things are considered in a general sense beyond any particular stone or automobile. Awareness of such classes can help guide behaviour in new situations. Thus two people in a bakery may never have met before, but, if one can be classified as customer and the other as clerk, they tend to behave appropriately.

Similarly, many people are able to drive almost any automobile by knowing how to drive a specific automobile. The term concept formation describes how a person learns to form classes, whereas the term conceptual thinking refers to an individual's subjective manipulation of those abstract classes. A concept is a rule that may be applied to decide if a particular object falls into a certain class. The concept "citizen of the United States" refers to such a decision rule, meaning any person who was born in U.S. territory or who is a child of a U.S. citizen or who has been legally naturalized.

The rule suggests questions to ask in checking the citizenship of any particular individual. As most concepts do, it rests on other concepts; "U.S. citizen" is defined in terms of the concepts "child" and "territory." Many scientific or mathematical concepts cannot be understood until the terms by which they are defined have been grasped.

In this way concept formation builds on itself. Conceptual classification may be contrasted with another type of classification behaviour called discrimination learning. In discrimination learning, objects are classified on the basis of directly perceived properties such as physical size or shape. The emphasis on concrete physical features in discrimination learning can be contrasted with the more abstract nature of concept formation.

When a stimulus is perceived to match several different past experiences, however, the response may be a compromise, because an object need not bear an all-or-none relation to a set of others in discrimination learning; for example, there is no absolute distinction between tall and short people. While human beings are capable of abstract thought, many of the classifications people make seem to be concrete discriminations.

For example, people may use the same term in a discriminative or conceptual way. A child might use the term policeman in discriminating a man who wears a distinctive uniform, while a lawyer may use the term to represent a civil servant charged with enforcing criminal codes. In practice, people seem to think in ways that combine abstractness and concreteness.

They also may blend class membership with assignment along a scale—e.g., such concepts as

leadership, an abstract quality that people are said to exhibit in varying degrees. The same would apply to vivacity, avarice, and other personality traits. People seem to develop more-complex sets of classes than do other animals, but this does not necessarily mean that human modes of learning are unique.

It may be that all animals have the same basic biochemical machinery for learning, but human animals exhibit it in greater variety. Yet, it seems no more appropriate to account for human concept formation in terms of discrimination learning alone than it does to reduce the functions of a piston engine to chemical reactions.

AGE AND CONCEPTUAL BEHAVIOUR PIAGET'S OBSERVATIONS

Through clinical observations, Swiss psychologist Jean Piaget initiated considerable study of how young children learn concepts that help them cope with their physical surroundings. As models for defining feasible change, concepts are at least as important in such contexts as they are for classification.

Piaget stressed that infants must first learn to distinguish themselves from the external environment. Next they form understandings of the physical world (for example, identifying objects that fall) that allow further exploration of the world. Later in the preschool period, children grasp the concept of spatial localization—objects that are separated in space.

Piaget characterized this period of learning as classifying objects only on the basis of perceptually attractive, concrete physical features (in agreement with laboratory studies of inter dimensional and extradimensional shift). He and others who used his methods reported that preschool children are apt to explain external change in terms of their own needs: a four-year-old is likely to say that a cloud moves "because the sun is in my eyes."

Among children in early primary grades, other interpretations of cause and effect might be expressed by saying a moving cloud "wants to hide the sun." In later primary grades, volitional and passive movement usually become conceptually distinct. By adolescence, children develop an ability to deal analytically with objects apart from their immediate perceptual characteristics.

This marks an understanding of the hierarchies of subclasses within more general classes—for example, a normal child of eleven applies the properties of all living things to the class called birds. Given proper information, by the age of six many children display significant concept-forming abilities.

They ordinarily have considerable linguistic competence, using (though often not being able to explain) such abstract qualifications as present and past tense. Rules of formal logic (such as "new math") can be taught in the elementary grades. Progressive use of abstract concepts seem to reflect both maturation and learning.

AGING

It is generally thought that the potential for learning new abstractions tends to decrease in old age and that in extreme cases (such as senility, severe alcoholism, or brain injury) the deficit is dramatic.

Much less is known, however, about changes in conceptual ability during the active period of adult life, in part because much of the evidence is conflicting.

CONCEPT FORMATION IN ANIMALS

Rats learn to enter lighted or unlighted alleys to get food, and goldfish can be taught to swim toward or away from an object. In such discrimination learning, the animal is said to associate a physical property of the stimulus with its response, and with some contingency of reward or punishment. Thus, while a dog can be trained to come when called, it need not mean that he knows his name in the same sense that a man apparently does.

Most animals show classification behaviour that seems indicative of discrimination learning. A crow will respond to the danger call of a bird of another species—but only if that call resembles the crow's. Chimpanzees, however, which have been observed using sticks as primitive tools, behave as if they have a concept of things that extend reach. Based on considerable evidence of this sort, many are reluctant to say that animals are incapable of abstract thinking.

Most studies aimed at evidence of concept formation among laboratory animals have involved primates, although there are reports of abstract behaviour among other animals such as dogs, dolphins, pigs, and parrots. Monkeys have been taught to solve the oddity problem: presented with two objects of one kind and one of another, they can be trained to select the discrepant one. This behaviour persists even for sets of objects that have never been presented to them before.

The animals behave as if they grasp the general concept of similarity, which is an abstraction rather than a simple discrimination. Animals also have been tested on the ability to learn languages. With great effort, chimpanzees have been taught to “speak” (through physical gestures) and to use correctly a very few words. A much more successful attempt was made by Beatrice and Allan Gardner to teach a chimpanzee, Washoe, the sign language used by deaf people—the gestures of this language apparently being more appropriate to the anatomic structure of chimpanzees.

The chimpanzee learned to use the signs for hat, dog, food, yes, me(self), sorry, funny, go, come, and many others. Washoe's foster son learned 68 words simply through observation, while Washoe's companions learned to use sign language to communicate transactions and reassurance. They also taught others the concepts they had learned.

CONCEPT FORMATION BY MACHINE

Computers can be programmed to process information and to develop classification rules (e.g., they can play chess and make decisions about business or military problems; see artificial intelligence). Essentially, such devices are programmed to mimic the processes of human problem solving. In this sense, machines have formed concepts; but their functions remain relatively impoverished.

Efficient linguistic behaviour has proved particularly difficult to produce in a machine. While many

believe that human thinking can be explained mechanistically in physiological terms, scientists themselves have yet to develop concepts adequate for producing machines that can approach the full range of human talent. Machine translation of language, however, has shown some success.

A Computational Metaphor for the Mind We can imagine the human mind as an evolving store of knowledge, which constantly updates itself from new information built from previous information through some kind of reasoning. In this model, the problems, events, or feelings, et cetera, of which we are consciously aware at any given time trigger a partly, or wholly, unconscious search through the knowledge store for those pieces of information that relate to the problem. Once found, these pieces of information permit the inference of new knowledge.

For instance, a rule that is appropriate for modeling the formation of the new knowledge might look roughly as follows: $c_1, c_2, \dots, c_n \in \text{newc}$.

1) Here c_i and newc are concepts expressed as logic atoms. We call these rules concept formation rules. Occasionally, we may need to test some condition before being able to form a new concept. For example, consider the knowledge that if the speed limit is X and our car's velocity is Y , then we will likely receive a speeding ticket if Y is greater than X . If we also know that we are traveling at 100km/hour and the speed limit is 50km/hour, then we might form the new concept that it is likely we will receive a speeding ticket.

In other words, using a primitive (i.e., system-defined) unary atom test, whose argument contains the test to be performed, we can model the above concept formation rule as the following: $\text{speed_limit}(X), \text{current_speed}(Y) \Rightarrow \text{test}(Y > X), \text{speeding_ticket}(\text{likely})$.

2) We next examine each feature that our concept-formation paradigm must have in order to:

- i. Constitute an adequate, constructivist metaphor for the workings of the human mind,
- ii. Provide some of the flexibility exhibited in human reasoning, and
- iii. Be directly executable.

Information Selection Most of the rules in our knowledge store will be irrelevant to the situation at hand, so the first problem in our model, and in constructivism in general, is the problem of selecting the appropriate information in order to form new concept(s) (which are actually relevant to the problem).

We solve this by using a system that constantly searches for any information that may match the new information (i.e., the initial problem's concepts, or the concepts formed while attempting a solution) and consequently triggers those rules whose left-hand side at least partially matches some of the new information.

If we consider our previous example, then as soon as the new information that the speed limit is 50km/hr and the current speed is 100km/hr arrives in the knowledge store, a search through that

store is initiated which ultimately yields rule (2), whose lefthand side will be matched with unifier $\{X=50, Y=100\}$. The unifier will apply to the rest of the rule as well, and a test to see whether $100 > 50$ will be performed.

Since the test will succeed, the new information speeding ticket(likely) will be added to the knowledge store. Flexible Concept Formation Binary logic is notoriously insufficient for modeling the human mind. The main alternatives are based either on probabilistic or fuzzy reasoning. As pointed out in [4], although probability theory is appropriate for measuring randomness of information, it is inappropriate for measuring the meaning of information.

For many applications, measuring vagueness (e.g. through a membership function that measures the "degree" to which an element belongs to a set) is more important than measuring randomness. While the fuzzy set approach has successfully overcome some of the problems with probabilistic reasoning, it relies on fairly detailed comparative knowledge of the domain being described. Not only must one say that Tom is tall, for instance, but one must also state specifically to what degree.

Here we propose a simpler model based on properties between concepts. Vagueness can be expressed by relaxing the properties between concepts in accordance with a user's criteria. The criteria can be flexibly and modularly adjusted for experimental purposes while still maintaining direct executability. For our model described so far, we need only introduce the following enhancement.

That is, rather than inflexibly allowing a concept to be formed if a test succeeds while disallowing its formation if that test fails, we instead denote those tests which we wish to make flexible as properties. Properties are like any other test, except that their failure does not necessarily result in the failure of the rule itself. Rather, the concept will still be formed and two lists will be associated with it: a list of the properties that the concept satisfies, S, and a list of those that it violates, V.

This allows us to construct possibly incorrect or incomplete concepts while collecting the information as to what way they are not totally justified. The user then has all the information pertaining to the construction of a particular concept and can interpret these results in a much more informed, holistic way. This is in contrast to the blind computation of the degree of randomness or vagueness from those assigned a priori to each individual piece of the reasoning puzzle.

In other cases, however, it will be more appropriate for the new concepts to replace the concepts that led to it. For instance, imagine a rule which uses the concept that a teacher is free at time T and that a parent is free at the same time T in order to add the concept that a meeting between these two individuals should be scheduled for time T. Obviously, once a meeting at time T has been arranged between them, they can no longer be considered as free at that time. Yet another type of rule is needed to remove redundant concepts such as "John must meet Alice at six" and "Alice must meet John at six".

In this paper we primarily use the first type of rule, but all three types maintain computational counterparts within our model. Information Selection Most of the rules in our knowledge store will be irrelevant to the situation at hand, so the first problem in our model, and in constructivism in general, is the problem of selecting the appropriate information in order to form new concept(s) (which are actually relevant to the problem).

We solve this by using a system that constantly searches for any information that may match the new information (i.e., the initial problem's concepts, or the concepts formed while attempting a solution) and consequently triggers those rules whose left-hand side at least partially matches some of the new information.

If we consider our previous example, then as soon as the new information that the speed limit is 50km/hr and the current speed is 100km/hr arrives in the knowledge store, a search through that store is initiated which ultimately yields rule (2), whose left hand side will be matched with unifier $\{X=50, Y=100\}$. The unifier will apply to the rest of the rule as well, and a test to see whether $100 > 50$ will be performed. Since the test will succeed, the new information speeding_ticket(likely) will be added to the knowledge store.

FLEXIBLE CONCEPT FORMATION

Binary logic is notoriously insufficient for modeling the human mind. The main alternatives are based either on probabilistic or fuzzy reasoning. As pointed out in [4], although probability theory is appropriate for measuring randomness of information, it is inappropriate for measuring the meaning of information.

For many applications, measuring vagueness (e.g. through a membership function that measures the "degree" to which an element belongs to a set) is more important than measuring randomness. While the fuzzy set approach has successfully overcome some of the problems with probabilistic reasoning, it relies on fairly detailed comparative knowledge of the domain being described. Not only must one say that Tom is tall, for instance, but one must also state specifically to what degree.

Here we propose a simpler model based on properties between concepts. Vagueness can be expressed by relaxing the properties between concepts in accordance with a user's criteria. The criteria can be flexibly and modularly adjusted for experimental purposes while still maintaining direct executability. For our model described so far, we need only introduce the following enhancement.

That is, rather than inflexibly allowing a concept to be formed if a test succeeds while disallowing its formation if that test fails, we instead denote those tests which we wish to make flexible as properties. Properties are like any other test, except that their failure does not necessarily result in the failure of the rule itself. Rather, the concept will still be formed and two lists will be associated

with it: a list of the properties that the concept satisfies, S, and a list of those that it violates, V.

This allows us to construct possibly incorrect or incomplete concepts while collecting the information as to what way they aren't totally justified. The user then has all the information pertaining to the construction of a particular concept and can interpret these results in a much more informed, holistic way. This is in contrast to the blind computation of the degree of randomness or vagueness from those assigned a priori to each individual piece of the reasoning puzzle.

Transforming the Knowledge Store Just as rule selection follows automatically from the system's normal search for applicable rules, the transformation of the knowledge store is achieved as a side effect of the system's normal procedure of applying a concept formation rule. In some cases the newly formed concepts will need to coexist with the concepts that participated in their formation, such as when forming a concept based on some transitive property.

In other cases, however, it will be more appropriate for the new concepts to replace the concepts that led to it. For instance, imagine a rule which uses the concept that a teacher is free at time T and that a parent is free at the same time T in order to add the concept that a meeting between these two individuals should be scheduled for time T. Obviously, once a meeting at time T has been arranged between them, they can no longer be considered as free at that time. Yet another type of rule is needed to remove redundant concepts such as "John must meet Alice at six" and "Alice must meet John at six". In this paper we primarily use the first type of rule, but all three types maintain computational counterparts within our model.

2.4 Making Decisions

It is also interesting to note that decisions also follow from the normal operation of the rules.

That is, depending on which of the currently considered concepts matches which rule, the decision on the appropriate rule to trigger is made, determining which new concepts will be formed. Newly added concepts then help further trigger rules, and so on until a solution is found or no new, useful, concepts can be constructed.

2.6 Cognitive Structure

Cognitive structure (such as schemas or mental models) provides meaning and organization to experiences and allows individuals to draw conclusions beyond the information actually given.

In our model, cognitive structure is provided by the rules themselves. The properties that are required between the concepts a given rule is trying to relate are particularly important, both for the formation of new concepts and achieving human-like flexibility.

CONCEPT FORMATION PROGRAMS/GRAMMARS

It is clear that CHRs can provide most of the features needed for a computational incarnation of our concept formation rules model: - Information selection is a side effect of the CHR engine's search over applicable rules. -

The transformation of information takes place automatically when a rule triggers, in the way sanctioned by the rule (namely, propagation rules update the knowledge store with the concept

newly formed). - Hypotheses can be made through assumptions.

In addition, we need to provide flexible cognitive structure through relax able, directly executable properties between concepts. This is achieved through concept formation rules, which have the same general form as CHR rules except that the guard may include any number of property calls for properties that have been defined by the user.

These calls are automatically handled by the system, provided that the user defines the properties as follows: a) A property must be named and defined through the binary predicate `prop/2`, whose first argument is the property's name and whose second argument is the list of arguments that are involved in checking the property and signaling the results.

Scheduled Meetings Consider the problem of scheduling meeting events between two groups of people given the availability of each person and the specific individuals that must meet. Regular scheduling software systems typically work in stages. The schedule is partially assigned until it reaches a meeting that it cannot schedule.

By re-shuffling the other meetings that have already been scheduled, it is then often possible to open up matching timeslots for the individuals in question. Our concept formation framework allows us to produce a higher-level solution in a concise and effective manner.

CONCLUSIONS

We have shown a powerful yet relatively simple cognitive model for concept formation inspired by constructivism. The methodology we present for implementing directly executable concept formation paradigms generalizes parsing methods we have developed specifically for natural language processing [6]. We have discussed our methodology for a directly executable, CHR-based rendition of this model, and exemplified its promise through two examples: (time) resource allocation, and error detection and correction.

Other approaches need considerable more apparatus to solve the same problem (for example, [7] uses a fairly involved abductive model based on CHRGs for error detection and correction in string processing problem domains). We are also currently working on applying concept formation to the problem of identifying biomarkers in cancer diagnosis systems [8].

STRATEGIES; ROLE OF CONCEPTS IN THINKING

As discussed in the previous section, you may recall that the potential for creative thinking is in all of us. It is not limited to a few talented artists or scientists or to a chosen few. The expression of creative thinking may vary from individual to individual. Although hereditary factors are important in determining the extent to which one can be creative, environmental factors facilitate or hamper the development of creative thinking abilities.

Research in different countries including India has shown a slump in the level of creative thinking of

school children at different stages due to environmental factors. On the other hand, research also indicates that children from lower socio-economic groups, ethnic and minority groups have substantial untapped creativity and that they are creative in many different ways.

Research has also shown that all of us can make better use of our abilities for creative thinking through practice and training. We can become more imaginative, flexible, and original in solving day-to-day problems creatively and effectively. Development of creative thinking is important for one's personal growth and fulfilment.

BARRIERS TO CREATIVE THINKING

The first step in developing creative thinking is to identify inhibiting factors that impede creative expression and then make conscious attempts to overcome the same. As we are discussing, you may analyse how you approach your tasks and problems.

There are blocks to creative thinking which can be categorised as habitual, perceptual, motivational, emotional, and cultural. Although much habitual learning is necessary for smooth and efficient functioning within the daily routine, the tendency to be overpowered by habits particularly in one's ways of thinking.

STRATEGIES FOR CREATIVE THINKING

Research on characteristics of creative people has revealed that there are certain attitudes, dispositions, and skills which facilitate creative thinking. Here are some strategies to help you enhance your creative thinking abilities and skills:

- Become more aware and sensitive to be able to notice and respond to feelings, sights, sounds, textures around you. Spot problems, missing information, anomalies, gaps, deficiencies, and so on. Try to notice contradictions and incompleteness in situations that others may not do.

For this, cultivate the habit of wider reading, exposure to a variety of information, and develop the art of asking questions, pondering over the mysteries of situations and objects.

- Generate as many ideas, responses, solutions or suggestions on a given task or situation to increase your flow of thoughts. Try deliberately to look for multiple angles of a task and situation to increase flexibility in your thinking.

It could be, for example, thinking of alternative arrangements of furniture in a room to generate more space, different ways of conversing with people, looking for costs and benefits of a course of study or career, looking for ways of dealing with an angry friend, helping others, etc.

- Osborn's Brainstorming technique can be used to increase fluency and flexibility of ideas to open-ended situations. Brainstorming is based on the principle that producing ideas should be kept separate from the evaluation of their worth. The basic assumption is to let them think

freely and the tendency to put judgment on the worth of ideas may be postponed, i.e. imagination should be given priority over judgment till all the ideas are exhausted.

This helps in increasing the fluency of ideas and piling up alternatives. Brainstorming can be practised by playing brainstorming games with family members and friends keeping its principles in mind. Use of checklists and questions often provide a new twist for ideas like, What other changes? What else? In how many ways could it be done? What could be the other uses of this object? and so on.

- Originality can be developed by practicing fluency, flexibility, habit of associative thinking, exploring linkages, and fusing distinct or remote ideas. A creative thinker, it is said, may not evolve new ideas but evolve new combination of ideas. It is the chain of thoughts and cross-fertilisation of ideas that may bring out something new.
- The idea of the 'rocking chair' has come from the combination of 'chair' and 'seesaw'. Practice making unusual and unexpected associations using analogies. Sometimes finding original ideas/solutions requires a dramatic shift of focus which can be facilitated by asking oneself : what is the opposite of the commonplace or usual solution to the problem? Allow conflicting thoughts to co-exist. Looking for solutions opposite to the obvious may lead to original solutions.
- Engage yourself more frequently in activities which require use of imagination and original thinking rather than routine work according to your interest and hobbies. It may be decorating the house, improvising or redesigning of old objects, making use of waste products in multiple ways, completing incomplete ideas in unique ways, giving new twist to stories or poems, developing riddles, puzzles, solving mysteries and so on.
- Never accept the first idea or solution. Many ideas die because we reject them thinking that the idea might be a silly idea. You have to first generate a number of possible ideas or solutions, then select the best from among them.
- Get a feedback on the solutions you decide on from others who are less personally involved in the task.
- Try to think of what solutions someone else may offer for your problems.
- Give your ideas the chance to incubate. Allowing time for incubation between production of ideas and the stage of evaluation of ideas, may bring in the 'Aha!' experience.
- Sometimes ideas cluster like branches of a tree. It is useful to diagram your thinking so that you can follow each possible branch to its completion.
- Resist the temptation for immediate reward and success and cope with the frustration and failure. Encourage self-evaluation. • Develop independent thinking in making judgments, figuring out things without any help or resources.
- Visualize causes and consequences and think ahead, predicting things that have never

happened, like, suppose the time starts moving backwards, what would happen? If we had no zero?, etc.

- Be aware of your own defenses concerning the problem. When we feel threatened by a problem, we are less likely to think of creative ideas.
- Last but not the least, be self-confident and positive. Never undermine your creative potential. Experience the joy of your creation.

TYPES OF REASONING

Reasoning is the process of using existing knowledge to draw conclusions, make predictions, or construct explanations. Three methods of reasoning are the deductive, inductive, and abductive approaches.

- 1) **Deductive reasoning: conclusion guaranteed** Deductive reasoning starts with the assertion of a general rule and proceeds from there to a guaranteed specific conclusion. Deductive reasoning moves from the general rule to the specific application: In deductive reasoning, if the original assertions are true, then the conclusion must also be true.

Assuming the propositions are sound, the rather stern logic of deductive reasoning can give you absolutely certain conclusions. However, deductive reasoning cannot really increase human knowledge (it is nonampliative) because the conclusions yielded by deductive reasoning are tautologies-statements that are contained within the premises and virtually self-evident.

Therefore, while with deductive reasoning we can make observations and expand implications, we cannot make predictions about future or otherwise non-observed phenomena.

- 2) **Inductive reasoning: conclusion merely likely** Inductive reasoning begins with observations that are specific and limited in scope, and proceeds to a generalized conclusion that is likely, but not certain, in light of accumulated evidence. You could say that inductive reasoning moves from the specific to the general. Much scientific research is carried out by the inductive method: gathering evidence, seeking patterns, and forming a hypothesis or theory to explain what is seen.

Conclusions reached by the inductive method are not logical necessities; no amount of inductive evidence guarantees the conclusion. This is because there is no way to know that all the possible evidence has been gathered, and that there exists no further bit of unobserved evidence that might invalidate my hypothesis.

Because inductive conclusions are not logical necessities, inductive arguments are not simply true. Rather, they are cogent: that is, the evidence seems complete, relevant, and generally convincing, and the conclusion is therefore probably true. Nor are inductive arguments simply false; rather, they are not cogent.

It is an important difference from deductive reasoning that, while inductive reasoning cannot

yield an absolutely certain conclusion, it can actually increase human knowledge (it is ampliative). It can make predictions about future events or as-yet unobserved phenomena. For example, Albert Einstein observed the movement of a pocket compass when he was five years old and became fascinated with the idea that something invisible in the space around the compass needle was causing it to move.

This observation, combined with additional observations (of moving trains, for example) and the results of logical and mathematical tools (deduction), resulted in a rule that fit his observations and could predict events that were as yet unobserved.

- 3) **Abductive reasoning: taking your best shot** Abductive reasoning typically begins with an incomplete set of observations and proceeds to the likeliest possible explanation for the set. Abductive reasoning yields the kind of daily decision-making that does its best with the information at hand, which often is incomplete.

A medical diagnosis is an application of abductive reasoning: given this set of symptoms, what is the diagnosis that would best explain most of them? Likewise, when jurors hear evidence in a criminal case, they must consider whether the prosecution or the defense has the best explanation to cover all the points of evidence. While there may be no certainty about their verdict, since there may exist additional evidence that was not admitted in the case, they make their best guess based on what they know.

While cogent inductive reasoning requires that the evidence that might shed light on the subject be fairly complete, whether positive or negative, abductive reasoning is characterized by lack of completeness, either in the evidence, or in the explanation, or both. A patient may be unconscious or fail to report every symptom, for example, resulting in incomplete evidence, or a doctor may arrive at a diagnosis that fails to explain several of the symptoms. Still, he must reach the best diagnosis he can.

LANGUAGE AND THOUGHT

Till now, we have discussed the nature and meaning of thinking and how thinking is based on images and concepts. We have also discussed the various processes of thought. Throughout the discussion did you feel that words or language are essential to express what we think?

This section examines the relationship between language and thought: that language determines thought, that thought determines language, and that thought and language have different origins. Let us examine these three viewpoints in some detail.

LANGUAGE AS DETERMINANT OF THOUGHT

In Hindi and other Indian languages we use a number of different words for various kinship relationships. We have different terms for mother's brother, father's elder brother, father's younger

brother, mother's sister's husband, father's sister's husband, and so on. An English person uses just one word uncle to describe all these kinship relationships.

In the English language there are dozens of words for colours whereas some tribal languages have only two to four colour terms. Do such differences matter for how we think? Does an Indian child find it easier to think about and differentiate between various kinship relationships compared to her Englishspeaking counterpart? Does our thinking process depend on how we describe it in our language? Benjamin Lee Whorf was of the view that language determines the contents of thought.

This view is known as linguistic relativity hypothesis. In its strong version, this hypothesis holds what and how individuals can possibly think is determined by the language and linguistic categories they use (linguistic determinism). Experimental evidence, however, maintains that it is possible to have the same level or quality of thoughts in all languages depending upon the availability of linguistic categories and structures. Some thoughts may be easier in one language compared to another.

Thought as Determinant of Language The noted Swiss psychologist, Jean Piaget believed that thought not only determines language, but also precedes it. Piaget argued that children form an internal representation of the world through thinking. For example, when children see something and later copy it (a process called imitation), thinking does take place, which does not involve language. A child's observation of other's behaviour and imitation of the same behaviour, no doubt involves thinking but not language. Language is just one of the vehicles of thinking.

As actions become internalised, language may affect children's range of symbolic thinking but is not necessary for the origins of thought. Piaget believed that though language can be taught to children, understanding of the words require knowledge of the underlying concepts (i.e. thinking). Thus, thought is basic, and necessary if language is to be understood. Different Origins of Language and Thought.

The Russian psychologist, Lev Vyogotsky, argued that thoughts and language develop in a child separately until about two years of age, when they merge. Before two years thought is preverbal and is experienced more in action (Piaget's sensory motor stage). The child's utterances are more automatic reflexes - crying when uncomfortable - than thought based. Around two years of age, the child expresses thought verbally and her/his speech reflects rationality. Now children are able to manipulate thoughts using soundless speech.

He believed that during this period the development of language and thinking become interdependent; the development of conceptual thinking depends upon the quality of inner speech and vice versa. Thought is used without language when the vehicle of thinking is non-verbal such as visual or movement related. Language is used without thought when expressing feelings or exchanging pleasantries, for example "Good morning! How are you?" "Very well,

MEANING AND NATURE OF LANGUAGE

In the previous section we discussed the relationship between language and thought. In this section, we will examine how human beings acquire and use language in different age groups. Think for a moment: what would have happened if you did not have a language to express whatever you wanted to say? In the absence of language you will not be able to communicate your ideas and feelings, nor will you have the opportunity to know or have access to what others think and feel.

As a child when you first started saying “ma..ma..ma.”, it not only gave you tremendous boost to continue repeating this activity but also was a great moment of joy for your parents and other caregivers. Slowly you learnt to say ‘ma’ and ‘papa’ and sometime later combined two or more words to communicate your needs, feelings, and thoughts. You learnt words appropriate for situations and also learnt the rules of putting these words in sentences.

Initially you learnt to communicate in the language being used at home (usually the mother-tongue), went to school and learnt the formal language of instruction (in many cases this language is different from the mother-tongue), and were promoted to higher grades and learnt other languages. If you look back, you will realise that your journey from crying and saying “ma..ma..ma” to the attainment of mastery in not one but many languages, has been a fascinating one. In this section we shall be discussing the salient features of language acquisition.

You have been using language all your life. Now try to define accurately what it is that you have been using. Language consists of a system of symbols organised by means of certain rules that we use to communicate with each other. You will notice that language has three basic characteristics: (a) the presence of symbols, (b) a set of rules to organise these symbols, and (c) communication. Here we shall be discussing these three characteristics of language.

The first characteristic of language is that it involves symbols. Symbols represent something or someone else, for example, the place where you live is called ‘home’, the place where you study is called ‘school’, the thing that you eat is called ‘food’. Words like home, school, food, and numerous other words do not in themselves carry any meaning.

When these words are associated with some objects/ events they attain meaning and we begin recognising those objects/events, etc. with particular words (symbols). We use symbols while thinking. The second characteristic of language is that it involves rules. While combining two or more words we usually follow a definite and accepted order of presenting these words.

For example, one would most likely say “I am going to school” and not “school am going I”. The third characteristic of language is that it is used for communicating one’s thought, ideas,

DEVELOPMENT OF LANGUAGE LANGUAGE

is a complex system and unique to human beings. Psychologists have tried to teach sign language,

use of symbols to chimpanzees, dolphins, parrots, etc. But it is observed that, human language is more complex, creative, and spontaneous than the system of communication other animals can learn. There is also a great deal of regularity with which children all over the world seem to be learning the language or languages to which they are exposed.

When you compare individual children, you find that they differ in intentions, and feelings to others. On many occasions we communicate through the use of our body parts, called gestures or postures. This type of communication is called non-verbal communication. Some people who cannot use oral speech, like the ones with severe hearing and speech problems, communicate through signs. Sign language is also a form of language.

great deal in the rate of their language development as well as in how they go about it. But when you take a general view of children's acquisition of language all over the world you find some predictable pattern in which children proceed from almost no use of language to the point of becoming competent language users.

Language develops through some of the stages discussed below. Newborn babies and young infants make a variety of sounds, which gradually get modified to resemble words. The first sound produced by babies is crying. Initial crying is undifferentiated and similar across various situations. Gradually, the pattern of crying varies in its pitch and intensity to signify different states such as hunger, pain, and sleepiness, etc.

These differentiated crying sounds gradually become more meaningful cooing sounds (like 'aaa', 'uuu', etc.) usually to express happiness. At around six months of age children enter the babbling stage. Babbling involves prolonged repetition of a variety of consonants and vowel sounds (for example, da—, aa—, ba—). By about nine months of age these sounds get elaborated to strings of some sound combinations, such as 'dadadadada' into repetitive patterns called echolalia. While the early babblings are random or accidental in nature, the later babblings seem to be imitative of adult voices. Children show some understanding of a few words by the time they are six months old. Around the first birthday (the exact age varies from child to child) most children enter the one-word- stage. Their first word usually contains one syllable – ma or da, for instance.

Gradually they move to one or more words which are combined to form whole sentences or phrases. So they are called holophrases. When they are 18 to 20 months of age, children enter a two-word stage and begin to use two words together. The two-word stage exemplifies telegraphic speech. Like telegrams (got admission, send money) it contains mostly nouns and verbs.

Close to their third birthday, i.e. beyond two-and-a-half years, children's language development gets focused on rules of the language they hear. Comparisons of different languages can lead one to pay attention to 'universals'—the ways in which all languages are similar, and to 'particulars' — the ways in which each individual language, or type of language, is special, even unique.

Linguists and other social scientists interested in universals have formulated theories to describe and explain human language and human language behavior in general terms as species-specific capacities of human beings. However, the idea that different languages may influence thinking in different ways has been present in many cultures and has given rise to many philosophical treatises.

Because it is so difficult to pin down effects of a particular language on a particular thought pattern, this issue remains unresolved. It comes in and out of fashion and often evokes considerable energy in efforts to support or refute it.

LANGUAGE USE

As we have discussed earlier, language use involves knowing socially appropriate ways of communication. Knowledge of vocabulary and syntax of a language does not ensure proper use of language to achieve the purpose of communication in a variety of social situations. When we use language we have various pragmatic intentions such as requesting, asking, thanking, demanding, etc.

In order to effectively serve these social goals, language use must be pragmatically correct or contextually appropriate besides being grammatical and meaningful. Children often have difficulty with choice of appropriate utterances for politeness or for requests and their use of language conveys a demand or a command instead of a polite request. When children are engaged in conversations, they also have difficulty in taking turns in speaking and listening like adults.

RELATIVITY AND DETERMINISM

There are two problems to confront in this arena: linguistic relativity and linguistic determinism. Relativity is easy to demonstrate. In order to speak any language, you have to pay attention to the meanings that are grammatically marked in that language.

For example, in English it is necessary to mark the verb to indicate the time of occurrence of an event you are speaking about: It's raining; It rained; and so forth. In Turkish, however, it is impossible to simply say, 'It rained last night'.

This language, like many American Indian languages, has more than one past tense, depending on one's source of knowledge of the event. In Turkish, there are two past tenses—one to report direct experience and the other to report events that you know about only by inference or hearsay.

Thus, if you were out in the rain last night, you will say, 'It rained last night' using the past-tense form that indicates that you were a witness to the rain; but if you wake up in the morning and see the wet street and garden, you are obliged to use the other past-tense form—the one that indicates that you were not a witness to the rain itself.

Differences of this sort have fascinated linguists and anthropologists for centuries. They have reported hundreds of facts about 'exotic' languages, such as verbs that are marked or chosen according to the shape of an object that is being handled (Navajo) or for the relative ages of speaker and hearer (Korean). Such facts are grist for the mill of linguistic relativity. And, indeed, they can be found quite readily in 'nonexotic' languages as well.

To cite a fact about English that is well known to linguists: It is not appropriate to say Richard Nixon has worked in Washington, but it is perfectly OK to say Gerald Ford has worked in Washington. Why? English restricts the present perfect tense ('has worked') to assertions about people who are alive. Exotic! Proponents of linguistic determinism argue that such differences between languages influence the ways people think—perhaps the ways in which whole cultures are organized.

Among the strongest statements of this position are those by Benjamin Lee Whorf and his teacher, Edward Sapir, in the first half of this century—hence the label, 'The Sapir-Whorf Hypothesis', for the theory of linguistic relativity and determinism. Whorf proposed: 'We cut nature up, organize it into concepts, and ascribe significances as we do, largely because we are parties to an agreement to organize it in this way—an agreement that holds throughout our speech community and is codified in the patterns of our language' (Whorf, 1940; in Carroll, 1956, pp. 213-4).

And, in the words of Sapir: 'Human beings...are very much at the mercy of the particular language which has become the medium of expression for their society. ...The fact of the matter is that the "real world" is to a large extent unconsciously built up on the language habits of the group' (Sapir, 1929; in Manlbaum, 1958, p. 162).

INVESTIGATING LANGUAGE AND THOUGHT

How can such bold claims be substantiated beyond examination of individual languages themselves? If one takes the hypothesis seriously, it should be possible to show that Turks are more sensitive to evidence than are Americans, but that Americans are more aware of death than Turks. Clearly, the hypothesis cannot be supported on so grand a level.

Rather, experimental psychologists and cognitive anthropologists have sought to find small differences, on controlled tasks, between speakers of various languages. Maybe Navajos are somewhat more sensitive to shapes of objects, for example. The results have been mixed. In most cases, human thought and action are overdetermined by an array of causes, so the structure of language may not play a central causal role.

Linguistic determinism can best be demonstrated in situations in which language is the principal means of drawing people's attention to a particular aspect of experience. For example, if you regularly speak a language in which you must pick a form of second-person address (you) that marks your social relationship to your interlocutor.

such as Spanish *tu* ('you' for friends and family and for those socially subordinate) vs. *usted* ('you'

for those socially above in status or for those with whom you have no close connection) or French tu versus vous—you must categorize every person you talk to in terms of the relevant social dimensions. (As a thought experiment of linguistic determinism, think of the categorizations of social relationships that would have to be made if Spanish became the common language of the United States.)

PROBLEM SOLVING

How do we proceed while repairing a broken cycle, or planning a summer tour or patching up a broken friendship? In some cases the solution is reached quickly as in repair of a bicycle based on immediately available cues whereas others are more complex and require time and effort. Problem solving is thinking that is goal-directed.

Almost all our day-to-day activities are directed towards a goal. Here it is important to know that problems are not always in the form of obstacles or hurdles that one faces. It could be any simple activity that you perform to reach a defined goal, for example, preparing a quick snack for your friend who has just arrived at your place. In problem solving there is an initial state (i.e. the problem) and there is an end state (the goal).

These two anchors are connected by means of several steps or mental operations. would clarify your understanding of various steps through which one solves a problem. You can try out the problems given in Activity 8.3 with your friends and observe how they are approaching the problem. You can ask them the steps they follow while solving these problems From organizing your movie collection to deciding to buy a house, problem-solving makes up a large part of daily life.

Problems can range from small (solving a single math equation on your homework assignment) to very large (planning your future career). In cognitive psychology, the term problem-solving refers to the mental process that people go through to discover, analyze, and solve problems.¹ This involves all of the steps in the problem process, including the discovery of the problem, the decision to tackle the issue, understanding the problem, researching the available options and taking actions to achieve your goals.

Before problem-solving can occur, it is important to first understand the exact nature of the problem itself. If your understanding of the issue is faulty, your attempts to resolve it will also be incorrect or flawed.

MENTAL PROCESSES AT WORK DURING PROBLEM-SOLVING

There are a number of mental processes at work during problem-solving. These include:

- Perceptually recognizing a problem
- Representing the problem in memory
- Considering relevant information that applies to the current problem
- Identify different aspects of the problem
- Labeling and describing the problem

PROBLEM-SOLVING STRATEGIES

- **Algorithms:** An algorithm is a step-by-step procedure that will always produce a correct solution. A mathematical formula is a good example of a problem-solving algorithm. While an algorithm guarantees an accurate answer, it is not always the best approach to problem-solving. This strategy is not practical for many situations because it can be so time-consuming.

For example, if you were trying to figure out all of the possible number combinations to a lock using an algorithm, it would take a very long time!

- **Heuristics:** A heuristic is a mental rule-of-thumb strategy that may or may not work in certain situations. Unlike algorithms, heuristics do not always guarantee a correct solution. However, using this problem-solving strategy does allow people to simplify complex problems and reduce the total number of possible solutions to a more manageable set.
- **Trial and Error:** A trial-and-error approach to problem-solving involves trying a number of different solutions and ruling out those that do not work. This approach can be a good option if you have a very limited number of options available. If there are many different choices, you are better off narrowing down the possible options using another problem-solving technique before attempting trial-and-error.
- **Insight:** In some cases, the solution to a problem can appear as a sudden insight. According to researchers, insight can occur because you realize that the problem is actually similar to something that you have dealt with in the past, but in most cases, the underlying mental processes that lead to insight happen outside of awareness.

OBSTACLES IN PROBLEM-SOLVING

Of course, problem-solving is not a flawless process. There are a number of different obstacles that can interfere with our ability to solve a problem quickly and efficiently. Researchers have described a number of these mental obstacles, which include functional fixedness, irrelevant information, and assumptions.

- **Functional Fixedness:** This term refers to the tendency to view problems only in their customary manner. Functional fixedness prevents people from fully seeing all of the different options that might be available to find a solution.
- **Irrelevant or Misleading Information:** When you are trying to solve a problem, it is important to distinguish between information that is relevant to the issue and irrelevant data that can lead to faulty solutions. When a problem is very complex, the easier it becomes to focus on misleading or irrelevant information.
- **Assumptions:** When dealing with a problem, people often make assumptions about the constraints and obstacles that prevent certain solutions.
- **Mental Set:** Another common problem-solving obstacle is known as a mental set, which is the tendency people have to only use solutions that have worked in the past rather than looking for

alternative ideas.

A mental set can often work as a heuristic, making it a useful problem-solving tool. However, mental sets can also lead to inflexibility, making it more difficult to find effective solutions.

☒

A particular strategy would sometimes help in solving a new problem. However, this tendency also creates a mental rigidity that obstructs the problem solver to think of any new rules or strategies. Thus, while in some situations mental set can enhance the quality and speed of problem solving, in other situations it hinders problem solving.

You might have experienced this while solving mathematical problems. After completing a couple of questions, you form an idea of the steps that are required to solve these questions and subsequently you go on following the same steps, until a point where you fail. At this point you may experience difficulty in avoiding the already used steps. Those steps would interfere in your thought for new strategies.

However, in day-to-day activities we often rely on past experiences with similar or related problems. Like mental set, functional fixedness in problem solving occurs when people fail to solve a problem because they are fixed on a thing's usual function. If you have ever used a hardbound book to hammer a nail, then you have overcome functional fixedness.

LACK OF MOTIVATION

People might be great at solving problems, but all their skills and talents are of no use if they are not motivated. Sometimes people give up easily when they encounter a problem or failure in implementing the first step. Therefore, there is a need to persist in their effort to find a solution.

DECISION-MAKING

Inductive and deductive reasonings allow us to make judgments. In judgment we draw conclusions, form opinions, evaluate events, objects, based on knowledge and available evidences. Consider this example, the man is very talkative, likes to mix with people, can convince others with ease – he would be most suitable for a salesperson's job.

Our judgment of this person is based on the specific characteristics of an expert salesperson. Here we will discuss how we make decisions and judgments. Sometimes judgments are automatic and require no conscious effort by the person and occur as a matter of habit, for example, applying brakes on seeing the red light.

However, evaluating a novel or a literary text requires reference to your past knowledge and experience. Judging the beauty of a painting would involve your personal preferences. Thus our judgments are not independent of our beliefs and attitudes. We also make changes in our judgments based on newly acquired information. Consider this example.

A new teacher joins the school, students make on-the-spot judgment of the teacher as being very strict. However, in subsequent classes, they closely interact with the teacher and make changes in their evaluation. Now they judge the teacher to be extremely student-friendly. Many of the problems you solve each day require you to make decisions. What to wear for the party? What to eat for dinner? What to say to your friend?

The answer to all these lies in picking or choosing one of several choices. In decision-making, we sometimes choose among options based on choices of personal significance. Judgment and decision-making are interrelated processes. In decision-making the problem before us is to choose among alternatives by evaluating the cost and benefit associated with each alternative.

For example, when you have the option to choose between psychology and economics as subjects in Class XI, your decision would be based upon your interest, future prospects, availability of books, efficiency of teachers, etc. You could evaluate them by talking to seniors and faculty members and attending a few classes, etc. Decision-making differs from other types of problem solving.

In decision-making we already know the various solutions or choices and one has to be selected. Suppose your friend is a very good player of badminton. S/he is getting an opportunity to play at the state level. At the same time the final examination is approaching and s/he needs to study hard for it. S/he will have to choose between two options, practising for badminton or studying for the final examination.

In this situation her/his decision will be based upon evaluation of all possible outcomes. You would observe that people differ in their priorities and therefore their decisions will differ. In real-life situations we take quick decisions and therefore, it is not possible always to evaluate every situation thoroughly and exhaustively.

The decision-making process though a logical one is a difficult task. All decisions can be categorized into the following three basic models.

- 1) The Rational/Classical Model.
- 2) The Administrative or Bounded Rationality Model.
- 3) The Retrospective Decision-Making Model.

All models are beneficial for understanding the nature of decision-making processes in enterprises or organisations. All models are based on certain assumptions on which the decisions are taken.

- 1) **THE RATIONAL/CLASSICAL MODEL:** The rational model is the first attempt to know the decision-making process. It is considered by some as the classical approach to understand the decision-making process. The classical model gave various steps in decision-making process which have been discussed earlier.

FEATURES OF CLASSICAL MODEL

- 1) Problems are clear.

- 2) Objectives are clear.
- 3) People agree on criteria and weights.
- 4) All alternatives are known.
- 5) All consequences can be anticipated.
- 6) Decision makes are rational.

- i. They are not biased in recognizing problems.
- ii. They are capable of processing all relevant information
- iii. They anticipate present and future consequences of decisions.
- iv. They search for all alternatives that maximizes the desired results.

2) **BOUNDED RATIONALITY MODEL OR ADMINISTRATIVE MAN MODEL:** Decision-making involve the achievement of a goal. Rationality demands that the decision-maker should properly understand the alternative courses of action for reaching the goals. He should also have full information and the ability to analyse properly various alternative courses of action in the light of goals sought.

There should also be a desire to select the best solutions by selecting the alternative which will satisfy the goal achievement. Herbert A. Simon defines rationality in terms of objective and intelligent action. It is characterized by behavioural nexus between ends and means. If appropriate means are chosen to reach desired ends the decision is rational. Bounded Rationality model is based on the concept developed by Herbert Simon.

This model does not assume individual rationality in the decision process. Instead, it assumes that people, while they may seek the best solution, normally settle for much less, because the decisions they confront typically demand greater information, time, processing capabilities than they possess. They settle for "bounded rationality or limited rationality in decisions. This model is based on certain basic concepts.

A) SEQUENTIAL ATTENTION TO ALTERNATIVE SOLUTION: Normally it is the tendency for people to examine possible solution one at a time instead of identifying all possible solutions and stop searching once an acceptable (though not necessarily the best) solution is found.

B) HEURISTIC: These are the assumptions that guide the search for alternatives into areas that have a high probability for yielding success.

(C) SATISFICING: Herbert Simon called this "satisficing" that is picking a course of action that is satisfactory or "good enough" under the circumstances. It is the tendency for decision makers to accept the first alternative that meets their minimally acceptable requirements rather than pushing them further for an alternative that produces the best results.

Satisficing is preferred for decisions of small significance when time is the major constraint or where most of the alternatives are essentially similar. Thus, while the rational or classic

model indicates how decisions should be made (i.e. it works as a prescriptive model), it falls somewhat short concerning how decisions are actually made (i.e.as a descriptive model).

3) **RETROSPECTIVE DECISION MODEL (IMPLICIT FAVOURITE MODEL):**This decision-making model focuses on how decision-makers attempt to rationalise their choices after they have been made and try to justify their decisions. This model has been developed by Per Soelberg.

He made an observation regarding the job choice processes of graduating business students and noted that, in many cases, the students identified implicit favorites (i.e. the alternative they wanted) very early in the recruiting and choice process. However, students continued their search for additional alternatives and quickly selected the best alternative.

The total process is designed to justify, through the guise of scientific rigor, a decision that has already been made intuitively. By this means, the individual becomes convinced that he or she is acting rationally and taking a logical, reasoned decision on an important topic.

SOME COMMON ERRORS IN DECISION-MAKING

Since the importance of the right decision cannot be overestimated enough for the quality of the decisions can make the difference between success and failure. Therefore, it is imperative that all factors affecting the decision be properly looked into and fully investigated.

In addition to technical and operational factors which can be quantified and analyzed, other factors such as personal values, personality traits, psychological assessment, perception of the environment, intuitional and judgmental capabilities and emotional interference must also be understood and credited.

Some researchers have pinpointed certain areas where managerial thinking needs to be re-assessed and where some common mistakes are made. These affect the decision-making process as well as the efficiency of the decision and must be avoided.

SOME OF THE ERRORS RE:

- (I) **INDECISIVENESS:** Decision-making is full of responsibility. The fear of its outcome can make some people timid about taking a decision. This timidity may result in taking a long time for making a decision and the opportunity may be lost. This trait is a personality trait and must be looked into seriously. The managers must be very quick in deciding.
- (II) **POSTPONING THE DECISION UNTIL THE LAST MOMENT:**This is a common feature which results in decision-making under pressure of time which generally eliminates the possibility of thorough analysis of the problem which is time consuming as well as the establishment and comparison of all alternatives. Many students, who postpone studying until near their final

exams, usually do not do well in the exams.

Even though some managers work better under pressures, most often an adequate time period is required to look objectively at the problem and make an intelligent decision. Accordingly, a decision plan must be formulated; time limits must be set for information gathering, analysis and selection of a course of action.

(III) **A FAILURE TO ISOLATE THE ROOT CAUSE OF THE PROBLEM:** It is a common practice to cure the symptoms rather than the causes. For example, a headache may be on account of some deep-rooted emotional problem. A medicine for the headache would not cure the problem. It is necessary to separate the symptoms and their causes.

(IV) **A FAILURE TO ASSESS THE RELIABILITY OF INFORMATIONAL SOURCES:** Very often, we take it for granted that the other person's opinion is very reliable and trustworthy, and we do not check for the accuracy of the information ourselves.

Many a time, the opinion of the other person is taken, so that if the decision fails to bring the desired results, the blame for the failure can be shifted to the person who had provided the information. However, this is a poor reflection on the manager's ability and integrity and the manager must be held responsible for the outcome of the decision.

(V) **THE METHOD FOR ANALYSING THE INFORMATION MAY NOT BE THE SOUND ONE:** Since most decisions and especially the non-programmed ones have to be based upon a lot of information and factors, the procedure to identify, isolate and select the useful information must be sound and dependable.

Usually, it is not operationally feasible to objectively analyze more than five or six pieces of information at a time. Hence, a model must be built which incorporates and handles many variables in order to aid the decision makers. Also, it will be desirable to define the objectives, criteria and constraints as early in the decision-making process as possible.

This would assist in making the process more formal so that no conditions or alternatives would be overlooked. Following established procedures would eliminate the efforts of emotions which may cloud the process and rationality.

(VI) **DO IMPLEMENT THE DECISION AND FOLLOW THROUGH:** Making a decision is not the end of the process, rather it is a beginning. Implementation of the decision and the results obtained are the true barometer of the quality of the decision. Duties must be assigned, deadlines must be set, evaluation process must be established and contingency plans must be prepared in advance. The decisions must be implemented whole heartedly to get the best results.

METACOGNITION: METACOGNITIVE KNOWLEDGE AND METACOGNITIVE REGULATION

Metacognitive knowledge

Metacognitive strategies refers to methods used to help students understand the way they learn; in other words, it means processes designed for students to 'think' about their 'thinking'. Teachers who use metacognitive strategies can positively impact students who have learning disabilities by helping them to develop an appropriate plan for learning information, which can be memorized and eventually routine.

As students become aware of how they learn, they will use these processes to efficiently acquire new information, and consequently, become more of an independent thinker. Below are three metacognitive strategies, which all include related resources, that can be implemented in the classroom:

THINK ALOUD

Great for reading comprehension and problem solving. Think-alouds help students to consciously monitor and reflect upon what they are learning. This strategy works well when teachers read a story or problem out loud and periodically stop to verbalize their thoughts. This allows students to follow the teacher's thinking process, which gives them the foundation they need for creating their own strategies and processes that can be useful for understanding what they are trying to comprehend.

CHECKLIST, RUBRICS AND ORGANIZERS

Great for solving word problems. These organizational tools support students in the decision-making process because they serve as an aid for planning and self-evaluation. Typically they ask what students know and need to know to arrive at an answer, and emphasize the need to reread the problem and self-check responses.

EXPLICIT TEACHER MODELING

Great for math instruction. Explicit teacher modeling helps students understand what is expected of them through a clear example/model of a skill or concept. When a teacher provides a easy to follow procedure for solving a problem, students have a memorable strategy to use for approaching a problem on their own.

READING COMPREHENSION

Truly comprehending reading involves students actively engaging with a text and accurately deciphering the layers of meaning. It is very important for students to develop solid reading comprehension skills because statistics show that people who have low reading comprehension ability suffer in academic, professional, and personal pursuits. The resources in this guide from supersummary.com are effective strategies for promoting reading comprehension.

METACOGNITION AND LEARNING

Metacognition denotes in-depth thinking in which cognitive processes involved in learning are actively controlled. This includes planning how to accomplish a given learning task, monitoring understanding, and estimating progress toward the completion of a task. It is believed that students have greater ability to control goals, dispositions, and attention when they are more aware of their thinking processes as they learn.

This means that self-regulation is a result of self-awareness. For instance, when a student is aware of his lack of commitment to write his thesis, and bears the knowledge that he is procrastinating, delaying, and allowing himself to be distracted by other less important things, then he could take action to get started on doing the task. This is possible only if the student becomes aware of his procrastination and takes control in planning on how to approach his thesis completion.

COMPONENTS OF METACOGNITION

Metacognition is divided into three components:

- **Metacognitive knowledge:** Metacognitive knowledge refers to the awareness individuals possess about themselves and other people as cognitive processors.
- **Metacognitive regulation:** Metacognitive regulation, on the other hand, has to do with people's control over cognition and learning experiences through a set of methods that help people regulate their learning.
- **Metacognitive experiences:** Metacognitive experiences involve cognitive efforts that are currently taking place.

TYPES OF METACOGNITIVE KNOWLEDGE

The metacognitive knowledge component of metacognition is divided into three different types of knowledge:

- **Declarative knowledge:** Declarative knowledge refers to the factual information that we know, and can both be spoken or written. This is also the knowledge about ourselves as learners and about what factors can influence our performances.
- **Procedural knowledge:** Procedural knowledge refers to information on how to do something or how to perform the procedural steps that make up a task. A high degree of procedural knowledge allows us to perform tasks more automatically through a variety of strategies.
- **Conditional knowledge:** Conditional knowledge refers to the knowledge about when to use a procedure, skill, or strategy or when not to. Such knowledge allows us to assign optimal resources for various tasks.

SKILLS IN METACOGNITIVE REGULATION

There are three important skills in metacognitive regulation:

- Planning
- Monitoring
- Evaluating

Planning involves suitable selection of strategies and the right assignment of resources. Monitoring

includes awareness of understanding and task performance, while evaluating refers to the assessment of the final result of a task and the efficiency carried out during task performance.

METACOGNITIVE STRATEGIES

Research has shown that teaching students metacognitive strategies can improve learning. Among the different learning strategies that are commonly used when studying or doing homework are rote memorization, goal setting, monitoring, self-assessing, and regulating during thinking and writing processes.

METACOGNITIVE EXPERIENCES AND PROBLEM SOLVING

Research revealed the two components of metacognition – metacognitive knowledge and metacognitive experiences – impact individuals' problem solving differently. Flavell (1979) described metacognitive experiences as “any conscious cognitive or affective experience that accompany or pertain to any intellectual enterprise” (p. 906).

He believed they were more likely to occur during a task due to the importance of individuals' decisions and actions in the endeavor. Efklides (2001) maintained that metacognitive experiences monitored task characteristics and also reflected an individual's goals in task-making. She identified different categories of metacognitive experiences, and some of these included: feeling of familiarity, feeling of confidence, feeling of difficulty, feeling of satisfaction, estimate of solution correctness, and estimate of effort expenditure.

She found individuals' metacognitive experiences were influenced by cognitive ability as well as “personality and other affective factors”. Moreover, the author joined Flavell (1979) in linking metacognitive experiences to triggering metacognitive knowledge. Efklides maintained that metacognitive experiences “monitor online cognitive processing” from the individual's perspective, and “online task-specific knowledge” as well as for influencing “control decisions”.

Her research revealed that metacognitive experiences varied according to the level of “task difficulty” and “phase of cognitive processing (advance, planning, and solution production)”. Akama and Yamauchi's (2004) study underscored the role of metacognitive experiences in problem solving. The authors examined the effect of task performance on individuals' metacognitive experiences.

Comparisons of participants' metacognitive experiences questionnaire results before and after the task illustrated differences between those who successfully solved the puzzle and those who did not. The success group “reported significantly higher feeling of satisfaction” confidence, knowledge, and correctness of the solution than the failure group. The authors found participants' prior performance affected “Feeling of difficulty, Need to think of the Success group and Feeling of having knowledge after the task for both groups.

The study also showed high correlations between individuals' task performance and metacognitive experiences after the task, which the authors attributed to participants' performance. The article maintained that this result supported earlier studies that illustrated "participants can get information from their performance and revise metacognitive experiences after problem-solving".

METACOGNITIVE REGULATION

Metacognitive Experiences involve the use of Metacognitive Strategies or Metacognitive Regulation (Brown, 1987). Metacognitive strategies are sequential processes that one uses to control cognitive activities, and to ensure that a cognitive goal (eg:- understanding a text) has been met. These processes help to regulate and oversee learning, and consist of planning and monitoring cognitive activities, as well as checking the outcomes of those activities.

Thus metacognitive regulation is the regulation of cognition and learning experiences through a set of activities that help people control their learning. For example, after reading a paragraph in a text, a learner may question herself about the concepts discussed in the paragraph. Her cognitive goal is to understand the text. Self questioning is a common Metacognitive Comprehension Monitoring Strategy.

If she finds that she cannot answer her own questions, or that she does not understand the material discussed, she must then determine what needs to be done to ensure that she meets the cognitive goal of understanding the text. She may decide to go back and reread the paragraph with the goal of being able to answer the questions she had generated if, after rereading through the text she can now answer the questions, she may determine that she understands the material.

Thus, the Metacognitive Strategy of self questioning is used to ensure that the cognitive goal of comprehension is met. Metacognitive experiences are those experiences that have something to do with the current, ongoing cognitive endeavour. Metacognitive experiences usually precede or follow a cognitive activity. They often occur when cognitions fail, such as the recognition that one did not understand what one just read.

Such an impasse is believed to activate metacognitive processes as the learner attempts to rectify the situation. Metacognition, or the ability to control one's cognitive processes (self regulation) has been linked to intelligence (Borokowski et al., 1987, Brown, 1987, Sternberg, 1984, 1986). Sternberg refers to these executive processes as "Metacomponents in his triarchic theory of control, other cognitive components as well as receive feed back from these components.

According to Sternberg, Metacomponents are responsible for "figuring out how to do a particular task or set of tasks, and then making sure that the task or set of tasks are done correctly" (Sternberg, 1986). These executive processes involve planning, evaluating, monitoring and problem solving activities. Sternberg maintains that the ability to appropriately allocate cognitive resources, such as deciding how and when a given task should be accomplished is central to intelligence.

INTELLIGENCE: SPEARMAN; THURSTONE; JENSEN; CATTELL; GARDNER; STENBERG; GOLEMAN; DAS, KAR & PARRILA

General intelligence, also known as g factor, refers to the existence of a broad mental capacity that influences performance on cognitive ability measures. Charles Spearman first described the existence of general intelligence in 1904. According to Spearman, this g factor was responsible for overall performance on mental ability tests.

Spearman noted that while people certainly could and often did excel in certain areas, people who did well in one area tended also to do well in other areas. For example, a person who does well on a verbal test would probably also do well on other tests. Those who hold this view believe that intelligence can be measured and expressed by a single number, such as an IQ score. The idea is that this underlying general intelligence influences performance on all cognitive tasks.

General intelligence can be compared to athleticism. A person might be a very skilled runner, but this does not necessarily mean that they will also be an excellent figure skater. However, because this person is athletic and fit, they will probably perform much better on other physical tasks than an individual who is less coordinated and more sedentary.

SPEARMAN AND GENERAL INTELLIGENCE

Charles Spearman was one of the researchers who helped develop a statistical technique known as factor analysis. Factor analysis allows researchers to use a number of different test items to measure common abilities. For example, researchers might find that people who score well on questions that measure vocabulary also perform better on questions related to reading comprehension.

Spearman believed that general intelligence represented an intelligence factor underlying specific mental abilities. All tasks on intelligence tests, whether they related to verbal or mathematical abilities, were influenced by this underlying g-factor.

Many modern intelligence tests, including the Stanford-Binet, measure some of the cognitive factors that are thought to make up general intelligence.

- **Visual-spatial processing:** Abilities such as putting together puzzles and copying complex shapes
- **Quantitative reasoning:** The capacity to solve problems that involve numbers
- **Knowledge:** A person's understanding of a wide range of topics
- **Fluid reasoning:** The ability to think flexibly and solve problems
- **Working memory:** The use of short-term memory (such as being able to repeat a list of items)

CHALLENGES TO THE CONCEPT OF GENERAL INTELLIGENCE

The notion that intelligence could be measured and summarized by a single number on an IQ test was controversial during Spearman's time and has remained so over the decades since. Some psychologists, including L.L. Thurstone, challenged the concept of a g-factor. Thurstone instead identified a number of what he referred to as "primary mental abilities."

More recently, psychologists such as Howard Gardner have argued against the notion that a single general intelligence can accurately capture all of human mental ability. Gardner instead proposed that multiple intelligences exist. Each intelligence represents abilities in a certain domain, such as visual-spatial intelligence, verbal-linguistic intelligence, and logical-mathematical intelligence. Research today points to an underlying mental ability that contributes to performance on many cognitive tasks.

IQ scores, which are designed to measure this general intelligence, are also thought to influence an individual's overall success in life. However, while IQ can play a role in academic and life success, other factors such as childhood experiences, educational experiences, socioeconomic status, motivation, maturity, and personality also play a critical role in determining overall success.

The early 1900s saw Charles Spearman using a mathematical approach to the question of measuring human intelligence. Using statistical factor analysis Spearman identified g, a single underlying intelligence factor he believed accounted for the variety of observable abilities. Spearman noticed that children's grades across all school subjects tended to be highly correlated.

If a child did well in one subject, they generally also did well in another subject, and vice versa. What did this say about the nature of intelligence? He devised factor analysis to measure the relationships between seemingly varied cognitive abilities and account for the correlations he saw between scores on different tests.

The result was Spearman's two-factor theory which attempted to show that all cognitive performance can be explained by two variables: one general ability (g) and the many specific abilities (s) it gave rise to. Later, however, further analysis showed that g alone was enough to explain the correlations between different tests. When people talk about IQ or intelligence, it's usually this general mental ability that they are referring to.

ALTERNATIVES AND CRITICISMS

The existence of a single quantifiable factor for human intelligence has been hotly debated ever since Spearman proposed it. Criticism came from one of Spearman's own students, Raymond Cattell, who thought that intelligence could be understood as two main capacities: "fluid" (Gf) and "crystallized" (Gc). Cattell thought that crystallized intelligence was a kind of cemented knowledge bank acquired over time, representing all those abilities that were already familiar from previous learning.

On the otherhand, fluid intelligence was the ability to acquire that knowledge in the first place, i.e. to learn in the moment. He saw g as more accurately Gc, and that tests focusing only on g would omit an important developmental factor in human intelligence. Others were similarly critical for the reductive nature of g, including psychologist L.L. Thurstone and J. P Guilford.

Both believed that there were several, irreducible and independent domains of intelligence, however many have since found correlations between their tests which strongly suggest a general factor. Still more criticism came from Howard Gardener who proposed nine domains of intelligence, including some decidedly non-cognitive ones like musical, existential and bodily-kinesthetic intelligence.

Almost everyone can think of a person who performed poorly at school but excelled in sport or dance, perhaps, or a person with musical genius that didn't translate to any other area in their life. Gardner argued that the academic environment over-emphasized verbal and logical skill while ignoring these other forms of intelligence. However, his critics have responded that we think of something like athletic skill as just that – a skill and not strictly intelligence.

THURSTONE'S THEORY

Primary mental abilities/Group factor theory: States that Intelligent Activities are not an expression of innumerable highly specific factors, as Thorndike claimed. Nor is it the expression primarily of a general factor that pervades all mental activities. It is the essence of intelligence, as Spearman held.

Instead, the analysis of interpretation of Spearman and others led them to the conclusion that 'certain' mental operations have in common a 'primary' factor that gives them psychological and functional unity and that differentiates them from other mental operations. These mental operations then constitute a group.

A second group of mental operation has its own unifying primary factor, and so on. In other words, there are a number of groups of mental abilities, each of which has its own primary factor, giving the group a functional unity and cohesiveness. Each of these primary factors is said to be relatively independent of the others.

Thurstone has given the following six primary factors:

- (i) The Number Factor
(N)—Ability to do Numerical Calculations rapidly and accurately.
- (ii) The Verbal Factor
(V)—Found in tests involving Verbal Comprehension.
- (iii) The Space Factor
(S)—Involved in any task in which the subject manipulates the imaginary object in space.
- (iv) Memory
(M)—Involving ability to memorize quickly.
- (v) The Word Fluency Factor

(W)—Involved whenever the subject is asked to think of isolated words at a rapid rate.

(vi) The Reasoning Factor

(R)—Found in tasks that require a subject to discover a rule or principle involved in a series or groups of letters. Based on these factors Thurstone constructed a new test of intelligence known as “Test of Primary Mental Abilities (PMA).”

JENSEN'S THEORY OF INTELLIGENCE

The criticism of my "theory of intelligence" by Humphreys and Dachler (1969), although making an interesting and worthwhile methodological point, is based on so limited a view of the theory and of the supporting evidence as to constitute a very weak criticism when viewed in proper perspective.

The questionable suitability of the Project TALENT tests used by Humphreys and Dachler for testing hypotheses derived from the theory, as compared with tests and studies specifically designed for this purpose, hardly warrants these authors' overly sweeping conclusion that "... Jensen's published results can be disregarded and that unbiased data lend no support to his theory [p. 426]."

Theoretical Misconceptions The theory, which has been explicated in detail elsewhere (Jensen, 1968a, 1969, in press), concerns the organization of mental abilities in individuals. It incidentally predicts, and was originally formulated to explain, relationships between intelligence, rote-learning ability, and socioeconomic status (SES).

It postulates two broad types of mental ability: Level I (associative and rote learning ability as measured, for example, by digit-span memory and rote serial learning), and Level II (abstract reasoning as measured by most IQ tests and in purer form by tests such as Raven's Progressive Matrices).

The correlation between Level I and Level II abilities, according to the theory, is due largely to the hierarchical functional dependence of Level II upon Level I. Requests for reprints should be sent to: Arthur R. Jensen, School of Education, University of California, Berkeley, California 94720. *esses upon* Level I.

The educational and occupational requirements of our society tend to sort out people much more by their Level II ability than by their Level I ability, so that lower and upper SES groups will differ markedly on Level II tests while differing little or not at all on Level I. Humphreys and Dachler are wrong to argue that a general theory of intelligence means that it must generalize to the entire population. The theory is about the organization of mental abilities.

It makes no statements about population parameters per se. Given such parameters, however, the theory should yield specific predictions. But populations differ in their social class composition and relative frequencies in various SES categories, and a truly general theory of intelligence cannot

include these specific population characteristics (though it needs to know them for specific predictions) any more than a general theory of gravitation includes such data as the mass of the earth or air resistance, which nevertheless need to be taken into account in order to make a specific prediction from the law of falling bodies.

Humphreys and Dachler have thus failed to distinguish clearly between the theory itself and the ancillary information required to derive any specific test of the theory. Furthermore, it is not at all clear just what alternative theory or empirical state of affairs prevails according to Humphreys and Dachler. Is it that all kinds of mental abilities are about equally correlated with SES? This is clearly refuted by much solid evidence.

CATTELL THEORY OF INTELLIGENCE

The fluid aspect of this theory says that intelligence is a basic capacity due to genetic potentiality. While this is affected by the past and new experiences, the crystallized theory is a capacity resultant of experiences, learning and environment.

In the 1930s and early 1940s, both Raymond B. Cattell and Donald O. Hebb were critical of the ability of the currently available tests to accurately measure intelligence and both began to develop improved tests of intelligence. Cattell was in search of a "culture-free" test of intelligence while Hebb was concerned with the development of tests of intelligence which could measure the effects of localized brain damage at different ages in patients with little schooling.

At that time, intelligence testing was fuelled by a scientific interest to quantify the intelligence of different groups of people, with a focus on special classes of individuals, such as the insane, feeble-minded, deaf, and delinquent. The intelligence scales used were influenced by the work of Alfred Binet and Theodore Simon with the publication of the first Binet-Simon scale in 1905 (Binet and Simon, 1905). This "measuring scale of intelligence" was originally developed for use with school children in Paris and consisted of a series of 30 brief cognitive tests.

The Binet-Simon intelligence scale and its modifications (such as the Stanford-Binet scale) were the most commonly used tests of intelligence in the 1930's (Pintner, 1931), but the Wechsler-Bellevue intelligence scale, published in 1939 (Wechsler, 1939) introduced a number of innovations in intelligence testing including a test more suitable for measuring intelligence in adults rather than children; the inclusion of both verbal and performance measures of intelligence; and the omission of memory tests (Boake, 2002).

CATTELL'S WORK ON INTELLIGENCE TESTING

Cattell (1940a) gave a detailed critique of the Binet test and was concerned that differences in scores on intelligence tests were due to differences in social status, special abilities distinct from intelligence, or other environmental factors. The problem that he identified was that tests of intelligence focused on acquired skills and verbal ability rather than on intelligence per se.

Cattell was interested in developing “culture free” intelligence tests based on non-verbal skills that would define a person's general intelligence “g” (Spearman, 1904) irrespective of their social status, race, verbal ability or environmental experience. Cattell thus developed a culture-free test with seven sub-tests. The tests were designed to be non-verbal and instructions were given using a series of worked examples rather than verbal instructions.

Cattell et al. (1941) outlined seven variables which influenced intelligence or “general ability” and then analyzed the effects of environmental variables such as cultural knowledge and training (practice) on each test. He then compared the scores of American-born and immigrant children on his culture-free test and three other tests of intelligence: the Terman-Merrill Revision of the Binet Test, the arithmetic section of the American Council of Education (A.C.E.) Test, and the Arthur Performance Test.

Based on these studies, Cattell et al. (1941) found that the Arthur test was the most culture-free, the culture-free test was second, the Terman-Merrill-Binet test was third and the A.C.E. test fourth, and concluded that culture-free tests should be administered using people from a wide range of cultures, “primitive and otherwise.”

Gardner Theory of intelligence

GARDNER'S THEORY OF MULTIPLE INTELLIGENCE

Howard Gardner in his book “Frames of Mind, The Theory of Multiple Intelligence” (1983), puts forth a new and different view of human intellectual competencies. He argues boldly and cogently that we are all born with potential to develop a multiplicity of Intelligence, most of which have been overlooked in our testing society, and all of which can be drawn upon to make us competent individuals.

The potential for musical accomplishments, bodily mastery and spatial reasoning, and the capacities to understand ourselves as well as others are, Gardner argues, “the multiple forms of intelligence that we must add to the conventional—and typical tested—logical and linguistic skills long called I.Q.”.

The multiple intelligence theory is that people possess eight types of intelligence : linguistic, logical, spatial, musical, motor ability, interpersonal, intrapersonal and naturalistic intelligence. Sternberg's triarchic theory: Psychologist Robert Sternberg (1985) has constructed a three-pronged, or triarchic theory of intelligence.

The **Three types** are :

Analytical Intelligence—is what we generally think of as academic ability. It enables us to solve problems and to acquire new knowledge. Problem-solving skills include encoding information, combining and comparing pieces of information and generating a solution.

Creative Intelligence—is defined by the abilities to cope with novel situations and to profit from experience. The ability to quickly relate novel situations to familiar situations (that is, to perceive similarities and differences) fosters adaptation. Moreover, as a result of experience, we also become able to solve problems more rapidly.

Practical Intelligence—or “street smarts”, enable people to adapt to the demands of their environment. For example, keeping a job by adapting one’s behavior to the employer’s requirements is adaptive. But if the employer is making unreasonable demands, reshaping the environment (by changing the employer’s attitudes) or selecting an alternate environment (by finding a more suitable job) is also adaptive.

STENBERG THEORY OF INTELLIGENCE

The triarchic theory of intelligence consists of **three** subtheories:

- (i) the componential subtheory which outlines the structures and mechanisms that underlie intelligent behavior categorized as metacognitive, performance, or knowledge acquisition components ,
- (ii) the experiential subtheory that proposes intelligent behavior be interpreted along a continuum of experience from novel to highly familiar tasks/situations,
- (iii) the contextual subtheory which specifies that intelligent behavior is defined by the sociocultural context in which it takes place and involves adaptation to the environment, selection of better environments, and shaping of the present environment.

According to Sternberg, a complete explanation of intelligence entails the interaction of these three subtheories. The componential subtheory specifies the potential set of mental processes that underlies behavior (i.e., how the behavior is generated) while the contextual subtheory relates intelligence to the external world in terms of what behaviors are intelligent and where.

The experiential subtheory addresses the relationship between the behavior in a given task/situation and the amount of experience of the individual in that task/situation. The componential subtheory is the most developed aspect of the triarchic theory and is based upon Sternberg (1977) which presents an information processing perspective for abilities.

One of the most fundamental components according to Sternberg’s research are the metacognition or “executive” processes that control the strategies and tactics used in intelligent behavior.

APPLICATION

The triarchic theory is a general theory of human intelligence. Much of Sternberg’s early research focused on analogies and syllogistic reasoning. Sternberg has used the theory to explain exceptional intelligence (gifted and retardation) in children and also to critique existing intelligence tests. Sternberg (1983) outlines the implications of the theory for skill training. Later work

examines topics such as learning styles (Sternberg, 1997) and creativity (Sternberg, 1999).

EXAMPLE

Sternberg (1985) describes the results of various analogy experiments that support the triarchic theory. For example, in a study that involved adults and children solving simple analogies, he found that the youngest children solved the problems differently and theorized that this was because they had not yet developed the ability to discern higher order relations.

In another study of analogies with children at a Jewish school, he discovered a systematic bias towards selection of the first two answers on the right and suggested that this could be accounted for by the right-to-left reading pattern of Hebrew.

PRINCIPLES

1. Training of intellectual performance must be socioculturally relevant to the individual.
2. A training program should provide links between the training and real-world behavior.
3. A training program should provide explicit instruction in strategies for coping with novel tasks/situations.
4. A training program should provide explicit instruction in both executive and non-executive information processing and interactions between the two.
5. Training programs should actively encourage individuals to manifest their differences in strategies and styles.

ORIGINS

Sternberg proposed his theory in 1985 as an alternative to the idea of the general intelligence factor. The general intelligence factor, also known as *g*, is what intelligence tests typically measure. It refers only to "academic intelligence."

Sternberg argued that practical intelligence—a person's ability to react and adapt to the world around them—as well as creativity are equally important when measuring an individual's overall intelligence. He also argued that intelligence isn't fixed, but rather comprises a set of abilities that can be developed. Sternberg's assertions led to the creation of his theory.

Subtheories

Sternberg broke his theory down into the following **three** subtheories:

Contextual subtheory: The contextual subtheory says that intelligence is intertwined with the individual's environment. Thus, intelligence is based on the way one functions in their everyday circumstances, including one's ability to a) adapt to one's environment, b) select the best environment for oneself, or c) shape the environment to better fit one's needs and desires.

Experiential subtheory: The experiential subtheory proposes that there is a continuum of experience from novel to automation to which intelligence can be applied. It's at the extremes of

this continuum that intelligence is best demonstrated. At the novel end of the spectrum, an individual is confronted with an unfamiliar task or situation and must come up with a way to deal with it. At the automation end of the spectrum, one has become familiar with a given task or situation and can now handle it with minimal thought.

Componential subtheory: The componential theory outlines the various mechanisms that result in intelligence.

According to Sternberg, this subtheory is comprised of **three kinds** of mental processes or components:

- **Metacomponents** enable us to monitor, control, and evaluate our mental processing, so that we can make decisions, solve problems, and create plans.
- **Performance components** are what enable us to take action on the plans and decisions arrived at by the metacomponents.
- **Knowledge-acquisition components** enable us to learn new information that will help us carry out our plans.

Kinds of Intelligence

Each subtheory reflects a particular kind of intelligence or ability:

- **Practical intelligence:** Sternberg called one's ability to successfully interact with the everyday world practical intelligence. Practical intelligence is related to the contextual subtheory. Practically intelligent people are especially adept at behaving in successful ways in their external environment.
- **Creative intelligence:** The experiential subtheory is related to creative intelligence, which is one's ability to use existing knowledge to create new ways to handle new problems or cope in new situations.
- **Analytical intelligence:** The componential subtheory is related to analytical intelligence, which is essentially academic intelligence. Analytical intelligence is used to solve problems and is the kind of intelligence that is measured by a standard IQ test. Sternberg observed that all three kinds of intelligence are necessary for successful intelligence, which refers to the ability to be successful in life based on one's abilities, personal desires, and environment.

DANIEL GOLEMAN'S EMOTIONAL INTELLIGENCE THEORY

With regard to emotional intelligence, Daniel Goldman was not the first to articulate the concept. However, in the double role of psychologist and journalist, Goleman made the elements of emotional intelligence accessible to broad segments of society.

His best-selling books – beginning with “Emotional Intelligence” (1995) – have already changed how some businesses interact with clients and some managers recruit employees. His impact has been even more profound on education. Thanks to Goleman, educators now recognize that emotional intelligence is every bit as important to learning as intellectual prowess or IQ.

As a result, tens of thousands of schools throughout the world currently incorporate “social and emotional learning” in their curricula. In some schools, courses geared toward developing emotional intelligence are mandatory.

GOLEMAN’S FIVE COMPONENTS OF EMOTIONAL INTELLIGENCE

Goleman broadened Mayer’s and Salovey’s four-branch system to incorporate five essential elements of emotional intelligence – or EQ, the shorthand he sometimes uses:

- **Emotional self-awareness** – knowing what one is feeling at any given time and understanding the impact those moods have on others
- **Self-regulation** – controlling or redirecting one’s emotions; anticipating consequences before acting on impulse
- **Motivation** – utilizing emotional factors to achieve goals, enjoy the learning process and persevere in the face of obstacles
- **Empathy** – sensing the emotions of others
- **Social skills** – managing relationships, inspiring others and inducing desired responses from them

APPLICATIONS FOR EDUCATORS

There are very practical reasons to promote social and emotional learning in schools, from kindergarten through college. According to Goleman, bullying, disciplinary problems, violence and drug abuse are reduced in schools with a high EQ. With a solid basis in emotional intelligence, academic performance – as well as behavior – improves.

There is an obvious connection to Goleman’s third, motivational component: learning stimulates curiosity and promotes feelings of satisfaction, even joy, when students immerse themselves in the process of assimilating new information. The EQ of children starts developing long before they ever enter a classroom. But EQ levels will vary widely, depending on each child’s home environment.

Thus teachers must be able to recognize those children whose emotional literacy needs a boost. Teachers should be ready to talk about feelings in the classroom. The message is that no emotion is “wrong,” but certain ways of expressing those emotions or acting on them are indeed inappropriate.

In 2002, UNESCO launched an international campaign to promote emotional learning in the classroom. The U.N. body sent a statement of 10 basic EQ principles to education ministries throughout the world. Those principles drew heavily from Goleman’s exposition of emotional intelligence.

RATING EMOTIONAL INTELLIGENCE

PositivePsychology.com has created a guide to help people assess their own levels of emotional

intelligence. Discover exercises ranging from classifying facial expressions, emotional articulation tools, and communication tasks among other activities. These are suitable for students and adults alike.

DAS, KAR & PARRILA THEORY

PASS Cognitive Processes Das and his colleagues (Das et al., 1975; Das, Parrila, & Kirby, 1994) have offered the Planning, Attention, Simultaneous and Successive processing (PASS) theory as an alternative to the conceptualization of intelligence as a general mental ability. The popular approach to theory of human intelligence that considers human intellectual functioning as a single unitary quality underlying all cognitive processes (g) provides ideology for PASS theory of Intelligence.

It challenges g-theory on the grounds that neuropsychological research has consistently demonstrated that the brain is made up of interdependent, but separate functional systems. Specifically, the PASS theory is based on the view that intelligence is composed of multiple interdependent cognitive processes.

The PASS theory has evolved through many years of theoretical and empirical work. Initially proposed and described as an information processing model derived from Luria (Das, 1973; Das, Kirby, & Jarman, 1975) and then as information-integration model (Das, Kirby, & Jarman, 1979), later the model was called the PASS model (Naglieri & Das, 1988, 1990). Further it was elaborated by Das, Naglieri and Kirby (1994); and Das, Kar and Parrila (1996) and referred to as PASS theory of intelligence.

Das et al. (1994) believed that it has a strong theoretical foundation, has been sufficiently operationalized and is making significant contributions to the understanding of exceptionality and predict academic as well as job performance. This view of intelligence is based on a neuropsychological work of Luria (1966, 1973) as well as cognitive psychological findings (Hunt & Lansman, 1986).

According to Luria, human cognitive processing involves three functional systems that work in concert and whose participation is necessary for any type of mental activity (1973, p.43). The first functional unit is responsible for regulating cortical tone and maintenance of attention. The second unit receives, processes and stores information using simultaneous and successive information coding and the third unit programs, regulates and directs mental activity.

The first functional unit is associated with the brainstem, diencephalon and medial regions of the hemispheres. This is the base of human mental processes, because it maintains a proper state of arousal which allows for the focus of attention. The arousal aspect of the first functional unit is important because it provides the opportunity for the voluntary action of attention.

Arousal is responsible for cortical tone and wakefulness and also attention which is more of a complex cognitive activity. Given an appropriate state of arousal, the two broad classes of selective and divided attention (Kahneman & Treisman, 1984) may occur. Any task involving the intentional discrimination between stimuli requires selective attention, which is important activity of the first functional unit.

The second unit's functions are regulated by the occipital, parietal and temporal lobes posterior to the central sulcus. The cognitive functions of this unit are receiving, processing and retaining information which a person obtains from the external world. Luria (1966) stated that there is a strong evidence for distinguishing the two basic forms of integrative activity of the cerebral cortex, by which different aspects of the outside world may be reflected.

These two types of processes are simultaneous processes which integration of stimuli into synchronous and primarily spatial groups and successive process which consists of integration of stimuli into temporally organized serial order. The third functional unit described by Luria (1973) allows the individual to form plans of action, carry them out and verify the effectiveness of the plans. It relies on the second functional unit for processing components and the first functional unit for proper attentional status.

With the prerequisite functioning of these units, the individual can develop plans of action, inspect performance and regulate behaviour so that it conforms to the plans and then compare the effects of these actions with the original intention so that correction of mistakes is possible. The third functional unit is also responsible for activities such as impulse control, regulation of voluntary actions and linguistic functions such as spontaneous speech (Luria, 1980, p. 517).

Das (1984) and Arlin (1977) suggested that planning is the essence of human intelligence, as it involves the aptitude for asking new questions, solving problems and self-monitoring as well as the application of information coding processes.

PLANNING

This is the ability to make decisions about how to solve problems and perform actions. It involves setting goals, anticipating consequences and using feedback. Planning also involves the attentionarousal, simultaneous and successive processing functions and is associated with the frontal lobes of the brain. Planning processes provide the individual with the facility to determine and utilize an efficient way to solve a problem through the application of attention, simultaneous and successive processes in conjunction with the base of knowledge.

The three main aspects of planning are generation, selection, and execution. If more than one plan is found, selecting the best one is important and monitoring the effectiveness of these solutions is always needed.

ATTENTION-AROUSAL

This involves the ability to selectively attend to stimuli while ignoring other distractions. Individuals

with Attention Deficit Disorder(ADD) have impairments in this area. The arousal functions are generally associated with the brain stem and thalamus, whereas the higher attentional processes are thought to be related to the planning functions of the frontal lobe.

SIMULTANEOUS PROCESSING

This involves the ability to integrate separate stimuli into a cohesive, interrelated whole. Simultaneous processing is necessary for language comprehension, as in: "Who is the person in the following statement: My mother's father was his only son (Naglieri & Das, 1997)?" The occipital and parietal lobes are thought to be important for these functions.

It also involves the integration of stimuli into groups or the recognition that a number of stimuli share a common characteristic. Both of these aspects require that all the stimuli be related to one another. Simultaneous processing may take place with perceived stimuli, remembered stimuli or the conceptual aspects of stimuli (Naglieri, 1985).

SUCCESSIVE PROCESSING

This involves the ability to integrate stimuli into a sequential order. An example of this process is the sequencing of letters and words in reading and writing. This type of processing is believed to be related to frontal-temporal lobe functioning (Das, 2002). The critical part of successive processing is that elements must be ordered without surveyability.

In successive processing elements are only linearly related. Successive coding is needed for skilled movements because such activity requires a series of movements which follow each other in a strictly defined order without surveyability (Luria 1966, p. 78). In the early stages of the skilled movement each successive link exists as a separate unit and may be taught as a specific step in a larger behaviour.

Only when each aspect becomes automatic can the initial stimulus in the chain become the signal that leads to the automatic execution of the complete successive action. Because the PASS processes are interactive, they act in concert to provide specific functions to virtually all tasks performed in everydaylife.

However, all the processes are not equally involved in all the tasks. A close relationship has been described by Luria (1980), and Stuss, Benson et al. (1986) between planning and attention. It results from large number of neural connections between the first and third functional units in the brain. Planning requires an adequate state of arousal so that attention can be focused.

An appropriate level of activation, attention and arousal is needed so that a plan of action can be generated and utilized. A similar strong correlation between coding and planning exists. Real life tasks can be coded in different ways. How one manages the information is a planning function that influences the coding approach used (Lawson & Kirby, 1981; Kirby & Das 1978; Kirby & Lawson,

1983).

Planning processes are believed to be distinct from simultaneous, successive and attentional processes because they provide the individual the means to analyse cognitive activity, develop some method to solve a problem, evaluate the effectiveness of a solution, and modify the approach used as needed. These processes are necessary when an efficient and systematic approach to solving a problem is required.

The output component of the PASS processes is a complex function by itself. Simultaneous processes may predominate in the solution of a task, but motor programming may be required if the response is written one. An individual may have competence in processing, but fail to come up with the motor program required to respond. This can be a problem in special groups such as brain damaged and mentally handicapped individuals.

Research by Das (e.g., Das 1972; Das, Kirby, & Jarman, 1975; 1979) has clearly shown that the simultaneous and successive information coding component of the PASS processes has construct validity. These researchers and others have found simultaneous and successive factors and evidence of developmental differences by chronological and mental age using tests such as progressive matrices, memory for designs and figure copying (simultaneous), and digit span forward, sound blending and sentence repetition (successive).

The studies have involved samples of elementary and middle school-aged students (Das, 1972, 1973; Das & Molloy, 1975; Garofalo, 1986; Jarman & Das, 1977; Kirby & Das, 1978; Kirby & Robinson, 1987; Naglieri & Das, 1988), high-school aged samples (Naglieri & Das, 1988), and adults (Das & Heemsbergen, 1983; McCallum, & Merritt, 1983; Merritt & McCallum, 1983; Wachs & Harris, 1986; Ashman, 1982).

PASS and other Cognitive Theories of Intelligence Contemporary theories about intelligence can be divided into two classes, psychometric and cognitive. Some of the main followers of the alternative approach of cognitive intelligence have been Jensen (1970, 1980) and Das et al. (1975, 1977). Jensen (1968, 1970) postulated the notion of two-level theory of mental abilities to account for the differences in cognitive test performance of certain racial and social class groups.

Level I ability is described as an associative ability in which the correspondence between stimulus information response output is relatively simple and direct. In contrast, Level II ability is described as conceptual ability in which the original stimulus information for learning is transformed and elaborated before the response can be made.

Level I and Level II can be taken as two poles of continuum along which tasks can be arranged in terms of degree of complexity of cognitive demands. Das's PASS model observed that a number of inconsistencies in Level I/II data could be interpreted with knowledge of types of transformation (e.g., simultaneous and successive) rather than amount of information transformation (Level I and II).

Jarman (1978) took some issues and stated that the evidence indicating that memory tasks are performed using various strategies raised question regarding validity of labeling Level I position to different memory tasks. What is Creativity: Torrance, Getzels & Jackson, Guilford, Wallach & Kogan Relationship between Intelligence and Creativity?

CREATIVITY: TORRANCE, GETZELS & JACKSON, GUILFORD, WALLACH & KOGAN RELATIONSHIP BETWEEN INTELLIGENCE AND CREATIVITY

Creativity theory by Torrance

The **TTCT (Torrance Tests of Creative Thinking)** assess how creatively a child's mind works and are often given to children in order to determine advanced placement or as part of an entrance examination. They are very different from the intelligence and reasoning tests your child may already have taken. Instead of traditionally taught subjects such as reading or math, these tests assess creativity.

Children are scored on a number of aspects, including creative titles for pictures, expressions, imagery and humor. Therefore, your child hasn't "learned" the content that will be tested on the Torrance, since it involves more ambiguous concepts than the ones that are driven home in the classroom. As the name suggests, the Torrance Tests of Creative Thinking test, in large part, how creative and imaginative your child is.

The Torrance Tests of Creative Thinking (TTCT) is designed to identify and evaluate creative potential using two parts – a Verbal test and a Figural test.

- The **Verbal test** contains seven subtests – Asking, Guessing Causes, Guessing Consequences, Product Improvement, Unusual Uses, Unusual Questions, and Just Suppose. Subtests are scored on the basis of fluency, flexibility, and originality (with a score on elaboration as optional), and these scores are accumulated across all subtests. The totals may be converted to standard T scores if normative reference is desired.
- The **Figural test** has three subsets – Picture Construction (from a marked cue), Picture Completion (again with cues), and Parallel Lines. The first of these subtests is scored on originality and elaboration while the remainder are scored on fluency, flexibility, originality, and elaboration. Totals are then accumulated across subtests to provide overall scores for Figural fluency, flexibility, originality, and elaboration. These scores, as in the Verbal test, can be converted to a standard T score.

MORE INFORMATION ON THE TORRANCE TEST

The tests are game-like to catch children's interests. The scoring of the tests is by hand and require careful attention to the manual for reliable results. However, "streamlined" guides are available and are helpful in developing greater familiarity with the test and its scoring procedures.

Grades K through graduate school. Many school districts include some kind of creativity testing as part of their assessment of gifted children. One of the most common tests used to assess creativity in a child or an adult is the Torrance Tests of Creative Thinking.

The TTCT test is a series of figural exercises (thinking with pictures) and verbal activities (thinking with words) that students do to showcase their creative abilities. The full test is a series of individual exercises that are administered by a psychologist over a 90-minute period. While it isn't the perfect creativity test, it has proved to be highly reliable over the years as a predictor of successful, creative individuals of all ages.

This test is used by both businesses and schools. Often, in a school setting, a few of the exercises from the TTCT test are chosen to be administered along with other intelligence or achievement tests. They might choose one figural and one verbal activity to include in their evaluation if they are looking for children who are both highly creative and intelligent to be part of their program.

GETZELS AND JACKSON THEORY OF CREATIVITY

The study which had a great impact on psychologists in the field of education and which had set off a boom in research into the area of creativity was the study of 449 high school children in Chicago, published by J. W. Getzels and P. W. Jackson in 1962. They compared a group of middle-class adolescent pupils who had scored well on intelligence tests with pupils who scored well on creativity tests designed by Guilford.

They found that highly creative children were superior in scholastic achievement to pupils with high I.Q., although the high creatives had 20 I.Q. points lower than the high I.Q. students - indicating a positive relationship between creativity and academic ability. The high creatives, although having an average I.Q. 5 points less than their school population taken as a whole performed better in school achievement.

Getzels and Jackson's (1962) study drew criticisms as to its design and the sampling procedures employed. But the educational implications of Getzels and Jackson's study were undeniable. Several research studies replicated the study on other samples. Torrance (1962), for example, undertook eight replications of this famous study. Five of these studies were on elementary school students, one at high-school level and two at graduate level.

It was found that six of these studies supported the findings of Getzels and Jackson that creativity is related to academic achievement. The two discrepant studies showed that creativity may be dependent on other factors such as the range of intelligence of the sample studied and the type of school the students attended. Yamamoto (1964a) replicated Getzels and Jackson's (1962) study on 272 ninth through twelfth grade students of the University of Minnesota High School. The students in each grade were grouped into three groups based on their level of creativity and

intelligence scores.

The groups were the high intelligence group (comprising students in the upper 20% on IQ but not in the upper 20% on creativity scores), the high creative group (comprising students in the upper 20% on creativity scores but not in the upper 20% on IQ) and the high intelligent-high creative group which comprised students in the upper 20% on both the I.Q. and creativity measures.

On analyzing the academic achievement scores of these groups, Yamamoto (1964a) found no difference in academic achievement between the high creatives and the high I.Q. groups although there was a mean difference of twenty I.Q. points. The creatives seem to be able to “compensate” for what they lack in intelligence by their creative ability to attain similar level of academic achievement. Other researchers like Ahrens (1962), Jacobson (1966), Lucht (1963), Feldhusen, Treffinger and Elias (1970) have come out in support of the Getzels and Jackson phenomenon.

Researchers who used the Grade Point Average as a measure of academic achievement, namely, Taylor (1958), Nuss (1961), Parker (1979), Wilson (1968) and Cline, Richards and Needham (1963) have also reported results consistent with the findings of Getzels and Jackson. However, there are studies that did not support the Getzels and Jackson phenomenon of equivalent achievement of the high creative and the high I.Q. groups. Among the earliest were the discrepant studies reported by Torrance (1962) based on his replications of the Getzels and Jackson's study.

Many reasons were put forward to explain this. Among them were the lower level of intelligence among the subjects studied, the different kinds of academic ability measured and to the presence of an I.Q. threshold in the relationship between creativity and academic achievement. This study intends to further investigate this phenomenon using Form Four (US Grade 10) Malaysian students to explore if this phenomena is prevalent in other cultures.

Procedure Subjects totaling 467 Form Four students were drawn from three secondary schools in the township of Kuantan, in the state of Pahang in Malaysia. Their average age was 13.3 years and the students had undergone six years of primary and three years of secondary school.

DISCUSSION

The equivalent academic achievement scores obtained by the HI-LC and LI-HC groups support the findings reported by Getzels and Jackson (1962), Torrance (1959) and Yamamoto (1964a). The fact that similar findings are obtained in another culture with a different education system after a lapse of about 40 years adds to the generalizability of this phenomenon of positive correlation between creativity and academic achievement across culture and time.

The similarity in achievement scores among the HI-HC and LI-HC groups further supports the contribution of creativity to academic achievement. The fact that students not in the top 20% in IQ are able to achieve just as well as students in the top 20% in IQ possibly due to their elevated

creativity, may be considered a significant finding in this research.

This finding also provides empirical evidence and support for the advocacy of creativity enhancing curricula and programs in Malaysia. At very high IQ levels, the strength of the relationship between creativity and academic achievement appears to diminish. This finding appears to support the threshold concept in this relationship. It appears that above an intelligence threshold of about 140, creativity may not enhance academic achievement.

However, this finding appears to contradict Yamamoto's (1964b) study which found that above the IQ level of 120, creativity would enhance academic achievement. It may be concluded that while the intelligence threshold concept appears to hold true, the nature of the relationship between creativity and academic achievement both above and below the threshold appears to differ in this Malaysian sample. Further research involving different samples and different measures of creativity, intelligence and academic achievement will throw more light on these relationships and the concept of intelligence threshold.

CONCLUSION

This paper provides empirical support for the positive relationship between creativity and academic achievement and the finding that this relationship appears to differ across the intelligence continuum. This relationship appears to be positive until an intelligence threshold of around 140 above which it appears to diminish.

Further studies need to be carried out to confirm the nature of this relationship for other measures academic achievement and across other cultures to establish the generalizability of this finding.

THEORIES OF CREATIVITY ON THE BASIS OF GUILFORD

Before I am able to explain several of the leading theories of creativity, one must understand a confusing intricacy surrounding this topic of study. What is different about the study of creativity is that in other fields of research the newest theory often replaces the older theories. The newest theory is often deemed as being "more correct" than the previously held school of thought.

However when researching creativity, one might find that there are a multitude of theories that are seen as "correct". The theories themselves each argue that creativity is caused by different factors. They each argue that the components of creativity are different. Interestingly enough, they each are correct in their own respect.

Now this may seem a tad confusing, but because creativity is a such a dynamic concept many theories are only able to define creativity in one particular field or career at one specific point in time (i.e. creativity among engineers, creativity among artists, etc.) That being said, it is important to view each model of creativity only as a single perspective among many perspectives.

GUILFORD'S STRUCTURE OF INTELLECT MODEL AND MODEL OF CREATIVITY

One of the earliest models of creativity was created by a man named J. P. Guilford. Originally, Guilford was trying to create a model for intellect as a whole, but in doing so also created a model for creativity. Guilford hypothesized that every mental task was made up of three separate parts: an operation, a content, and a product.

He stated that there were five types of operations, four types of content, and six types of products adding to a total of one hundred and twenty different types of possible mental tasks (he would later expand this number to one hundred and eighty different mental tasks, but for now let's focus on the original one hundred and twenty.) Of these one hundred and twenty different mental tasks Guilford identified one specific operation as "divergent production" and marked it as being a vital component of creativity. This divergent production coupled with a content and a product created twenty four possibilities that Guilford labeled collectively as "divergent thinking".

By labeling this group of mental tasks as divergent thinking Guilford made an important assumption for creative research: creativity isn't one abstract concept. The idea that creativity is a category rather than one single concept opened up the ability for other researchers to look at creativity with a whole new perspective.

Additionally, Guilford hypothesized one of the first models for the components of creativity. He explained that creativity was a result of having:

1) Sensitivity to problems, or the ability to recognize problems.

2) Fluency, which encompasses

- a) Ideational fluency, or the ability rapidly to produce a variety of ideas that fulfill stated requirements.
- b) Associational fluency, or the ability to generate a list of words, each of which is associated with a given word.
- c) Expressional fluency, or the ability to organize words into larger units, such as phrases, sentences, and paragraphs.

3) Flexibility, which encompasses

- a) Spontaneous flexibility, or the ability to demonstrate flexibility.
- b) Adaptive flexibility, or the ability to produce responses that are novel and high in quality.

This represents the base model by which several researchers would take and alter to produce their new theories of creativity years later. This base theory stated that creativity was a result of cognitive ability (intellect) alone. As Guilford was originally only studying intellect, it is not strange that he categorizes creativity as just a specific subset of cognitive ability.

After Guilford's initial model, researchers would begin to categorize and re-categorize mental ability into subsets that would further hypothesize how mental ability was broken up (as shown in the image to the left). These models would help others understand and put into place one specific part of creativity that Guilford brought to light: the intellectual requirement.

KERRIE UNSWORTH'S "UNPACKING CREATIVITY"

Moving on from Guilford's model of cognitive ability, Kerrie Unsworth proposed that there was more than just raw intelligence that influenced the creative process. Unsworth argues that context was just as important of a factor of creativity as cognitive ability was. Specifically, Unsworth looked two aspects of context: The problem type and motivation. Unsworth broke down each of these ideas into two categories to better explain each context affects the creative process.

In differentiating the type of problem, Unsworth separated cases based on whether or not a given problem was known. Where closed problems are instances when a problem is clearly defined, open problem must be discovered and searched for. The first step in dealing with open problems is that one needs to discover what the problem is before they can fix it.

Regarding motivation, Unsworth differentiated types of motivation based off of what the source of the driving action was. This means that the motivation could either be internally or externally driven. Using the different types of motivation and problems, Unsworth created a matrix (pictured above) that broke down creativity into four arch-types:

RESPONSIVE CREATIVITY: EXTERNALLY DRIVEN WITH A CLOSED PROBLEM

type, this type of creativity has the least amount of opportunity for creative input, but is often seen in occupational and professional scenarios. Expected creativity: Externally driven with an open problem type, this type of creativity is most often seen in art and poetry where the problem is self-discovered.

Contributory creativity: Internally driven with a closed problem type, this type of creativity often deals with volunteer behaviors as the problem is known, but an individual exercising contributory creativity is doing so on their own will and not being forced by an extrinsic motivator. Proactive creativity: Internally driven with a open problem type, this creativity is when dealing with an uncertain problem that must be found.

Often synonymous with spontaneous creativity as a problem wasn't apparent, but was found and creatively fixed. Through this model, Unsworth shed light on the important topic that is context. As she specifically states, "There are many theories concerning the creative process, yet the proposition that the process may change depending upon the type of creativity has not been considered" (Unsworth, 294).

This is to say that just as Guilford offered cognitive ability as a component of creativity, context is another factor that shapes and mold types of creativity. Additionally, Unsworth made the distinction between innovation and creativity that I had not seen explained before. She explains that innovation is used in regards to the implementation of ideas whereas creativity describes only the generation of ideas.

THE PERSONALITY CONNECTION

Apart from intelligence and context, there is one other leading theory to explain the components of creativity: The personality factor. While being closely related to cognitive ability, personality is another internal factor that affects the creative process. This theory breaks down how personality affects creativity into two options: Little-C: Creativity that can be seen in your everyday life, but these are usually small little opportunities to adapt and change to fit a situation. Big-C: Significant change that affects how others think, feel, and live their lives.

Depending on what kind of personality one has determines what effect it will have on the creative process. For example, say that someone has found a new way to dust shelves. The new method takes half of the normal time of dusting. Now, the little-C personality might think to themselves that this is a creative way for them to go about cleaning the house, and it will even save them a solid hour of cleaning each week. On the other hand, the big-C personality might realize that the implications of this creative breakthrough.

By sharing this news with the world and garnishing support behind this new method, people everywhere might be saving millions of hours collectively dusting their shelves. The creative idea is the same in both cases, however one scenario affects just one individual, while the other situation affected millions of people. The difference is in the personality.

One of the main ways that personality is measured is through J.M. Digman's Big-5 personality traits or OCEAN: Openness, Conscientiousness, Extraversion, Agreeableness, and Neuroticism. Digman uses these traits to categorize personality types into measurable quantities. While it is not clear how each of these individual traits affect the creative process, the main point is that personality in its entirety has an influence of the creative process.

TAKEAWAYS FROM THE CREATIVE THEORIES

The evolution of creative theory has brought our understanding of what creativity is from Guilford's solely cognitive representation in the 1900's to our modern day model that includes intellect, context (problem type and motivation), and personality each as factors of influence. Again, I would like to reiterate that each of these models are correct in and of themselves.

Each individual theory is correct not only because the next theory builds off the previous one, but also because they each help explain the creative process for different fields. For instance, personality plays less of a role than cognitive ability in the creative process when trying to find a new way to weld two pieces of metal together. However when trying to find a new way to creatively get votes for a politician, personality might have a much larger role than cognitive ability.

CREATIVITY MISCONCEPTIONS

While I believe that each of these theories have evolved and changed our fundamental understanding of creativity, some would argue that our overall perceptions and understanding of

creativity has not changed. Some would say that while a few components of creativity have changed, our overlying view of creativity as a whole has not changed. This is a common misconception about creativity.

Originally, creativity was thought to be one individual trait that could be measured in the same way that base intellect and physical strength are measured. However due to the research in the above theories and models, the fundamental components of creativity have in fact changed.

This change in the rudimentary parts of the creative process has caused our overarching view of creativity to switch from viewing it as a personality trait to being a broad category that better encompasses all types of creativity than a singular model could ever hope to.

WHY SO MANY THEORIES?

The main point these theories attempt to display is that creativity is a dynamic concept with a multitude of sub-types of creativity. Because creativity is as dynamic and diverse as previously stated, the need for multiple theories to be correct to fit any given context arises.

Now that we understand that there are many different components, parts, and perspectives on what creativity is, I would like to piece together the core arguments in each of these theories to define creativity, not as an single entity, but as a broad category.

WALLACH KOGAN CREATIVITY TEST

In Wallach and Kogan's assessment of creativity, examinees are asked to come up with many possible items that are in a general group.

For example: Name things with wheels. Responses could be:

- a car
- a bicycle
- a lorry
- a train
- a go-cart
- a skateboard
- a scooter
- your mind

This test is scored using four components:

1. **Fluency:** The number of responses is calculated. In the above example, the score would be 8.
2. **Flexibility:** The number of different categories is calculated. The above example would score 2; the first seven are all methods of transportation but "wheel turning in your mind" is a different category, e.g. a metaphor.
3. **Originality:** Each response is compared to the total amount of responses from all of the people given the test.

Responses that were given by only 5% of the group are unusual (1 point).

Responses that were given by only 1% of the group are unique (2 points). Higher total scores indicate an aptitude for original thinking.

4. **Elaboration:** The amount of detail is assessed. For example, "a scooter" = 0, whereas "an electric scooter racing down the pavement" = 1

An additional point would be given if the examinee noted where the scooter car was going. In terms of administration, Wallach and Kogan's test can be done by anyone and there is no special training needed. Typically the test is administered in a classroom setting.

Here are some more examples:

1. Name all the round things you can think of.
2. Name all the things you can think of that will make a noise.
3. Name all the square things you can think of.
4. Name all the things you can think of that move on wheels.

One of my favourite tests is focuses on similarities where children have to think of as many possible similarities between two objects.

Examples:

1. Tell me all the ways in which an apple and orange are alike.
2. Tell me all the ways in which a cat and mouse are alike.
3. Tell me all the ways in which milk and meat are alike.
4. Tell me all the ways in which a radio and a telephone are alike.

Example answers for apple and orange: both round, sweet, have seeds, are fruit, grow on trees, have skins, etc.

This has developed into an active assessment strategy called 'reasoning by analogy' which commonly uses a graphic organiser to identify similarities between objects or events, such as structural or functional similarities. They are used to illustrate some sort of relationship between things being compared.

In the book Start Thinking by Marcelo Staricoff and Alan Rees, they provide an example of reasoning by analogy that also asks students to consider differences.

What are the similarities and differences between blood and tomato ketchup?

Similarities include: both a red, both have sugar in them, both are used by people etc

Differences include: blood is thinner, blood is darker, ketchup is made in a factory, etc

RELATIONSHIP BETWEEN INTELLIGENCE AND CREATIVITY

Intelligence is a complex characteristic of cognition. Many theories have been developed to explain what intelligence is and how it works. There's Sternberg's triarchic theory of intelligence that focuses on analytical, creative, and practical intelligence, but there is also Gardner's theory which holds that intelligence is comprised of many factors. Still other theories focus on the

importance of emotional intelligence.

Classifying Intelligence

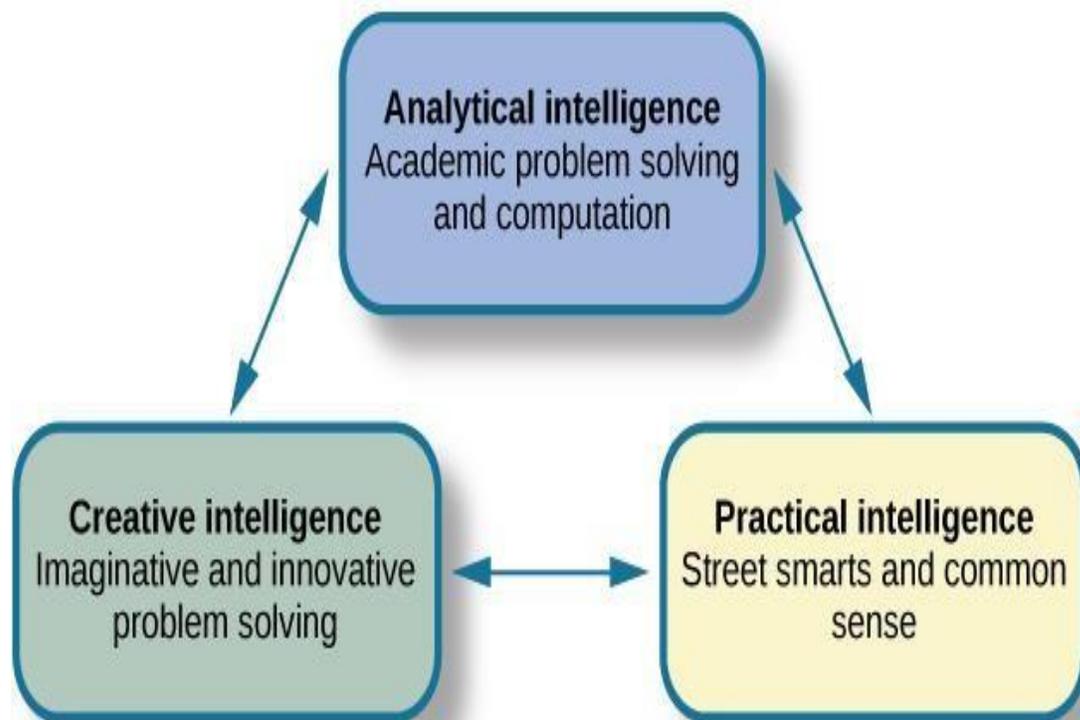

What exactly is intelligence? The way that researchers have defined the concept of intelligence has been modified many times since the birth of psychology. British psychologist Charles Spearman believed intelligence consisted of one general factor, called *g*, which could be measured and compared among individuals. Spearman focused on the commonalities among various intellectual abilities and de-emphasized what made each unique.

Long before modern psychology developed, however, ancient philosophers, such as Aristotle, held a similar view (Cianciolo & Sternberg, 2004). Other psychologists believe that instead of a single factor, intelligence is a collection of distinct abilities. In the 1940s, Raymond Cattell proposed a theory of intelligence that divided general intelligence into two components: crystallized intelligence and fluid intelligence (Cattell, 1963).

Crystallized intelligence is characterized as acquired knowledge and the ability to retrieve it. When you learn, remember, and recall information, you are using crystallized intelligence. You use crystallized intelligence all the time in your coursework by demonstrating that you have mastered the information covered in the course.

Fluid intelligence encompasses the ability to see complex relationships and solve problems. Navigating your way home after being detoured onto an unfamiliar route because of road construction would draw upon your fluid intelligence. Fluid intelligence helps you tackle complex, abstract challenges in your daily life, whereas crystallized intelligence helps you overcome concrete, straightforward problems (Cattell, 1963).

Other theorists and psychologists believe that intelligence should be defined in more practical terms. For example, what types of behaviors help you get ahead in life? Which skills promote success? Think about this for a moment. Being able to recite all 44 presidents of the United States in order is an excellent party trick, but will knowing this make you a better person?

Robert Sternberg developed another theory of intelligence, which he titled the **triarchic theory of intelligence** because it sees intelligence as comprised of three parts (Sternberg, 1988): practical, creative, and analytical intelligence (Figure 1).

Figure 1. Sternberg's theory identifies three types of intelligence: practical, creative, and analytical.

Practical intelligence, as proposed by Sternberg, is sometimes compared to "street smarts." Being practical means you find solutions that work in your everyday life by applying knowledge based on your experiences. This type of intelligence appears to be separate from traditional understanding of IQ; individuals who score high in practical intelligence may or may not have comparable scores in creative and analytical intelligence (Sternberg, 1988).

This story about the 2007 Virginia Tech shootings illustrates both high and low practical intelligences. During the incident, one student left her class to go get a soda in an adjacent building. She planned to return to class, but when she returned to her building after getting her soda, she saw that the door she used to leave was now chained shut from the inside.

Instead of thinking about why there was a chain around the door handles, she went to her class's

window and crawled back into the room. She thus potentially exposed herself to the gunman. Thankfully, she was not shot. On the other hand, a pair of students was walking on campus when they heard gunshots nearby. One friend said, "Let's go check it out and see what is going on." The other student said, "No way, we need to run away from the gunshots." They did just that. As a result, both avoided harm.

The student who crawled through the window demonstrated some creative intelligence but did not use common sense. She would have low practical intelligence. The student who encouraged his friend to run away from the sound of gunshots would have much higher practical intelligence.

Analytical intelligence is closely aligned with academic problem solving and computations. Sternberg says that analytical intelligence is demonstrated by an ability to analyze, evaluate, judge, compare, and contrast. When reading a classic novel for literature class, for example, it is usually necessary to compare the motives of the main characters of the book or analyze the historical context of the story.

In a science course such as anatomy, you must study the processes by which the body uses various minerals in different human systems. In developing an understanding of this topic, you are using analytical intelligence. When solving a challenging math problem, you would apply analytical intelligence to analyze different aspects of the problem and then solve it section by section.

Multiple Intelligences Theory was developed by Howard Gardner, a Harvard psychologist and former student of Erik Erikson. Gardner's theory, which has been refined for more than 30 years, is a more recent development among theories of intelligence. In Gardner's theory, each person possesses at least eight intelligences. Among these eight intelligences, a person typically excels in some and falters in others (Gardner, 1983).

The following table describes each type of intelligence.

Intelligence Type	Characteristics
Linguistic	Perceives different functions of language, different
Intelligence Type	Characteristics
intelligence	sounds and meanings of words, may easily learn multiple languages
Logical- mathematical intelligence	Capable of seeing numerical patterns, strong ability to use reason and logic
Musical intelligence	Understands and appreciates rhythm, pitch, and tone; may play multiple instruments or perform as a vocalist

Bodily kinesthetic intelligence	High ability to control the movements of the body and use the body to perform various physical tasks	
Spatial intelligence	Ability to perceive the relationship between objects and how they move in space	
Intelligence Type	Characteristics	
Linguistic	Perceives different functions of language, different	
Intelligence Type	Characteristics	
intelligence	sounds and meanings of words, may easily learn multiple languages	
Logical- mathematical intelligence	Capable of seeing numerical patterns, strong ability to use reason and logic	
Musical intelligence	Understands and appreciates rhythm, pitch, and tone; may play multiple instruments or perform as a vocalist	
Bodily kinesthetic intelligence	High ability to control the movements of the body and use the body to perform various physical tasks	
Spatial intelligence	Ability to perceive the relationship between objects and how they move in space	
Intelligence Type	Characteristics	
Interpersonal intelligence	Ability to understand and be sensitive to the various emotional states of others	s
Intrapersonal intelligence	Ability to access personal feelings and motivations, and use them to direct behavior and reach personal goal	
Naturalist intelligence	High capacity to appreciate the natural world and interact with the species within it	
Multiple Intelligences		

Gardner's theory is relatively new and needs additional research to better establish empirical support. At the same time, his ideas challenge the traditional idea of intelligence to include a wider variety of abilities, although it has been suggested that Gardner simply relabeled what other theorists called "cognitive styles" as "intelligences" (Morgan, 1996). Furthermore, developing traditional measures of Gardner's intelligences is extremely difficult (Furnham, 2009; Gardner & Moran, 2006; Klein, 1997). Gardner's inter- and intrapersonal intelligences are often combined into a single type: emotional intelligence.

Emotional intelligence encompasses the ability to understand the emotions of yourself and others, show empathy, understand social relationships and cues, and regulate your own emotions and respond in culturally appropriate ways (Parker, Saklofske, & Stough, 2009). People with high

emotional intelligence typically have well-developed social skills. Some researchers, including Daniel Goleman, the author of *Emotional Intelligence: Why It Can Matter More than IQ*, argue that emotional intelligence is a better predictor of success than traditional intelligence (Goleman, 1995).

However, emotional intelligence has been widely debated, with researchers pointing out inconsistencies in how it is defined and described, as well as questioning results of studies on a subject that is difficult to measure and study empirically (Locke, 2005; Mayer, Salovey, & Caruso, 2004). Intelligence can also have different meanings and values in different cultures. If you live on a small island, where most people get their food by fishing from boats, it would be important to know how to fish and how to repair a boat.

If you were an exceptional angler, your peers would probably consider you intelligent. If you were also skilled at repairing boats, your intelligence might be known across the whole island. Think about your own family's culture. What values are important for Latino families? Italian families? In Irish families, hospitality and telling an entertaining story are marks of the culture. If you are a skilled storyteller, other members of Irish culture are likely to consider you intelligent.

Some cultures place a high value on working together as a collective. In these cultures, the importance of the group supersedes the importance of individual achievement. When you visit such a culture, how well you relate to the values of that culture exemplifies your cultural intelligence, sometimes referred to as cultural competence.

Creativity happens when someone comes up with a creative idea. An example would be a creative solution to a difficult problem. But what makes an idea or solution creative? Creativity is the ability to generate, create, or discover new ideas, solutions, and possibilities. Very creative people often have intense knowledge about something, work on it for years, look at novel solutions, seek out the advice and help of other experts, and take risks.

Although creativity is often associated with the arts, it is actually a vital form of intelligence that drives people in many disciplines to discover something new. Creativity can be found in every area of life, from the way you decorate your residence to a new way of understanding how a cell works.

Although psychologists have offered several definitions of creativity (Plucker, Beghetto, & Dow, 2004; Runco & Jaeger, 2012), probably the best definition is the one recently adapted from the three criteria that the U.S. Patent Office uses to decide whether an invention can receive patent protection (Simonton, 2012). The first criterion is originality. The idea must have a low probability. Indeed, it often should be unique. Albert Einstein's special theory of relativity certainly satisfied this criterion. No other scientist came up with the idea.

The second criterion is usefulness. The idea should be valuable or work. For example, a solution must, in fact, solve the problem. An original recipe that produces a dish that tastes too terrible to eat cannot be creative. In the case of Einstein's theory, his relativity principle provided explanations for what otherwise would be inexplicable empirical results.

The third and last criterion is surprise. The idea should be surprising, or at least nonobvious (to use the term used by the Patent Office). For instance, a solution that is a straightforward derivation from acquired expertise cannot be considered surprising even if it were original. Einstein's relativity theory was not a step-by-step deduction from classical physics but rather the theory was built upon a new foundation that challenged the very basis of traditional physics.

When applying these three criteria, it is critical to recognize that originality, usefulness, and surprise are all quantitative rather than qualitative attributes of an idea. Specifically, we really have to speak of degree to which an idea satisfies each of the three criteria. In addition, the three attributes should have a zero point, that is, it should be possible to speak of an idea lacking any originality, usefulness, or surprise whatsoever.

Finally, we have to assume that if an idea scores zero on any one criterion then it must have zero creativity as well. For example, someone who reinvents the wheel is definitely producing a useful idea, but the idea has zero originality and hence no creativity whatsoever. Similarly, someone who invented a parachute made entirely out of steel reinforced concrete would get lots of credit for originality—and surprise!—but none for usefulness.

The first is the Remote Associates Test, or RAT, that was introduced by Mednick (1962). Mednick believed that the creative process requires the ability to associate ideas that are considered very far apart conceptually. The RAT consists of items that require the respondent to identify a word that can be associated to three rather distinct stimulus words. For example, what word can be associated with the words "widow, bite, monkey"?

The answer is spider (black widow spider, spider bite, spider monkey). This particular question is relatively easy, others are much more difficult, but it gives you the basic idea. The second measure is the Unusual Uses Task (Guilford, 1967; Torrance, 1974). Here, the participant is asked to generate alternative uses for a common object, such as a brick.

The responses can be scored on four dimensions: (a) fluency, the total number of appropriate uses generated; (b) originality, the statistical rarity of the uses given; (c) flexibility, the number of distinct conceptual categories implied by the various uses; and (d) elaboration, the amount of detail given for the generated uses. For example, using a brick as a paperweight represents a different conceptual category that using its volume to conserve water in a toilet tank. The capacity to produce unusual uses is but one example of the general cognitive ability to engage in **divergent thinking** (Guilford, 1967).

Unlike **convergent thinking**, which converges on the single best answer or solution, divergent thinking comes up with multiple possibilities that might vary greatly in usefulness. Unfortunately, many different cognitive processes have been linked to creativity (Simonton & Damian, 2013). That

is why we cannot use the singular; there is no such thing as the “creative process.” Nonetheless, the various processes do share one feature:

All enable the person to “think outside the box” imposed by routine thinking—to venture into territory that would otherwise be ignored (Simonton, 2011). Creativity requires that you go where you don’t know where you’re going.

UNIT-6

THINKING, INTELLIGENCE AND CREATIVITY MCQS

1) The fundamental purpose for the existence of any organization is described by its

- a. policies
- b. mission
- c. procedures
- d. strategy

Ans. B

2) The fundamental purpose of an organization’s mission statement is to

- a. create a good human relations climate in the organization
- b. define the organization’s purpose in society
- c. define the operational structure of the organization
- d. generate good public relations for the organization

Ans. B

3) The acronym SWOT stands for

- a. Special Weapons for Operations Timeliness
- b. Services, Worldwide Optimization, and Transport
- c. Strengths Worldwide Overcome Threats
- d. Strengths, Weaknesses, Opportunities, and Threats

Ans. D

4) Which of the following is not a characteristic of strategic management that makes it different from other types of management?

- a. It is interdisciplinary.
- b. It has an external focus.
- c. It has an internal focus.
- d. It concerns the present direction of the organization.

Ans. D

5) Which of the following is an issue considered in developing corporate strategies?

- a. What business(es) are we in?

- b. What direction are we going?
- c. What resources do we have to implement our strategies?
- d. What businesses are we in and what to do with those businesses?

Ans. C

- 6) Which of the following is NOT a major element of the strategic management process?
- a. Formulating strategy
 - b. Implementing strategy
 - c. Evaluating strategy
 - d. Assigning administrative tasks

Ans. D

- 7) Competitive advantage can best be described as:
- a. increased efficiency.
 - b. what sets an organization apart.
 - c. a strength of the organization.
 - d. intangible resources.

Ans. A

- 8) ___ is the foundation of blue ocean strategy.
- a. Innovation
 - b. Value creation
 - c. Value innovation
 - d. value cost trade-off

Ans. C

- 9) The various organizational routines and processes that determine how efficiently and effectively the organization transforms its inputs into outputs are called:
- a. strengths.
 - b. core competencies.
 - c. capabilities.
 - d. customer value.

Ans. B

- 10) When defining strategic management the most important thing to remember is that it is:
- a. Not as easy as you think
 - b. Mainly the province of senior managers
 - c. A living evolving process
 - d. More conceptual than practical
 - e. A way of determining responsibilities

Ans. C

- 11) An organisation's strategy:

- a. remains set in place longer than the mission and objectives
- b. generally forms over a period of time as events unfold
- c. tends to be formed at the same time the mission is developed and objectives are formulated
- d. is usually conceived at a single time when managers sit down and work out a comprehensive strategic plan for the next 3-5 years

Ans. B

12) The primary focus of strategic management is:

- a. strategic analysis
- b. the total organisation
- c. strategy formulation
- d. strategy implementation.

Ans. B

13) Which of the following is not an advantage of strategic management?

- a. It provides organisations with a clearer sense of direction and purpose
- b. It helps improve the political, economic, social and technological environment of the organisation
- c. It helps orientate management decisions to relevant environmental conditions
- d. It helps organisations be proactive rather than reactive

Ans. B

14) Which of the following defines what business or businesses the firm is in or should be in?

- a. Business strategy
- b. Corporate strategy
- c. Functional strategy
- d. National strategy

Ans. B

15) Which of the following defines how each individual business unit will attempt to achieve its mission?

- a. Business strategy
- b. Corporate strategy
- c. Functional strategy
- d. National strategy

Ans. A

16) Which of the following focuses on supporting the corporate and business strategies?

- a. Competitive strategy
- b. Corporate strategy
- c. Operational strategy
- d. National strategy

e. Mission strategy

Ans. C

17) Which one of the following is not a primary task of strategic managers?

- a. Establishing strategic objectives
- b. Developing the steps to follow in implementing operational level plans
- c. Defining the business and developing a mission
- d. Developing a strategy
- e. Implementing and evaluating the chosen strategy

Ans. B

18) The task of strategy choice involves:

- a. developing plans and activities which will improve the
- b. organisation's performance and competitive position
- c. determining how the organisation can be more market and efficiency oriented
- d. monitoring whether the organisation is achieving good financial performance
- e. keeping the organisation free of debt

Ans. A

19) Which one of the following is at the core of strategic management?

- a. Choosing which organisational objectives to focus on
- b. Being alert for opportunities to change work responsibilities
- c. Adapting the organisation to a changing external environment
- d. Choosing whether to make decisions autocratically or on the basis of participation

Ans. C

20) The corporate level is where top management directs:

- a. all employees for orientation
- b. its efforts to stabilize recruitment needs
- c. overall strategy for the entire organization
- d. overall sales projections

Ans. C

21) The three organizational levels are:

- a. corporate level, business level, functional level
- b. corporate level, business unit level, functional level
- c. corporate strategy level, business unit level, functional level
- d. corporate strategy level, business level, specialist level

Ans. A

22) Which of the following is an example of competing on quick response?

- a. a firm produces its product with less raw material waste than its competitors
- b. a firm offers more reliable products than its competitors
- c. a firm's products are introduced into the market faster than its competitors'
- d. a firm's research and development department generates many ideas for new products

Ans. C

23) Which one of the following is NOT included in the Porter's Five Forces model:

- a. Potential development of substitute products
- b. Bargaining power of suppliers
- c. Rivalry among stockholders
- d. Rivalry among competing firms

Ans. C

24) What is meant by the term 'Stakeholder'?

- a. A person who is not related with a business.
- b. A person who is related with a business.
- c. A person who owns a business.
- d. A person who purchases the shares of a business.

Ans. B

25) Of the following, which one would NOT be considered one of the components of a mission statement?

- a. The target market for XYZ is oil and gas producers as well as producers of chemicals.
- b. XYZ shall hire only those individuals who have with sufficient educational levels so as to be of benefit to our customers
- c. The customers of XYZ shall include global and local consumers of gas and oil products and domestic users of nontoxic chemicals
- d. The technologies utilized by XYZ shall focus upon development of alternative sources of gas and oil so as to remain competitive within the industry

Ans. B

26) The strategic management process is

- a. a set of activities that will assure a temporary advantage and average returns for the firm.
- b. a decision-making activity concerned with a firm's internal resources, capabilities, and competencies, independent of the conditions in its external environment.
- c. a process directed by top- management with input from other stakeholders that seeks to achieve above-average returns for investors through effective use of the organization's resources.
- d. the full set of commitments, decisions, and actions required for the firm to achieve above-average returns and strategic competitiveness..

Ans. D

27) The goal of the organization's _____ is to capture the hearts and minds of employees, challenge them, and evoke their emotions and dreams.

- a. vision

- b. mission
- c. culture
- d. strategy

Ans. A

28) A firm's mission

- a. is a statement of a firm's business in which it intends to compete and the customers which it intends to serve.
- b. is an internally-focused affirmation of the organization's financial, social, and ethical goals.
- c. is mainly intended to emotionally inspire employees and other stakeholders.
- d. is developed by a firm before the firm develops its vision.

Ans. A

29) The environmental segments that comprise the general environment typically will NOT include

- a. demographic factors.
- b. sociocultural factors.
- c. substitute products or services.
- d. technological factors.

Ans. C

30) An analysis of the economic segment of the external environment would include all of the following EXCEPT

- a. interest rates.
- b. international trade.
- c. the strength of the U.S. dollar.
- d. the move toward a contingent workforce.

Ans. D

31) Product differentiation refers to the:

- a. ability of the buyers of a product to negotiate a lower price.
- b. response of incumbent firms to new entrants.
- c. belief by customers that a product is unique.
- d. fact that as more of a product is produced the cheaper it becomes per unit.

Ans. C

32) Which of the following is NOT an entry barrier to an industry?

- a. expected competitor retaliation
- b. economies of scale
- c. customer product loyalty
- d. bargaining power of suppliers

Ans. D

- 33) Switching costs refer to the:
- a. cost to a producer to exchange equipment in a facility when new technologies emerge.
 - b. cost of changing the firm's strategic group.
 - c. one-time costs suppliers incur when selling to a different customer.
 - d. one-time costs customers incur when buying from a different supplier.

Ans. D

- 34) New entrants to an industry are more likely when (i.e., entry barriers are low when...)
- a. it is difficult to gain access to distribution channels.
 - b. economies of scale in the industry are high.
 - c. product differentiation in the industry is low.
 - d. capital requirements in the industry are high.

Ans. C

- 35) Suppliers are powerful when:
- a. satisfactory substitutes are available.
 - b. they sell a commodity product.
 - c. they offer a credible threat of forward integration.
 - d. they are in a highly fragmented industry.

Ans. C

- 36) The highest amount a firm can charge for its products is most directly affected by
- a. expected retaliation from competitors.
 - b. the cost of substitute products.
 - c. variable costs of production.
 - d. customers' high switching costs.

Ans. B

- 37) All of the following are forces that create high rivalry within an industry EXCEPT
- a. numerous or equally balanced competitors.
 - b. high fixed costs.
 - c. fast industry growth.
 - d. high storage costs.

Ans. C

- 38) According to the five factors model, an attractive industry would have all of the following characteristics EXCEPT:
- a. low barriers to entry.
 - b. suppliers with low bargaining power.
 - c. a moderate degree of rivalry among competitors.
 - d. few good product substitutes.

Ans. A

- 39) Internal analysis enables a firm to determine what the firm

- a. can do.
- b. should do.
- c. will do.
- d. might do.

Ans. A

40) An external analysis enables a firm to determine what the firm

- a. can do.
- b. should do.
- c. will do.
- d. might do.

Ans. D

41) _____ is/are the source of a firm's _____, which is/are the source of the firm's _____.

- a. Resources, capabilities, core competencies
- b. Capabilities, resources, core competencies
- c. Capabilities, resources, above-average returns
- d. Core competencies, resources, competitive advantage

Ans. A

42) In the airline industry, frequent-flyer programs, ticket kiosks, and e-ticketing are all examples of capabilities that are

- a. rare.
- b. causally ambiguous.
- c. socially complex.
- d. valuable.

Ans. D

43) Firms with few competitive resources are more likely

- a. to not respond to competitive actions.
- b. respond quickly to competitive actions.
- c. delay responding to competitive actions.
- d. respond to strategic actions, but not to tactical actions.

Ans. C

44) Competitors are more likely to respond to competitive actions that are taken by

- a. differentiators.
- b. larger companies.
- c. first movers.
- d. market leaders.

Ans. D

45) What can be defined as the art and science of formulating, implementing and evaluating cross functional decisions that enable an organization to achieve its objectives?

- a. Strategy formulation
- b. Strategy evaluation
- c. Strategy implementation
- d. Strategic management
- e. Strategic leading

Ans. D

46) Which of the following is not a cultural product?

- a. Rites
- b. Emotions
- c. Rituals
- d. Sagas
- e. Symbols

Ans. B

47) Which individuals are most responsible for the success and failure of an organization?

- a. Strategists
- b. Financial planners
- c. Personnel directors
- d. Stakeholders
- e. Human resource managers

Ans. A

48) Which of the following is an element of a firm's remote external environment?

- a. Competition
- b. Political agencies
- c. Suppliers
- d. Trade union

Ans. B

49) Long-term objectives should be all of the following except:

- a. measurable.
- b. continually changing.
- c. reasonable.
- d. challenging.
- e. consistent.

Ans. B

50) What are guides to decisionmaking?

- a. laws
- b. rules
- c. policies
- d. procedures
- e. goals

Ans. C

- 51) According to Greenley, strategic management offers all of these benefits except that
- a. it provides an objective view of management problems.
 - b. it creates a framework for internal communication among personnel.
 - c. it encourages a favorable attitude toward change.
 - d. it maximizes the effects of adverse conditions and changes.
 - e. it gives a degree of discipline and formality to the management of a business.

Ans. D

- 52) The vision and mission statement can often be found
- a. in the SEC report.
 - b. in annual reports.
 - c. on customer receipts.
 - d. on supplier invoices.
 - e. on community news bulletins

Ans. B

- 53) Which group would be classified as a stakeholder?
- a. Communities
 - b. Banks
 - c. Suppliers
 - d. Employees
 - e. All of these

Ans. E

- 54) The process of performing an external audit needs to include:
- a. only top level managers, as it's a planning function.
 - b. as many managers and employees as possible.
 - c. primarily front-line supervisors
 - d. between 15 to 20 managers for it to be valid
 - e. stockholders and external government agencies

Ans. B

- 55) Which of the following is not a stage of strategy formulation techniques?
- a. Formulation Framework
 - b. Matching stage
 - c. External factor evaluation
 - d. Decision stage

Ans. B

- 56) ST Strategies is an important strategy to
- a. Match weakness with opportunities of the firm
 - b. Overcome external threats
 - c. Obtain benefit from its resources

d. Overcome its weakness and reducing threats

Ans. B

57) The immediate external environment includes:

- a. Divisions
- b. S. B. U. s
- c. Competitors
- d. Management

Ans. C

58) The ___ comprises economic and social conditions, political priorities and technological developments, all of which must be anticipated, monitored, assessed and incorporated into the executive's decision making.

- a. Internal environment
- b. Task environment
- c. Operating environment
- d. Societal environment

Ans. D

59) Strategic management involves the _____, directing, ___ and controlling of a company's strategy-related decisions and actions.

- a. Financing; marketing
- b. Planning; financing
- c. Planning; organizing
- d. Marketing; planning

Ans. C

60) A strategy is a company's

- a. Value statement
- b. Pricing policy
- c. Game Plan to outsmart competitor
- d. Long-term objective

Ans. C

61) Strategy-formulation concepts and tools

- a. Do not differ greatly for different size and type of organizations
- b. Differ greatly for different size and type of organizations
- c. Do not differ greatly for profit or nonprofit organizations but differ in small and large organizations
- d. None of the mentioned options

Ans. A

62) Annual objectives

- a. Are not critical to success

- b. Serve as guidelines for action, directing and channeling efforts and activities of organization members
- c. Are not important for employee motivation and identification
- d. Do not provide a basis for organizational design

Ans. B

63) Annual objectives

- a. Need not to be consistent
- b. Should be easily achievable
- c. Should be measurable
- d. Should be confidential and not to be communicated throughout the organization

Ans. C

64) Which of the following resources is used by all organizations to achieve desired objectives?

- a. Financial resources,
- b. Physical resources,
- c. Human resources
- d. All of the mentioned options

Ans. D

65) Strategic management is

- a. A pure science.
- b. Based mainly on intuition.
- c. Needed mainly when organizational performance falls.
- d. Based on the use of quantitative and qualitative information.

Ans. D

66) Large-scale, future-oriented plans, for interacting with the competitive environment to achieve company objectives refers to its

- a. Strategy
- b. Goals
- c. Competitive analysis
- d. Dynamic policies

Ans. A

67) Strategic issues require which level of management decisions?

- a. Operative
- b. Top
- c. Front-line
- d. Middle

Ans. B

68) Which of these basic questions should a vision statement answer?

- a. What is our business?

- b. Who are our employees?
- c. Why do we exist?
- d. What do we want to become?

Ans. D

69) _____ is not part of an _____ external audit.

- a. Analyzing competitors
- b. Analyzing financial ratios
- c. Analyzing available technologies
- d. Studying the political environment

Ans. B

70) Strategic management process activate in the sequence of_____

I.Environmental scanning, Strategyformulation, Implementation, control and evaluation

II.Strategy formulation, Environmental scanning,

- a. Mission
- b. Strategy
- c. Objective
- d. Policy

Ans. C

71) "A possible and desirable futurestate of an organization" is called:

- a. Mission
- b. Vision
- c. Strategy implementation
- d. None of above

Ans. B

72) Strategic decisions are based onwhat managers_, rather than on what they__.

- a. Know; forecast
- b. React to; anticipate
- c. Forecast; know
- d. Compromise with; analyze

Ans. C

73) "To improve economic strengthof society and function as a good corporate citizen on a local, state, and national basis in all countries inwhich we do business". This is a mission statement that contains:

- a. Self-concept
- b. Economic concern
- c. Products or Services
- d. Concern for Public Image

Ans. D

74) Strategic-management audit is known as:

- a. Environmental scanning
- b. Strategy formulation
- c. Strategy control
- d. Strategy evaluation

Ans. A

75) Forecasting tools can be broadly categorized into two groups. Those are:

- a. Qualitative, Operational
- b. Quantitative, Operational
- c. Qualitative, Quantitative
- d. Regression and time series analysis

Ans. C

76) _____ identifies a firm's major competitors and their particular strengths and weaknesses in relation to a sample firm's strategic position.

- a. Competitive Profile Matrix
- b. External Factor Evaluation matrix
- c. Internal Factor Evaluation Matrix
- d. Boston consulting group matrix

Ans. A

77) Organizing means an identifiable group of people contributing their efforts towards the attainment of same goal. It is important at the time of:

- a. Environmental scanning
- b. Strategy formulation
- c. Strategy Implementation
- d. Strategy evaluation

Ans. C

78) In a turbulent and competitive free enterprise environment, a firm will succeed only if it takes a(n) _____ stance towards change.

- a. Reactive
- b. Proactive
- c. Anti-regulatory or anti-government
- d. Vision and not mission

Ans. B

79) Which statement best describes intuition?

- a. It represents the marginal factor in decision-making.
- b. It represents a minor factor in decision-making integrated with analysis.
- c. It should be coupled with analysis in decision-making.

- d. It is better than analysis indecision-making.
- e. It is management by ignorance.

Ans. C

80) What are the means by which long-term objectives will be achieved?

- a. Strategies.
- b. Strengths.
- c. Weaknesses.
- d. Policies.
- e. Opportunities.

Ans. A

81) Which of these basic questions should a vision statement answer?

- a. What is our business?
- b. Who are our employees?
- c. Why do we exist?
- d. What do we want to become?
- e. Who are our competitors?

Ans. D

82) When an industry relies heavily on government contracts, which forecasts can be the most important part of an external audit.

- a. economic
- b. political
- c. technological
- d. competitive
- e. Multinational

Ans. B

83) _____ is not part of an external audit.

- a. Analyzing competitors
- b. Analyzing financial ratios
- c. q. Analyzing available technologies
- d. Studying the political environment
- e. Analyzing social, cultural, demographic and geographic forces

Ans. B

84) Which individuals are most responsible for the success and failure of an organization?

- a. Strategists
- b. Financial planners
- c. Personnel directors
- d. Stakeholders
- e. Human resource managers

Ans. A

85) Long-term objectives should be all of the following except:

- a. Measurable.
- b. Continually changing.
- c. Reasonable.
- d. Challenging.
- e. Consistent.

Ans. B

86) What are guides to decisionmaking?

- a. laws
- b. rules
- c. policies
- d. procedures
- e. goals

Ans. C

87) Which group would be classified as a stakeholder?

- a. Communities
- b. Banks
- c. Suppliers
- d. Employees
- e. All of the given options

Ans. E

88) Typically how many strategic decision levels are in the corporate decision-making hierarchy?

- a. 3
- b. 4
- c. could be more than 5
- d. 2

Ans. A

89) Which type of trend can be exemplified by the increasing numbers of two-income households in a society?

- a. Social
- b. Economic
- c. Cultural
- d. Technological

Ans. B

90) External assessment is performed in which of the strategic management phase?

- a. Strategy formulation stage
- b. Strategy implementation stage
- c. Strategy evaluation stage
- d. All of the given options

Ans. A

- 91) Political variables have a significant effect on
- Strategy formulation and implementation
 - Strategy formulation and evaluation
 - Strategy implementation and evaluation
 - Strategy formulation, implementation and evaluation

Ans. A

- 92) Strategic decisions ostensibly commit the firm for
- 1-2 years
 - The short term
 - one year
 - A long time, typically five years

Ans. D

- 93) Social responsibility is a critical consideration for a company's strategic decision makers since
- Stockholders demand it
 - The mission statement must express how the company intends to contribute to the societies that sustain it
 - It increases a company's profits
 - It helps make decisions

Ans. B

94) "The perfect search engine would understand exactly what you mean and give back exactly what you want", this statement is included in the mission statement of an online firm and is showing which one of the following components?

- Self-concept
- Concern for public image
- A declaration of attitude
- Philosophy

Ans. B

- 95) Which of the following are signs of weakness in a company's competitive position?
- A return-on-equity is below 25% and earnings per share of less than Rs. 2.00
 - A price set by the firm higher than its rivals
 - A declining market share, poor product quality and few sales in market
 - Lower revenues and profit margin and narrow product line than the market leader

Ans. C

96) It directs at developing new products before competitors do at improving product quality or at improving manufacturing processes to reduce costs.

- Marketing

- b. Opportunity analysis
- c. Research and development
- d. Management

Ans. C

97) "Identifying and evaluating key social, political, economic, technological and competitive trends and events". Which of the following best describes this statement?

- a. Developing an effective mission statement
- b. Conducting an internal audit
- c. Performing an external audit
- d. Formulating strategy

Ans. C

98) What is the central purpose of strategic evaluation?

- a. Evaluate effectiveness of strategy to achieve organisational objectives.
- b. Evaluate effectiveness of control system to measure achievements.
- c. Evaluate effectiveness of strategies to be implemented efficiently.
- d. Evaluate effectiveness of the strategy implementation process.

Ans. A

99) Strategy evaluation at the ___ level involves using specific performance measures-qualitative and quantitative-for each functional area.

- a. organizational
- b. operational
- c. functional
- d. production

Ans. c

100) According to Flavell (1977), perception, thinking and reasoning about humans and human affairs is known as:

- a. Social Cognition
- b. Social Perception
- c. Conceptualization
- d. Socialization

Ans. A

101) When children recognize that each individual is aware of other people's thoughts and feelings, it is called:

- a. Self-reflection
- b. Mutual role taking
- c. Social information role taking
- d. Social and conventional system role taking

Ans. A

102) The shared emotional responses which the child experiences on perceiving other's emotional reactions is known as:

- a. Empathy
- b. Epathy
- c. Mood
- d. Emotional Trauma

Ans. A

103) "Mutual Role Taking Stage" is found among children:

- a. Between the ages 10 and 12
- b. Between the ages 18 and 24
- c. Between the ages 6 and 8
- d. between the ages 2 and 6

Ans. A

104) In which "role taking stage", children realize that there are integrated networks of perspectives such as American or a catholic point of view?

- a. Social and Conventional System of Role Taking
- b. Mutual Role Taking
- c. Self-reflection
- d. Social Informational Role Taking

Ans. A

105) Who concluded in his theory that from ages 5 to about 12, a child's concept of justice passes from moral realism to moral relativism?

- a. W. B. Watson
- b. Sigmund Freud
- c. Jean Piaget
- d. Karniol

Ans. C

106) Around age 11, children think that everyone has equal right to justice and consideration. It is called:

- a. Moral Relativism
- b. Moral Realism
- c. Moral Biting
- d. Moral Consequence

Ans. A

107) Stages of moral development for children were emphasized by:

- a. LB. Watson
- b. E. B. Titchener
- c. Sigmund Freud
- d. Kohlberg

Ans. D

108) Moral Development is related to and dependent upon:

- a. Intellectual Development
- b. Socialization
- c. Learning
- d. Perception

Ans. A

109) Genetic studies of children over varying lengths of time have emphasized the persistence of the two elements of the personality pattern:

- a. The self-concept and traits
- b. Moral development and socialization
- c. Language development and concept formation
- d. Prenatal development and play

Ans. A

110) According to Freud, the period from the end of the oedipal stage around 6 years is called:

- a. Genital Stage
- b. Latency Period
- c. Phallic Stage
- d. Oral Stage

Ans. B

111) A system of learning which was first demonstrated by Tolman in 1932 is known as:

- a. Latent Learning
- b. Trial and Error Learning
- c. Conditioning
- d. Insightful learning

Ans. A

112) A girl who is sexually attracted to members of her own sex is called:

- a. A lesbian
- b. A sexologist
- c. A heterosexual girl
- d. A homosexual girl

Ans. A

113) The term originally used by Freud to refer to sexual energy which is derived from the id and is available to power mental and physical activity is known as:

- a. Ego
- b. Super ego
- c. Libido
- d. Instinct

Ans. C

114) A simplified form of speech that adults adopt when talking to very young children is called:

- a. Motherese
- b. Mothering
- c. Matter
- d. Maturation

Ans. A

115) Bowlby's original idea of the way in which attachment develops between the young infant and its mother is called:

- a. Maternal Drive
- b. Monotrophy
- c. Socialization
- d. Affection

Ans. B

116) The identical twins who are developed from the same fertilized ovum which has subsequently split to develop as two independent Fetus are known as:

- a. Monozygotic Twins
- b. Fraternal Twins
- c. Separated Twins
- d. Socialized Twins

Ans. A

117) The condition in which an adult is sexually attracted to children and can only achieve sexual arousal with them is popularly known as:

- a. Pedophilia
- b. Astasia Abasia
- c. Amnesia
- d. Phobia

Ans. A

118) A term is frequently used in experiments for the level at which a person or animal or a child performs on a particular task. What is it?

- a. Variable
- b. Performance
- c. Hypothesis
- d. Problem

Ans. B

119) The words that children seem to use in the earliest stage of language acquisition are known as:

- a. Symbols

- b. Pivot words
- c. Gestures
- d. Concepts

Ans. B

120) An approach for studying language which concentrates on the functions that language performs rather than on the structure of the language itself is called:

- a. Pragmatics
- b. Psycholinguistics
- c. Concept formation
- d. Symbolism

Ans. A

121) The study of personal space and the use of touch as nonverbal cues in communication is known as:

- a. Concept
- b. Proxemics
- c. Symbol
- d. Gesture

Ans. B

122) The study of psychological aspects of language and the relationships between language and other psychological processes is known as:

- a. Psycholinguistics
- b. Concept formation
- c. Verbal learning
- d. Verbal Accommodation

Ans. B

123) The stage of physical growth during which the child becomes capable of reproduction is called:

- a. Puberty
- b. Maturation
- c. Menstruation
- d. Adolescence

Ans. A

124) The extent to which a message does not provide new information in "Information Theory" is called:

- a. Redundancy
- b. Concept
- c. Construct
- d. Hypothesis

Ans. A

125) A retreat under stress to an earlier psychosexual stage is called:

- a. Aggression
- b. Regression
- c. Rationalization
- d. Rehearsal

Ans. B

126) "One's expectations can have an effect on an outcome that is being observed."—who has given the above statement?

- a. Rosenthal
- b. Wilhelm Wundt
- c. W.B. Watson
- d. Jean Piaget

Ans. A

127) The process by which our senses adjust their sensitivity to the surrounding environment is called:

- a. Perception
- b. Attention
- c. Sensory Adaptation
- d. Distraction

Ans. A

128) The process by which a child becomes integrated into society by adopting its norms and values, acquiring the necessary skills of social interaction is known as :

- a. Socialization
- b. Social Interaction
- c. Sociability
- d. Affiliation

Ans. A

129) The process by which two people or animals directly each other's behaviour is called:

- a. Social Interaction
- b. Socialization
- c. Affiliation
- d. Sociability

Ans. A

130) Yerkes-Dodson Law is associated with:

- a. Socialization
- b. Affiliation
- c. Social Facilitation
- d. Social Interaction

Ans. C

131) The study of social forms of language and the ways in which language is used in society is known as:

- a. Sociolinguistics
- b. Psycholinguistics
- c. Bilingualism
- d. Trilingualism

Ans. A

132) A device to convert a biological signal such as heart-beat or skin resistance into an electrical signal suitable for recording is known as:

- a. Transducer
- b. Trans-sexual
- c. Galvanometer
- d. Transdoctor

Ans. C

133) A genetic disorder in which the individual has one fewer chromosome than normal resulting in sexual abnormalities is called:

- a. Turner's Syndrome
- b. Brown's Syndrome
- c. Down's Syndrome
- d. Schizophrenia

Ans. A

134) An irrational and excessive fear of strangers is known as:

- a. Ophophobia
- b. Acrophobia
- c. Xenophobia
- d. Agrophobia

Ans. C

135) A rigid and inflexible notion of right and wrong in which "justice is subordinated to adult authority" is known as:

- a. Moral Realism
- b. Moral Relativism
- c. Moral Consequences
- d. Moral Biting

Ans. A

136) Developmental Psychology studies the description, explanation and prediction of:

- a. Child Behaviour
- b. Adult Behaviour

- c. Old age problems
- d. School problems

Ans. A

137) In which period, children were forced to behave and act like adults and according to adult standards?

- a. Ancient Period
- b. Medieval Period
- c. Vedic Period
- d. Modern Period

Ans. A

138) According to the preformationist concept, all adult qualities are found at:

- a. Birth
- b. Death
- c. Adulthood
- d. Adolescence

Ans. A

139) The society during pre-victorian era was:

- a. Adult-centred
- b. Child-centred
- c. Adolescent-centred
- d. Old men-centred

Ans. A

140) In a book "EMILE" (1762), it was depicted that the child is gifted with an innate moral sense. Who is the author of that book?

- a. J. J. Rousseau
- b. Pestalozzi
- c. Tiedmann
- d. John Locke

Ans. A

141) Maximum number of Baby Biographies was published in:

- a. The 19th century
- b. The 20th century
- c. The 18th century
- d. The 16th century

Ans. A

142) Because of large number of studies on "Child Behaviour" and tremendous emphasis on Child and Developmental psychology, 20th century is called the :

- a. Century of Adults

- b. Century of the child
- c. Century of men and women
- d. Century of women

Ans. A

143) The "Questionnaire technique" was made popular by famous American Psychologist:

- a. G. Stanley Hall
- b. J. B. Watson
- c. Rayner
- d. B. F. Skinner

Ans. A

144) At Yale University, who introduced the "Moving Picture Camera" as an aid to observe young children?

- a. Gessel (1926)
- b. Wallace (1961)
- c. Wyalt (1959)
- d. Spitz (1965)

Ans. A

145) The clinic for the treatment of "problem children" was first established by:

- a. Goodenough (1949)
- b. Wittmer (1896)
- c. Hunt (1961)
- d. Wilt Enborn (1956)

Ans. B

146) The behaviour and activities of the child are expressed quantitatively through the:

- a. Behaviour Rating Method
- b. Projective Technique
- c. Follow up Method
- d. Psychophysical Method

Ans. A

147) The testing method for studying children was first introduced by:

- a. Binet (1905)
- b. Piaget (1960)
- c. Gesell (1949)
- d. Hoffman (1967)

Ans. B

148) Which method is generally used when it becomes necessary to find out if the disease or behaviour problems of the child have relapsed after treatment?

- a. Psychophysical Method

- b. Follow-up Method
- c. Behaviour Rating Method
- d. Method of Individual Diagnosis

Ans. B

149) The progressive series of changes of an orderly, coherent type towards the direction of maturity is called:

- a. Growth
- b. Development
- c. Maturation
- d. Adolescence

Ans. B

150) Among the periods of prenatal development, the period of fetus is:

- a. Most lengthy
- b. Dangerous
- c. Called the period of zygote
- d. Very short

Ans. A

151) The period of Ovum is called the:

- a. Period of Zygote
- b. Period of Embryo
- c. Period of fetus
- d. Period of Disturbances

Ans. A

152) Period of Parturate refers to the:

- a. First 15 to 30 minutes of life
- b. First 15 days of life
- c. First three hours of life
- d. First ten days of life

Ans. A

153) Normally the neonate sleeps for:

- a. 24 hours a day
- b. 18 to 20 hours a day
- c. 6 hours a day
- d. 2 hours a day

Ans. B

154) The Period of Parturate refers to the first 15 to 30 minutes of life, until the infant is cut from:

- a. The umbilical cord
- b. The internal world

- c. The external world
- d. The environmental pressure

Ans. A

155) Darwinian Reflex decreases gradually due to:

- a. Cross connectivism
- b. Transfer
- c. Interference
- d. Atrophy through disuse

Ans. D

156) If an object is placed in the baby's palm, the fingers are closed so strongly that the neonates can support their entire weight by their hands. This prenatal posture is retained by most infants for 3 to 4 weeks after birth. This is popularly known as:

- a. Darwinian Reflex
- b. Luckian Reflex
- c. Pavlovian Reflex
- d. Watsonian Reflex

Ans. A

157) When the infant is placed on his back, he will throw his legs and hands upward as if he is going to embrace somebody. This is popularly known as:

- a. Moro Embrace Reflex
- b. Sucking Reflex
- c. Ocular Reflex
- d. Foot Reflex

Ans. A

158) The development of the ability to walk upright is called:

- a. Locomotor Development
- b. Sensorimotor Learning
- c. Transfer of Training
- d. Bilateral Transfer

Ans. A

159) Ames and Shirley have emphasized the relative stability of the locomotor sequence as an indicator of a function of:

- a. Learning
- b. Maturation
- c. Emotion
- d. Intelligence

Ans. B

160) Who is the author of the famous book "Hereditary Genius"?

- a. Watson
- b. Galton
- c. John Locke
- d. Binet

Ans. B

161) Schiff (1978) has examined the role of genetics in:

- a. Sensory Development
- b. Motor Development
- c. Intellectual Development
- d. Emotional Development

Ans. C

162) Who said – "I propose to show in this book that a man's natural abilities are derived by intelligence under exactly the same limitations as the form and physical features of the whole organic world"?

- a. Galton
- b. J.B. Watson
- c. Binet
- d. Ravens

Ans. A

163) The first part of "Preoperational Period" (Piaget) is known as:

- a. Preconceptual Period
- b. Internal Mental Period
- c. Tertiary Circular Reactions
- d. Secondary Circular Reactions

Ans. A

164) During Pre-operational Period, Children are found to be extremely:

- a. Benevolent
- b. Egocentric
- c. Clever
- d. Intelligent

Ans. B

165) Syrup can be made with water and sugar. Again syrup can be reduced to sugar by putting it in fire. When the child is to understand this, he is said to have the capacity of:

- a. Reversibility
- b. Conservation
- c. Seriation
- d. Casuality

Ans. A

166) The mental ability to arrange things in order is known as:

- a. Seriation
- b. Casuality
- c. Reversibility
- d. Conservation

Ans. A

167) The concrete operational stage is responsible for the stability and integration of the child's:

- a. Emotional System
- b. Cognitive System
- c. Learning System
- d. Memory System

Ans. B

168) The concepts of children are generally developed during the period of:

- a. Intuitive Thought
- b. Preoperational Stage
- c. Secondary Circular Reactions
- d. Tertiary Circular Reaction

Ans. A

169) Mental Age (MA) is a measure of the absolute level of:

- a. Emotion
- b. Intelligence
- c. Creativity
- d. Learning

Ans. B

170) The process of classifying all intellectual abilities into a systematic framework is called:

- a. Structure of Intellect
- b. Structure of Emotion
- c. Structure of Feeling
- d. Structure of Creativity

Ans. A

171) The concept of "Structure of Intellect" was proposed by:

- a. Blewett (1964)
- b. Guilford (1961)
- c. Jensen (1969)
- d. Bayley (1969)

Ans. B

172) According to the model "Structure of Intellect", Guilford revealed that intelligence can be broken into:

- a. 100 factors
- b. 120 factors
- c. 50 factors
- d. 55 factors

Ans. B

173) Who is the author of the article "How much can we boost I.Q. and Scholastic Achievement"?

- a. Prof. Arthur Jensen (1969)
- b. Blewett (1954)
- c. Venkatachar (1930)
- d. Bayley (1969)

Ans. A

174) Jensen's findings indicate the role of heredity on the development and growth of:

- a. Creativity
- b. Emotion
- c. Learning
- d. Intelligence

Ans. D

175) Who has evaluated the findings of "Project Head Start" conducted as a contemporary project to help the socially disadvantaged Negroes and Asiatic origin lower class people ?

- a. Arthur Jensen (1969)
- b. Shields (1962)
- c. Blewett (1954)
- d. Holzinger (1937)

Ans. A

176) While E.B. Titchener holds emotion as an effective state of the organism, Carr (1925) views emotion as a form of:

- a. Energy mobilization
- b. Creativity
- c. Feeling
- d. Daydream

Ans. A

177) Emotional response is weakened if:

- a. Overlearning takes place
- b. Reason is applied
- c. Interference is there
- d. Goal is achieved

Ans. B

178) The most systematic study on the development of emotion in children from a state of general

excitement found at birth has been made by:

- a. Robert Bridges (1932)
- b. J. Hunt (1961)
- c. Hurlock (1978)
- d. Kagan (1962)

Ans. A

179) Impulsive responses of anger are otherwise known as:

- a. Aggression
- b. Regression
- c. Sublimation
- d. Repression

Ans. A

180) Violent outbursts of anger are called:

- a. Temper tantrum
- b. Frustration
- c. Mood
- d. Imprinting

Ans. A

181) Temper tantrum reaches its peak at the age of:

- a. 3 to 4 years
- b. 7 years
- c. 20 years
- d. 25 years

Ans. A

182) Under inhibited response of anger, the child may withdraw to himself as a result of:

- a. Frustration
- b. Learning
- c. Achievement motivation
- d. Distant goal

Ans. A

183) Which mechanism of dream work makes the dream coherent and meaningful?

- a. Secondary Elaboration
- b. Displacement
- c. Sublimation
- d. Dramatization
- e. Condensation

Ans. A

184) Temper tantrum comes to an end by:

- a. 7 years
- b. 19 years
- c. 2 years
- d. 22 years

Ans. B

185) The bright example of self destruction and self aggression is:

- a. Frustration
- b. Suicide
- c. Projection
- d. Introjection

Ans. C

186) Jealousy is an outgrowth of:

- a. Repression
- b. Regression
- c. Anger
- d. Fear

Ans. A

187) The systematized set of vocal habits by means of which the members of a human society interact in terms of their culture is called:

- a. Language
- b. Concept
- c. Thought
- d. Vocabulary

Ans. A

188) When children show resistance to adult authority and does just the opposite of what they ask him to do is called:

- a. Negativism
- b. Rivalry
- c. Bullying
- d. Quarreling

Ans. A

189) "It does indeed seem possible to teach children to think creatively. The most successful approaches seem to be those that involve both cognitive and emotional functioning, provide adequate structures and motivation and give opportunities for involvement, practice and interaction with teachers and other children. Motivating and facilitating conditions certainly make a difference in creative functioning but differences seem to be greatest and most predictable when deliberate teaching is involved. Teachers, though their behaviour in an instructional setting can make a lot of difference in the cognitive and affective life of children but they must be sure of their objectives, whether they count to foster creativity in pupils or their own self-fulfilling prophecy."

Who has made this statement?

- a. Torrance
- b. Jensen
- c. Binett
- d. J.W. Taylor

Ans. A

190) Moral Development is intimately linked with stages of:

- a. Intellectual Development
- b. Emotional Development
- c. Creativity
- d. Imitation

Ans. B

191) Who have shown how the ability to moral judgement behaviour that conforms to approved social standard follow a predictable pattern related to the sequence of stages in intellectual development?

- a. Jensen and Binett
- b. Piaget and Kohlberg
- c. Watson and Reynor
- d. Blanton and Blatt

Ans. A

192) Who viewed that moral development occurs in two clear-cut stages—Morality by constraint and morality by Reciprocity?

- a. Jean Piaget
- b. Jensen
- c. Ravens
- d. Binett

Ans. A

193) Guilt is a negative:

- a. Self evaluation
- b. Attitude
- c. Creativity
- d. Sociability

Ans. A

194) Childhood schizophrenia is otherwise known as:

- a. Autism
- b. Temper tantrum
- c. Antridia
- d. Anaphthalmia

Ans. A

195) If a child's eye ball is abnormally small, he is supposed to be affected by:

- a. Oxycephaly
- b. Antridia
- c. Microphthalmia
- d. Anaphthalmia

Ans. B

196) If a child's eyes do not develop at all, he is supposed to be affected by:

- a. Anaphalmia
- b. Oxycephaly
- c. Anaphthalmia
- d. Microphthalmia

Ans. A

197) Sometimes a child's iris fails to develop, visual acuity becomes poor and there is rapid involuntary movement of eye ball. Here the child is affected by:

- a. Anaphthalmia
- b. Oxycephaly
- c. Antridia
- d. Microphthalmia

Ans. C

198) Schiller Spencer theory of play is otherwise known as:

- a. Preparation for Future Adult Activities
- b. Surplus energy theory of play
- c. Recapitulation theory
- d. Instinct Theory

Ans. B

199) Who was the propounder of "Instinct Theory of Play"?

- a. Staneley Hall
- b. McDougall
- c. Patrick
- d. Spencer

Ans. B

200) 201 Which is the most basic and common obstacle to problem solving ?

- a. Confirmation bias
- b. Fixation
- c. Functional fixedness
- d. Mental set

Ans: B

201) The child who says "Milk gone" is engaging in_____. This type of utterance demonstrates that children are actively experimenting with rules of_.

- a. Babbling; syntax
- b. Telegraphic speech; syntax
- c. Babbling; semantics
- d. Telegraphic speech; semantics

Ans: D

202) Problem solving comprises of four stages. Choose the correct sequence of stages

- a. 1 Incubation, preparation, verification, illumination
- b. Preparation, incubation, illumination, verification
- c. Incubation, preparation, illumination, verification
- d. 4 Preparation, illumination, incubation, verification

Ans: B

203) Given below are two statements, one labelled as Assertion (A) and the other labelled as Reason (R). Assertion (A) : Thinking about objects brings change in attitudes. Reason (R) : Attitudes toward complex issues and objects are typically a mixture of positive and negative feelings. Codes:

- a. Both (A) and (R) are true and (R) is the correct explanation of (A).
- b. Both (A) and (R) are true, but (R) is not the correct explanation of (A).
- c. (A) is true, but (R) is false.
- d. (A) is false, but (R) is true.

Ans: B

204) A subject is presented four non-sense syllabus one by one each for two seconds. After presentation of the four items, the subject is asked to count backward aloud by threes from some number for fifteen seconds and after that he/she is asked to recall the non-sense syllabus. What memory storage is being measured in this experiment ?

- a. Sensory memory storage
- b. Working memory storage
- c. Short term memory storage
- d. Long term memory storage

Ans: C

205) When the previously learned task affects the retention of task being currently acquired, the phenomenon is referred to as:

- a. Retroactive interference
- b. Proactive interference
- c. Retroactive effect
- d. Proactive effect

Ans: C

206) Assertion (A) : Positive psychology draws its strength from humanistic psychology. Reason (R) : Both humanistic and positive psychology believe in positive human qualities. Codes:
a. Both (A) and (R) are true and (R) is the correct explanation of (A).
b. Both (A) and (R) are true, but (R) is not the explanation of (A).
c. (A) is true, but (R) is false.
d. (A) is false, but (R) is true.
Ans: B

207) The basic difference between classical conditioning and instrumental learning is of
a. Presentation of stimulus
b. Emitting of response
c. Temporal contiguity
d. Mechanism
Ans: D

208) Major criticisms of Thurston's theory of intelligence are based on
I. Use of subjective measures
II. Restricted heterogeneity in sample
III. Method of factor analysis
a. I and II are correct.
b. I and III are correct.
c. II and III are correct.
d. I, II and III are correct.
Ans: C

209) Given below are two statements, one labelled as Assertion (A) and the other labelled as Reason (R). Indicate your answer using the codes given below : Assertion (A) : Heritability of intelligence explains variations due to genetics for individuals within a given population. Reason (R) : Earlier the children from deprived families were adopted, the higher their intelligence score will be. Codes:
a. Both (A) and (R) are true and (R) is the correct explanation of (A).
b. Both (A) and (R) are true, but (R) is not the correct explanation of (A).
c. (A) is true, but (R) is false.
d. (A) is false, but (R) is true.
Ans: B

210) What is the correct sequence of ear parts given below ?
a. Eardrum – Hammer – Anvil – Stirrup – Oval window
b. Oval window – Hammer – Eardrum Anvil – Stirrup
c. Eardrum – Anvil – Stirrup – Hammer – Oval window
d. Oval window – Anvil Hammer – Stirrup – Eardrum

Ans: C

211) We can cope with stress by becoming aware of our irrational, upsetting thoughts and replacing them with rational, calming thoughts. This view represents.

- a. Cognitive behavioural approach
- b. Psychoanalytical approach
- c. Socio-cultural approach
- d. Bio-social approach

Ans: A

212) An instrumental response is conditioned only when organism interprets the reinforcement as being controlled by its response. This view is supported by

- a. Tolman
- b. Skinner
- c. Seligman
- d. Beck

Ans: C

213) When a child gets two chocolates once every week for its performance in the class it is an instance of

- a. Fixed ratio, variable interval
- b. Fixed ratio, fixed interval
- c. Variable ratio, fixed interval
- d. Variable ratio, variable interval

Ans: C

214) In a study on 'Career Aspirations of Students', the respondents were required to state their career aspirations in about sixty words. This would be an example of

- a. Fixed-alternative item
- b. Scale item
- c. Open-end item
- d. Checklist item

Ans: C

215) Which of the following implications cannot be derived from Piaget's theory of cognitive development?

- a. Acceptance of individual differences
- b. Sensitivity of children's readiness to learn
- c. Discovery learning
- d. Need of verbal teaching

Ans: D

216) According to Lev Vygotsky, the primary cause of cognitive development is:

- a. stimulus-response pairing
- b. social interaction
- c. adjustment of mental schemas
- d. equilibration

Ans: B

217) In the context of Kohlberg's stages of moral reasoning, under which stage would the given typical response of a child fall? "Your parents will be proud of you if you are honest. So you should be honest."

- a. Social contract orientation
- b. Punishment-obedience orientation
- c. Good girl-good boy orientation
- d. Law and order orientation

Ans: C

218) According to Jean Piaget, which of the following is necessary for learning?

- a. Active exploration of the environment by the learner
- b. Observing the behaviour of adults
- c. Belief in immanent justice
- d. Reinforcement by teachers and parents

Ans: A

219) According to Jean Piaget, schema building occurs as a result of modifying new information to fit existing schemes and by modifying old schemes as per new information. These two processes are known as:

- a. assimilation and adaptation
- b. accommodation and adaptation
- c. equilibration and modification
- d. assimilation and accommodation

Ans: D

220) According to Piaget, children's thinking differs in from adults than in

- a. size, correctness
- b. amount, kind
- c. kind, amount
- d. size, type

Ans: C

221) According to Vygotsky, children learn

- a. by maturation
- b. when reinforcement is offered
- c. by imitation

d. by interacting with adults and peers

Ans: D

222) Kohlberg has given

- a. the stages of cognitive development
- b. the stages of physical development
- c. the stages of emotional development
- d. Children learn through social interaction with peers and adults

Ans: D

223) According to the pre-conventional level of Kohlberg's theory, to which of the following would an individual turn when making a moral decision?

- a. Personal needs and desires
- b. Individual values
- c. Family expectations
- d. Potential punishment involved

Ans: D

224) Which one of the following statements about children would Vygotsky agree with?

- a. Formal operational
- b. Concrete operational
- c. Sensorimotor
- d. Preoperational

Ans: D

225) In Lawrence Kohlberg's theory, which level signifies the absence of morality in the true sense?

- a. Level III
- b. Level IV
- c. Level I
- d. Level II

Ans: C

226) In Vygotsky's theory, which aspect of development gets neglected

- a. Social
- b. Cultural
- c. Biological
- d. Linguistic

Ans: C

227) Which of the following is based on Vygotsky's socio-cultural theory?

- a. Operant conditioning
- b. Reciprocal teaching
- c. Culture-neutral cognitive development

d. Insight learning

Ans: B

228) Vygotsky emphasized the significance of the role played by which of the following factors in the learning of children?

- a. Moral
- b. Physical
- c. Social
- d. Hereditary

Ans: C

229) A teacher makes use of a variety of tasks to cater to the different learning styles of her learners. She is influenced by

- a. Gardner's multiple intelligence theory
- b. Vygotsky's socio-cultural theory
- c. Piaget's cognitive development theory
- d. Kohlberg's moral development theory

Ans: A

230) According to Kohlberg, a teacher can instill moral values in children by

- a. giving strict instructions on 'how to behave'
- b. involving them in discussions on moral issues
- c. laying clear rules of behaviour
- d. giving importance to religious teachings

Ans: B

231) According to Piaget's stages of Cognitive Development, the sensori-motor stage is associated with

- a. ability to solve problems in logical fashion
- b. concerns about social issues
- c. ability to interpret and analyse options
- d. imitation, memory and mental representation

Ans: D

232) "Children actively construct their understanding of the world" is a statement attributed to

- a. Piaget
- b. Kohlberg
- c. Pavlov
- d. Skinner

Ans: A

233) The 'insight theory of learning' is promoted by

- a. 'Gestalt' theorists

- b. Jean Piaget
- c. Pavlov
- d. Vygotsky

Ans: A

234) Four distinct stages of children's intellectual development are identified by

- a. Erikson
- b. Kohlberg
- c. Skinner
- d. Piaget

Ans: D

235) Which of the following statements describes Piaget and Vygotsky's views on language and thought correctly?

- a. According to Vygotsky, thought emerges first and according to Piaget, language has a profound effect on thought.
- b. Both view language as emerging from the child's thought.
- c. According to Piaget, thought emerges first and according to Vygotsky, language has a profound effect on thought.
- d. Both view thought as emerging from the child's language.

Ans: C

236) The concept of 'private speech' of children as proposed by Vygotsky

- a. shows that children are stupid and thus need guidance of adults.
- b. illustrates that children are egocentric.
- c. shows that children love themselves.
- d. illustrates that children use speech to guide their own actions.

Ans: D

237) According to Vygotsky, learning cannot be separated from

- a. its social context.
- b. perception & attentional processes.
- c. reinforcement.
- d. a measurable change in behaviour.

Ans: A

238) In a constructivist classroom as envisioned by Piaget and Vygotsky, learning

- a. is constructed by the students themselves who play an active role.
- b. is offering of reinforcement by the teacher.
- c. is dictated by the teacher and the students are passive recipients of the same.
- d. happens by pairing of a stimulus and a response.

Ans: A

239) The choice between automatic and controlled processes is:

- a. Typically automatic
- b. Typically controlled
- c. Always automatic
- d. Always controlled

Ans: A

241. Which one of the following statements best summarizes the relationship between development

- a. Influence
- b. Are influenced by
- c. A and B
- d. Neither A nor B

Ans: C

240) Proceduralized judgments are:

- a. Developed without practice
- b. Preemptive over non-proceduralized judgments
- c. Slower than non-proceduralized judgments
- d. Deliberate and thoughtful

Ans: B

241) Judgments about others' ___ are often automatic.

- a. Traits
- b. Behavior
- c. A and B
- d. Neither A nor B

Ans: A

242) Automatic and controlled processes can be triggered by:

- a. Subliminal primes
- b. Supraliminal primes
- c. A and B
- d. Neither A nor B

Ans: C

243) An ironic rebound effect:

- a. Occurs during the period of time when one is asked to suppress thoughts
- b. Occurs when one is no longer attempting to suppress thoughts
- c. Can be prevented by substituting different thoughts for the unwanted thoughts
- d. B and C

Ans: A

244) Goal-directed automaticity is:

- a. Adaptive

- b. Maladaptive
- c. A and B
- d. Neither A nor B

Ans: C

245) The conscious will is an example of:

- a. Automatic process
- b. Controlled process
- c. Intention
- d. Behavior

Ans: B

246) First-order consciousness necessarily involves:

- a. Being mindful
- b. Having self-esteem
- c. Thinking about one's own thoughts
- d. Causing one's own behavior

Ans: A

247) Mind-wandering is an example of:

- a. Stimulus-dependent thought
- b. Stimulus-independent thought
- c. Unconscious thought
- d. Default network deactivation

Answer: B

248) _____ is a thought- sampling technique frequently used outside the laboratory:

- a. Experience sampling
- b. Think-aloud paradigm
- c. Videotaping
- d. A and C

Ans: A

249) It is possible to study people's thoughts in a useful way when:

- a. People report on their thoughts while they are happening
- b. People report on the content of their thoughts
- c. People report on their thought processes
- d. A and B

Ans: D

250) The human need to belong preempts:

- a. The need for understanding
- b. The need for social control
- c. Controlled processes in social cognition

d. All of the above

Ans: A

251) The dual-process model and continuum model of impression formation:

- a. Do not depend on motivation
- b. Both propose stable cognitive representations at different stages of impression formation
- c. Both suggest distinct rules for proceeding to each stage of impression formation
- d. Both involve an interplay of automatic and controlled processes

Ans: D

252) Cognitive structures, according to Piaget's theory, are all of the following except—

- a. Concept, beliefs, abilities or perceptual styles
- b. Physiological organs
- c. End results of continuous interrupting between maturation and experience
- d. Foundation stones of child's intellectual development.

Ans: B

253) What is the example of thinking fan, car, radio as alive things by child?

- a. Inappropriate thinking
- b. Imaginative thinking
- c. Animism
- d. Egocentrism

Ans: C

254) Distinctive feature of a concept varying from concept to concept is known as—

- a. Concept value
- b. Concept attribute
- c. Concept quality
- d. Concept uniqueness

Ans: B

255) When the muscles necessary for speaking are paralyzed then—

- a. Thinking cannot go on
- b. Verbal thinking cannot go on
- c. Verbal thinking can go on
- d. Problem solving ability is hampered

Ans: C

256) The symbols used in thinking are—

- a. Images
- b. Languages
- c. Concept
- d. All of the above

Ans: D

257) A condition which is not favourable in reasoning is—

- a. Suggestion
- b. Interest
- c. Attention
- d. Motivation

Ans. A

258) The rules used in problem solving are—

- a. Algorithm
- b. Heuristics
- c. Both (A) and (B)
- d. Theorems

Ans. C

259) According to Guilford creative ability is—

- a. Highly specified associated with particular subject matter or disciplines.
- b. Somewhat general which can be applied to a variety of tasks.
- c. A composite of primary mental abilities as found by Thurstone
- d. A developed mental capacity of highly abstract nature.

Ans. B

260) Which is not an attribute of the concept?

- a. Concreteness, observability and measurability
- b. Psychological meaningfulness
- c. Intrinsic, functional and formal properties.
- d. Abstractness, inclusiveness or generality
- e. Structure

Ans. A

261) Concept of food including bread, butter, milk etc. is based on—

- a. Formal properties
- b. Intrinsic properties
- c. Psychological meaningful property
- d. Functional properties

Ans. D

262) The best way of problem-solving is—

- a. Rigidity
- b. Chance
- c. Insight
- d. Trial and error

Ans. C

263) Which is not the structural attribute of the concept?

- a. Conjunctive
- b. Associative
- c. Disjunctive
- d. Relational

Ans. B

264) Religion is a—

- a. Conjunctive concept
- b. Disjunctive concept
- c. Relational concept
- d. Functional concept

Ans. B

265) Who had proposed the concept of goal gradient in problem solving?

- a. Kohler
- b. Hull
- c. Brich
- d. Wertheimer

Ans. B

266) All of the following factors influence concept formation except—

- a. Distinctiveness
- b. Manipulability of material
- c. Instructions
- d. Psychological variables

Ans. D

267) Who demonstrated that negative examples are of no use in concept learning?

- a. Smoke, 1932
- b. Hovland and Weiss, 1953
- c. Both of these
- d. None of these

Ans. C

268) Which of the following is not a method or procedure of concept learning?

- a. Method of reception
- b. Method of recitation
- c. Method of selection
- d. Both method of reception and method of selection

Ans. B

269) All of the following are kind of reasoning except—

- a. Deductive reasoning

- b. Inductive reasoning
- c. Creative reasoning
- d. Evaluative reasoning
- e. Analogical reasoning

Ans. C

270) Three of the following means same thing while one does not—

- a. Productive thinking
- b. Reproductive thinking
- c. Creative thinking
- d. Divergent thinking

Ans. B

271) A symbol has an/a—

- a. Universal meaning
- b. Innate meaning
- c. Natural meaning
- d. Arbitrary meaning

Ans. D

272) Creative thinking involves the phenomenon of—

- a. Deduction
- b. Insight
- c. Induction
- d. Decision making

Ans. B

273) Spoken language is—

- a. An ability found among all animals
- b. A species specific ability limited to Home Sapiens
- c. An ability confined only to the primates
- d. An innately determined mechanism in all animals

Ans. B

274) The concepts of taller, older, up-down, north-south etc. are examples of—

- a. Relational concepts
- b. Conjunctive concepts
- c. Disjunctive concepts
- d. Functional concepts

Ans. A

275) Most of creative thinking activity occurs during the stage of—

- a. Preparation
- b. Illumination

- c. Incubation
- d. Evaluation

Ans. C

276) The smallest unit of meaning in speech perception is—

- a. Morphemes
- b. Phonemes
- c. Words
- d. Syllables

Ans. A

277) In a typical memory experiment, participants are asked to recall stimuli in which phase?

- a. Presentation
- b. Test
- c. Material
- d. Distinction

Ans: B

278) Participants are NOT told that they will be tested on a list of words presented in an experiment.

This provides evidence of

- a. Intentional learning
- b. A practice effect
- c. Incidental learning
- d. Masked learning

Ans: C

279) A test where participants are asked to retrieve in any order stimuli previously presented is

- a. Cued recall
- b. Implicit memory
- c. Explicit memory
- d. Free recall

Ans: D

280) Participants take part in an experiment where they learn a number of words and are told that they will be tested later on what they have learned. This is a test of

- a. Explicit memory
- b. Recognition
- c. Implicit memory
- d. Interference

Ans: A

281) Storage is

- a. The stage of memory where information is interpreted and transferred
- b. The stage of memory where information is committed

- c. The stage of memory most affected by direct manipulation in experiments
- d. The stage of memory between presentation of stimuli and before test

Ans: D

282) Investigating what factors can affect memory storage can be done by

- a. Manipulating what happens before the test phase
- b. Informing people that they will be tested
- c. Providing recall cues
- d. Manipulating what happens at the presentation phase

Ans: A

283) Which is NOT typically used to test memory retrieval?

- a. Dot probe task
- b. Word stem completion
- c. Cued recall
- d. Serial position effects

Ans: A

284) With immediate testing, recall accuracy is poorest for items that occur in which position of a list?

- a. Beginning
- b. Middle
- c. End
- d. No difference

Ans: B

285) Immediately testing recall can lead to greater recall for words at the end of a list. This is

- a. Recency effect
- b. Primacy effect
- c. Serial position effect
- d. Superiority effect

Ans : A

286) The recency effect in memory retrieval can be reduced when

- a. rehearsal is prevented
- b. short- to long-term memory interference is introduced
- c. a backwards masking task is used
- d. retention interval is increased

Ans: D

287) Which authors proposed the modal model of memory?

- a. Lansdale and Baguley (2008)
- b. Tulving and Thompson (1975)

- c. Atkinson and Shiffrin (1968)
- d. Craik and Lockhart (1972)

Ans: C

- 288) The modal model of memory was challenged on the grounds that
- a. Impaired short-term memory does not disrupt long-term memory
 - b. Short-term memory has a limited capacity
 - c. Longer time in short-term memory predicts likelihood of long-term memory
 - d. Long-term memory has a limited capacity

Ans: A

289) According to levels of processing, which of the following leads to the deepest level of memory?

- a. Perceptual
- b. Semantic
- c. Associative
- d. Cue dependent

Ans: B

290) A critical issue with the 'levels of processing' account of memory is

- a. The distinction between perceptual and semantic processing
- b. It is not compatible with the modal model
- c. Determining the level of processing
- d. It does not explain how information is retrieved

Ans: C

291) Retrieval cues can improve recall because of

- a. Overlap between memories at encoding
- b. Interference or decay
- c. Traces still in short-term memory
- d. Greater storage capacity

Ans: A

292) 'Specific operations [.....] determine what is stored, and what is stored determines what retrieval cues are effective' refers to what term?

- a. Context-dependent memory
- b. Encoding specificity principle
- c. Levels of processing
- d. Forgetting function

Ans: B

293) Retroactive inhibition is a term of memory

- a. Decay

- b. Delay
- c. Retrieval
- d. Interference

Ans: D

294) Having prior memory associations that make it difficult to form new memory associations is termed

- a. Proactive inhibition
- b. Transfer appropriate processing
- c. Time-dependent decay
- d. Encoding specificity

Ans: A

295) Which of the following was proposed by Keppel (1968) to be most likely?

- a. Prior learning may interfere with new learning only when items are similar, but new learning interferes with all old learning
- b. Old learning can interfere with new learning, but new learning interferes with all old learning
- c. All forgetting is caused by non-specific proactive inhibition
- d. Old learning only interferes with new learning when encoded in the same modality

Ans: A

296) What explains the mathematical forgetting curve?

- a. Retroactive inhibition
- b. Serial position
- c. Jost's law
- d. Consolidation theory

Ans: C

297) Lansdale and Baguley (2008) predict that the probability of correct recall depends on

- a. Proportion of correct memory traces
- b. Encoding specificity
- c. Context-dependent recall
- d. Retroactive inhibition

Ans: A

298) Lansdale and Baguley (2008) argue that memory dilution occurs because

- a. Long-term memory capacity is limited
- b. The number of null traces decreases
- c. Memories become indistinct from similar memories
- d. The memory becomes less temporally distinctive

Ans: D

299) Which element was NOT found to alter accounts of the 'War of the Ghosts' story?

- a. Rationalizations
- b. Distortions
- c. Omissions
- d. Intrusions

Ans: C

300) The study of how the 'War of the Ghosts' story accounts became altered at recall was carried out by

- a. Bartlett (1932)
- b. Godden and Baddeley (1975)
- c. Postman and Phillips (1965)
- d. Eysenck (1979)

Ans: A

301) Eyewitness testimonies are an example of what kind of memory experiment?

- a. Intentional learning
- b. Context-dependent learning
- c. Incidental learning
- d. Cue-dependent learning

Ans: C

302) Which key academic is involved in the study of memory as a reconstructive process?

- a. Baddeley
- b. Eysenck
- c. Hitch
- d. Loftus

Ans: D

303) The accuracy of eyewitness testimonies can be improved with

- a. recovered memories
- b. cognitive interviews
- c. noise reduction
- d. neurofeedback

Ans: B

304) What can help improve the accuracy of eye witness testimonies?

- a. serial position
- b. context reinstatement
- c. mnemonics
- d. distributed practice

Ans: B

305) Memory can be improved when information to be learnt is

- a. organized

- b. written
- c. spoken
- d. elaborated

Ans: A

306) Which is a good method of revision:

- a. intense sessions
- b. spaced learning
- c. hour on/1 hour off
- d. late night sessions

Ans: B

307) Trying to predict your roommate is an example of:

- a. Operant thought
- b. Respondent thought
- c. A and B
- d. Neither A nor B

Ans: A

UNIT – 7

**PERSONALITY,

STRESS, AND
COPING**

PERSONALITY, MOTIVATION, EMOTION, STRESS AND COPING

WHAT IS DETERMINANTS OF PERSONALITY: BIOLOGICAL AND SOCIO-CULTURAL APPROACHES TO THE STUDY OF PERSONALITY: PSYCHOANALYTICAL, NEO-FREUDIAN, SOCIAL LEARNING, TRAIT AND TYPE, COGNITIVE, HUMANISTIC, EXISTENTIAL, TRANSPERSONAL PSYCHOLOGY. OTHER THEORIES: ROTTER'S LOCUS OF CONTROL, SELIGMAN'S EXPLANATORY STYLES, KOHLBERG'S THEORY OF MORAL DEVELOPMENT?

DETERMINANTS OF PERSONALITY: BIOLOGICAL AND SOCIO-CULTURAL APPROACHES TO THE STUDY OF PERSONALITY: PSYCHOANALYTICAL, NEO-FREUDIAN, SOCIAL LEARNING, TRAIT AND TYPE, COGNITIVE, HUMANISTIC, EXISTENTIAL, TRANSPERSONAL PSYCHOLOGY. OTHER THEORIES: ROTTER'S LOCUS OF CONTROL, SELIGMAN'S EXPLANATORY STYLES, KOHLBERG'S THEORY OF MORAL DEVELOPMENT ?

Determinants of personality: Biological and socio-cultural

Man is not born a person. At birth he is an infant possessing the potentiality of becoming a person. After birth he associates with other human beings and comes under the influence of their culture. As a result of a variety of experiences and social influences he becomes a person and comes to possess a personality. The nature of personality and to show the role of culture and social experience in the formation of personality along with the problem personality disorganisation. Since socialization plays the most important part in the development of personality and we have discussed it already, the present discussion, therefore, can only be brief.

I. THE MEANING OF PERSONALITY:

The term 'personality' is derived from the Latin word 'persona' which means a mask. According to K. Young, "Personality is a patterned body of habits, traits, attitudes and ideas of an individual, as these are organised externally into roles and statuses, and as they relate internally to motivation, goals, and various aspects of selfhood." G. W. Allport defined it as "a person's pattern of habits, attitudes, and traits which determine his adjustment to his environment." According to Robert E. Park and Earnest W. Burgess, personality is "the sum and organisation of those traits which determine the role of the individual in the group." Herbert A. Bloch defined it as "the characteristic organisation of the individual's habits, attitudes, values, emotional characteristics..... which imparts consistency to the behaviour of the individual." According to Arnold W. Green, "personality is the sum of a person's values (the objects of his striving, such as ideas, prestige, power and sex) plus his non-physical traits (his habitual ways of acting and reacting)." According to Linton, personality embraces the total "organised aggregate of psychological processes and status pertaining to the individual."

Personality, as we understand it, says Maclver, "is all that an individual is and has experienced so far as this "all" can be comprehended as unity." According to Lundberg and others, "The term personality refers to the habits, attitudes, and other social trait that are characteristic of a given individual's behaviour." By personality Ogburn means "the integration of the socio psychological behaviour of the human being, represented by habits of action and feeling, attitudes and opinions." Davis regards personality "a psychic phenomenon which is neither organic nor social but an emergent from a combination of the two."

ON THE BASIS OF THESE DEFINITIONS IT MAY BE SAID THERE ARE TWO MAIN APPROACHES TO THE STUDY OF PERSONALITY:

- (1) The psychological**
- (2) THE SOCIOLOGICAL.**

Although there is also a third approach, the biological approach, but the biological definition of personality which comprehends only the bio-physical characteristics of the individual organism is inadequate. The psychological approach considers personality as a certain style peculiar to the individual. This style is determined by the characteristic organisation of mental trends, complexes, emotions and sentiments. The psychological approach enables us to understand the phenomena of personality disorganisation and the role of wishes, of mental conflict, and of repression and sublimation in the growth of personality. The sociological approach considers personality in terms of the status of the individual in the group, in terms of his own conception of his role in the group of which he is a member. What others think of us plays a large part in the formation of our personality. Thus personality is the sum of the ideas, attitudes and values of a person which determine his role in society and form an integral part of his character. Personality is acquired by the individual as a result of his participation in group life. As a member of the group he learns certain behaviour systems and symbolic skills which determine his ideas, attitudes and social values.

TO SUM UP WE WOULD SAY THAT:

- (i) Personality is not related to bodily structure alone. It includes both structure and dynamics
- (ii) Personality is an indivisible unit.
- (iii) Personality is neither good nor bad.
- (iv) Personality is not a mysterious phenomenon.
- (v) Every personality is unique.
- (vi) Personality refers to persistent qualities of the individual. It expresses consistency and regularly.
- (vii) Personality is acquired.
- (viii) Personality is influenced by social interaction. It is defined in terms of behaviour.

THE TYPES OF PERSONALITY:

Some attempts have been made to classify personalities into types. In the 5th century B. C., the Greek physician Hippocrates divided human beings into four types: the sanguine, the melancholic, the choleric, and the phlegmatic. The Swiss psychoanalyst, Carl Gustav Jung, distinguished between two main types, the introvert and the extrovert. The introvert is preoccupied with his own self; the extrovert with things outside self. In these two types there is a third type—the ambiverts who are neither the one nor the other but vacillate between the two. The majority of people are ambiverts. According to Ernest Kretschmer the German psychiatrist, the extrovert personality is a stout person while the introvert one is a tall and slender person. The first type of persons he called “pyknic” the second type he called “leptosomic” W.I. Thomas and Florian Znaniecki distinguished among the Bohemian, the Philistine, and the Creative.

II. DETERMINANTS OF PERSONALITY:

Personality is a result of the combination of four factors, i.e., physical environment, heredity, culture, and particular experiences. Here we discuss each factor determining personality separately.

PERSONALITY AND ENVIRONMENT:

Above we described the influence of physical environment on culture and pointed out that geographical environment sometimes determines cultural variability. That the Eskimos have a culture different from that of the Indians is due to the fact that the former have a geography different from the latter. Man comes to form ideas and attitudes according to the physical environment he lives in. To the extent that the physical environment determines cultural development and to the extent, that culture in turn determines personality, a relationship between personality and environment becomes clear. Some two thousand years ago, Aristotle claimed that people living in Northern Europe were owing to a cold climate full of spirit but lacking in intelligence and skill. The natives of Asia, on the other hand, are intelligent and inventive but lack in spirit, and are, therefore, slaves.

Montesquieu, in the eighteenth century, claimed that the bravery of those blessed by a cold climate enables them to maintain their liberties. Great heat enervates courage while cold causes a certain vigour of body and mind. At high temperatures, it is said there is disinclination to work and so civilizations have grown up where the temperatures have been average near or below the optimum. The people of mountains as well as deserts are usually bold, hard and powerful. Huntington's discussion of the effects of physical environment on man's attitudes and mental make-up is very exhaustive. However, as told previously, the physical conditions are more permissive and limiting factors than causative factors. They set the limits within which personality can develop.

Thus, climate and topography determine to a great extent the physical and mental traits of a people, but it cannot be said that they alone determine human behaviour. Most kinds of personality are found in every kind of culture. The fact remains that civilizations have appeared in regions of widely different climate and topography. Christianity knows no climate belts. Peoples are monogamous in high altitudes and flat lands, under tropical temperate and arctic conditions. Men's attitudes and ideas change even when no conceivable geographic change has occurred. Proponents of geographic determinism oversimplify the human personality and so their interpretations are to be accepted only after close scrutiny.

HEREDITY AND PERSONALITY

Heredity is another factor determining human personality. Some of the similarities in man's personality are said to be due to his common heredity. Every human group inherits the same general set of biological needs and capacities. These common needs and capacities explain some of our similarities in personality. Man originates from the union of male and female germ cells into a single cell which is formed at the moment of conception. He tends to resemble his parents in physical appearance and intelligence. The nervous system, the organic drives and the ductless glands have a great bearing upon personality. They determine whether an individual will be vigorous or feeble, energetic or lethargic, idiot or intelligent, coward or courageous.

A man with a good physical structure and health generally possess an attractive personality. A man of poor health, pigmy size and ugly physical features develops inferiority complex. The growth of his personality is checked. Rejected and hated by the society he may turn out to be a thief, dacoit, or drunkard. It is also probable that he may become a leader, or a genius like Socrates and Napoleon. Likewise the nervous system and glandular system may affect the personality of an individual. The nervous system affects the intelligence and talent of the individual. The hormones affect the growth of personality. Too many or too less of hormones are harmful. Some men are over-patient, overzealous, overactive and overexcited while others are lazy, inactive, and weak. The reason may

be secretion of more hormones in the first case and less hormones in the latter case. For a normal personality there should be a balanced secretion of hormones. Heredity may affect personality in another way, i.e., indirectly. If boys in a society prefer slim girls as their companion, such girls will receive greater attention of the society providing them thereby more opportunities to develop their personality. According to Allport, Gordon, W. no feature of personality is devoid of hereditary influence. However, heredity does not mould human personality alone and unaided. "For the present, we can only assume that there are - genes for normal personality traits just as there are genes for other aspects of human make-up and functioning. Where in members of the same family, in a similar environment, we can see great differences in personality, we may ascribe these in part at least to differences in gene contributions.

We can also guess that some of the family similarities in personality are genetically influenced. But we are still a long way from identifying specific 'personality' genes, gauging their effects or hazarding predictions as to what the personality of a given child will be on the basis of what we know about its parents." However, according to a news report (Times of India, Jan. 3, 1996) the scientists have identified a gene which influences impulsiveness, excitability and extravagance. In short, heredity can never be considered as charting a fixed and definite course of anyone's personality. At the best, what anyone inherits are the potentialities for a wide range of personalities, the precise form into which a personality will "jell" being determined by circumstances. Ogburn and Nimkoff write, "It would be an error to hold, as' endocrine enthusiasts do, that the glands determine the whole personality, include rich things, as one's opinions, one's habits, and one's skills." It is possible to over-activate or under activate some of these kinds by injecting certain kinds of hormones and thereby affect human personality. In other words, it may be said that the available evidence does not support the dogmatic view that personality is biologically transmitted.

Of course, there are some traits which seem to be more directly affected by heredity than others. Manual skills, intelligence and sensory discriminations are some of the abilities which appear more highly developed in some family lines than others. But other traits such as one's beliefs, loyalties, prejudices and manners are for the most part the result of training and experience. Heredity only furnishes the materials out of which experience will mould the personality. Experience determines the way these materials will be used. An individual may be energetic because of his heredity, but whether he is active on his own belief or on behalf of others is a matter of his training.

Whether he exerts himself in making money or in scholarly activity is also dependent upon his bringing. If personality is a direct consequence of heredity tendencies or traits then all the sons and daughters of the same parents brought up in the same environment should have identical personalities or at least personalities that are very much alike. But investigation shows that even at the tender age of three or four years they show quite distinct personalities. The new born human being is, to use the phrase of Koenig, Hopper and Gross, a "candidate for personality." It is, therefore, clear that an individual's heredity alone would not enable us to predict his traits and values.

PERSONALITY AND CULTURE

There can be little doubt that culture largely determines the types of personality that will predominate in the particular group. According to some thinkers, personality is the subjective aspect of culture. They regard personality and culture as two sides of the same coin. Spiro has observed, 'The development of personality and the acquisition of culture are not different processes, but one and the same learning process.' Personality is an individual aspect of culture, while culture is a

collective aspect of personality." Each culture produces its special type or types of personality. In 1937 the anthropologist Ralph Linton and the psychoanalyst Abram Kardinar began a series of joint explorations of the relationship between culture and personality by subjecting to minutestudy reports of several primitive societies and one modern American village. Their studies have demonstrated that each culture tends to create and is supported by a "basic personality type." A given cultural environment sets its participant members off from other human beings operating under different cultural environments. According to Frank, 'culture is a coercive influence dominating the individual and moulding his personality by virtue of the ideas, conceptions and beliefs which had brought to bear on him through communal life."

The culture provides the raw material of which the individual makes his life. The traditions, customs, mores, religion, institutions, moral and social standards of a group affect the personality of the group members. From the moment of birth, the child is treated in ways which shape his personality. Every culture exerts a series of general influences upon the individuals who grow up under it Ogburn as we noted above, divided culture into "material" and "non-material." According to him, both material and non-material culture have a bearing on personality. As for the former he provides examples of the influence of plumbing on the formation of habits and attitudes favourable to cleanliness and the relation of time-pieces to punctuality. The American Indians who have no clocks or watches in their culture have little notion of keeping appointments with any exactness. According to him, they have no sense of time. The personality of an American Indian differs from that of a white man in the matter of punctuality and this is because of differences in their culture. Similarly, some cultures greedy value cleanliness as witnessed by the saying: "Cleanliness is next to godliness." This trait of cleanliness is greatly encouraged by the technology of plumbing and other inventions that are found with it.

The Eskimos are dirty because they have to hang a bag of snow down their backs to melt it in order to get water. A man who has just to turn on a tap of water will naturally be more clean than an Eskimo. Cleanliness, therefore, is a matter not of heredity but of the type of culture. As for the connection between the non-material culture and personality, language affords an instructive example. We know that one of the principal differences between man and animals is that he alone possesses speech. Language can be learnt only in society. People who cannot speak exhibit warped personality. Since language is the essential medium through which the individual obtains his information and his attitudes, therefore, it is the principal vehicle for the development of personality. Moreover, speech itself becomes a trait of personality.

The coarse voice of woodcutter can be readily distinguished from the hushed tones of a man. The short, crisp, guttural speech of the German seems to be part of his personality, as does the fluid, flowing voluble speech of the Spaniard. Movements of the hands and shoulders in speech are regarded as part of the very core of the personalities of Italians and Jews. The Jews use their gestures for emphasis only, while Italians depend upon them to convey part of the meaning. Another illustration of the influence of culture on personality is the relationship of men and women. In the earlier period when farming was the principal business, women generally had no occupations outside the home, and naturally, therefore, they were economically dependent upon their fathers or husbands. Obedience was a natural consequence of such conditions. But today hundreds of women work outside the homes and earn salaries.

They enjoy equal rights with men and are not so dependent upon them as they were in the past.

Attitude of independence instead of obedience has today become a trait of women's personality. With the growing realisation of the importance of culture for personality, sociologists have recently made attempts to identify the factors in particular cultures which give a distinctive stamp to the individuals within the group. Ruth Benedict analyzed the cultures of three primitive tribes and found that cultures may be divided into two major types—The Apollonian and the Dionysian. The Apollonian type is characterised by restraint, even temperances, moderation and co-operativeness, whereas the Dionysian type is marked by emotionalism, excess, pursuit of prestige, individualism and competitiveness. The Zuni culture I classified as Appollonian, while the Kwakiuti and Dobuans as Dionysian.

The personality of the Hindus in India differs greatly from that of Englishmen. Why ? The answer is 'a different Hindu culture'. The Hindu culture lays emphasis not on material and worldly things, but on things spiritual and religious. In every Hindu family there is a religious environment. The mother gets up early in the morning, takes bath and spends an hour in meditation. When the children get up, they go and touch the feet of their parents and bow before the family gods or goddesses. The Hindu child from the very birthbegins to acquire a religious and philosophical personality built on the "inner life." From the various illustrations cited so far it is thus clear that culture greatly moulds personality. The individual ideas and behaviour are largely the results of cultural conditioning. There is a great difference of ideas between the Hindu devotee immersed in religion and the Russian Communist who thoroughly rejects it.

However, it should not be concluded that culture is a massive die that shapes all who come under it with an identical pattern. All the people of a given culture are not of one cast. Personality traits differ within any culture, some people in any culture are more aggressive than others, some are more submissive, kind and competitive. Personality is not totally determined by culture, even though no personality escapes its influence. It is only one determinant among others. Ruth Benedict writes, "No anthropologist with a background of experiences of other cultures has ever believed that individuals were automatons, mechanically carrying out the decrees of their civilizations No culture yet observed has been able to eradicate the difference inthe temperaments of the persons who compose it. It is always a give and take affair." Linton classified cultural influence into the universals, specialities and alternatives and came to the conclusion that culture makes for uniformity of personality only through the universals and since universals are few in number as compared with specialities and alternatives, the effect of culture is to make for variety as well as uniformity.

PERSONALITY AND PARTICULAR EXPERIENCES:

Personality is also determined by another factor, namely, the particular and unique experiences. There are two types ofexperiences one, those that stem from continuous association with one's group, second, those that arise suddenly and are not likely to recur. The type of people who meet the child daily has a major influence on his personality. The personality of parents does moreto affect a child's personality. If the parents are kind, tolerant of boyish pranks, interested in athletics and anxious to encourage their child's separate interests the child will have a different experience and there shall be different influence on his personality than the one when the parents are unkind, quick tempered and arbitrary. In the home is fashioned the style of personality that will by and large characterise the individual throughout his life.

Social rituals,' ranging from table manners to getting along with others, are consciously inculcated in the child by parents. The child picks up the language of his parents. Problems of psychological

and emotional adjustments arise and are solved appropriately by each child in terms of the cultural values and standards of the family. The family set up tends to bring the child into contact with his play-mates and teachers. What his play-game members are, and his school teachers are will also determine his personality development. Group influences are relatively greater in early childhood. This is the period when the relationships of the child with his mother, father and siblings affect profoundly the organisation of his drives and emotions, the deeper and unconscious aspects of his personality.

A certain degree of maturation is needed before the child can understand the adult norms. The basic personality structure that is formed during this period is difficult to change. Whether a person becomes a leader, a coward, an imitator? whether he feels inferior or superior, whether he becomes altruistic or egoistic depends upon the kind of interaction he has with others. Group interaction moulds his personality. Away from the group he may become insane or develop queer attitudes. As a child grows he develops wish for response and wish for recognition. To his organic needs are added what are called 'sociogenic' needs which are highly important motivating forces in personality. How the idea of self develops in the child is an important study. The self does not exist at birth but begins to arise as the child learns something of the world of sensation about him.

He comes to learn of what belongs to him and takes pride in his possessions. He learns that parts of his body belong to him. He becomes acquainted with his name and paternity and comes to distinguish himself from others. The praise and blame he receives from others account in large measure for his conduct. The development of self leads to the growth of conscience and ego. Our view of self conception is usually based on the opinion of others about us. It does not, however, mean that we value all opinions about our conduct equally. We attach importance only to the opinions of those whom we consider for one reason or the other significant than others. Our parents are usually most significant than others since they are the ones who are intimately related to us and have greatest power than others over us especially during the early years of life. In short, our early experiences are very important in the formation of our personality. It is in early life that the foundations of personality are laid.

Why are the children brought up in the same family differ from one another in their personality, even though they have had the same experiences? The point is that they have not had the same experiences. Some experiences are similar while others are different. Each child enters a different family unit. One is the first born, he is the only child until the arrival of the second. The parents do not treat all their children exactly alike. The children enter different play groups, have different teachers and meet different incidents. They do not share all incidents and experiences. Each person's experience is unique as no body else perfectly duplicates it. Thus, each child has unique experiences exactly duplicated by no one and, therefore, grows a different personality.

Sometimes a sudden experience leaves an abiding influence upon the personality of an individual. Thus a small child may get frightened at the view of a bloody accident, and even after the accident he may be obsessed of the horror of fear. Sometimes girl's experience with a rapist may condemn her to a life of sexual maladjustment. A book may not uneaten challenge a man to renounce the world and seek God. If a man meets an accident which cripples or weakens him, he may come to entertain the feelings of inadequacy. Lord Buddha is said to have been led to renunciation by the sight of a funeral procession. In this way experiences also determine one's personality. However, it may be noted that one's own personality that one has acquired at any moment will in

part determine how the experiences influence his pre-acquired personality. Thus a child who is robust, outgoing, athletic would find his parents in the first case a model for behaviour, a model that would deepen the already apparent personality traits. But if the child is shy, retiring and bookish he may find such parents' personality distasteful and intensify the opposed personality trends already apparent. It may also be referred that personality is a matter of social situations. It has been shown by social researchers that a person may show honesty in one situation and not in another. The same is true for other personality traits also. Personality traits tend to be specific responses to particular situations rather than general behaviour patterns. It is a dynamic unity with a creative potential. Heredity, physical environment, culture and particular experiences are thus the four factors that explain personality—its formation, development and maintenance. Beyond the joint influence of these factors, however, the relative contribution of each factor to personality varies with the characteristic or personality process involved and, perhaps, with the individual concerned.

Genetic or hereditary factors may be more critical for some personality characteristics, while environmental factors, (cultural, financial), may be more important for others. Furthermore, for any one characteristic, the relative contribution of one or another factor may vary from person to person. Also there is no way yet known to measure the effect of each factor or to state how the factors combine to produce a given result. The behaviour of a juvenile delinquent is affected by his heredity and by his home life. But how much is contributed by each factor, cannot be measured in exact terms.

III. PERSONALITY DISORGANIZATION:

Society everywhere demands from its members conformity to its folkways and mores, to its values and standards. But often the individual fails to meet the requirements of the society in which he lives. As a result, he develops personality problems and becomes disorganised. Such a person is considered a mental case, a case of mental derangement or abnormality. The peculiarity about him is that his behaviour is unpredictable. He differs so systematically and persistently from the normative assumptions and mental habits of others that they cannot understand the motivations and hence do not know what to expect. He remains socially isolated because in his ease there is breakdown of communicative understanding.

Personality disorganisation, therefore, means that the individual is out of adjustment with society who has failed to organize the chief goals of his life into an integrated whole so as to achieve unity of the self. Personality disorganisation may take the milder or serious forms of mental disorder such as neuroses or psychoses. In addition to mentally disorganized persons there are other examples of personality disorganisation in the alcoholics, criminals, gamblers, prostitutes and drug addicts who are mentally normal but socially abnormal.

CAUSES OF PERSONALITY DISORGANISATION:

The failure of an individual to adjust himself to society may be due to the factors inherent in the individual or in the society in which he lives. He may have been born with a mental disability which prevents his integration into society. Organism is, no doubt, a necessary condition for an integrated personality; but it is society which is far more frequently responsible for personality disorganisation. Moreover, in sociology our interest is only in the social aspects of human behaviour and hence to the social causes of personality disorganisation. Our society is very complex, competitive and contradictory. It makes excessive demands upon the individual. Different groups with different moral standards and different cultural backgrounds create different notions of what is right and what is

wrong. In the midst of these varying notions the individual gets confused. He fails to find out the right way of social behaviour and relapses into abnormal behaviour. Secondly, in the modern society man's desires have increased manifold. The advertising has stimulated his desires which often cannot be satisfied. If the desires remain unsatisfied frustration naturally results. Repeated frustration tends to produce a generalized lack of confidence in one's ability to achieve any end, and a generalized conception of oneself as less efficient and less worthy than others. Karen Horney has pointed out that neurotic person continually stands in his own way. His lack of order in his ends makes it hard for him to achieve any particular end. Thirdly, the rapid changes in society create new ideas, set up new standards while the old ones still persist. All this leaves the individual bewildered and helpless in coping with the new situation in which he finds himself. Under these circumstances the individual may become a victim of mental disorder, commit suicide or become a criminal. Block distinguished five paths which an individual may pursue when he is caught in a situation of profound social change to which he has difficulty in adjusting. He may –

- (i) Return to the old forms of behaviour, or
- (ii) Create his own way of behaviour and seek to have it adopted by society, or
- (iii) Attack the existing social order through various types of antisocial behaviour, such as crime or theft or
- (iv) Take refuge in a retreat from society, or
- (v) Escape from life by committing suicide.

CULTURE AND PERSONALITY DISORGANISATION:

There is a close relation between culture and personality disorganisation. Every human being in modern culture suffers from inner conflicts. Though some mental disorders may be of an organic or constitutional nature, but most mental disorders arise from, inner conflicts and are created by the incompatible values of Culture. Davis writes, "So far as mental disorder is concerned the significant question is..... Whether the social system..... is unified by a nucleus of common values When the structure embraces conflicting principles of social organisation based on the incompatible values, psychic conflicts inevitably result." The stresses and strains imposed by culture sometimes seem to be too heavy to bear and lead to mental disorders. According to Ogburn and Nimkoff, "Cultures have their own characteristic mental disorders reflecting distinctive cultural influences." Every culture embodies cultural categories and values. If the individual fails to make good within the framework of cultural categories and values, the result is personal disorganisation. Moreover, there are conflicts and contradictions in every culture. Not only different persons hold different attitudes but the same individual holds contradictory and conflicting attitudes. Even within the family there may be incompatible values and loyalties. The girl's father may be a non-vegetarian, a smoker and strict materialist.

But her mother may be a vegetarian, teetotaler and a believer in spiritualism. Her brother may be a strong opponent of women's rights and a staunch nationalist whereas her sister may be an ardent advocate of women's rights and an internationalist. Her uncle may be a lover of art and of things medieval while her aunt may scorn art and scoff at everything that was said and thought before the nineteenth century. Her grandmother may be given to idol-worship while her grand- father may be an atheist. Add to it the different values held by her friends, her teachers, and her favourite authors and the situation becomes appalling. In short, it may be said that every culture is heterogeneous presenting incompatible values. It is a house divided against itself In the temple we exalt spiritualism, but in the market we glorify materialism. We profess co-operation but actually practise cut

throatcompetition. We swear by rights and yet practise untouchability. These inner contradictions arise from the myriads of possible wishes of individuals and scores of alternative ways of satisfying some of these wishes. Hence personality disorganisation is bound to occur in every culture. Many psychiatrists believe that it is during the main period of socialization, i.e., during childhood and in the main socialization groups such as family, play groups and school that the basis is laid for the personality disorganisation. Inconsistent discipline by people who themselves are disintegrated tends to produce cases of personal disorganisation. The child may fail to form habits or acquire attitudes which may protect him from going to pieces in face of problems which another person might easily solve.

PERSONAL DISORGANISATION IN PRIMITIVE SOCIETIES:

Primitive societies are said to be comparatively free of disorganized individual. Thus Ellis-worth Faris found an almost complete absence of psychoses among the Congo Bantu. Not a single member of the staff of four hospitals visited could tell Faris of a single case of split personality. Similarly, Ruth Benedict found it hard to explain the meaning of suicide to the peaceful Zuni Indians, the word was unfamiliar to them. The absence of personality disorganisation to a marked degree in the primitive societies is due to the fact that they are better integrated societies. The degree of personality disorganisation depends upon the degree of society's integration rather than upon the number of regulatory agencies and the extent of social control. In modern society man is subject to a number of regulatory agencies, every aspect of his life stands controlled today by one or the other agency.

Social control in modern society though less effective is nevertheless more prevailing. The volume of state legislation having gone very high, the individual finds himself under the control of one regulation or the other at every step. Yet in spite of such an extending social control and there being numerous formal regulatory agencies the degree of personal disorganisation in modern society is greater.

In the simple folk society, man may not have possessed a high degree of freedom, yet he was free of the many of the uncertainties and insecurities which beset modern 'civilized' man. The modern society is a "mass society" wherein despite the greater interdependence, individuals have been alienated from one another.

The individual has lost a coherent sense of self. He feels disillusioned about his own identity and detached from the goals valued in society. He is confused about what he ought to believe and feels that he cannot control the events which impinge upon him. Modern man is an impoverished "thing." Thus what is important in causing or preventing personal disorganisation is not so much the extent of social control or the number of regulatory agencies, but the degree of the society's disintegration. If the life of an individual is well-rounded, if every part of his life—economic, social, religious and aesthetic—is bound together into a significant whole in respect to which he is far from a passive pawn and if he plays a moulding role in the mechanism of this culture, he will seldom suffer from personal disorganisation.

Individuals in primitive societies, as many anthropological studies show, become seriously disorganized when their society and culture come into close contact with western civilization and their system of folkways and mores breaks down. In such a situation the individual slips out of "the warm embrace of a culture into the cold air of fragmentary existence."

There is a close relationship between the lack of integration of a society and personal disorganisation. Thomas and Znaniecki attributed personal disorganisation in the Polish community in the

United States to the complex urban civilization as the peasant community in Poland suffered few problems of personality disorganisation. The transplantation of individuals from a simpler life to a complex urban civilization opens them to the greater risks of personality disorganisation.

That is why that urban people suffer more from personality disorganisation than the rural people.

Mandel Sherman and Thomas R. Henry, the two American psychologists after having studied five mountain communities discovered that the one farthest removed from the influence of civilization had the most stable personalities than the one in closest contact with modern urban life.

Similarly, a number of psychologists, psychiatrists and psychoanalysts agreeing with the point of view of sociologists and anthropologists referred to society as to? Main source of personality problems. In short, the complexity of chosen society and its accompanying problems are the major Causes of personality disorganisation. This also emphasizes the production that personality is in the main a societal product

However, this is not the whole story, for there are obviously organic factors in addition. The organic side of personality disorganisation cannot be dispensed with altogether. True, the organism is a necessary condition in personality integration and disintegration; however, there are strains that nobody, no matter how well balanced, can withstand. Everyone has his breaking point. It is a question of how a man takes the situation. So the determining factor is the situation. The situational factors should not be underemphasized and the organic factors overemphasized when considering the problem of personality disorganisation.

PERSONALITY REORGANISATION:

The cases of personality disorganisation have increased in modern society, there is no denying the fact. The social scientists are busy in analyzing the causes and finding out the remedies. There is, however, still a difference of opinion as to the best way to proceed.

Those who regard organic factors as the main determinants of social behaviour seek to improve it through eugenic means of one kind or another. The psychologists, psychiatrists and psychoanalysts try to find the cause and remedy in the individual alone as if he were living in a vacuum.

BIOLOGICAL PERSONALITY

How much of our personality is in-born and biological, and how much is influenced by the environment and culture we are raised in? Psychologists who favor the biological approach believe that inherited predispositions as well as physiological processes can be used to explain differences in our personalities (Burger, 2008).

In the field of behavioral genetics, the Minnesota Study of Twins Reared Apart—a well-known study of the genetic basis for personality—conducted research with twins from 1979 to 1999. In studying 350 pairs of twins, including pairs of identical and fraternal twins reared together and apart, researchers found that identical twins, whether raised together or apart, have very similar personalities (Bouchard, 1994; Bouchard, Lykken, McGue, Segal, & Tellegen, 1990; Segal, 2012). These findings suggest the heritability of some personality traits. **Heritability** refers to the proportion of difference among people that is attributed to genetics.

Some of the traits that the study reported as having more than a 0.50 heritability ratio include leadership, obedience to authority, a sense of well-being, alienation, resistance to stress, and fearfulness. The implication is that some aspects of our personalities are largely controlled by genetics; however, it's important to point out that traits are not determined by a single gene, but by a combination of many genes, as well as by epigenetic factors that control

whether the genes are expressed.

TEMPERAMENT

Most contemporary psychologists believe temperament has a biological basis due to its appearance very early in our lives (Rothbart, 2011). As you learned when you studied lifespan development, Thomas and Chess (1977) found that babies could be categorized into one of three temperaments: easy, difficult, or slow to warm up. However, environmental factors (family interactions, for example) and maturation can affect the ways in which children's personalities are expressed (Carter et al., 2008). Research suggests that there are two dimensions of our temperament that are important parts of our adult personality—reactivity and self-regulation (Rothbart, Ahadi, & Evans, 2000). Reactivity refers to how we respond to new or challenging environmental stimuli; self-regulation refers to our ability to control that response (Rothbart & Derryberry, 1981; Rothbart, Sheese, Rueda, & Posner, 2011). For example, one person may immediately respond to new stimuli with a high level of anxiety, while another barely notices it.

CONNECT THE CONCEPTS: BODY TYPE AND TEMPERAMENT

Is there an association between your body type and your temperament? The constitutional perspective, which examines the relationship between the structure of the human body and behavior, seeks to answer this question (Genovese, 2008). The first comprehensive system of constitutional psychology was proposed by American psychologist William H. Sheldon (1940, 1942). He believed that your body type can be linked to your personality. Sheldon's life's work was spent observing human bodies and temperaments. Based on his observations and interviews of hundreds of people, he proposed three body/personality types, which he called somatotypes.

The three somatotypes are ectomorphs, endomorphs, and mesomorphs. Ectomorphs are thin with a small bone structure and very little fat on their bodies. According to Sheldon, the ectomorph personality is anxious, self-conscious, artistic, thoughtful, quiet, and private. They enjoy intellectual stimulation and feel uncomfortable in social situations. Actors Adrien Brody and Nicole Kidman would be characterized as ectomorphs. Endomorphs are the opposite of ectomorphs. Endomorphs have narrow shoulders and wide hips, and carry extra fat on their round bodies. Sheldon described endomorphs as being relaxed, comfortable, good-humored, even-tempered, sociable, and tolerant. Endomorphs enjoy affection and detest disapproval.

Queen Latifah and Jack Black would be considered endomorphs. The third somatotype is the mesomorph. This body type falls between the ectomorph and the endomorph. Mesomorphs have large bone structure, well-defined muscles, broad shoulders, narrow waists, and attractive, strong bodies. According to Sheldon, mesomorphs are adventurous, assertive, competitive, and fearless. They are curious and enjoy trying new things, but can also be obnoxious and aggressive. Channing Tatum and Scarlett Johansson would likely be mesomorphs.

SOCIO-CULTURAL PERSONALITY

Psychology has been slow to embrace the value of cross-cultural research (see Lee et al., 1999; Sue, 1999; Triandis & Suh, 2002). This concern is by no means new. In 1936, Ralph Linton wrote that "different societies seem to show differences in the relative frequency of occurrence of the various psychological types" (pg. 484), and in 1973, Robert LeVine suggested that "this is a moment at which even those who are skeptical about the value of culture and personality study might consider stretching their curiosity in this direction" (pg. ix) Throughout this textbook we will

examine a number of theorists who emphasized studying cultural differences as a significant part of their careers and, often, their personality theories as well.

However, it remains true that cross-cultural studies in psychology have only recently moved closer to the mainstream of psychological research and clinical practice. As of 2002, the American Psychological Association has “Guidelines on Multicultural Education, Training, Research, Practice, and Organizational Change for Psychologists” (www.apa.org/pi/multiculturalguidelines/homepage.html). To cite just a few examples of the range of current interest in cross-cultural psychology, we now have a Dictionary of Multicultural Psychology (Hall, 2005) and books on the relationships between culture, mental illness, and counseling (Axelson, 1999; Castillo, 1997), as well as on the relationships between race, class, and the social and personal development of women (Jordan, 1997b; Pack-Brown, Whittington-Clark, & Parker, 1998). There are also major new texts on African American psychology (Belgrave & Allison, 2006) and racism, prejudice, and discrimination in America (Miller & Garran, 2008; Whitley & Kite, 2006).

The fact that studying cross-cultural factors in personality has always been present in the careers and theories of certain individuals, while not becoming a mainstream focus of attention, is more than just an historical curiosity. By emphasizing biological factors (i.e., genetics), Freud’s theory did not allow for cultural differences. Behavioral theorists emphasized environmental factors, a seemingly cultural approach, but they did not allow themselves to address factors beyond immediate scientific control.

Thus, they defined with great precision the role of reinforcement, punishment, discriminative stimuli, etc., while not allowing for the richness of cognition and cultural experiences. Likewise, cognitive theorists clung to the scientific approach of the behaviorists, rather than embracing the potential of sociocultural perspectives.

In other words, because strict Freudian theorists, as well as behavioral and cognitive theorists, believed that their theories applied to all people equally, they typically chose not to address differences between people. Thus, those who wished to bring sociocultural perspectives on the development of personality into the field of personality theory faced a degree of direct opposition. And yet, their perseverance is now being fulfilled.

CULTURAL STUDIES IN THE FIELD OF PSYCHOLOGY

Since the 1990s, a number of general books on psychology and culture have been available (e.g., Brislin, 2000; Lonner & Malpass, 1994; Matsumoto, 1994, 1997; Matsumoto & Juang, 2004; Okun, Fried, & Okun, 1999; Price & Crapo, 2002; Segall et al., 1990). Although all of these books address topics such as the “self” and person-perception, and other various aspects of personality, only a few of them devote an actual chapter or section to the topic of personality itself (Matsumoto & Juang, 2004; Price & Crapo, 2002; Segall et al., 1990), and in each case the topics are fairly specific. There is, however, some older literature on the relationships between culture, society, and personality. We will examine that research in the second part of this section. First, let us examine some of the general principles of incorporating cross-cultural perspectives into the study of personality.

THE CHALLENGES OF CULTURAL RESEARCH

The first problem faced by those who are interested in the study of culture and personality is the question: what exactly is to be studied? At the most basic level, there are two types of research.

Cross-cultural research typically refers to either parallel studies being conducted in different cultures, or similar concepts being studied in different cultures. In contrast, **intercultural research** is the study of individuals of different cultures interacting with one another (Brislin, 2000; Matsumoto & Juang, 2004; Segall et al., 1990). As you will see in later chapters, some personality theorists consider interpersonal relationships to be the only true domain for studying individual personality. While most of the research done in psychology has been cross-cultural, as the world becomes more and more of a global community the opportunity for, and importance of, intercultural research is rapidly expanding.

Another fundamental problem with the study of culture is our attention to it, or rather, the lack of attention we pay to something that is so deeply ingrained in our daily lives. Richard Brislin suggests the following exercise: write down three answers for someone from a different culture who asks "What should I know about your culture so that we can understand each other better?" (pg. 10; Brislin, 2000). Because we simply take our cultural influences for granted, it proves quite difficult for us to think that they need to be identified or explained. For example, freedom of speech is a cherished right in America. Consequently, we often speak our minds. If I am upset about some new college policy, I might say very negative things about the administration of our college, even about particular administrators.

It does not mean I intend to be disrespectful, or that I dislike those individuals, or that I won't say positive things about them when I agree with the next new policy. It is simply an expression of one of the great freedoms in our society: the right to speak out. However, someone from a different culture, particularly a collectivist culture, might be shocked at my apparent disrespect toward my "superiors." The next important issue is the difference between **emic** and **etic** tasks or behaviors. Simply put, emic tasks are those that are familiar to the members of a given culture, whereas etic tasks are common to all cultures.

In an elegantly simple, yet revealing study, Irwin, Schafer, & Feiden (1974) demonstrated these phenomena in two cultures: American undergraduates and Mano rice farmers (from Liberia). The American college students were consistently better at performing the Wisconsin Card Sort, a well-known psychological test measuring cognitive reasoning skills, which relies on geometric shapes and color.

The Mano farmers, however, were consistently better at sorting different categories of rice. Thus, the ability to sort items into categories appears to be an etic task (most likely common to all humans, regardless of culture), whereas the more specific abilities to sort by geometry and color (common to American college students) or type of rice grain (common to Mano farmers in Liberia) is an emic task that requires familiarity. Thus, if we made a judgment about the Mano farmers' cognitive abilities based on the Wisconsin Card Sort, we would clearly be making a mistake in comparing them to Americans, due to the unfamiliarity of the particular task.

Another important aspect of cross-cultural research, which may involve applying our understanding of etics and emics, is the issue of **equivalence**. Is a concept being studied actually equivalent in different cultures? In other words, does a concept mean the same thing in different cultures, is the comparison valid? For example, an etic related to intelligence is the ability to solve problems.

So how might we compare different cultural groups? Would the speed with which they solve a problem make sense as a measure of intelligence? Such an answer would be emic, and therefore valid, in America (where we typically value independence and competition). However, among the Baganda of Uganda, slow and careful thought is the emic. Among the Chi-Chewa of Zambia, the emic is responsibility to the community, i.e., solving the problem in order to best get along with other people.

Thus, the speed at which people solve problems is conceptually equivalent, since it is the way in which people in each culture identify those individuals who are considered intelligent (Brislin, 2000). However, we cannot compare the actual speed of reporting a solution to others, as this is viewed quite differently in each culture.

One particular type of equivalence that raises a very interesting problem is that of **translation equivalence**. Psychologists often want to use tests developed in their own language with people of a different culture who speak a different language. Translating a test from one language to another can be a difficult task. The best way to assess translation equivalence is through **back translation**. In this procedure, one person translates the test, or survey, into the foreign language, and then a different person translates the foreign language test back into the original language. The original test can then be compared to the back translated test to see how closely they are worded.

Ideally they would be identical, but this is seldom the case. To give you a simple example, when I was in graduate school, we had a student from Taiwan join our research group. One day I asked her to translate my last name, Kelland, into a Chinese character. When she had done that, I asked her how she would translate that particular Chinese character into English for someone who was not Chinese. She translated the character as Kwang. Despite the first letter, I hardly consider Kwang to be a reasonable translation of Kelland, but she didn't seem to think of this as much of a problem (perhaps revealing another cultural difference!). When the process of back translation is used successfully, which may involve working back and forth with the translations, it has the effect of **decentering** the test from the original language. Specifically, that means that the test should be free of any culturally emic references or aspects that interfere with the translation equivalence of the different versions of the test (Brislin, 2000; Matsumoto & Juang, 2004).

While the list of issues pertaining to cross-cultural research goes on, let's consider just two more specific issues: **cultural flexibility** and **cultural response sets**. Cultural flexibility refers to how individuals are willing to change, or adapt, in situations in which they know there are cultural differences. For example, American businesspeople can stand about 15 minutes of small talk before getting down to business. Their Japanese counterparts, in contrast, consider it important to get to know their business partners, and they are comfortable with hours of conversation about a variety of topics. This would, of course, be an important consideration for anyone studying the relationship between individual personality and success in business situations in this intercultural setting.

Cultural response sets refer to how a given culture typically responds. If a given culture is more reserved, and they are asked to rate the importance of some value in comparison to how a more open culture rates that value, a difference in the rating may reflect the cultural difference in responding, rather than the degree to which people in each culture value the variable being measured (Brislin, 2000; Matsumoto & Juang, 2004).

PLACING CROSS-CULTURAL STUDIES IN CONTEXT: BLENDING

PSYCHOLOGY WITH ANTHROPOLOGY

As the field of psychology entered the twenty-first century, there was a groundswell of interest in cultural factors as they pertain to all areas of psychology. In the field of personality, as well as in other areas, there have always been individuals with an interest in culture and society, but they tended to remain as individuals. Although they were often admired for their unique interests and ideas, the major

emphasis in psychology was on the scientific method and data that had been obtained in carefully controlled situations, and then analyzed with similar, exacting precision. Culture, as difficult as it is to define, was left largely to anthropologists and sociologists.

Anthropologists, in particular, were not as shy about addressing the domain of psychology, and a number of anthropologists crossed over into the study of psychology to such an extent that they are often mentioned even in the introductory psychology textbooks. But given that their primary interest was in anthropology, they did not form detailed personality development theories of the type presented in this (or other) personality textbooks. In this chapter, however, we will take a look at some of the ideas presented by the renowned anthropologist Ralph Linton, and his occasional colleague Abram Kardiner, a psychoanalyst with an associate appointment in the same anthropology department as Linton. In addition to their books, students of personality with a strong interest in cultural influences on personality will also find the works of Ruth Benedict and Margaret Mead of great interest.

THE INFLUENCE OF CULTURE AND SOCIETY ON PERSONALITY

Many psychology textbooks mention a few famous anthropologists, such as Ruth Benedict and Margaret Mead, whose research included work on child development and personality. However, less well-known in the field of psychology is the renowned anthropologist Ralph Linton, who paid particular attention to personality development in relation to culture and society. Linton also collaborated with Abram Kardiner, a founding member of the New York Psychoanalytic Institute (and who was analyzed by Sigmund Freud himself in 1921-1922). Linton and Kardiner freely acknowledged the connections between anthropology and psychology, noting the influence of Benedict and Mead, Franz Boas (recognized as the father of American anthropology and mentor to both Benedict and Mead), and the psychoanalysts Anna Freud, Erich Fromm, Karen Horney, and Wilhelm Reich (Kardiner, 1939; Kardiner, Linton, DuBois, & West, 1945; Kardiner & Preble, 1961).

Linton described personality as existing on three levels. First, personality can be described based on either its content or its organization. The organization, furthermore, can be examined in terms of its superficial organization or its central organization. The central organization of personality gives the whole personality its distinctive character, and includes the most invariant aspects of personality, such as the degree of introversion/extraversion, or other aspects of temperament (Linton, 1936, 1945). Although these temperamental attributes are present at birth, they do not comprise personality *per se*.

The superficial organization of personality, however, is based on the goals and interests of the individual, and incorporates the individual's experiences in life within the context of the central organization. In this regard, the superficial organization should not be confused with something transient or insignificant. It is "superficial" only in the sense that it is on the surface of the personality, and the goals and interests of the person are based on the content of personality that represents their life experiences as they are organized within the personality.

The goals and interests themselves, which incorporate the content of personality, are determined almost entirely by the culture in which the individual is raised. According to Linton (1936), the process of integrating the individual's experience within the context of one's temperament (or "constitutional qualities") forms a "mutually adjusted, functional whole."

A critical question, of course, is whether cultural experiences can affect the central organization. Linton (1936, 1945, 1955) believed that no matter how an individual receives the cultural characteristics of their society, they are likely to internalize them, a process known as **enculturation**. One of the main reasons that enculturation is so influential in every aspect of the person's being, is that it pervades every aspect of the society in which the person lives. Thus, even someone who is considered a rebel, most likely exists within a range of rebellion that is possible within that particular culture. This is directly related to the apparent reality that cultures do give rise to certain types of personality. Making the matter even more complicated, or simpler depending on one's perspective, is the role of status within a culture. Thus, although a given culture or society, or one's own temperament, may influence personality in one direction, a particular social class might influence personality in a different direction. An individual born into a given class, whose personal constitution does not fit that class, may develop what Linton called a **status personality**, i.e., a persona that fits with society's expectations for the individual in certain settings. For example, someone born into an upper middle class family involved in business, who is personally rather introverted and withdrawn, may present a confident and outgoing personality when working, and only upon returning home do they revert to their natural inclination to be shy and quiet.

One of the most interesting points made by Linton is that individuals with complimentary personalities are also mutually adjusted. The most obvious example is that of the gender roles of men and women. Men are expected, in many cultures and societies, to be the dominant member of the family, as well as the "bread-winner." Conversely, women are expected to be submissive, and to remain home and care for the household and the children. In this way, the men and women together complete the necessary tasks for family life without entering into conflict (at least in theory!). In some cultures, these gender roles are quite relaxed with regard to the sex of the individual.

Amongst the Comanche (a Native American tribe), men whose personalities were not at all suited to being warriors assumed a special role, that of **berdache** (Linton, 1936). The berdache wore women's clothes, and typically fulfilled a woman's role, but they were treated with somewhat more respect than women (in keeping with the patriarchal nature of the society). Some were homosexuals (though not all), and even married. This was generally accepted, and any disapproval these relationships received was directed toward the warrior husband, not the berdache!

Abram Kardiner, a psychoanalyst who collaborated with Linton, shared the same general perspective on the relationship between personality and culture, and attempted to put the relationship into psychological terms. He distinguished between the **basic personality**, or **ego structure**, which he considered to be a cultural phenomenon, and the individual's **character**, which is their unique adaptation to the environment within their cultural setting. Thus, each individual develops a unique character, but only within the constraints of the culturally-determined range of potential ego structure (Kardiner, 1939).

The process of personality development, within a cultural setting, results in what Kardiner called a **security system**. The security system of the individual is the series of adaptations that serve to

ensure the individual's acceptance, approval, support, esteem, and status within the group. Thus, for each person within a given cultural group, their basic personality is formed through an ongoing interaction with the very culture in which that person needs to be (and, hopefully, will be) accepted as a member. Both of Kardiner's major books, *The Individual and His Society* (Kardiner, 1939) and *The Psychological Frontiers of Society* (Kardiner, et al., 1945), offer extraordinary examples of detailed anthropological studies of a wide variety of cultures followed by psychoanalytic evaluations of the functions served by various aspects of the cultural practices of those people.

Robert LeVine, like Kardiner, was an anthropologist and psychoanalyst with a strong interest in personality (LeVine, 1973, 1974). He begins by asking the question of whether there are differences in personality between different cultural groups. If there are not, then any analysis of the nature or causes of those alleged differences is meaningless. If there are differences, can we then point to specific evidence that the environment can elicit changes in those differences? The answer is yes to both, and as one example LeVine points to the dramatic **acculturation** of rural immigrants from underdeveloped areas of Europe and Asia who emigrated to industrialized countries, such as the United States, and within two or three generations had radically altered not only their basic ways of life, but also their social class (moving from traditional peasantry to the middle-class; LeVine, 1973).

LeVine also continued Kardiner's approach of using a psychoanalytic perspective to evaluate and compare the nature of different cultures, and he proposed the term **psychoanalytic ethnography**. In an effort to justify the use of psychoanalytic ethnography, LeVine argues that there are enough common elements in the nature of all people and cultures to provide for valid comparisons of the differences between those same people and cultures (LeVine, 1973).

One of the most striking discussions of the relationship between culture and the potential for personality development was offered by Pitirim Sorokin, the founder of Harvard University's sociology department and a colleague of the trait theorist Gordon Allport (see Chapter 13). Sorokin points out that culture can have a dramatic influence on the biological substrates of personality. For example, through the use of contraception, abortion, etc., many potential individuals are never born. Conversely, if such measures are prohibited, many unwanted children are born.

In addition, cultural rules and norms against sexual intercourse and/or marriage between certain age groups, races, social classes, families, religions, etc., directly influence the potential for genetic variation within and across different groups of humans (Sorokin, 1947). Indeed, Sorokin took such a broad view of the role of society and culture in the environmental universe of each individual, that he described trying to understand sociocultural phenomena by locating them in terms of **sociocultural space** and **sociocultural distance**. The concept of sociocultural distance has taken on new meaning since Sorokin proposed it over 50 years ago.

Today, anyone can travel around the world in a matter of hours or days, and many people do so regularly. Technology and globalization have dramatically reduced the distance between people, and consequently brought their cultural differences into contact with one another. Efforts to study cultures and societies alter the location of sociocultural phenomena within our own universe of personal development. In other words, by studying the relationships between society, culture, and personality, we are altering the meaning and influence of those relationships, hopefully for the better.

As a final note, although this section has highlighted the influence of anthropologists and sociologists on cross-cultural research in the study of personality, there has also been an influence from psychology on these investigators. As noted above, both Abram Kardiner and Robert LeVine were psychoanalysts. In addition, Kardiner acknowledges having learned a great deal from a professor named John Dollard. Dollard was a sociologist who had studied psychoanalysis and who collaborated with Neal Miller (a psychologist trained in learning theory) in an effort to apply classical learning theory to psychodynamic theory (see Chapter 10).

Dollard contributed a chapter to one of Linton's books, and was cited by both LeVine and Sorokin (who was, again, also a colleague of Allport). Given such an interesting interaction between the fields of psychology, anthropology, and sociology over half a century ago, it seems surprising that psychology is only now emphasizing the value of focusing on cultural influences on personality development.

APPROACHES TO THE STUDY OF PERSONALITY: PSYCHOANALYTICAL

Research into these five philosophical questions has branched into several different approaches to studying personality. The major theories include the psychodynamic, neo-Freudian, learning (or behaviorist), humanistic, biological, trait (or dispositional), and cultural perspectives.

- Psychodynamic theory, originating with Sigmund Freud, posits that human behavior is the result of the interaction among various components of the mind (the id, ego, and superego) and that personality develops according to a series of psychosexual developmental stages.
- Neo-Freudian theorists, such as Adler, Erikson, Jung, and Horney, expanded on Freud's theories but focused more on the social environment and on the effects of culture on personality. Learning theories, such as behaviorism, regard an individual's actions as ultimately being responses to external stimuli. Social learning theory believes that personality and behavior are determined by an individual's cognition about the world around them.
- Humanistic theory argues that an individual's subjective free will is the most important determinant of behavior. Humanistic psychologists such as Abraham Maslow and Carl Rogers believed that people strive to become self-actualized—the "best version" of themselves.
- Biological approaches focus on the role of genetics and the brain in shaping personality. Related to this, evolutionary theories explore how variation in individual personalities variance may be rooted in natural selection.
- Trait theorists believe personality can be conceptualized as a set of common traits, or characteristic ways of behaving, that every individual exhibits to some degree. In this view, such personality traits are different from person to person but within an individual are stable over time and place.
- With any of these theories, it is important to keep in mind that the culture in which we live is one of the most important environmental factors that shapes our personalities. Western ideas about personality are not necessarily applicable to other cultures, and there is evidence that the strength of personality traits varies across cultures.

GENETICS, THE BRAIN, AND PERSONALITY

The biological perspective on personality emphasizes the influence of the brain and genetic factors on personality. The biological perspective on personality focuses on why or how personality traits

manifest through biology and investigates the links between personality, DNA, and processes in the brain.

- In psychology, "temperament" refers to the personality tendencies that we show at birth (and that are therefore biologically determined). After birth, environmental factors and maturation interact with a child's temperament to shape their personality.
- The field of behavioral genetics focuses on the relationship between genes and behavior. Research from twin studies suggests that some aspects of our personalities are largely controlled by genetics.
- The biological approach to personality has also identified areas and pathways within the brain, as well as various hormones and neurotransmitters, that are associated with the development of personality.
- One of the first documented cases that demonstrated the link between personality and the brain was that of Phineas Gage, who underwent a drastic personality change after a brain

PHINEAS GAGE: A CASE STUDY

One of the first documented cases that demonstrated the link between personality and the brain was that of Phineas Gage. In 1848, Gage was working as a blasting foreman for a railroad company. Due to a faulty blast, a railroad spike was blown through his head; miraculously, he survived the accident. The spike pierced Gage's frontal lobe, and Gage experienced many subsequent changes in aspects of personality that we now know are associated with this area of the brain. The changes in Gage's personality after his brain injury spurred interest in the biological factors involved in personality and implicated the frontal lobe as an important area associated with higher-order personality functions.

GENDER AND PERSONALITY

In much the same manner that cultural norms can influence personality and behavior, gender norms (the behaviors that males and females are expected to conform to in a given society) can also influence personality by emphasizing different traits between different genders. Ideas of appropriate behavior for each gender (masculine and feminine) vary among cultures and tend to change over time. For example, aggression and assertiveness have historically been emphasized as positive masculine personality traits in the United States. Meanwhile, submissiveness and caretaking have historically been held as ideal feminine traits. While many gender roles remain the same, others change over time. In 1938, for example, only 1 out of 5 Americans agreed that a married woman should earn money in industry and business. By 1996, however, 4 out of 5 Americans approved of women working in these fields. This type of attitude change has been accompanied by behavioral shifts that coincide with changes in trait expectations and shifts in personal identity for men and women.

APPROACHES TO STUDYING PERSONALITY IN A CULTURAL CONTEXT

There are three approaches that can be used to study personality in a cultural context: the cultural-comparative approach, the indigenous approach, and the combined approach, which incorporates elements of the first two approaches.

- The cultural-comparative approach seeks to test Western ideas about personality in other

cultures to determine whether they can be generalized and if they have cultural validity (Cheung van de Vijver, & Leong, 2011). For example, researchers used the cultural-comparative approach to test the universality of McCrae and Costa's Five Factor Model. They found applicability in numerous cultures around the world, with the Big Five traits being stable in many cultures (McCrae & Costa, 1997; McCrae et al., 2005).

- The indigenous approach came about in reaction to the dominance of Western approaches to the study of personality in non-Western settings (Cheung et al., 2011). Because Western-based personality assessments cannot fully capture the personality constructs of other cultures, the indigenous model has led to the development of personality assessment instruments that are based on constructs relevant to the culture being studied (Cheung et al., 2011).
- The third approach to cross-cultural studies of personality is the combined approach, which serves as a bridge between Western and indigenous psychology as a way of understanding both universal and cultural variations in personality (Cheung et al., 2011).

FREUDIAN SLIP

Unconscious thoughts and feelings can transfer to the conscious mind in the form of parapraxes, popularly known as Freudian slips or slips of the tongue. We reveal what is really on our mind by saying something we didn't mean to. For example, a nutritionist giving a lecture intended to say we should always demand the best in bread, but instead said bed. Another example is where a person may call a friend's new partner by the name of a previous one, whom we liked better. Freud believed that slips of the tongue provided an insight into the unconscious mind and that there were no accidents, every behavior (including slips of the tongue) was significant (i.e., all behavior is determined).

SOCIAL LEARNING THEORY

In social learning theory, Albert Bandura (1977) agrees with the behaviorist learning theories of classical conditioning and operant conditioning. However, he adds two important ideas:

1. Mediating processes occur between stimuli & responses.
2. Behavior is learned from the environment through the process of observational learning.
- 3.

OBSERVATIONAL LEARNING

Children observe the people around them behaving in various ways. This is illustrated during the famous Bobo doll experiment (Bandura, 1961). Individuals that are observed are called models. In society, children are surrounded by many influential models, such as parents within the family, characters on children's TV, friends within their peer group and teachers at school. These models provide examples of behavior to observe and imitate, e.g., masculine and feminine, pro and anti-social, etc. Children pay attention to some of these people (models) and encode their behavior. At a later time they may imitate (i.e., copy) the behavior they have observed.

They may do this regardless of whether the behavior is 'gender appropriate' or not, but there are a number of processes that make it more likely that a child will reproduce the behavior that its society deems appropriate for its gender. First, the child is more likely to attend to and imitate those people it perceives as similar to itself. Consequently, it is more likely to imitate behavior modeled by people of the same gender. Second, the people around the child will respond to the behavior it imitates with either reinforcement or punishment. If a child imitates a model's behavior and the consequences are rewarding, the child is likely to continue performing the behavior. If a parent sees a little girl consoling her teddy bear and says "what a kind girl you are," this is rewarding for the child

and makes it more likely that she will repeat the behavior. Her behavior has been reinforced (i.e., strengthened).

Reinforcement can be external or internal and can be positive or negative. If a child wants approval from parents or peers, this approval is an external reinforcement, but feeling happy about being approved of is an internal reinforcement. A child will behave in a way which it believes will earn approval because it desires approval. Positive (or negative) reinforcement will have little impact if the reinforcement offered externally does not match with an individual's needs. Reinforcement can be positive or negative, but the important factor is that it will usually lead to a change in a person's behavior.

Third, the child will also take into account of what happens to other people when deciding whether or not to copy someone's actions. A person learns by observing the consequences of another person's (i.e., models) behavior, e.g., a younger sister observing an older sister being rewarded for a particular behavior is more likely to repeat that behavior herself. This is known as vicarious reinforcement. This relates to an attachment to specific models that possess qualities seen as rewarding. Children will have a number of models with whom they identify. These may be people in their immediate world, such as parents or older siblings, or could be fantasy characters or people in the media. The motivation to identify with a particular model is that they have a quality which the individual would like to possess. Identification occurs with another person (the model) and involves taking on (or adopting) observed behaviors, values, beliefs and attitudes of the person with whom you are identifying.

The term identification as used by Social Learning Theory is similar to the Freudian term related to the Oedipus complex. For example, they both involve internalizing or adopting another person's behavior. However, during the Oedipus complex, the child can only identify with the same sex parent, whereas with Social Learning Theory the person (child or adult) can potentially identify with any other person. Identification is different to imitation as it may involve a number of behaviors being adopted, whereas imitation usually involves copying a single behavior.

THERE ARE FOUR MEDIATIONAL PROCESSES PROPOSED BY BANDURA:

1. **Attention:** The extent to which we are exposed/notice the behavior. For a behavior to be imitated, it has to grab our attention. We observe many behaviors on a daily basis, and many of these are not noteworthy. Attention is therefore extremely important in whether a behavior influences others imitating it.

2. **Retention:** How well the behavior is remembered. The behavior may be noticed but is it not always remembered which obviously prevents imitation. It is important therefore that a memory of the behavior is formed to be performed later by the observer.

Much of social learning is not immediate, so this process is especially vital in those cases. Even if the behavior is reproduced shortly after seeing it, there needs to be a memory to refer to.

Reproduction: This is the ability to perform the behavior that the model has just demonstrated. We see much behavior on a daily basis that we would like to be able to imitate but that this not always possible. We are limited by our physical ability and for that reason, even if we wish to reproduce the

behavior, we cannot This influences our decisions whether to try and imitate it or not. Imagine the scenario of a 90-year-old-lady who struggles to walk watching Dancing on Ice. She may appreciate that the skill is a desirable one, but she will not attempt to imitate it because she physically cannot do it.

3. **Motivation:** The will to perform the behavior. The rewards and punishment that follow a behavior will be considered by the observer. If the perceived rewards outweigh the perceived costs (if there are any), then the behavior will be more likely to be imitated by the observer. If the vicarious reinforcement is not seen to be important enough to the observer, then they will not imitate the behavior.

TRAITS & PERSONALITY TYPES:

What makes someone who they are? Each person has an idea of their own personality type if they are bubbly or reserved, sensitive or thick-skinned. Psychologists who try to tease out the science of who we are define personality as individual differences in the way people tend to think, feel and behave. There are many ways to measure personality, but psychologists have mostly given up on trying to divide humanity neatly into types. Instead, they focus on personality traits.

The most widely accepted of these traits are the Big Five:

- Openness
- Conscientiousness
- Extraversion
- Agreeableness
- Neuroticism

Conveniently, you can remember these traits with the handy OCEAN mnemonic (or, if you prefer, CANOE works, too). The Big Five were developed in the 1970s by two research teams. These teams were led by Paul Costa and Robert R. McCrae of the National Institutes of Health and Warren Norman and Lewis Goldberg of the University of Michigan at Ann Arbor and the University of Oregon, according to Scientific American. The Big Five are the ingredients that make up each individual's personality. A person might have a dash of openness, a lot of conscientiousness, an average amount of extraversion, plenty of agreeableness and almost no neuroticism at all. Or someone could be disagreeable, neurotic, introverted, conscientious and hardly open at all. Here's what each trait entails:

OPENNESS

Openness is shorthand for "openness to experience." People who are high in openness enjoy adventure. They're curious and appreciate art, imagination and new things. The motto of the open individual might be "Variety is the spice of life." Advertisement People low in openness are just the opposite: They prefer to stick to their habits, avoid new experiences and probably aren't the most adventurous eaters. Changing personality is usually considered a tough process, but openness is a personality trait that's been shown to be subject to change in adulthood. In a 2011 study, people who took psilocybin, or hallucinogenic "magic mushrooms," became more open after the experience. The effect lasted at least a year, suggesting that it might be permanent.

CONSCIENTIOUSNESS

People who are conscientious are organized and have a strong sense of duty. They're dependable,

disciplined and achievement- focused. You won't find conscientious types jetting off on round-the-world journeys with only a backpack; they're planners. People low in conscientiousness are more spontaneous and freewheeling. They may tend toward carelessness. Conscientiousness is a helpful trait to have, as it has been linked to achievement in school and on the job.

EXTRAVERSION

Extraversion versus introversion is possibly the most recognizable personality trait of the Big Five. The more of an extravert someone is, the more of a social butterfly they are. Extraverts are chatty, sociable and draw energy from crowds. They tend to be assertive and cheerful in their social interactions. Introverts, on the other hand, need plenty of alone time, perhaps because their brains process social interaction differently. Introversion is often confused with shyness, but the two aren't the same. Shyness implies a fear of social interactions or an inability to function socially. Introverts can be perfectly charming at parties — they just prefer solo or small-group activities.

AGREEABLENES

Agreeableness measures the extent of a person's warmth and kindness. The more agreeable someone is, the more likely they are to be trusting, helpful and compassionate. Disagreeable people are cold and suspicious of others, and they're less likely to cooperate. Men who are high in agreeableness are judged to be better dancers by women, suggesting that body movement can signal personality. (Conscientiousness also makes for good dancers, according to the same 2011 study.) But in the workplace, disagreeable men actually earn more than agreeable guys. Disagreeable women didn't show the same salary advantage, suggesting that a no-nonsense demeanor is uniquely beneficial to men.

Being envious, which can lead to people being perceived as not agreeable, was found to be the most common personality type out of the four studies by a report published in August 2016 in the journal *Science Advances*. Envious people feel threatened when someone else is more successful than they are.

NEUROTICISM

To understand neuroticism, look no further than George Costanza of the long-running sitcom "Seinfeld." George is famous for his neuroses, which the show blames on his dysfunctional parents. He worries about everything, obsesses over germs and disease and once quits a job because his anxiety over not having access to a private bathroom is too overwhelming. George may be high on the neuroticism scale, but the personality trait is real. People high in neuroticism worry frequently and easily slip into anxiety and depression. If all is going well, neurotic people tend to find things to worry about. One 2012 study found that when neurotic people with good salaries earned raises, the extra income actually made them less happy.

ADVERTISEMENT

In contrast, people who are low in neuroticism tend to be emotionally stable and even-keeled. Unsurprisingly, neuroticism is linked with plenty of bad health outcomes. Neurotic people die younger than the emotionally stable, possibly because they turn to tobacco and alcohol to ease their nerves. Possibly the creepiest fact about neuroticism, though, is that parasites can make you feel that way. And we're not talking about the natural anxiety that might come with knowing that a tapeworm has made a home in your gut. Undetected infection by the parasite *Toxoplasma gondii* may make people more prone to neuroticism, a 2006 study found.

OTHER PERSONALITY MEASURES

Sensing and intuition refer to how people prefer to gather information about the world, whether through concrete information (sensing) or emotional feelings (intuition). Thinking and feeling refer to how people make decisions. Thinking types go with logic, while feeling types follow their hearts. The Myers-Briggs system is rounded out with the judging/perception dichotomy, which describes how people choose to interact with the world. Judging types like decisive action, while perceiving types prefer open options. The system further identifies 16 personality types based on a combination of four of the categories, leading to descriptions such as ISTP, ENFP, ESFJ, etc.

COGNITIVE PERSONALITY THEORIES

Cognitive theories of personality focus on the processes of information encoding and retrieval, and the role of expectations, motives, goals, and beliefs in the development of stable personality characteristics. This approach differs from personality theories that emphasize either the conditions within which personality develops (e.g., behavioral theories) or the trait structures that are revealed in those various conditions (e.g., evolutionary and trait theories). As such, cognitive theories of personality are particularly relevant for counseling psychology because of their core assumption that lasting personality change can occur as a result of rational analysis and insight. Personality theories are often categorized as either nomothetic (i.e., personality is understood in terms of an individual having greater or lesser amounts of traits that are common to all people) or idiographic (i.e., each individual has a unique personality structure and may possess traits that others do not possess). Taking a nomothetic approach, a personality theory can be used to generalize about an individual or to categorize the person. For example, a person can be said to have a particular trait or style. On the other hand, personality theories that take an idiographic approach attempt to describe the specific individual in such a way as to show how this one individual is different from all other individuals. Cognitive theories of personality are both nomothetic and idiographic. Nomothetic theorists have demarcated dimensions of individual difference such as cognitive styles. Idiographic theorists have developed complex descriptions of individuals cognitively embedded within their own life contexts.

GENERAL COMPONENTS OF COGNITIVE PERSONALITY THEORIE

Most cognitive theories of personality focus on the ways in which personal knowledge and judgment are developed. Often this development occurs in a distorted fashion because it is necessary for people to adapt to their environment. Humans desire to be consistent in their beliefs and behaviors so that they can predict the outcome of their actions. They are also motivated to gain social approval from others and to enhance their perception of themselves. This can result from a process of comparing one's self with those of others or a process of comparing what one believes is one's actual self with an imagined ideal self. Cognitive personality theorists have focused their efforts on describing the development of cognitions that explain the world and the individual's concept of self in it, and they have also developed some understanding of variations in cognitive styles that predict individual differences.

HISTORY OF COGNITIVE PERSONALITY THEORIES

Early ideas related to cognitive theory can be traced back to the Greek Stoic Epictetus, who claimed that processes of rational judgment were at the basis of all emotion, be it happiness or suffering. He stated that events in and of themselves have no moral or ethical meaning. Moral judgment and choice are the consequences of how people come to interpret and understand events. At the turn

of the 20th century, William James championed the idea that no psychological theory is complete that does not allow for a mechanism by which thought will regulate actions. James emphasized the role of the focus of attention in determining behavior. He also anticipated the concept of cognitive schemata by characterizing the stream of consciousness as anticipating and adapting to current events by comparing current experiences to past experiences.

Early work in social cognition forms a basis of current cognitive personality theory. Fritz Heider, an early social psychologist, emphasized that people act with others on the basis of their conceptions of themselves and of others. Heider developed the notion of phenomenal causality, which is the perception of causality that leads to judgment and action. Heider's ideas led to the development of the field within social psychology known as attribution theory, which is the study of the determinants of phenomenal causality or causal attributions. One important dimension of causal attributions is that of internal (or dispositional) versus external (or situational) attributions. People's judgments and conceptions of an event are largely determined by their beliefs regarding whether people act according to internal dispositions or because of situational pressure. Heider's ideas are often called naive psychology in that the person is described as acting according to his or her own personal theory of psychology regarding others.

KELLY'S THEORY OF PERSONAL CONSTRUCTS

George A. Kelly's theory of personal constructs is most frequently cited as the first modern cognitive personality theory. Kelly proposed and elaborated upon the metaphor of "person as scientist." Drawing on the theories of Heider and attribution researchers, Kelly proposed that people use observations to develop beliefs about themselves and their world. These observations are organized into personal constructs, which were described by Kelly in terms very similar to the current concept of cognitive schemata. Cognitive schemata are meaningful organizations of related pieces of knowledge. Kelly proposed that people make predictions and interpretations regarding their experience on the basis of their personal constructs (or schemata), and they endeavor to behave in a manner that is consistent with their personal constructs.

Kelly proposed that personal constructs develop and change through processes that are similar to assimilation and accommodation. As described by the cognitive developmental theorist Jean Piaget, assimilation is the process by which people integrate new information into the existing body of information they already possess. Accommodation is the process by which people change or modify their existing knowledge based on the information gained from new experiences. Like Piaget, Kelly viewed cognitive development as a continuing interplay between assimilation and accommodation.

For example, children learn to catch a large ball by holding out their arms a certain distance apart as the ball is thrown. Later, when a smaller ball is thrown, they will hold out their arms the same distance apart (assimilation) but fail to catch the ball. They will need to accommodate the new information that the size of the ball must determine the distance apart that they spread their arms (i.e., their catching schema).

HUMANISTIC APPROACH

Humanistic, humanism and humanist are terms in psychology relating to an approach which

studies the whole person, and the uniqueness of each individual. Essentially, these terms refer to the same approach in psychology. The humanistic approach in psychology developed as a rebellion against what some psychologists saw as the limitations of the behaviorist and psychodynamic psychology. The humanistic approach is thus often called the "third force" in psychology after psychoanalysis and behaviorism (Maslow, 1968).

Humanism rejected the assumptions of the behaviorist perspective which is characterized as deterministic, focused on reinforcement of stimulus-response behavior and heavily dependent on animal research. Humanistic psychology also rejected the psychodynamic approach because it is also deterministic, with unconscious irrational and instinctive forces determining human thought and behavior. Both behaviorism and psychoanalysis are regarded as dehumanizing by humanistic psychologists.

HUMANISTIC PSYCHOLOGY EXPANDED ITS INFLUENCE THROUGHOUT THE 1970S AND THE 1980S. ITS IMPACT CAN BE UNDERSTOOD IN TERMS OF THREE MAJOR AREAS:

- 1) It offered a new set of values for approaching an understanding of human nature and the human condition.
- 2) It offered an expanded horizon of methods of inquiry in the study of human behavior.
- 3) It offered a broader range of more effective methods in the professional practice of psychotherapy.

Humanistic psychology begins with the existential assumptions that people have free will. Personal agency is the humanistic term for the exercise of free will. Personal agency refers to the choices we make in life, the paths we go down and their consequences.

People are basically good, and have an innate need to make themselves and the world better: The humanistic approach emphasizes the personal worth of the individual, the centrality of human values, and the creative, active nature of human beings.

The approach is optimistic and focuses on the noble human capacity to overcome hardship, pain and despair.

PEOPLE ARE MOTIVATED TO SELF-ACTUALIZE:

Self-actualization concerns psychological growth, fulfillment and satisfaction in life. Both Rogers and Maslow regarded personal growth and fulfillment in life as a basic human motive. This means that each person, in different ways, seeks to grow psychologically and continuously enhance themselves. However, Rogers and Maslow both describe different ways of how self-actualization can be achieved.

THE SUBJECTIVE, CONSCIOUS EXPERIENCES OF THE INDIVIDUAL IS MOST IMPORTANT:

Humanistic psychologists argue that objective reality is less important than a person's subjective perception and understanding of the world. Sometimes the humanistic approach is called phenomenological. This means that personality is studied from the point of view of the individual's subjective experience. For Rogers the focus of psychology is not behavior (Skinner), the unconscious (Freud), thinking (Wundt) or the human brain but how individuals perceive and interpret events. Rogers is therefore important because he redirected psychology towards the study of the self.

HUMANISM REJECTS SCIENTIFIC METHODOLOGY:

Rogers and Maslow placed little value on scientific psychology, especially the use of the psychology laboratory to investigate both human and animal behavior. Humanism rejects scientific methodology like experiments and typically uses qualitative research methods. For example, diary accounts, open-ended questionnaires, unstructured interviews and unstructured observations. Qualitative research is useful for studies at the individual level, and to find out, in depth, the ways in which people think or feel (e.g. case studies).

The way to really understand other people is to sit down and talk with them, share their experiences and be open to their feelings. Humanism rejected comparative psychology (the study of animals) because it does not tell us anything about the unique properties of human beings. Humanism views human beings as fundamentally different from other animals, mainly because humans are conscious beings capable of thought, reason and language. For humanistic psychologists' research on animals, such as rats, pigeons, or monkeys held little value. Research on such animals can tell us, so they argued, very little about human thought, behavior and experience.

EXISTENTIAL PSYCHOLOGY

Existential psychology is the area within psychology most closely linked to the field of philosophy. Curiously, this provides one of the most common complaints against existential psychology. Many historians identify the establishment of Wilhelm Wundt's experimental laboratory in Germany in 1879 as the official date of the founding of psychology. Sigmund Freud, with his strong background in biomedical research, also sought to bring scientific methodology to the study of the mind and mental processes, including psychological disorders and psychotherapy.

Shortly thereafter, Americans such as Edward Thorndike and John Watson were establishing behaviorism, and its rigorous methodology, as the most influential field in American psychology. So, as existential psychology arose in the 1940s and 1950s it was viewed as something of a throw-back to an earlier time when psychology was not distinguished from philosophy (Lundin, 1979). However, as with those who identify themselves as humanistic psychologists, existential psychologists are deeply concerned with individuals and the conditions of each unique human life. The detachment that seems so essential to experimental psychologists is unacceptable to existential psychologists.

The difference can easily be seen in the titles of two influential books written by the leading existential psychologists: *Man's Search for Meaning* by Viktor Frankl (1946/1992) and *Man's Search for Himself* by Rollo May (1953). Existential psychology differs significantly from humanistic psychology, however, in focusing on present existence and the fear, anguish, and sorrow that are so often associated with the circumstances of our lives (Lundin, 1979). The German existentialists Martin Heidegger (1889-1976) and Karl Jaspers (1883-1969) focused on human existence itself and our role in the world. In a sense, Heidegger trivialized the nature of God, equating God with little more than the greatest being in the world, but a being nonetheless (just as humans are).

Jaspers was not an atheist, but still his existential theory focused on the human journey toward a **freedom** that has meaning only when it reveals itself in union with God (Breisach, 1962; Lescoe, 1974). Heidegger considered individuals as beings who are all connected in **Being**, thus

distinguishing between mere beings (including other animals) and the nature of truth or Being. Only humans are capable of understanding this connection between all beings, and Heidegger referred to this discovery as **Dasein** ("being here," or existence). On one level, Dasein is common to all creatures, but the possibility of being aware of one's connection to Being is uniquely human. For those who ask the big questions, Dasein can become authentic existence. This experience comes in the fullness of life, but only if one adopts the mode of existence known as **being-in-the-world**. Heidegger insisted that Dasein and being-in-the-world are equal.

Being-in-the-world is an odd concept, however, since Heidegger believed that Being can only arise from nothingness, and so we ourselves arise as **being-thrown-into-this-world**. Having been thrown into this mysterious world we wish to make it our own, but our desire for connection with Being leads to anxiety. This anxiety cannot be overcome, because we are aware that we will die! Surprisingly, however, Heidegger considers death to be something positive. It is only because we are going to die that some of us strive to experience life fully.

If we can accept that death will come, and nothing will follow, we can be true to ourselves and live an authentic life (Breisach, 1962; Lundin, 1979). Finally we come to the French existentialist Jean-Paul Sartre (1905-1980). Sartre was an extraordinary author and one of the most important philosophers of the twentieth century. He was awarded the Nobel Prize in Literature in 1964, but chose to reject it. More importantly for us, however, is the fact that he carried existential philosophy directly into psychology, with books such as *The Transcendence of the Ego* (Sartre, 1937/1957) and a section entitled "Existential Psychoanalysis" in his extraordinary work *Being and Nothingness* (Sartre, 1943). Whereas Kierkegaard believed that man could never truly be one with God, and Heidegger trivialize.

God, Sartre simply stated that God does not exist. But this is not inconsequential: The Existentialist, on the contrary, thinks it very distressing that God does not exist, because all possibility of finding values in a heaven of ideas disappears along with Him; there can no longer be an a priori Good, since there is no infinite and perfect consciousness to think it. (pg. 459; Sartre, 1947/1996). Unfortunately, many people do reject their unique consciousness and desire to be en-soi, just letting life happen around them. As the en-soi closes in around them, they begin to experience nausea, forlornness, anxiety, and despair. Herein lays the need for **existential psychoanalysis**.

TRANSPERSONAL PSYCHOLOGY

Transpersonal psychology is a field or school of thought in psychology centered on the spiritual aspects of human life. The term transpersonal psychology was first introduced in the 1960s by psychologists such as Abraham Maslow and Victor Frankl. This field utilizes psychological methods and theories to examine the spiritual subject matter. Transpersonal psychology is a label for a type of psychological theory that embraces a wide variety of ideas that have nothing to do with religion and everything to do with the mind and behavior. Transpersonal psychology looks at the whole human experience.

While not all definitions of transpersonal psychology are exactly the same, researchers Lajoie and Shapiro have suggested that there are several key factors that figure into most explanations of the field. These include spirituality, higher potential, transcendence and other states of consciousness. In her 2009 book *Eyes Wide Open: Cultivating Discernment on the Spiritual Path*, Mariana Caplan wrote: "Transpersonal psychologists attempt to integrate timeless wisdom with modern

Western psychology and translate spiritual principles into scientifically grounded, contemporary language. Transpersonal psychology addresses the full spectrum of human psychospiritual development—from our deepest wounds and needs to the existential crisis of the human being, to the most transcendent capacities of our consciousness." Instead of focusing on one school of psychological thought, or even just one discipline, transpersonal psychology seeks to incorporate a broad array of ideas, disciplines, and theories like philosophy, literature, health theories, art, social theory, cognition science, and different spiritual traditions, says Sofia University, formerly the Institute of Transpersonal Psychology. Sofia University is a private institution that was initially founded to educate students in transpersonal psychology and continues to pass on transpersonal values.

POPULARITY

Although transpersonal psychology is not often explored in traditional psychology programs, there is increasing interest in this perspective and how theories and ideas from this field can be applied to different subfields of psychology. Mindfulness meditation, for example, is one element of transpersonal psychology that is becoming more popularly used.

DIFFERENCE FROM PARAPSYCHOLOGY

Transpersonal psychology is sometimes confused with parapsychology, although it is important to note that the two are not the same. While transpersonal psychology focuses on the spiritual side of human nature, parapsychology is concerned with the paranormal, such as psychic phenomena, including precognition, clairvoyance, near-death experiences, and psychokinesis.

OTHER THEORIES: ROTTER'S LOCUS OF CONTROL

A scientific theory presents an explanation about some aspect of human behavior or the natural world which is supported through repeated testing and experiments. This means that scientists have collected evidence that supports the theory. Many different researchers have gathered the evidence that supports the theory. As new evidence and research are added, a theory may then be refined, modified, or even rejected if it does not fit with the latest scientific findings. The overall strength of a scientific theory hinges on its ability to explain diverse phenomena.

PURPOSE OF A PSYCHOLOGY THEORY

In psychology, theories are used to provide a model for understanding human thoughts, emotions, and behaviors. Throughout psychology's history, a number of theories have been proposed to explain and predict various aspects of human behavior. A psychological theory has two key components: It must describe a behavior.

1. It must make predictions about future behaviors.

Each theory has helped contribute to our knowledge of the human mind and behavior. Some theories, such as classical conditioning, are still well accepted today.² Others, like Freud's theories, have not held up so well and have been mostly replaced by new theories that better explain human development.

DIFFERENT TYPES OF PSYCHOLOGICAL THEORIES

There are many psychology theories, but most can be categorized as one of four key types.

DEVELOPMENTAL THEORIES

Theories of development provide a framework for thinking about human growth, development, and

learning. If you have ever wondered about what motivates human thought and behavior, understanding these theories can provide useful insight into individuals and society. Developmental theories provide a set of guiding principles and concepts that describe and explain human development. Some developmental theories focus on the formation of a particular quality, such as Kohlberg's theory of moral development.³ Other developmental theories focus on growth that happens throughout the lifespan, such as Erikson's theory of psychosocial development.

GRAND THEORIES

Grand theories are those comprehensive ideas often proposed by major thinkers such as Sigmund Freud, Erik Erikson,⁴ and Jean Piaget. Grand theories of development include psychoanalytic theory, learning theory, and cognitive theory. These theories seek to explain much of human behavior, but are often considered outdated and incomplete in the face of modern research. Psychologists and researchers often use grand theories as a basis for exploration, but consider smaller theories and recent research as well.

MINI-THEORIES

Mini-theories describe a small, very particular aspect of development. A mini-theory might explain relatively narrow behaviors, such as how self-esteem is formed⁵ or early childhood socialization. These theories are often rooted in the ideas established by grand theories, but they do not seek to describe and explain the whole of human behavior and growth.

EMERGENT THEORIES

Emergent theories are those that have been created relatively recently and are often formed by systematically combining various mini-theories. These theories draw on research and ideas from different disciplines but are not yet as broad or far-reaching as grand theories. The sociocultural theory proposed by Lev Vygotsky is a good example of an emergent theory of development.⁶

EXAMPLES OF PSYCHOLOGY THEORIES

Some of the best-known theories of psychology focus on specific branches within psychology. Some of these include:

BEHAVIORAL THEORIES

Behavioral psychology, also known as behaviorism, is a theory of learning based on the idea that all behaviors are acquired through conditioning. Advocated by famous psychologists such as John B. Watson and B.F. Skinner, behavioral theories dominated psychology during the early half of the twentieth century.⁷ Today, behavioral techniques are still widely used by therapists to help clients learn new skills and behaviors.

COGNITIVE THEORIES

Cognitive theories of psychology are focused on internal states, such as motivation, problem-solving, decision-making, thinking, and attention. Such theories strive to explain different mental processes including how the mind processes information.

HUMANISTIC THEORIES

Humanistic psychology theories began to grow in popularity during the 1950s.⁸ While earlier theories often focused on abnormal behavior and psychological problems, humanist theories instead emphasized the basic goodness of human beings. Some of the major humanist theorists included Carl Rogers and Abraham Maslow.

PERSONALITY THEORIES

Personality psychology looks at the patterns of thoughts, feelings, and behavior that make a person unique. Some of the best-known theories in psychology are devoted to the subject of personality, including the trait theory of personality, the "big 5" theory of personality, and Erikson's theory of psychosocial development.⁹

SOCIAL PSYCHOLOGY THEORIES

Social psychology is focused on helping us understand and explain social behavior. Social theories are generally centered on specific social phenomena, including group behavior,¹⁰ prosocial behavior, social influence, love and much more.

WHY THEORIES MATTER

In your psychology courses, you may find yourself questioning how necessary it is to learn about different psychology theories, especially those that are considered inaccurate or outdated. However, all of these theories provide valuable information about the history of psychology, the progression of thought on a particular topic, and a deeper understanding of current theories.

LOCUS OF CONTROL

Julian Rotter developed a social learning theory that emphasized the role of the cognitive expectancy of reward in determining behavior. The major contribution of this theory to the psychology of personality was the proposal of a generalized cognitive expectancy that Rotter called locus of control. Individuals differ to the extent that they generally believe their own actions are related to personal outcomes. Those with an internal locus of control have a strong expectation that success or failure will result from their own efforts. Those with an external locus of control generally believe that success or failure is determined by fate, chance, or the will of others.

Currently, psychologists believe individuals can have different locus of control beliefs for different aspects of their life. For example, an individual could have an internal locus of control regarding social relationships and an external locus of control regarding his or her health. One domain that has been predictive of therapy outcome is the individual's locus of control beliefs concerning illness or health outcomes. Causal attributions also determine whether events are believed to be stable or transient. For example, a stable causal attribution might be, "I did poorly on the algebra test because I have never been very good at math." A transient attribution could be, "I did poorly on the algebra test because I did not get enough sleep last night." Finally, causal attributions may be general (i.e., relevant to many experiences) or specific (i.e., applicable only to a single instance). For example, a stable causal attribution might be, "I didn't dance well because I have never been coordinated." A specific attribution could be, "I didn't dance well because I have never liked dancing."

Locus of control refers to the extent to which people feel that they have control over the events that influence their lives.

When you are dealing with a challenge in your life, do you feel that you have control over the outcome? Or do you believe that you are simply at the hands of outside forces? If you believe that you

have control over what happens, then you have what psychologists refer to as an internal locus of control. If you believe that you have no control over what happens and that external variables are to blame, then you have what is known as an external locus of control. Your locus of control can influence not only how you respond to the events that happen in your life, but also your motivation to take action.

If you believe that you hold the keys to your fate, you are more likely to take action to change your situation when needed. If on the other hand, you believe that the outcome is out of your hands, you may be less likely to work toward change.

INTERNAL VS. EXTERNAL LOCUS OF CONTROL

It is important to note that locus of control is a continuum. No one has a 100 percent external or internal locus of control. Instead, most people lie somewhere on the continuum between the two extremes. These are characteristics of people with dominant internal or external locus of control.

INTERNAL LOCUS OF CONTROL

- Are more likely to take responsibility for their actions
- Tend to be less influenced by the opinions of other people
- Often do better at tasks when they are allowed to work at their own pace
- Usually, have a strong sense of self-efficacy
- Tend to work hard to achieve the things they want
- Feel confident in the face of challenges
- Tend to be physically healthier
- Report being happier and more independent
- Often achieve greater success in the workplace

EXTERNAL LOCUS OF CONTROL

- Blame outside forces for their circumstances
- Often credit luck or chance for any successes
Don't believe that they can change their situation through their own effort
- Frequently feel hopeless or powerless in the face of difficult situations
- Are more prone to experiencing learned helplessness

SELIGMAN'S EXPLANATORY STYLES

Over time the concept of attributional and explanatory styles evolved into a comprehensive theoretical framework, becoming a major research paradigm within psychology with a bearing on individuals' propensity towards optimism or **pessimism** and in turn, subsequent positive or negative mental states and outcomes. In psychology, the term attribution has two predominant meanings. The first refers to explanations of behavior; the second refers to inferences (attributing blame, for example). "What the two meanings have in common is a process of assigning: in attribution as an explanation, a behavior is assigned to its cause; in attribution as inference, a quality or attribute is assigned to the agent on the basis of observed behavior." (Malle, 2011, p.17).

Similarly, Fiske & Taylor (1991, p. 23) suggested attribution theory "deals with how the social perceiver uses information to arrive at causal explanations for events. It examines what information is gathered and how it is combined to form a causal judgment."

Not to be confused with dispositional optimism – which sees optimism as a broad personality trait (Carver & Scheier, 2003) – the explanatory style is more concerned with immediate tendencies to view everyday events from a predominantly optimistic or pessimistic perspective. According to Buchanan & Seligman (1995, p.1), “the general definition of explanatory style is quite simple, it is our tendency to offer similar explanations for different events.” Additionally, explanatory styles can cause people to have disparate perceptions of the same event. Put simply your attributional and explanatory style is the way in which you explain your circumstances to yourself.

A LOOK AT THE PSYCHOLOGY

People have a propensity to seek explanations for events. Whether it is within politics, science, philosophy, psychology or in everyday life, we want to know why things happen. Within psychology, this persistent drive to work out the ‘why’ compelled researchers to investigate why some individuals favor certain explanatory approaches over others (Buchanan & Seligman, 1995). While human responses to uncontrollable events in laboratory settings were of interest, psychologists naturally became curious about real-world applications. This real-world focus was particularly in relation to how individuals make sense of their actions, how this impacts **emotions** (Buchanan & Seligman, 1995) and how we **regulate** these emotions (Gross, 2000).

Does an individual’s explanatory characteristics determine their emotional state? Why do some individuals seem to give up and accept their fate in the face of **adversity** while some remain upbeat despite a string of ‘failures’? Why do some appear powerless in the absence of control? Through asking such questions psychologists developed a number of hypotheses resulting in a plethora of studies concerning optimistic and pessimistic behavioral patterns and the potential long term effects on psychological health. 60 years of research into the ways individuals habitually explain events has cultivated a theory which is not only reliable but also measurable.

THE THEORY OF EXPLANATORY STYLES

Grounded in scientific method, theories of psychology are ever-evolving as practitioners and researchers in the space constantly review, validate and propose new hypotheses. The theory of explanatory styles is no different; research in the field stretches back decades and continues to spur fresh publications as time goes on. Heider (1958, as cited in Malle, 2011) initially distinguished between perceived internal and external causes for events. Subsequently, attributional theorist, Weiner (1972) drew a distinction between (temporally) stable versus unstable causes, with stable attributions for failure being seen to contribute towards poor or low levels of **motivation**. The third dimension of helplessness was first introduced by Kelley (1972) who focussed on ascriptions of global versus specific causes for adverse events.

The concept of explanatory style with three parameters (internality, stability, and globality) and the inclusion of a proposed distinction between optimistic and pessimistic attributional styles was hypothesized by Abramson, Semmel, Seligman, & Von Baeyer (1978). Explanatory style as we know it was born primarily from two antecedents: The Learned Helplessness Model and The Reformulation of the Learned Helplessness Model. Learned helplessness mode **Learned helplessness** proposes that control over the environment is a fundamental precursor of positivism for any organism. If an individual is repeatedly exposed to unavoidable painful or otherwise negative stimuli, they will come to expect that such events are uncontrollable and potentially develop a sense of hopelessness and depression as a result (Overmier & Seligman, 1967). First observed in laboratory experiments in

which animals were subjected to painful electric shocks with no opportunity for escape or avoidance, Maier & Seligman (1976) found that, after a period, animals would passively endure the pain. The research suggested that helplessness is a learned behavior. When placed in a situation where there is no control over the outcome, the animals were conditioned to expect that future attempts to negate the shocks would be futile and therefore gave up trying. Hiroto & Seligman (1975) hypothesized that humans, like animals, would cease attempts to change their circumstances if it was deemed to be out of their control, highlighting the importance of how we attribute causality and control in mediating our mental state.

PESSIMISTIC EXPLANATORY STYLE

Pessimists have the opposite explanatory style. They personally blame themselves for bad events and perceive the root cause to be a fixed factor. When something good happens, they tend to attribute it to luck and see the cause as temporary. The reformulation of the learned helplessness model of depression and the hopelessness model of depression predict that individuals who have a proclivity for pessimistic styles of explaining events experience failure more frequently than those with a more optimistic style in achievement-based scenarios.

Additionally, individuals with pessimistic explanatory styles are more likely to experience pervasive and chronic symptoms of helplessness when faced with uncontrollable negative events. Maladaptive thought patterns can fuel issues such as depression by creating a cycle of **negative thought** that perpetuates the problem (Eisner, 1995). Depressive symptoms are most likely to occur when a vulnerable person experiences negative environmental circumstances (Schneider, Gruman, & Coutts, 2012). In this situation, a person is deemed vulnerable if they interpret the cause of negative events as something that cannot be changed (stable attribution) and affecting their whole life (global attribution). A person with these traits could be described as having a specific type of depression, called hopelessness depression (Schneider et al., 2012).

Seligman (1998) proposed that the explanatory style theory of optimism provides pessimistic people with an avenue to alter their pessimistic thinking patterns to be more optimistic, thus fostering mastery and **resilience**. For example, studies with middle-school children showed that retraining pessimistic thinking into optimistic thinking can significantly reduce the incidence of depression (Nolen-Hoeksema, Girgus, and Seligman, 1986).

EXPLANATORY STYLE DIMENSIONS & EXAMPLES

A person's attributional style describes how they explain life events to themselves. When someone forms an explanation it involves three dimensions which influence how we explain an outcome, namely internality versus externality, stability versus instability, and globality versus specificity (Peterson, 1991), easily remembered as the three Ps: personalization, permanence, and pervasiveness, respectively. Abraham, Seligman and Teasdale (1978) postulated that the way in which we attribute negative outcomes plays a role in mediating the negative psychological impact of adverse events.

INTERNAL VS EXTERNAL (PERSONALIZATION)

Is an outcome caused by factors within oneself or outside oneself? Was success or failure down to inherent abilities or failings or caused by favorable or impinging external conditions? An individual with a propensity to blame failure on themselves and success on external factors shows more severe helplessness deficits such as passivity, depression, poor problem solving, low self-esteem, poor immune function, and even higher morbidity than a person who explains failure as being due

to extraneous factors (Maier & Seligman, 1976; Peterson, 1988). An internal attribution occurs when an individual blames a negative outcome to an inherent failing or a positive outcome to their own abilities. For example, “I failed the exam because I’m stupid” (pessimistic) or “I passed the exam because I worked hard” (optimistic).

An external attribution occurs when a negative or positive event is attributed to the situational context. For example, “I failed the exam because the room was too noisy” (optimistic) or “I passed the exam because I got the right questions” (pessimistic). Examples of Explanatory Style Michelle the optimist and Susan the pessimist complete an assignment for school: Michelle the optimist receives an ‘A’ from her teacher. Michelle’s optimistic explanatory style means she is more inclined to attribute her success to her own hard work and ability – she worked hard on the assignment and is good at this subject.

If Michelle had failed the assignment, she would likely have attributed this to external factors – she didn’t do well because her neighbors were having a loud party. Michelle stills believe that she will do well in future assignments, the failure was not due to her lackof knowledge and will not impact future grades. Susan the pessimist receives an ‘A’ for her assignment. Susan’s pessimistic explanatory style means she is less inclined to attribute her success to her own skills – it was probably just luck or maybe her teacher was feeling generous, it certainly wasn’t due to her ability in the subject.

If Susan had failed her assignment, she would most likely blame herself – she’s just no good at these things. Susan knows that she will probably do badly in future assignments. Alex the optimist and Michael the pessimist work hard on important proposals for work: Alex the optimist meets with his directors and they love his idea. Alex’s optimistic explanatory style means he is more likely to attribute this success to his own skills and ability – his skills are internal, stable, and global. If Alex’s employers had disliked his proposal, he would likely have attributed this to external factors – maybe they were preoccupie with other things. Alex still expects future proposals to be successful because the proposal failed due to their temporary problem and not his lack of ability.

Michael the pessimist meets with his directors and they are impressed with his idea. Michael’s pessimistic explanatory styles mean he is more likely to attribute this success to external factors – he was lucky on the day but this does not mean he will be successful in future endeavors. If Michael’s employers had not been impressed with his proposal hewould be inclined to attribute this to internal factors – he’s just no good at presentations. Michael knows that future attempts will be unsuccessful because the failure was due to his own lack of ability.

MARTIN SELIGMAN AND EXPLANATORY STYLE

One name you may have come across in your inexhaustible journeyalong the road of positive psychology is Dr. [Martin Seligman](#). Considered a founding father of positive psychology, former head ofthe American Psychological Association (APA), Dr. Seligman is a leading authority in the field and had a hand in developing early attribution style theories based on the learned helplessness model which later evolved into a more robust explanatory style. Explanatory style is but the latest theory on how we as individuals explain our experiences to ourselves and has roots stretching back decades in terms of peer-reviewed literature.

The modern theory of explanatory style and the postulated role it plays in mediating between positive and negative mental states stemmed originally from the work of Overmier and Seligman (1967)

in which they formulated the learned helplessness model. During the study, rats were given electric shocks over which they had no control. It was found that rats learned that the outcome was independent of their responses and became passive, thereby learning helplessness.

However, the model didn't account for the potential of learned optimism or for individual differences in resilience when applied to humans, therefore, prompting a reformulation of the learned helplessness model by Abramson et al., (1978). In their reformulated model of learned helplessness, the researchers proposed that an individual's explanatory style influenced the level of optimism/pessimism with which they regarded future events. Based on the findings, Seligman proposed three dimensions of explanatory style, neatly summarised by the three Ps: Pervasiveness – Global / Specific: Whether or not the factors influencing an outcome are seen to be event-specific or globally applicable.

Permanence – Stable / Unstable: If the outcome is based on factors which are changeable (unstable) or perceived to be temporally fixed (stable). Personalization – Internal / External: Relating to the level of personal control an individual feels they hold relating to an outcome. Based on these dimensions, individuals can display an optimistic or pessimistic explanatory style. This by no means encapsulates Dr. Seligman's total involvement in the spawning of our modern day theory of explanatory style and how it impacts on levels of optimism, pessimism and associated positive or negative emotional states.

Over the years, Seligman has refined and validated the theory as well as proposed several methods of measuring an individual's explanatory style, including the Attributional Style Questionnaire (Peterson, Semmel, von Baeyer, Abramson, Metalsky, & Seligman, 1982), the Children's Attributional Style Questionnaire (Kaslow, Tannenbaum, & Seligman, 1978) and the Content Analysis of Verbatim Explanations Technique (Peterson, Schulman, Castellon, & Seligman, 1992). There has been an abundance of research in the area of attribution theory and explanatory style, but the drive to adapt and update theories means this remains an active area of investigation.

While much of the past research regarding interventions to an individual's explanatory style has focused on the link between a pessimistic explanatory style and depressive symptoms, the field of research into interventions which promote an optimistic explanatory style and any subsequent positive mental outcomes remains relatively wide-open (Fredrickson, 2001).

METHODS OF MEASUREMENT

How do we go about measuring explanatory styles? There are two main methods by which researchers assess attributional style: the Attributional Style Questionnaire (ASQ: Peterson et al., 1982) and the Content Analysis of Verbatim Explanations (CAVE: Peterson et al., 1992). Both measures collect information from participants regarding their attributions on the three dimensions. Determining precisely where the participant's attributions lie on each of these three dimensions is the goal of both the ASQ and the CAVE methods. The response allow researchers to make general conclusions about the overall attributional style of the participant.

One of the earliest and most commonly utilized assessment tools for adults is the attributional style questionnaire. Developed as a test to investigate and measure individual differences in habitual explanatory tendencies, a composite explanatory style score is formed by combining scores from the three dimensions (Peterson et al., 1993).

The ASQ presents individuals with hypothetical events and asked to imagine they involve them

personally. In each case, they are asked questions related to perceived causes and the situation as a whole. Responses are then rated on a scale of 1-7 along the three dimensions of internality, stability, and globality (Dykema, Bergbower, Doctra & Peterson, 1996). While the ASQ is an efficient method to obtain attributions for multiple events, as with many questionnaire-based studies it can potentially limit the quantity and demographics of participants. In response to this, the CAVE technique is a method that allows the researcher to analyze naturally occurring verbatim materials for explanatory style.

This technique has been successfully employed with adults particularly when a retrospective analysis of explanatory style is required. In this method, verbal or written causal effect statements by subjects are rated along the same permanent, personal and pervasive dimensions. The CAVE technique allows the measurement of populations or individuals whose behavior is of interest but who cannot take questionnaires. Explanatory style can be assessed by blind, reliable content analysis of verbatim explanations from the historical records. Subjects who are famous, dead, or otherwise unavailable can be studied as easily as anyone else so long as they have left some verbatim record whether it be transcripts, interviews, letters, diaries, or journals (Zullow, Oettingen, Peterson & Seligman, 1988).

EXPLANATORY STYLE TEST

By this point, you may think that you have a pretty good idea what your explanatory style is. To garner a deeper understanding you can take one of the many explanatory style tests online (often referred to as **learned optimism** tests), most of which are adapted from that of Dr. Martin Seligman. But why is it important to know your explanatory style? This habitual way in which people explain causes has been used to predict depression, achievement, and health, with a pessimistic style predicting poor outcomes (Zullow, Oettingen, Peterson, Seligman, 1988).

According to Seligman (1990) learned helplessness has negative effects similar to depression – the belief that in the face of uncontrollable events, individual actions do not matter. Fortunately, there are ways we can unlearn this helplessness and actively learn optimism.

Remember when you complete an explanatory style test there are no right or wrong answers. The best way to recognize and change your style is to respond honestly. The Authentic Happiness **test center** provides an excellent optimism test formulated by Dr. Martin Seligman. On completion of the 32 question test, you will be provided with a thorough explanation and breakdown of your results in relation to permanence and pervasiveness.

Seligman's website also provides a wealth of other tests and questionnaires ranging from life satisfaction to motivation and everything in between. Completing this 48 question **test** by Stanford University should take around 15 minutes. On completion, you will be given scores based on positive and negative permanence, pervasiveness, personalization, and a cumulative overall score.

KOHLBERG'S STAGES OF MORAL DEVELOPMENT

Kohlberg's theory of moral development states that we progress through three levels of moral thinking that build on our cognitive development.

KEY POINTS

- **Lawrence Kohlberg** expanded on the earlier work of **cognitive** theorist Jean Piaget to explain the moral development of children, which he believed follows a series of stages.
- Kohlberg defined three levels of moral development: pre-conventional, conventional, and post-conventional. Each level has two distinct stages.
During the pre-conventional level, a child's sense of **morality** is externally controlled. Children accept and believe the rules of **authority** figures, such as parent and teachers, and they judge an action based on its consequences.
- During the conventional level, an individual's sense of morality is tied to personal and societal relationships. Children continue to accept the rules of authority figures, but this is now because they believe that this is necessary to ensure positive relationships and societal order.
- During the post-conventional level, a person's sense of morality is defined in terms of **more** abstract principles and values. People now believe that some laws are unjust and should be changed or eliminated.
- Kohlberg's **theory** has been criticized for its cultural and gendered **bias** toward white, upper-class men and boys. It also fails to account for inconsistencies within moral judgments.

Lawrence Kohlberg expanded on the earlier work of cognitive theorist Jean Piaget to explain the moral development of children. Kohlberg believed that moral development, like **cognitive development**, follows a series of stages. He used the idea of moral dilemmas—stories that present conflicting ideas about two moral values—to teach 10 to 16 year-old boys about morality and values. The best known moral dilemma created by Kohlberg is the “Heinz” dilemma, which discusses the idea of obeying the law versus saving a life. Kohlberg emphasized that it is the way an individual **reasons** about a dilemma that determines positive moral development. After presenting people with various moral dilemmas, Kohlberg reviewed people's responses and placed them in different stages of moral reasoning.

KOHLBERG'S STAGES OF MORAL DEVELOPMENT

Kohlberg identified three levels of moral reasoning: pre-conventional, conventional, and post-conventional. Each level is associated with increasingly complex stages of moral development. According to Kohlberg, an individual progresses from the capacity for pre-conventional morality (before age 9) to the capacity for conventional morality (early adolescence), and toward attaining post-conventional morality (once Piaget's idea of formal operational thought is attained), which only a few fully achieve. Each level of morality contains two stages, which provide the basis for moral development in various contexts.

LEVEL 1. PRECONVENTIONAL MORALITY

The earliest stages of moral development, obedience and punishment, are especially common in young children, but adults are also capable of expressing this type of reasoning. At this stage, Kohlberg says, people see rules as fixed and absolute.⁶ Obeying the rules is important because it is a means to avoid punishment. At the individualism and exchange stage of moral development, children account for individual points of view and judge actions based on how they serve individual needs. In the Heinz dilemma, children argued that the best course of action was the choice that best served Heinz's needs. Reciprocity is possible at this point in moral development, but only if it serves one's own interests.

LEVEL 2. CONVENTIONAL MORALITY

Often referred to as the "good boy-good girl" orientation, the stage of the interpersonal relationship of moral development is focused on living up to social expectations and roles.⁶ There is an emphasis on conformity, being "nice," and consideration of how choices influence relationships. This stage is focused on maintaining social order. At this stage of moral development, people begin to consider society as a whole when making judgments. The focus is on maintaining law and order by following the rules, doing one's duty, and respecting authority.

LEVEL 3. POSTCONVENTIONAL MORALITY

The ideas of a social contract and individual rights cause people in the next stage to begin to account for the differing values, opinions, and beliefs of other people.⁶ Rules of law are important for maintaining a society, but members of the society should agree upon these standards. Kohlberg's final level of moral reasoning is based on universal ethical principles and abstract reasoning. At this stage, people follow these internalized principles of justice, even if they conflict with laws and rules.

CRITICISMS

Kohlberg's theory is concerned with moral thinking, but there is a big difference between knowing what we ought to do versus our actual actions. Moral reasoning, therefore, may not lead to moral behavior. This is just one of the many criticisms of Kohlberg's theory. Critics have pointed out that Kohlberg's theory of moral development overemphasizes the concept of justice when making moral choices. Factors such as compassion, caring, and other interpersonal feelings may play an important part in moral reasoning.⁷

Does Kohlberg's theory overemphasize Western philosophy? Individualist cultures emphasize personal rights, while collectivist cultures stress the importance of society and community. Eastern, collectivist cultures may have different moral outlooks that Kohlberg's theory does not take into account. Were Kohlberg's dilemmas applicable? Most of his subjects were children under the age of 16 who obviously had no experience with marriage. The Heinz dilemma may have been too abstract for these children to understand, and a scenario more applicable to their everyday concerns might have led to different results.

Kohlberg's critics, including Carol Gilligan, have suggested that Kohlberg's theory was gender-biased since all of the subjects in his sample were male.⁸ Kohlberg believed that women tended to remain at the third level of moral development because they place a stronger emphasis on things such as social relationships and the welfare of others. Gilligan instead suggested that Kohlberg's theory overemphasizes concepts such as justice and does not adequately address moral reasoning founded on the principles and ethics of caring and concern for others.

WHAT IS BASIC MOTIVATIONAL CONCEPTS: INSTINCTS, NEEDS, DRIVES, AROUSAL, INCENTIVES, MOTIVATIONAL CYCLE. APPROACHES TO THE STUDY OF MOTIVATION: PSYCHOANALYTICAL, ETHOLOGICAL, S-R COGNITIVE, HUMANISTIC?

BASIC MOTIVATIONAL CONCEPTS: INSTINCTS, NEEDS, DRIVES, AROUSAL, INCENTIVES, MOTIVATIONAL CYCLE. APPROACHES TO THE STUDY OF MOTIVATION: PSYCHOANALYTICAL, ETHOLOGICAL, S-R COGNITIVE, HUMANISTIC

Basic motivational concepts: Instincts, Needs, Drives, Arousal, Incentives, Motivational Cycle

CONCEPT OF MOTIVATION:

The term motivation is derived from the word 'motive'. The word 'motive' as a noun means an objective, as a verb this word means moving into action. Therefore, motives are forces which induce people to act in a way, so as to ensure the fulfillment of a particular human need at a time. Behind every human action there is a motive. Therefore, management must provide motives to people to make them work for the organization. Motivation may be defined as a planned managerial process, which stimulates people to work to the best of their capabilities, by providing them with motives, which are based on their unfulfilled needs.

"Motivation means a process of stimulating people to action to accomplish desired goods." –William G. Scott "Motivation is the process of attempting to influence others to do your will through the possibility of gain or reward." – Flippo Motivation is, in fact, pressing the right button to get the desired human behaviour. Motivation is no doubt an essential ingredient of any Organisation. It is the psychological technique which really executes the plans and policies through the efforts of others.

FOLLOWING ARE THE OUTSTANDING FEATURES OF THE CONCEPT OF MOTIVATION:

1. Motivation is a personal and internal feeling:

Motivation is a psychological phenomenon which generates within an individual.

2. MOTIVATION IS NEED BASED:

If there are no needs of an individual, the process of motivation fails. It is a behavioural concept that directs human behaviour towards certain goals.

3. MOTIVATION IS A CONTINUOUS PROCESS:

Because human wants are unlimited, therefore motivation is an ongoing process

4. MOTIVATION MAY BE POSITIVE OR NEGATIVE:

A positive motivation promotes incentives to people while a negative motivation threatens the enforcement of disincentives.

5. MOTIVATION IS A PLANNED PROCESS:

People differ in their approach, to respond to the process of motivation; as no two individuals could be motivated in an exactly similar manner. Accordingly, motivation is a psychological concept and a complex process.

6. MOTIVATION IS DIFFERENT FROM JOB SATISFACTION:

THE PROCESS OF MOTIVATION IS ILLUSTRATED IN THE FIGURE GIVEN BELOW:

Figure 15.1 shows an employee has a need or urge for promotion to a higher position. If this need is strong, the employee will fix his goal and find alternatives to reach the goal.

The employee might have two alternatives, namely,

- (i) hard work and
- (ii) enhancement of qualification (e.g., getting MBA) and hard work.

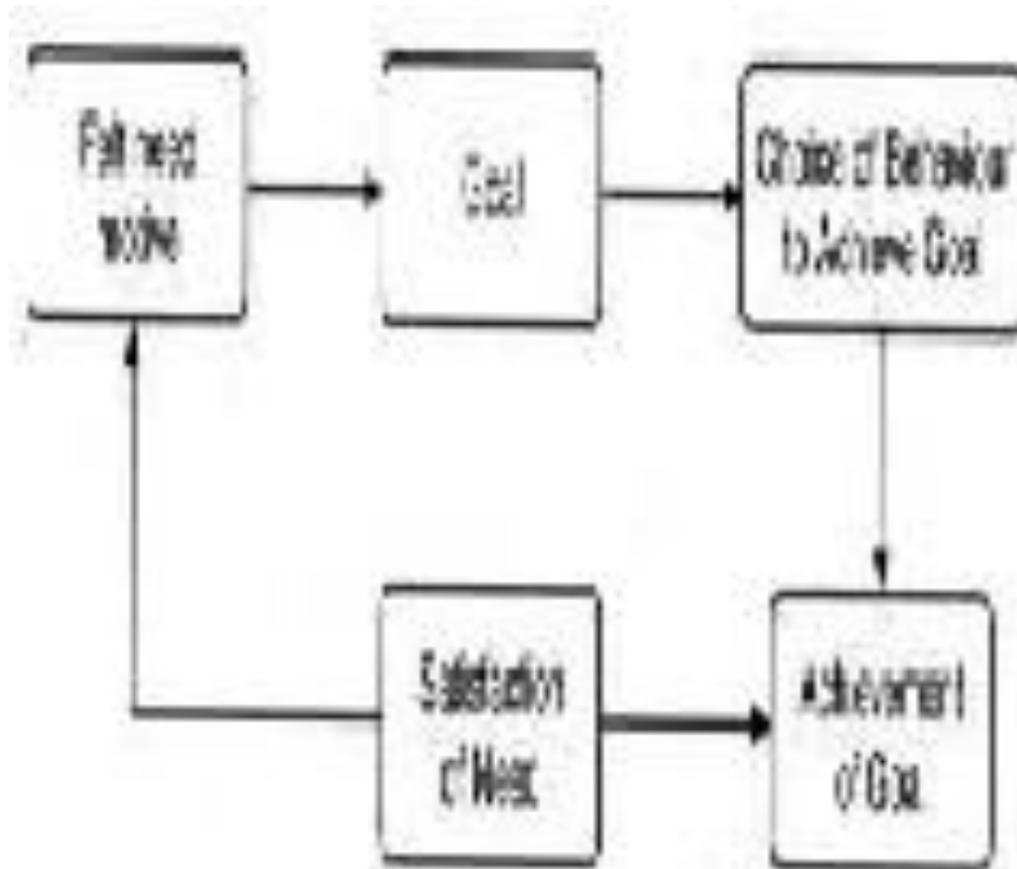

Fig. 15.1 The Process of Motivation

enhancement of qualification (e.g., getting MBA) and hard work. He might choose the second alternative and succeed in getting promotion (goal achievement) thus, his need for promotion would be satisfied and he would start again for the satisfaction of a new need.

SIGNIFICANCE/IMPORTANCE OF MOTIVATION:

Motivation is an integral part of the process of direction.

WHILE DIRECTING HIS SUBORDINATE, A MANAGER MUST CREATE AND SUSTAIN IN THEM THE DESIRE TO WORK FOR THE SPECIFIED OBJECTIVES:

1. High Efficiency:

A good motivational system releases the immense untapped reservoirs of physical and mental capabilities. A number of studies have shown that motivation plays a crucial role in determining the level of performance. "Poorly motivated people can nullify the soundest organisation," said Allen.

By satisfying human needs motivation helps in increasing productivity. Better utilisation of resources lowers cost of operations. Motivation is always goal directed. Therefore, higher the level of motivation, greater is the degree of goal accomplishment.

2. BETTER IMAGE:

A firm that provides opportunities for financial and personal advancement has a better image in the employment market. People prefer to work for an enterprise because of opportunity for development, and sympathetic outlook. This helps in attracting qualified personnel and simplifies the staffing function.

3. FACILITATES CHANGE:

Effective motivation helps to overcome resistance to change and negative attitude on the part of employees like restriction of output. Satisfied workers take interest in new organisational goals and are more receptive to changes that management wants to introduce in order to improve efficiency of operations.

4. HUMAN RELATIONS:

Effective motivation creates job satisfaction which results in cordial relations between employer and employees. Industrial disputes, labour absenteeism and turnover are reduced with consequent benefits. Motivation helps to solve the central problem of management, i.e., effective use of human resources. Without motivation the workers may not put their best efforts and may seek satisfaction of their needs outside the organisation. The success of any organisation depends upon the optimum utilisation of resources. The utilisation of physical resources depends upon the ability to work and the willingness to work of the employees. In practice, ability is not the problem but necessary will to work is lacking. Motivation is the main tool for building such a will. It is for this reason that Rensis Likert said, "Motivation is the core of management." It is the key to management in action.

MOTIVATION: NEED FOR ACHIEVEMENT

Have you ever met people who are always interested in improving themselves (and actually others as well), to become faster, smarter and more productive than ever? It seems they cannot stop developing themselves to be better; they are eager for achievements and enhancements. To tell you the truth, I also share this drive and would like to provide a "how-to" that can help readers motivate and manage these achievers, as they are called in the Need Theory model, more efficiently and less stressfully.

What Motivates People with the Need for Achievement	How to Deal with This Drive
<p>Be better than yourself</p> <ul style="list-style-type: none">• They develop themselves;• May compare past and current achievements;• Winning is more important than participating;	<ul style="list-style-type: none">• Provide a clear plan/path for professional growth;• Define how the person can build his/her career within the project/program;• Give an opportunity for them to attend conferences and trainings;• Set clear goals and meaningful KPIs;

<p>Be better than others</p> <ul style="list-style-type: none"> • Compare their results to others; • Show interest in how others are progressing; • Don't like when others make fun of them 	<ul style="list-style-type: none"> • Share what the evaluation criteria is for team members; • Explain why someone is/is not getting something; • Ensure that the bonuses and appraisal systems are transparent; • Communicate openly about the achievements of team members;
<p>Challenging tasks</p> <ul style="list-style-type: none"> • The task should be difficult, but achievable • Can do monotonous work, 	<ul style="list-style-type: none"> • Clarify how the task impacts the project or program; • Make sure the person is clear on why it is important that they are doing the task;
<p>when it's a part of an interesting endeavor;</p> <ul style="list-style-type: none"> • Prefer to fulfill tasks step by step; 	<ul style="list-style-type: none"> • Check that the task corresponds to the person's skills;
<p>A stable and long-term career</p> <ul style="list-style-type: none"> • Interested in becoming a good professional in one area, rather than a jack-of-all-trades 	<ul style="list-style-type: none"> • Provide opportunities to deepen their knowledge; • Confirm that the project/program is stable enough for long-term career planning

MOTIVATION: NEED FOR AFFILIATION

Sometimes we have to make hard choices and decide: what is more important? Is it to A. get the desired result, or B. maintain good relationships with your colleagues? For people with a strong need for achievement, the "result" answer is obvious. But for the ones with a need for affiliation, relations usually matter more. Let's see what else motivates people with this drive.

What Motivates People with the Need for Affiliation	How to Deal with This Drive
<p>Find new friends</p> <ul style="list-style-type: none"> • The possibility to meet 	<p>Allow them to contact new people from other teams and the client side. They are good communicators and are able to set up connections between people;</p>
<p>new people;</p> <ul style="list-style-type: none"> • Can easily start conversation with strangers; • Are open-minded and easy-going. 	<ul style="list-style-type: none"> • Invite to kick-off meetings; • Involve them in onboarding new team members;

<p>Stay in touch with friends</p> <ul style="list-style-type: none"> • Enjoy calling and writing to people they know; • Like showing they care and when others care about them; • Prefer to work with friends more than with experts; • Have lots of friends in different areas and companies. 	<ul style="list-style-type: none"> • Engage in mentoring and coaching activities; • Make sure they have enough interactions with other project/team members (they like face-to-face meetings, calls and correspondence – the more communication options they have, the happier they feel); • Show empathy and interest; • Allow them to assist other team members when they are able;
<p>Spend time together with people</p> <p>Know how to have fun and inspire people around them;</p> <ul style="list-style-type: none"> • Are able to provide support and encouragement; • Loyal to different points of view; • Appreciate teamwork; • Don't mind doing routine/monotonous work; • Can easily practice the Management 3.0 style (even without knowing what it is). 	<ul style="list-style-type: none"> • Assign them tasks that require good collaboration skills; • Can experience stress in an unfriendly/competitive atmosphere; Try to avoid involving them in confrontations/conflict, as they can feel discomfort because of it; • Be careful with negative feedback, especially when sharing it publicly – they can take it personally and become deeply hurt; • Encourage them to share their ideas and contribute to team activities, as they will be grateful for this; • Show appreciation for their good results at work, as they will be glad to hear "thank you"; • Involve them in social and • volunteering activities, as they can bring lots of value.

Interesting fact: parents with prominent affiliation drives, usually raise children with the need for achievement drive.

MOTIVATION: NEED FOR POWER

Do you know people who often use the following words: influence, control, status, struggle, discipline, subordination and leadership? These kinds of people also find pleasure in vertical career development. They like to manage others and they are driven by power.

What Motivates People with the Need for Power	How to Deal with This Drive
<p>Control</p> <ul style="list-style-type: none"> • Opportunities to exude control over 	<ul style="list-style-type: none"> • Provide them with opportunities to manage others;

<p>other people;</p> <ul style="list-style-type: none"> • Given power to delegate tasks; • Enjoy doing multiple activities at once; • Like to know what is going on around them; • Need to keep track of their own and others' activities; 	<ul style="list-style-type: none"> • "Career development" to them means increasing the number of people they manage; • Give them some freedom in decision-making; • Assign multiple tasks; • Don't assign tasks directly to their subordinates; • Consult them and ask for advice;
<p>Influence</p> <ul style="list-style-type: none"> • Need to see the reactions to their ideas or actions; 	<ul style="list-style-type: none"> • Allow them to influence you and show your reaction; • Direct their power games into
<ul style="list-style-type: none"> • Care about how other people perceive them; • Can find pleasure in influencing the emotions of others; • Enjoy intrigues, power games. 	<p>constructive areas/context;</p> <ul style="list-style-type: none"> • Develop your own management style, soft and hard skills – they need strong leaders around them; • Pay attention to them, and don't ignore their ideas/actions;
<p>Leadership</p> <ul style="list-style-type: none"> • Enjoy being followed; • Are pleased when praised; • Glad to lead others; • Like public speaking. 	<ul style="list-style-type: none"> • Delegate them to give presentations to the public; • Publicly announce their successes; • Set community creation tasks for them; • Allow them to train and mentor employees;
<p>Status recognition</p> <p>Social success means a lot to them;</p> <p>Collect status artifacts; Count their victories;</p> <p><input type="checkbox"/> Like to be engaged in volunteering activities.</p>	<ul style="list-style-type: none"> • Make sure their position has the corresponding status environment; • Provide them opportunities to join corporate clubs, non-public communities, and other special events.

MOTIVATION AND DRIVE

A person's motivation is a combination of desire and energy directed at achieving a goal. It is the cause of action. Influencing someone's motivation means getting them to want to do what you know must be done. (U.S. Army Handbook, 1973).

A person's motivation depends upon two things:

- **The strength of certain needs.** For example, you are hungry, but you must have a task completed by a nearing deadline. If you are starving you will eat. If you are slightly hungry you will finish the task at hand.
- **The perception that taking a certain action will help satisfy those needs.** For example, you have two burning needs – the desire to complete the task and the desire to go to lunch. Your perception of how you view those two needs will determine which one takes priority. If you believe that you could be fired for not completing the task, you will probably put off lunch and complete the task. If you believe that you will not get into trouble or finish the task in time, then you will likely go to lunch.

Forces, such as beliefs, values, interests, fear, and worthy causes can motivate people. Some of these forces are internal, such as needs, interests, and beliefs. Others are external, such as danger, the environment, or pressure from a loved one. There is no simple formula for motivation – you must keep an open viewpoint on human nature. There is a complex array of forces steering the direction of each person and these forces cannot always be seen or studied. In addition, if the same forces are steering two different people, each one may act differently. Knowing that each person may react to different needs will guide your decisions and actions in certain situations.

GUIDELINES FOR MOTIVATION

As a leader you have the power to influence motivation. The following guidelines form a basic view of motivation (U.S. Army Handbook, 1973). They will help guide your decision making process:

ALLOW THE NEEDS OF YOUR TEAM TO COINCIDE WITH THE NEEDS OF YOUR ORGANIZATION

Nearly everyone is influenced by the needs for job security, promotion, raises, and approval of their peers and leaders. Internal forces, such as values, morals, and ethics, also influence them. Likewise, the organization needs good people in a wide variety of jobs. Ensure that your team is trained, encouraged, and has opportunities to advance. Also, ensure that the way you conduct business has the same values, moral, and ethic principles that you seek in others. If you conduct business in a dishonest manner, your team will be dishonest to you; for that will be the kind of people that you will attract.

REWARD GOOD BEHAVIOR

Although a certificate, letter, or a thank you may seem small and insignificant, they can be powerful motivators. The reward should be specific and prompt. Do not say something general, such as “for doing a good job,” rather you should cite the specific action that made you believe it was indeed a good job.

SET THE EXAMPLE

You must be the role model that you want others to grow into. As Mahatma Gandhi said, “We must become the change we want to see.”

DEVELOP MORALE AND ESPRIT DE CORPS

Morale is the mental, emotional, and spiritual state of a person. Almost everything you do will have an impact on your organization. You should always be aware how your actions and decisions might affect it.

DRIVE

This lively RSA Animate, based on Daniel Pink's book, *Drive: The Surprising Truth About What Motivates Us*, illustrates some of the hidden truths behind what really motivates us: The most common form of culture in modern organizations is often referred to as informed acquiescence. It is rule-based in that the workers learn the rules and agree to abide by them. Rules normally work their way from the top-down in a fairly controllable and predictable manner. Thus, a large organization can become management-orientated that often leads to bureaucracy. And it is this bureaucracy that tends to slow things down.

However, many of the leading organizations are becoming more value-based self-governance in that rather than the workforce being governed by "should," they act upon "can" (Seidman, 2007). They have a small core set of rules that are valued by the workforce. Rather than being motivated to do better, they are inspired. Motivation is controlled somewhat by outside factors, while inspire (similar to "esprit") is more inside the individual's soul or spirit and is usually considered the greatest motivator. Being freed from the crippling pace of bureaucracy, value-based companies operate and move faster.

Probably no organization is based solely on one or the other, but rather someplace on a continuum, with the better and faster ones being more value-based. Nordstrom is one good example of an organization that leans heavily towards value-based self-governance. For example, Nordstrom's rule is to "Use good judgment in all situations." Employees are encouraged to ask questions from anyone because they believe that all information should be accessible to everyone, regardless of seniority or status.

MOTIVATION AS AROUSAL

A second biological approach to the study of human motivation has been the study of mechanisms that change the arousal level of the organism. Early research on this topic emphasized the essential equivalency of changes in arousal, changes in emotion, and changes in motivation. It was proposed that emotional expressions and the motivation of behaviour are the observable manifestations of changes in arousal level.

One of the earliest arousal theories suggested that one's perception of emotion depends upon the bodily responses the individual makes to a specific, arousing situation. This theory became known as the James-Lange theory of emotion after the two researchers, William James and the Danish physician Carl Lange, who independently proposed it in 1884 and 1885 respectively.

The theory argued, for example, that experiencing a dangerous event such as an automobile accident leads to bodily changes such as increased breathing and heart rate, increased adrenaline output, and so forth. These changes are detected by the brain and the emotion appropriate to the situation is experienced. In the example of the automobile accident, fear might be experienced as a result of these bodily changes.

THE CANNON-BARD THEORY

Walter B. Cannon, a Harvard physiologist, questioned the James-Lange theory on the basis of a

number of observations; he noted that the feedback from bodily changes can be eliminated without eliminating emotion; that the bodily changes associated with many quite different emotional states are similar, making it unlikely that these changes serve to produce particular emotions; that the organs supposedly providing the feedback to the brain concerning these bodily changes are not very sensitive; and that these bodily changes occur too slowly to account for experienced emotions. Cannon and a colleague, Philip Bard, proposed an alternative arousal theory, subsequently known as the Cannon-Bard theory. According to this approach, the experience of an event, such as the automobile accident mentioned earlier, leads to the simultaneous determination of emotion and changes to the body. The brain, upon receiving information from the senses, interprets an event as emotional while at the same time preparing the body to deal with the new situation.

SLEEP PROCESSES AND STRESS REACTIONS

Research on arousal mechanisms of motivation has furthered understanding of both sleep processes and stress reactions. In the case of sleep, arousal levels generally seem lower than during waking; however, during one stage of sleep arousal levels appear highly similar to those in the waking state. Sleep itself may be considered a motivational state. The biological motivation to sleep can become so overpowering that individuals can fall asleep while driving an automobile or while engaged in dangerous tasks.

Five stages of sleep have been defined using the electroencephalograph (EEG). The EEG records the electrical activity of neurons in the outermost portion of the brain known as the cerebral cortex. According to EEG-based findings, everyone cycles through five stages during sleep. A complete cycle averages approximately 90 minutes. The two most interesting stages of sleep from a motivational point of view are stages 4 and 5.

Stage 4 represents the deepest sleep in that the brain-wave activity as measured by the EEG is farthest from the activity seen when a person is awake. The brain-wave pattern is characterized by delta waves, which are large, irregular, and slow; breathing, heart rate, and blood pressure are also reduced. Because the overall activity of the individual in stage 4 is greatly reduced, it has been suggested by some researchers that stage 4 (and perhaps also stage 3) sleep serves a restorative function. However, a potential problem with such an explanation is that stage 4 sleep drops dramatically after age 30 and may be entirely absent in some people aged 50 or over who nevertheless appear to be perfectly healthy. Additionally, studies have shown that in the typical individual physical exhaustion does not lead to increases in stage 4 sleep as might be expected if it were serving a restorative function. The purpose of stage 4 sleep remains unknown.

Stage 5 sleep is also known as rapid eye movement (REM) sleep because during this stage the eyes begin to move rapidly under the eyelids. Interest in stage 5 sleep has been considerable since it was discovered that most, if not all, dreaming occurs during this stage. During stage 5 sleep the EEG pattern of brain-wave activity appears very similar to the brain-wave activity of an awake, alert person. Breathing, heart rate, and blood pressure rise from the low levels observed during stage 4 and can fluctuate rapidly.

In addition to eye movements, fast, small, and irregular brain waves, and autonomic changes indicative of an aroused state, individuals in stage 5 sleep display a large loss in skeletal muscle tone that amounts to a temporary paralysis. Researchers have suggested that the muscle paralysis prevents the "acting out" of our dreams. Another aspect of arousal processes concerns the high levels of arousal leading to a triggering of the stress reaction. The stress reaction can be triggered

by a challenge to the physical integrity of the body, or it can occur as a result of some psychological challenge. Furthermore, the body appears to react in a similar fashion regardless of whether the demands made upon it are physical or psychological.

Hans Selye, a Viennese-born Canadian medical researcher, showed that stressors trigger a chain of processes that begins with what is called the alarm reaction, may proceed to a second stage called the stage of resistance, and, if the stressor has still not been removed, may lead to a final stage called exhaustion.

BIOLOGICAL MONITORING SYSTEMS

For some basic motives such as hunger, thirst, and sex, a biological approach emphasizing regulatory mechanisms has dominated the thinking of researchers. The fundamental premise has been that such basic motives are homeostatically regulated—that is, the nervous system monitors levels of energy, fluid balance, and hormone production (in the case of sex) and alters motivation when these levels deviate too far from some optimum level.

HUNGER

The question of why we eat when we do appears to involve two separate mechanisms. The first mechanism, typically called short-term regulation, attempts to take in sufficient energy to balance what is being expended. It is usually assumed that time between meals and meal size are determined by this short-term mechanism. A second mechanism, called long-term regulation, is directed toward storing away sufficient energy for possible later use should the short-term mechanism fail to adequately replenish energy expended. Energy for long-term use is stored in the form of fat within the fat cells of the body. Short-term regulation processes have generally been assumed to monitor the blood glucose (blood sugar) level and to initiate eating when this level falls below some predetermined optimum. Long-term regulation processes appear to monitor fat levels and to initiate eating when fat stores fall below some optimal level.

THIRST

Processes similar to the physiological control mechanisms of hunger are thought to regulate thirst motivation and sexual behaviour. In the case of thirst, the desire to drink appears to be initiated by fluid loss from within specialized brain cells known as osmoreceptors and also from fluid loss from the area outside of cells, such as from bleeding. Thirst, therefore, would seem to be triggered by mechanisms controlling the fluid integrity both within and around the cells of the body. Cells within the hypothalamus also seem to be involved in the control of thirst motivation.

SEXUAL MOTIVATION

In most animals sexual motivation is under stricter hormonal control than is the case in humans. The female of most species is not interested in sexual behaviour until cyclic hormonal changes produce estrus. The male, however, is usually sexually ready but is prevented from engaging in sexual behaviour by the female until estrus occurs. Research indicates that the anterior (front) portion of the hypothalamus is involved with the estrous cycle of female mammals; it has been demonstrated that destruction of these hypothalamus cells eliminates estrus. Similarly, destruction of the anterior region of the hypothalamus reduces or eliminates sexual behaviour in male rats. According to the arousal theory of motivation, each person has a unique arousal level that is right for them. When our arousal levels drop below these personalized optimal levels, we seek some sort of stimulation to elevate them.

For example, if our levels drop too low we might seek stimulation by going out to a nightclub with friends. If these levels become too elevated and we become overstimulated, we might be motivated to select a relaxing activity such as going for a walk or taking a nap. One of the key assumptions of the arousal theory is that we are motivated to pursue actions that help us maintain an ideal balance. When we become overly aroused, we seek soothing activities that help calm and relax us. If we become bored, we head in search of more invigorating activities that will energize and arouse us. It's all about striking the right balance, but that balance is unique to each individual. Arousal theory shares some commonalities with drive-reduction theory. But instead of focusing on reducing tension, arousal theory suggests that we are motivated to maintain an ideal level of arousal.

AROUSAL LEVELS ARE HIGHLY INDIVIDUAL

Optimal arousal levels vary from one individual to the next. There are many factors that might influence each person's optimal arousal levels, including genetics, experience, and current mood. Your arousal preferences, in general, may be specified by your genetic makeup, but environmental factors can also play a role in how you are feeling at any given moment. One person may have very low arousal needs while another individual might require very high levels.

BEHAVIOR IS MOTIVATED BY AROUSAL LEVELS

The person with low arousal needs might be motivated to pursue simple activities such as crocheting or watching a movie in order to maintain their arousal levels. The individual with high arousal needs, on the other hand, might be motivated to seek risky or thrilling activities such as motorcycle racing or skydiving in order to maintain his or her ideal levels.

IF YOU NEED TO RAISE YOUR AROUSAL LEVELS, YOU MIGHT:

- Engage in physical activity
- Socialize with friends
- Try something new and exciting
- Watch an action-packed movie

IF YOU NEED TO LOWER YOUR AROUSAL LEVELS, YOU MIGHT:

- Enjoy a relaxing hobby
- Read a book
- Take a bath
- Take a nap

No matter what your arousal needs are, you will be motivated to act in order to maintain these levels. If you need more arousal, you will pursue actions designed to raise those levels. If you need less, you will seek out ways to calm down and relax.

AROUSAL INFLUENCES PERFORMANCE

One of the assertions of the arousal theory of motivation is that our levels of arousal can influence our performance. But again, balance is key. Higher arousal levels can sometimes help us perform better, but it can also impair performance if arousal levels are too high. This concept is commonly referred to as the Yerkes-Dodson Law. The law states that increased levels of arousal will improve

performance, but only up until the optimum arousal level is reached. At that point, performance begins to suffer as arousal levels increase. Additionally, if you're doing a complex task, high or low levels of arousal will affect you more than if you're doing something simple.

INCENTIVE MOTIVATION THEORY

The incentive theory of motivation suggests that people are motivated by a drive for incentives and reinforcement. It also proposes that people behave in a way that they believe will result in a reward and avoid actions that may entail punishment. Employees might behave differently in similar situations depending on the incentives available. For example, an employee might work harder on a project to earn a good review or to avoid a poor review than if they don't receive a review at all. Their motivation is their desire to receive a reward or avoid punishment via a performance review at the end of the project.

The value of the same incentive may change depending on the time and circumstance. People may value similar incentives differently. Psychological and social factors can have a role in determining which people have a motivation for different incentives. Incentives only work as motivational tools if individuals place value on the reward they will receive for their actions. Incentives in the workplace, as in other facets of life, can also be positive or negative:

- **Positive incentives:** Provide positive assurance that an employee will receive something they desire in exchange for doing their work well. Examples of positive incentives include recognition, promotions, raises and so forth.
- **Negative incentives:** Correct mistakes or discourage certain behaviors. Negative incentives include reprimands, demotions, pay decreases and other kinds of penalties.

DIFFERENT WORKPLACE INCENTIVES

Monetary and non-monetary are the two main categories of workplace incentives. Monetary incentives are straightforward— many employees work harder if they have a chance to receive a raise or have a higher salary. Financial compensation can be psychologically rewarding, but it also helps employees to feel secure within the company and their roles.

Non-monetary incentives include a range of types:

- Job security
- Recognition
- Professional development
- Promotion

JOB SECURITY

Job security is one form of non-monetary incentive that can motivate people at work. For example, receiving tenure or ending a probationary period can make someone feel more secure and motivated to contribute to the company or organization. Once they feel like their contributions matter, they may work harder to help the business excel. You can reinforce job security by giving annual performance reviews in which you offer positive reinforcement and constructive feedback.

RECOGNITION

Recognition is also an important form of non-monetary workplace incentives. Employers may offer rewards for hard work, achieving a goal or working with the company for so many years. In many

cases, companies offer a monetary reward along with recognition. An employee of the month award is a common recognition that many companies use. Another type of small recognition could include praising an employee during a team meeting. Publicly praising an employee for their hard work can also show other team members the work ethic they should strive to meet.

PROFESSIONAL DEVELOPMENT

Professional development opportunities can also provide incentives to employees. Developing their skills can be an important motivator. Employers may offer tuition reimbursement, send employees to conferences or seminars or develop an in-house training program for developing skills. You could also begin a shadowing program in which employees in your department work with colleagues in another area of the company to learn more about the organizational process.

PROMOTION

The opportunity for promotion is an important workplace motivator. Promotions offer the opportunity for growth and advancement and can be very satisfying and motivating. They also help employees excel in their professional development. When an employee receives a promotion, they usually have a higher sense of job security. Employees usually receive promotions at the same time as a raise.

APPLYING THE INCENTIVE THEORY OF MOTIVATION IN YOUR CAREER

Understanding how your core values affect your motivations can help you excel in your career. Core values are the ideals, beliefs and personal ethics that guide your decision-making process. Determining what your core values are can help you better understand what kinds of incentives you respond best to. You can then use those incentives to motivate yourself into achieving your professional goals. Understanding your core values can also help you find jobs and companies that align more closely with your ideals, which will make you happier and more productive at work.

To identify your core values, consider the following:

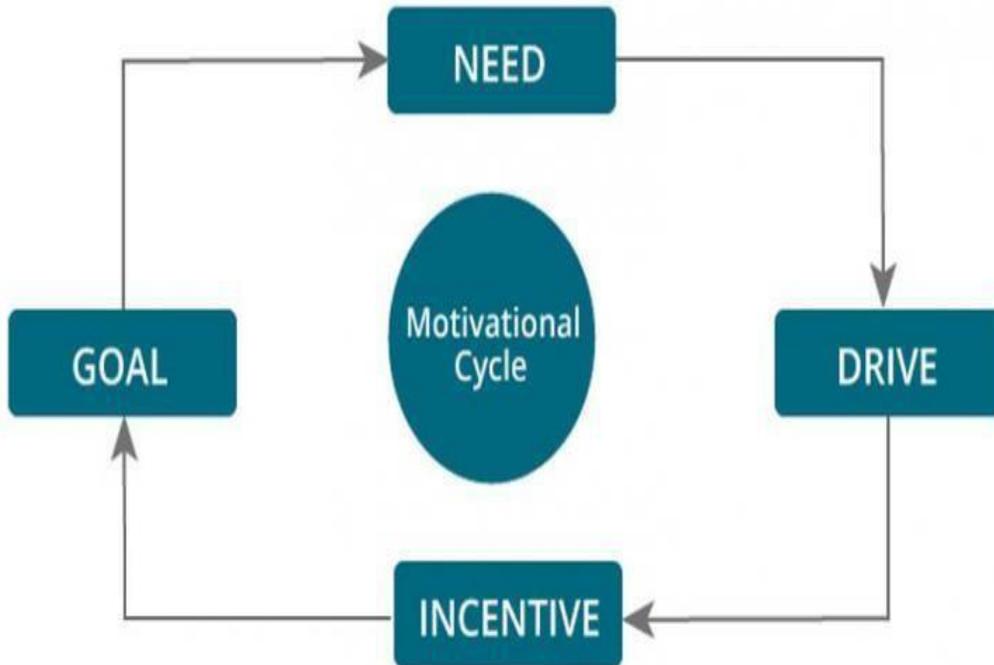

- Your favorite part about your current job
- The aspects of your job that make you happiest
- What you look forward to during your workday

By identifying your core values, you can make adjustments in your work life in response. For example, if you find that you are motivated by non-monetary incentives, you could ask your manager for a promotion or about opportunities offered by the company for professional development.

MOTIVATIONAL CYCLE

Motivation cycle is a transition of states within an organism that propels the organism toward the satisfaction of a particular need, where motivation itself is considered a hypothesized state. Psychologists use the concept of need to describe the motivational properties of behavior. The state of motivation is further comprised of four different states, which takes place in an organism to drive him towards each action. Each action is first initiated because of a particular need. The need drives the person into taking actions. Positive results, caused due to the actions, further acts as an incentive motivating a person towards the goal. But the individual can never stop after achieving a certain goal, and this phenomenon continues on and on. This phenomenon has been termed as Motivational Cycle. the person into taking actions. Positive results, caused due to the actions, further acts as an incentive motivating a person towards the goal. But the individual can never stop

after achieving a certain goal, and this phenomenon continues on and on. This phenomenon has been termed as Motivational Cycle.

NEED

A need is lack or deficit of some necessity. It's a state of physical deprivation that causes tension within an organism. The tension caused when the organism is deprived of basic necessities of life as food, water, and sleep, causes the internal environment of an organism to be imbalanced. The imbalance caused by the need arouses the organism to maintain its balance. For any goal directed behavior, need is the first condition or stimulating factor.

DRIVE

Need leads to drive, which is the second step towards achieving goal. Drive can be defined as the state of tension or arousal produced by need. The drive can also be considered as the original source of energy that activates an organism. For instance, when an organism is hungry and/or thirsty, the organism seeks to reduce this drive by eating and/or drinking. Drive acts as a strong persistent stimulus to push an organism towards its goal. It is the state of heightened tension leading to restless activity and preparatory behavior.

INCENTIVE

The object of the environment that activates, directs, and maintains behavior is called incentive. It can be anything as long as it has either positive or negative value in motivating behavior. The incentive theory rests on the assumption that the behaving organism is well aware of his actions and the consequences received as a result. The theory also understands incentives as the motivation, which a person has to achieve any particular goal object. The motivated behavior is directed towards incentive and getting closer to the incentive provides satisfaction of the aroused drive. For example: behavior like eating food is an incentive that reduces the drive of the person caused by the need to fulfill his hunger. The reduction of behavior then cuts off and restores balance in an organism.

ACCORDING TO HILGARD,

“The incentive is something in the external environment that satisfies the need and thus reduces the drive through consummative activity.”

GOAL

The reduction of tension in the body can be considered as the goal of any motivated behavior. Let's go back to the example of a hungry man. A hungry man eats food, and his body restores to a balanced condition. This then reduces the tension. This reduction of tension as a result of an energized activity is called goal. Once the goal has been completed, the organism is again ready for another goal-motivated behavior.

Goals might be both positive or negative. Positive goals are the ones that an organism tries to attain, such as sexual companionship, food, victory etc. Negative goals are the ones that an organism tries to escape from or avoid, such as embarrassing situations, punishments

These four steps continue on and on throughout the life-course of an organism. Because the needs are never ending, it leads to drive, which then leads to incentive and the goal.

For Example: The motivational cycle of the hungry man is over once when he eats and the goal is satisfied. But, the cycle will restart once the man gets hungry again. The cycle goes on and on only to end at the demise of an organism, at which point, the needs permanently stop. Motivational cycle means that behavior goes on in a sequence. Often times, a single motivated behavior can also fulfill multiple needs.

APPROACHES TO THE STUDY OF MOTIVATION

Two quite different theoretical approaches to human motivation are illustrated by psychoanalytic theory and social learning theory. The psychoanalytic theory of Freud emphasizes two basic drives: sex and aggression. These motives arise in infancy, but their expression is forbidden by parents, and repression occurs. A repressed tendency remains active, however, as an unconscious motive and finds expression in indirect or symbolic ways.

Social learning theory, on the other hand, focuses on patterns of behavior that are learned in coping with the environment; learning may occur through direct reinforcement or vicariously through observing the consequences of behavior modeled by another person. A cognitive process enables a person to foresee probable consequences and to alter behavior accordingly. Self-reinforcement, based on one's own standards of conduct, also provides an important motivational control.

The psychoanalytic and the social learning approaches to human motivation can be illustrated by considering aggression as a motive. Aggression, defined as behavior intended to injure another person or to destroy property, may be primarily hostile-aimed at inflicting injury or instrumental aimed at goals other than the victim's suffering. For Freudian theorists, aggression is an instinct or a frustration-produced drive; for social learning theorists it is a learned response. Evidence indicates that observing aggressive behavior, either live or filmed, is not cathartic; it tends to increase aggressiveness.

The humanistic approach to motivation primarily focuses on the motivation towards self-actualization. Thus Abraham Maslow in his need hierarchy theory places self-actualization at the peak. A minimum level of lower level needs satisfaction has to be attained before one could strive towards self-actualization. Apart from self-actualization, the other needs analysed by him are: need to explore the environment for competence and need to master the environment. Finally the homeostatic approach to motivation is based on behavior directed towards the reduction of tension in the system caused by the deprivation of a need. Thus according to this approach behavior is motivated towards

need- reduction.

THE PSYCHOANALYTIC THEORY OF MOTIVATION

One of the paradigms for the present study of human motivation is Psychoanalytic theory. Before going specifically into the details of the motivational theory, we shall attempt a survey of Psychoanalytic theory. Historical Background of Psychoanalysis Psychoanalysis was one of the most influential theories of 20th century, but it was no less controversial. Both chance and self-determinism played their role in the development of the theory. Chance, because Sigmund Freud, the father of psychoanalysis, had been dragged into the field of psychiatry for personal reasons. Determinism because, Freud's obsessive nature and "penchant for rejecting people who did not totally agree with him" largely determined the history of psychoanalysis (Boeree).

Freud owed influences both to his contemporaries in the field of psychiatry and to the scientific tradition of his time (Burns 70). Freud was born on the 6th of May 1856 in Freiberg in a small town in Moravia- a part of Austria- Hungary. Hailing from a middleclass Jewish family, he graduated in medicine and started his research career involving the dissection of nervous system of eels. Following this, he worked for the next six years in the Psychological Laboratory under Brucke, from where he acquired the outlines of physical sciences in general (Strachey 13). Here he worked on the anatomy of central nervous system.

earnings from laboratory studies, in 1882 he left Brucke and began to work at Vienna General Hospital. In 1885 he started work at Salpêtrière, the famous Parris Hospital for nervous diseases, with Charcot, the then reigning figure in psychiatry. Freud's career with Charcot influenced much of his later theories. In 1886 Freud returned to Vienna and got married. He set up a private clinic there to practise as a consultant for nervous diseases. Charles Darwin in *On the Origin of Species* rejected the special divine status of man, and henceforth mind became a legitimate subject for scientific investigation. The concept of psychic energy governed much of Freud's theories. The channelling out, displacement and sublimation of the energy played a key role in 'defence mechanisms' and neurotic behaviour in Freudian psychoanalysis. These concepts were much influenced by the then emerged notion of 'law of conservation of energy', according to which energy can neither be created nor be destroyed. Freud's application of these principles into his concept of psychic energy led him to the postulation of sublimation and displacement of that energy.

AN OUTLINE OF THE PSYCHOANALYTIC THEORY

The term psychoanalysis has three distinct meanings. Firstly it is a school of psychology, which emphasises psychic determinism and dynamics. As a school of psychology it also emphasises the importance of childhood experiences in moulding one's adult personality and behaviour. Secondly, psychoanalysis, with its emphasis on the role of unconscious in determining human behaviour, is a specialised method for investigating the unconscious mental activities. Finally, psychoanalysis is a therapeutic method for the investigation and treatment of mental disorders, especially the neurotic disorders (Page 179).

It is to be noted that much of psychoanalytic theory was derived from Freud's clinical experience in treating neurotic patients. So the theory focused more on the origin of abnormal behaviour in the formulation of the concept of mind. It is also to be considered that the distinction between sanity and insanity is not that of type but that of degree. The defence mechanisms that serve to compensate for the frustrations of the sane human, in exaggeration lead to the abnormality, of both

neurotic and psychotic. Hence it can be seen that clinical data may not be insufficient for the formulation of a theory of mind.

Motivation—Where There's a Will, There's a
Way

THE PSYCHOANALYTIC THEORY OF MOTIVATION

Freud's psychoanalytic theory offers the most general and well-known conception of the dynamics of motivation. This conception is so vast that it is meaningless to ask whether it is "correct" or "incorrect." Rather, some aspects of the theory have been shown to have reasonable validity, other facets have no empirical support at all, and still other propositions are beyond empirical test. In this chapter Freud's theory of motivation and subsequent modifications introduced by "ego psychologists" are presented. Conceptions devised by other theorists such as Adler, Jung, and Rank are ignored inasmuch as these have had less impact than Freud's ideas and the motivational aspects of these theories are not as clearly formulated. Following a description of the psychoanalytic approach, seven areas of research pertinent to Freud's conception are briefly examined. The research topics are instincts, aggression and catharsis, sexual behavior, dreams, defense mechanisms, delay of gratification, and cognitive styles. The first four of these areas (instincts, aggression, sex, and dreams) primarily pertain to id functioning, while the next grouping (defense, delay of gratification, and cognitive styles) concerns ego-mediated states and processes.

BASIC PRINCIPLES OF FREUD'S THEORY

It is useful to consider Freud's theory within the context of a biological and survival model. Given this viewpoint, which borrows much from Darwin, individuals are conceived as striving to satisfy personal needs within a world of limited and restricted resources. To satisfy these needs, behaviors must be undertaken that will lead to the desired goals. Virtually all such goals are located in the external world. Thus, the individual must adapt to, and function within, the world at hand. For example, consider a psychological analysis of how behavior is governed by the need for food. All organisms have a biological need to ingest food. This need makes itself known to the organism by causing discomfort. There is a limited supply of food in the external world, and organisms must compete for these resources. After the individual engages in the appropriate activities and eats, the internal stimulation and pain (e.g., hunger cramps) that accompany food deprivation cease. The organism then feels satisfied and remains in an unmotivated state or at rest until the onset of new hunger pains. These follow a cyclical pattern, again generating food-relevant behavior.

A SOCIAL-COGNITIVE APPROACH TO MOTIVATION

The task for investigators of motivation and personality is to identify major patterns of behavior and

link them to underlying psychological processes. In this article we.

- (a) describe a research-based model that accounts for major patterns of behavior,
- (b) examine the generality of this model—its utility for understanding domains beyond the ones in which it was originally developed, and
- (c) explore the broader implications of the model for motivational and personality processes. Toward this end, we begin by describing two major patterns of cognition-affect-behavior that we identified in our early work: the maladaptive "helpless" response and the more adaptive "mastery-oriented" response (Diener & Dweck, 1978, 1980; Dweck, 1975; Dweck & Reppucci, 1973).'

The helpless pattern, as will be seen, is characterized by an avoidance of challenge and a deterioration of performance in the face of obstacles. The mastery-oriented pattern, in contrast, involves the seeking of challenging tasks and the maintenance of effective striving under failure. Most interesting, our research with children has demonstrated that those who avoid challenge and show impairment in the face of difficulty are initially equal in ability to those who seek challenge and show persistence. Indeed some of the brightest, most skilled individuals exhibit the maladaptive pattern. Thus it cannot be said that it is simply those with weak skills or histories of failure who (appropriately) avoid difficult tasks or whose skills prove fragile in the face of difficulty. The puzzle, then, was why individuals of equal ability would show such marked performance differences in response to challenge.

Maladaptive Versus Adaptive Patterns: Cognitive, Affective, and Behavioral Components Why are the helpless and the mastery-oriented patterns considered to be maladaptive and adaptive, respectively, and why are they important? The helpless response as a characteristic style can be considered maladaptive because challenge and obstacles are inherent in most important pursuits. Indeed, one might ask, what valued long-term goal (e.g., pertaining to one's work, one's relationships, or one's moral strivings) does not at some point pose risks, throw up barriers, present dilemmas? A response pattern that deters individuals from confronting obstacles or that prevents them from functioning effectively in the face of difficulty must ultimately limit their attainments. The mastery-oriented pattern involves the seeking of challenging tasks and the generation of effective strategies in the face of obstacles. As a characteristic style, this enjoyment of challenge and willingness to sustain engagement with difficult tasks appears to be an adaptive stance toward valued goals. Of course, individuals need to be able to gauge when tasks should be avoided or abandoned (see Janoff-Bulman & Brickman, 1981); nonetheless, the ability to maintain a commitment to valued goals through periods of difficulty must maximize attainments in the long run. As we have noted, the helpless and the mastery-oriented patterns are two distinct, coherent patterns, with striking differences in the cognitions, affect, and behavior that characterize each. Because these patterns lie at the heart of our model, we shall describe them in some detail.

HUMANISTIC THEORY OF MOTIVATION

Humanistic theories of motivation are based on the idea that people also have strong cognitive reasons to perform various actions. This is famously illustrated in Abraham Maslow's hierarchy of needs, which presents different motivations at different levels. First, people are motivated to fulfill basic biological needs for food and shelter, as well as those of safety, love, and esteem. Once the lower level needs have been met, the primary motivator becomes the need for self-actualization, or the desire to fulfill one's individual potential.

WHAT IS EXPLORATORY BEHAVIOR AND CURIOSITY ZUCKERMAN'S SENSATION SEEKING ACHIEVEMENT, AFFILIATION AND POWER MOTIVATIONAL COMPETENCE SELF-REGULATION FLOW?

EXPLORATORY BEHAVIOR AND CURIOSITY ZUCKERMAN'S SENSATION SEEKING ACHIEVEMENT, AFFILIATION AND POWER MOTIVATIONAL COMPETENCE SELF-REGULATION FLOW

Exploratory behavior

EXPLORATION

Exploration is an information-gathering venture (e.g., mouthing and simple manipulation of objects) (Belsky and Most 1983). Through exploration children come to know their environments. Exploration dominates behavior for the first 9 months of life. By 12 months, play and exploration co-occur. By 18 months play accounts for more of the child's interactions with the environment than does exploration (Belsky and Most 1983). Exploration also precedes play to the extent that children of all ages must explore an object, or know its properties, before they can play with it. The knowledge resulting from exploration is basis for play.

EXPLORATORY BEHAVIOR

Exploratory behavior can be defined as behavior directed toward acquiring information about the environment. Exploration is generally considered to be different than simple ambulation, although in practice it is often difficult to completely separate one from the other. Harro (1993) has reviewed some of the common methods used to assess exploratory behavior, including the open field, elevated plus-maze, and hole-board test (which involves the measurement of head-dipping into an array of holes placed in an open field apparatus; see File and Wardill, 1975). It is important to note that behavior in these test situations reflects several factors besides exploration, including ambulatory tendencies and fear of novelty (neophobia).

IDENTITY

Identity exploration is a fundamental developmental task for adolescents and young adults. This exploration entails recognizing and solidifying one's personal interests, values, goals, commitments, and overall sense of self. As part of identity exploration, adolescents often question assumptions and beliefs that they previously took for granted, including beliefs about substance use. Over the past few decades, US youth have increasingly delayed careers, marriage, and parenthood, and as a result, identity exploration extends beyond adolescence and into young adulthood. These years of prolonged exploration are referred to by some as "emerging adulthood."

Although identity exploration is necessary, normal, and healthy, it may sometimes involve experimentation with substance use. Despite the short-term and long-term health risks of the behavior, substance use (and alcohol use in particular) can serve developmental functions such as making friends, testing boundaries of independence, and exploring one's sense of self. Thus, some youth view substance use as a natural pathway to identity formation.

SPATIAL COGNITION IN ANIMALS

Exploratory behaviors in mammals are reactions to novel settings. This is easily observable in a variety of animals, but most experimental work in psychology, for example, has focused on rodents or primates. Both engage in wayfinding activities and reveal specific patterns of movement-related behaviors. In rodents, exploration usually follows a short freezing phase in which the various senses are used to intake available information and evaluate and look for danger. Exploration

follows, and multiple contacts with objects located in the environment take place via the phenomenon of habituation. This is part of a more general process of knowledge acquisition. In settings previously encountered, reexploration or dishabituation occurs. Thus, novelty in an environment exists normally through reference to stored memories of previously explored or familiar places. The key here is that if novelty is detected and exploration behaviors are triggered, this implies that some representation of the initial situation has been constructed. Such exploratory behavior is assumed by neuropsychologists to be an updating activity of the currently stored cognitive map or spatial representation. When experiencing a new environment, a mismatch between what is stored in the cognitive map or spatial representation and what is observed triggers exploration. In this context, spatial cognitive abilities in animals are often evaluated in a reaction-to-change environment, when repeated exposures to a given spatial configuration are followed by habituation or exploration to fix spatial relationships between environmental objects. If an object is displaced, then the spatial arrangement changes. New exploratory activity provides evidence of a mismatch between the new representation or arrangement and a representation (or cognitive map) of the original situation. Spatial processing and learning in animals are often examined via shortcut and detour tasks (e.g., when a learned path becomes blocked and requires some alternate route to be selected to reach a goal).

Much animal wayfinding activity is said to be governed by the process of path integration. This type of activity has often been observed in the behavior of ants, bees, wasps, or other nesting or home-based organisms. Thus, when foraging behavior occurs and food is found, the organism can return in a direct line or shortcut to the home base. Often called dead reckoning, this action is taken to mean that spatial representations occur across species from insects and other invertebrates to mammals. In insects, the spatial representation may be produced as a retinoptic image (or snapshot) compared to the constructed representations of mammals. Homing has been observed in a wide variety of species, including ants, spiders, dogs, bees, wasps, and humans, suggesting that it may involve a similar algorithm for processing route-based information across these different species.

This appears to be true even when the input data vary among the different tasks. For example, day roving species may use visually detected landmarks to correct minor errors in homing. However, when visual cues are not directly available (e.g., in night active rodents), when deprived of any directional reference, or when animals are prevented from using the sun's magnetic field (as when a reflective surface is interposed), they still perform homing tasks successfully, implying that they assess distance and direction through inertial signals from the vestibular system, somatosensory feedback, and motor signals that specify speed of locomotion and change of direction. Vestibular signals are presumed to play a key role in the estimation of rotations but not translations. For day foraging rodents, it has been suggested that dead reckoning is mainly a backup system that allows an animal to explore novel or unfamiliar parts of an environment when access to familiar landmarks is not available.

CURIOSITY AND EXPLORATION

What makes people curious? Why do individuals explore the unknown? The research in these areas is inconclusive and often contradictory. Are curiosity and exploration motivations or drives? Can curiosity and exploration be operationally defined independent of one another? Motivation is defined as the arousal, direction and persistence of behavior (Franken, 1994); an internal state or condition that activates behavior and gives it direction; desire or want, that energizes and directs goal-

oriented behavior; the influence of needs and desires on the intensity and direction of behavior. Drive is defined as a basic or instinctive need; a vigorous effort toward a goal; to cause and guide the movement.

Curiosity is defined as a need, thirst or desire for knowledge. The concept of curiosity is central to motivation. The term can be used as both a description of a specific behavior as well as a hypothetical construct to explain the same behavior. Berlyne (1960) believes that curiosity is a motivational prerequisite for exploratory behavior. The term curiosity is used both as a description of a specific behavior as well as a hypothetical construct to explain the same behavior. Exploration refers to all activities concerned with gathering information about the environment. This leads to the conflict and question of whether exploratory behavior should be defined in terms of the movements that an animal or human performs while exploring or in terms of the goal or purpose of the behavior observed. A clear distinction between these two may not always be possible.

What exactly are curiosity and exploration? Loewenstein (1994) points out four central issues of curiosity: definition and dimensionally, cause, voluntary exposure to curiosity, and situational determinants. He adds a fifth issue of superficiality and intensity since he states that curiosity can arise, change focus or end abruptly. Loewenstein believes that despite its transience, curiosity can be a powerful motivational force. "Curiosity often produces impulse behavior and attempts at self control" (Loewenstein, 1994). Just look at the stories of Pandora and Eve, in which curiosity causes people to expose themselves knowingly to terrible consequences. Langevin (1971) has conducted research in the area of curiosity and classifies measures of curiosity into two categories. First, curiosity is viewed as a motivational state and measured with behavioral indices. Second, he conceptualizes curiosity as a personality trait that is assessed by personality measures. It has been suggested that curiosity is not a unitary construct. At the conceptual level there are numerous definitions of curiosity which tend to encompass a broad range of characteristics. For Fowler (1965), boredom is one prerequisite or motivation for curiosity (exploration).

Curiosity and exploration are difficult to define independently when looking at them from a psychological perspective, the concepts motivation and drive come into play and become intertwined. The underlying problem in using and defining (scientifically and socially) is the circularity of the terms. Roget's Thesaurus says that the absence of curiosity is boredom, ennui, satiety, take no interest, mind one's own business, uninquisitive.

HISTORICAL OVERVIEW OF CURIOSITY & EXPLORATION

The earliest discussions of curiosity were conducted by philosophers and religious thinkers and centered on the question of curiosity's moral status rather than on its psychological underpinnings. Cicero referred to curiosity as a "passion for learning" and argued that the story of Ulysses and the Sirens was really a parable about curiosity. Several forms of curiosity related behavior such as search behavior, movement toward an unknown object and asking questions are included in the area of motivational psychology, however, curiosity does not fit well into the conceptual framework developed along the traditional pathways of behavioral sciences. Firstly, the conception of an intrinsically motivated behavioral system, which cannot be linked to a reducible driver raises serious questions about motivational psychology since the 1950's. The idea of curiosity was rediscovered when laboratory researchers wondered about the maze activities of the lab rat when none of the drive states such as thirst or hunger were aroused. Secondly, Wohlwill (1981) states that the curiosity phenomena cannot be investigated without reference to the natural environment of an individual. Before 1950 curiosity was seen in the light of its social function, for example: the eagerness or

greed to get to know something new for the sake of newness, and in early psychological literature the term curiosity had a negative connotation. The scientific term "curiosity" is more neutral.

The most basic problem that has occupied curiosity researchers and theorists is the underlying cause of curiosity. Is curiosity a primary or secondary drive? A primary drive is inborn or innate whereas a secondary drive is learned or acquired. The research is inconclusive. If secondary, from what more basic drive or motive does it derive? Older theories oriented toward instinct and drive concepts. The defining feature is that curiosity produces an unpleasant sensation (usually labeled arousal) that is reduced by exploratory behavior.

William James (1890) pointed out two kinds of curiosity. He emphasized the biological function of curiosity as a mechanism of instinct driven behavior that serves in approaching new objects. Approach and exploration are described as being characteristic forms of behavior. The second kind of curiosity pointed out by James is "scientific curiosity" and "metaphysical wonder" with which "the practical instinctive root has probably nothing to do" rather "the philosophical brain responds to an inconsistency or a gap in its knowledge".

In the psychoanalytical literature Freud views curiosity as a derivative of the sex drive. The partial impulse of looking motivates the child's great interest in all things and all events that have to do with sexuality. Whereas the looking impulse and curiosity are primarily sexual in origin, the child's exploratory interest and desire for knowledge can be considered to be a by product of cognitive development. Due to social pressure, sexual exploration is later abandoned. Blarer (1951) states that the inhibition of curiosity may result in different forms of pathological behavior, such as depression, and higher levels of sensation-seeking or thrill seeking behavior. Blarer proposed curiosity to be intrinsic to the individual's perceptions and world experiences and thus Blarer is the basis for the intrinsic motivation viewpoint in curiosity theory.

THEORETICAL CONCEPTIONS OF CURIOSITY & EXPLORATION

The postulation of an independent exploratory drive is based on the observation of the exploratory activities of animals in situations where there were no external stimuli to satisfy homeostatic drives (water or food). Nissen (1930) experimented with rats and defines exploratory behavior in two ways 1. as an inborn exploratory drive 2. that curiosity is a secondary or learned drive acquired through classical conditioning. Originally, Berlyne (1954a, 1960) thought that the aversive and drive-reducing effect of deviations of the arousal potential from the individual's optimum level as the underlying mechanism of curiosity. Since then, Berlyne has come to believe that curiosity is externally stimulated, and that the curiosity drive is aroused by external stimuli specifically stimulus conflict. This encompasses complexity, novelty and surprise. Berlyne believed that in the short term, stimulus change and novelty is accompanied by physiological change. However, over longer periods of time, investigating behaviors are not accompanied by readily identifiable physiological changes. Berlyne also holds that exploratory behavior serves to maintain or attain a medium to optimal activation level for the organism. In all cases where exploration takes place, arousal or desire is reduced.

Fiske and Maddi (1961) hold a medium arousal level model and differentiate between the terms arousal and activation. They define arousal as "diverse manifestations of activation, such as muscle tone, heart rate, and increased sensitivity for stimuli". Their definition of activation is "the state of

a catalytic and energizing mechanism in the central nervous system". McReynolds bases his theories of exploratory behavior on animal experiments. Motivational aspects of exploratory behavior, for example: a living being is active in order to receive new perceptual information from its environment, as well as adaptive aspects, for example: a living being is in a situation of stimuli that it must regulate and adapt to. Fowler's (1965) boredom-based perspective interprets curiosity as a homeostatic drive (internally stimulated) since the curiosity drive seems to be both evoked and satisfied by the same stimuli. He attacked Berlyne by noting the inherent contradiction in the view that the curiosity drive was both evoked and satisfied by the same stimuli. Theorists that believe that curiosity is externally stimulated were "forced to ascribe both drive-eliciting and reinforcing properties to the same stimuli- namely the novel stimuli for which the animal responded" (Fowler, 1965). Fowler observed animals producing the exploration- initiating response before, rather than after, exposure to the stimulus.

Hunt (1963) states that curiosity refers to a "motivation inherent in information processing" this means that curiosity is a mixture of cognition and motivation. The main principle, which is equally as important as the drive reduction hypothesis is the establishment and maintenance of an optimal amount of incongruence. Incongruence determines the strength, direction and affective qualities of behavior.

DRIVE THEORIES

Drive theories differ on whether they view curiosity as a primary or secondary drive. Some research has shown that unsatisfied curiosity tends to intensify over some interval as do other drives such as hunger and thirst. Curiosity has a motivated force that is stimulated internally (boredom) or by external stimuli. However, Hebb (1955) believes that curiosity seeking behavior poses a paradox for drive based accounts of curiosity. "Drive is not simply a state the decrease of which is rewarding. At high levels the reduction of drive is rewarding, but at low levels, an increase may be rewarding" (Hebb, 1955).

What is the role of homeostatic drives to curiosity? Harlow states that exploration is an example of human motivation that is independent from homeostatic drives. Harlow's nonhomeostatic intrinsic drive theory has been attacked by drive and learning theorists. Kreitler and Kreitler (1976) have changed positions from the basic assumption of drive theory to a more cognitive process in the development of exploratory behavior.

CURIOSITY & CULTURE

There is evidence for cross-cultural similarities in exploratory behavior (Dragun, 1981). However, cultures generally vary both in attitudes towards exploration and information seeking as well as in the range of situations allowing the expression of the various manifestations of exploration and curiosity, this is especially true for the sensation-seeking motive. Zuckerman (1994) defines sensation seeking as "the seeking of varied, novel, complex and intense sensations and experiences, and the willingness to take physical, social, legal, and financial risks for the sake of such experiences." Berlyne also conducted research on cross cultural comparisons in the area of curiosity. His findings conclude that there is a high similarity of demand characteristics of stimuli in two cultures of widely differing historical antecedents and technological development. Also, different cultures from various geographical regions show evidence for cross-cultural similarities in exploratory behavior. More research is needed to study curiosity behavior in its own cultural context to gain a better understanding of the functional relationships between various environmental and

social facilitators and inhibitors of curiosity in a given society.

ZUCKERMAN'S SENSATION SEEKING

Sensation-seeking, defined as the tendency to seek out varied, complex, novel, and intense experiences, has been recognized as a general personality trait in psychological research since the 1960s. In the past decade, cognitive neuroscience has taken aim at the character trait, hoping to shed light on how the brains of thrill seekers might be wired differently than those who are content with more tame pursuits.

Beyond understanding why one person relishes the fright factor while the next studiously avoids it, scientists are asking how sensation-seeking relates to risky behaviors such as fast driving, drug experimentation, and risky sex, as well as psychiatric disorders ranging from substance use disorder to bipolar disorder—areas where the public-health implications are most clear. The hope is that by understanding the neural mechanisms underlying such behaviors, both at the molecular level and at the systems level, it might be possible to develop therapeutic interventions— pharmacological, behavioral, or neurostimulatory—that might prevent the deleterious effects of risk-taking or help people channel their taste for adventure toward safer pursuits.

NOT ALL SENSATION SEEKING IS THE SAME

It's clear from common experience that there is a huge range of sensation-seeking behavior, and that having an affinity for horror flicks or rollercoasters does not inherently make one a drug user or serial cheater. The late psychologist Marvin Zuckerman, Ph.D., who developed the original sensation-seeking scale in 1964 as part of sensory deprivation experiments, outlined four subtypes representing the various ways sensation-seeking is expressed behaviorally:

1. Thrill & Adventure Seeking: the pursuit of physical activities that are exciting, unusual, and potentially dangerous (e.g., sky-diving)
2. Experience Seeking: stimulation through the mind and senses; the pursuit of unfamiliar and complex environmental stimuli, as through travel or meeting new people.
3. Disinhibition: sensation-seeking through engagement with other people; searching for opportunities to lose inhibitions by engaging in variety in sex, alcohol, drugs, etc.
4. Boredom Susceptibility: the tendency to be easily bored by familiar or repetitive situations or people, or by routine work.

BALANCING REWARD AND IMPULSE CONTROL

Brain-imaging studies have offered some intriguing clues as to how the brain of a high-sensation seeker might be different from that of someone who generally avoids risk, but the answers are far from clear. Much of the work has focused on adolescence, a period when risk-taking is often notoriously elevated, as any parent of a teenager can attest. Adolescence is well recognized as a period of rapid brain changes, as neural systems are pruned and shaped in concert with one's environmental influences to lay the groundwork for adulthood. In this context, sensation-seeking can be and often is adaptive—a means by which learning and experience drive brain development.

"It's part of normal healthy development to be curious and seek out new sensations and

experiences,” says Mary Phillips, M.D., a neuropsychiatric researcher at the University of Pittsburgh School of Medicine. “The problem is if it’s sustained into adulthood and it’s not checked, and, secondly, if online regulatory systems don’t kick in like they should. Then the thrill-seeking gets out of hand and that’s when we run into problems with people developing substance use disorders and other problems.”

Among the prevailing models for explaining why adolescents tend to have a higher propensity for risk-taking is that the brain systems for reward, on the one hand, and impulse control, on the other, are developing along different trajectories. Reward systems in subcortical areas tend to develop first, while cognitive-control systems in the prefrontal cortex don’t fully develop until the early 20s.

“If the two systems are in balance, all is fine and eventually the regulatory systems take control. That’s adulthood,” says Phillips. But in psychiatric conditions such as bipolar disorder, which she studies, the thrill-seeking phase can continue unchecked. “In bipolar disorder, this sensation seeking is not only sustained and intense, but it is truly dysregulated, leading to problems with substance abuse as well as other behaviors that can have really bad outcomes,” she says.

In a series of functional brain imaging studies, Phillips’ research team has zeroed in on two brain regions of interest to reward processing: the ventral striatum, deep in the brain, and the ventrolateral prefrontal cortex (PFC), on the left side of the front brain. The ventral striatum, which includes the nucleus accumbens, is well recognized for its central role in reward learning—but it doesn’t appear to discern the relative value of reward, and requires other regulatory regions of the brain to rein it in, including the ventrolateral PFC.

The team’s 2017 paper reported an indirect pathway linking activity in specific reward-related brain structures to risky behavior in young adults who scored high on a scale of impulsive sensation-seeking. The work—the first to make this tripartite connection among brain system, risky behavior, and sensation-seeking as a trait—opens the door for targeted therapeutic interventions that might prevent or ameliorate deleterious risk taking, including neurostimulation protocols that could tamp down or ramp up brain activity that is too high or too low. The researchers have been testing a therapy using transcranial direct current stimulation, a noninvasive brain stimulation modality, to do just that in a group of young adults at high risk for psychopathology (paper in review). Dozens of other research groups are also investigating neural pathways underlying sensation-seeking and risk-taking in an attempt to localize the brain regions underlying this ubiquitous personality trait. Lauren Sherman, Ph.D., and colleagues at Temple University reviewed 23 brain imaging studies investigating individual differences in brain responses to risky decision making in adolescents from childhood to young adulthood. Somewhat surprisingly, their exhaustive review of the literature found no common neural locus and concluded that “neural factors differentiating riskier teens are not localized to a single region.”

The brain regions identified in the studies, which spanned ten years of cognitive neuroscience, included 25 cortical and subcortical areas. The authors urged researchers to “think outside the brain” in developing more complex models that account for brain as well as environmental factors that interact to make individuals more or less susceptible to risky business.

THE DOPAMINE CONNECTION

Studies of identical twins suggest that heritability accounts for about 60 percent of individual variance in sensation-seeking behavior, and scientists have identified genetic variations that may explain some of these differences. For example, some subtypes of brain receptors for dopamine, the primary neurotransmitter involved in reward processing, are associated with greater sensation-seeking tendencies, while other types appear to have an opposite effect: the fewer there are, the greater the novelty-seeking behavior. The latter may act as brakes on dopamine release, so having fewer of them means that more dopamine is released in response to novelty. This may in turn drive reward-seeking behavior.

The involvement of dopamine in novelty-seeking behavior may also explain the well-established relationship between high sensation-seeking and drug use. High-sensation seekers are more likely than lows to try drugs earlier, to become addicted, and to experiment with multiple drugs. Like drugs of abuse, exposure to novel stimuli releases a rush of dopamine in reward areas of the brain. And, high-sensation seekers often develop a sort of tolerance to high-risk activities—boredom sets in, and they are compelled to add new twists that re-create the initial charge.

EFFECTS OF ACHIEVEMENT MOTIVATION

Motivation is the basic drive for all of our actions. Motivation refers to the dynamics of our behavior, which involves our needs, desires, and ambitions in life. Achievement motivation is based on reaching success and achieving all of our aspirations in life. Achievement goals can affect the way a person performs a task and represent a desire to show competence (Harackiewicz, Barron, Carter, Lehto, & Elliot, 1997). These basic physiological motivational drives affect our natural behavior in different environments. Most of our goals are incentive-based and can vary from basic hunger to the need for love and the establishment of mature sexual relationships. Our motives for achievement can range from biological needs to satisfying creative desires or realizing success in competitive ventures. Motivation is important because it affects our lives everyday. All of our behaviors, actions, thoughts, and beliefs are influenced by our inner drive to succeed.

THE HIERARCHAL MODEL OF ACHIEVEMENT MOTIVATION

Achievement motivation has been conceptualized in many different ways. Our understanding of achievement-relevant effects, cognition, and behavior has improved. Despite being similar in nature, many achievement motivation approaches have been developed separately, suggesting that most achievement motivation theories are in concordance with one another instead of competing. Motivational researchers have sought to promote a hierarchal model of approach and avoidance achievement motivation by incorporating the two prominent theories: the achievement motive approach and the achievement goal approach. Achievement motives include the need for achievement and the fear of failure. These are the more predominant motives that direct our behavior toward positive and negative outcomes. Achievement goals are viewed as more solid cognitive representations pointing individuals toward a specific end. There are three types of these achievement goals: a performance-approach goal, a performance-avoidance goal, and a mastery goal. A performance-approach goal is focused on attaining competence relative to others, a performance-avoidance goal is focused on avoiding incompetence relative to others, and a mastery goal is focused on the development of competence itself and of task mastery. Achievement motives can be seen as direct predictors of achievement-relevant circumstances. Thus, achievement motives are said to have an indirect or distal influence, and achievement goals are said to have a direct or proximal

influence on achievement-relevant outcomes (Elliot & McGregor, 1999).

These motives and goals are viewed as working together to regulate achievement behavior. The hierarchical model presents achievement goals as predictors for performance outcomes. The model is being further conceptualized to include more approaches to achievement motivation. One weakness of the model is that it does not provide an account of the processes responsible for the link between achievement goals and performance. As this model is enhanced, it becomes more useful in predicting the outcomes of achievement-based behaviors (Elliot & McGregor, 1999).

ACHIEVEMENT GOALS AND INFORMATION SEEKING

Theorists have proposed that people's achievement goals affect their achievement-related attitudes and behaviors. Two different types of achievement-related attitudes include task-involvement and ego-involvement. Task-involvement is a motivational state in which a person's main goal is to acquire skills and understanding whereas the main goal in ego-involvement is to demonstrate superior abilities (Butler, 1999). One example of an activity where someone strives to attain mastery and demonstrate superior ability is schoolwork. However situational cues, such as the person's environment or surroundings, can affect the success of achieving a goal at any time.

Studies confirm that a task-involvement activity more often results in challenging attributions and increasing effort (typically in activities providing an opportunity to learn and develop competence) than in an ego-involvement activity. Intrinsic motivation, which is defined as striving to engage in activity because of self-satisfaction, is more prevalent when a person is engaged in task-involved activities. When people are more ego-involved, they tend to take on a different conception of their ability, where differences in ability limit the effectiveness of effort. Ego-involved individuals are driven to succeed by outperforming others, and their feelings of success depend on maintaining self-worth and avoiding failure. On the other hand, task-involved individuals tend to adopt their conception of ability as learning through applied effort (Butler, 1999). Therefore less able individuals will feel more successful as long as they can satisfy an effort to learn and improve. Ego-invoking conditions tend to produce less favorable responses to failure and difficulty.

Competence moderated attitudes and behaviors are more prevalent in ego-involved activities than task-involved. Achievement does not moderate intrinsic motivation in task-involving conditions, in which people of all levels of ability could learn to improve. In ego-involving conditions, intrinsic motivation was higher among higher achievers who demonstrated superior ability than in low achievers who could not demonstrate such ability (Butler, 1999). These different attitudes toward achievement can also be compared in information seeking.

Task- and ego-involving settings bring about different goals, conceptions of ability, and responses to difficulty. They also promote different patterns of information seeking. People of all levels of ability will seek information relevant to attaining their goal of improving mastery in task-involving conditions. However they need to seek information regarding self-appraisal to gain a better understanding of their self-capacity (Butler, 1999). On the other hand people in ego-involving settings are more interested in information about social comparisons, assessing their ability relative to others.

SELF-WORTH THEORY IN ACHIEVEMENT MOTIVATION

Self-worth theory states that in certain situations students stand to gain by not trying and

deliberately withholding effort. If poor performance is a threat to a person's sense of self-esteem, this lack of effort is likely to occur. This most often occurs after an experience of failure. Failure threatens self-estimates of ability and creates uncertainty about an individual's capability to perform well on a subsequent basis. If the following performance turns out to be poor, then doubts concerning ability are confirmed.

Self-worth theory states that one way to avoid threat to self-esteem is by withdrawing effort. Withdrawing effort allows failure to be attributed to lack of effort rather than low ability which reduces overall risk to the value of one's self-esteem. When poor performance is likely to reflect poor ability, a situation of high threat is created to the individual's intellect. On the other hand, if an excuse allows poor performance to be attributed to a factor unrelated to ability, the threat to self-esteem and one's intellect is much lower (Thompson, Davidson, & Barber, 1995).

A study was conducted on students involving unsolvable problems to test some assumptions of the self-worth theory regarding motivation and effort. The results showed that there was no evidence of reported reduction of effort despite poorer performance when the tasks were described as moderately difficult as compared with tasks much higher in difficulty.

The possibility was raised that low effort may not be responsible for the poor performance of students in situations which create threats to self-esteem. Two suggestions were made, one being that students might unconsciously withdraw effort, and the other stating that students may reduce effort as a result of withdrawing commitment from the problem. Regardless of which suggestion is true, self-worth theory assumes that individuals have a reduced tendency to take personal responsibility for failure (Thompson, Davidson, & Barber, 1995).

AVOIDANCE ACHIEVEMENT MOTIVATION

In everyday life, individuals strive to be competent in their activities. In the past decade, many theorists have utilized a social-cognitive achievement goal approach in accounting for individuals striving for competence. An achievement goal is commonly defined as the purpose for engaging in a task, and the specific type of goal taken on creates a framework for how individuals experience their achievement pursuits. Achievement goal theorists commonly identify two distinct ideas toward competence: a performance goal focused on demonstrating ability when compared to others, and a mastery goal focused on the development of competence and task mastery. Performance goals are hypothesized to produce vulnerability to certain response patterns in achievement settings such as preferences for easy tasks, withdrawal of effort in the face of failure, and decreased task enjoyment. Mastery goals can lead to a motivational pattern that creates a preference for moderately challenging tasks, persistence in the face of failure, and increased enjoyment of tasks (Elliot & Church, 1997).

Most achievement goal theorists conceptualize both performance and mastery goals as the "approach" forms of motivation. Existing classical achievement motivation theorists claimed that activities are emphasized and oriented toward attaining success or avoiding failure, while the achievement goal theorists focused on their approach aspect. More recently, an integrated achievement goal conceptualization was proposed that includes both modern performance and mastery theories with the standard approach and avoidance features. In this basis for motivation, the performance goal is separated into an independent approach component and avoidance component, and three achievement orientations are conceived: a mastery goal focused on the development of

competence and task mastery, a performance- approach goal directed toward the attainment of favorable judgments of competence, and a performance-avoidance goal centered on avoiding unfavorable judgments of competence.

The mastery and performance-approach goals are characterized as self-regulating to promote potential positive outcomes and processes to absorb an individual in their task or to create excitement leading to a mastery pattern of achievement results. Performance-avoidance goals, however, are characterized as promoting negative circumstances.

INTRINSIC MOTIVATION AND ACHIEVEMENT GOALS

Intrinsic motivation is defined as the enjoyment of and interest in an activity for its own sake. Fundamentally viewed as an approach form of motivation, intrinsic motivation is identified as an important component of achievement goal theory. Most achievement goal and intrinsic motivational theorists argue that mastery goals are facilitative of intrinsic motivation and related mental processes and performance goals create negative effects. Mastery goals are said to promote intrinsic motivation by fostering perceptions of challenge, encouraging task involvement, generating excitement, and supporting self-determination while performance goals are the opposite. Performance goals are portrayed as undermining intrinsic motivation by instilling perceptions of threat, disrupting task involvement, and creating anxiety and pressure (Elliot & Harackiewicz, 1996).

An alternative set of predictions may be derived from the approach- avoidance framework. Both performance-approach and mastery goals are focused on attaining competence and foster intrinsic motivation. More specifically, in performance-approach or mastery orientations, individuals perceive the achievement setting as a challenge, and this likely will create excitement, encourage cognitive functioning, increase concentration and task absorption, and direct the person toward success and mastery of information which facilitates intrinsic motivation. The performance-avoidance goal is focused on avoiding incompetence, where individuals see the achievement setting as a threat and seek to escape it (Elliot & Harackiewicz, 1996). This orientation is likely to elicit anxiety and withdrawal of effort and cognitive resources while disrupting concentration and motivation.

PERSONAL GOALS ANALYSIS

In recent years, theorists have increasingly relied on various goal constructs to account for action in achievement settings. Four levels of goal representation have been introduced: task-specific guidelines for performance, such as performing a certain action, situation-specific orientations that represent the purpose of achievement activity, such as demonstrating competence relative to others in a situation, personal goals that symbolize achievement pursuits, such as getting good grades, and self-standards and future self-images, including planning for future goals and successes. These goal-based achievement motivation theories have focused almost exclusively on approach forms behavior but in recent years have shifted more toward avoidance (Elliot & Sheldon, 1997).

Motivation is an important factor in everyday life. Our basic behaviors and feelings are affected by our inner drive to succeed over life's challenges while we set goals for ourselves. Our motivation also promotes our feelings of competence and self-worth as we achieve our goals. It provides us with means to compete with others in order to better ourselves and to seek out new information to learn and absorb. Individuals experience motivation in different ways, whether it is task- or ego-based in nature. Some people strive to achieve their goals for personal satisfaction and self-

improvement while others compete with their surroundings in achievement settings to simply be classified as the best. Motivation and the resulting behavior are both affected by the many different models of achievement motivation. These models, although separate, are very similar in nature and theory. The mastery and performance achievement settings each have a considerable effect on how an individual is motivated. Each theorist has made a contribution to the existing theories in today's achievement studies. More often than not, theorists build off of each other's work to expand old ideas and create new ones. Achievement motivation is an intriguing field, and I find myself more interested after reviewing similar theories from different perspectives.

MOTIVATIONAL COMPETENCE

Learning competence motivation theory can help you motivate your team to apply greater effort, be more persistent and take on more challenging tasks. By understanding this learning motivation theory, team leaders or managers can use appropriate praise and feedback to help employees become more motivated in learning new skills. Understanding the nuances of competence motivation and how you can apply it in the workplace can take time and practice. In this article, we explain how competence motivation impacts an employee's performance and share tips for helping employees build high perceptions of competence in the workplace.

COMPETENCE MOTIVATION THEORY

Competence motivation is a theory that centers on the idea that people are driven to engage in activities to develop or demonstrate their skills. If someone successfully performs a challenging task and receives praise from family or peers for it, then they will experience a belief in their competence in that achievement domain—physical, cognitive or social. Success in that domain will help them recognize that they can control their performance. High perceptions of competence and control create feelings of pleasure that maintain or lead to an increase in competence motivation.

BENEFITS OF COMPETENCE MOTIVATION THEORY IN THE WORKPLACE

Employees who are successful when attempting new skills or tasks and receive positive reinforcement will internalize a self-reward system as well as a set of mastery goals. This can have a positive and long-term effect on their confidence. Because they are internalizing their own set of standards, employees will no longer be dependent on others to evaluate their performances or motivate them to continue. Instead, they will be motivated to continue on their own because they recognize they are competent in that area.

People who perceive themselves as highly competent in one area will also demonstrate higher levels of effort and persistence as well as have a preference for more challenging tasks. People who have high levels of competence are also likely to have high levels of self-worth and self-esteem, which can impact every area of their lives, from relationships to employment. By using the right kind of praise and positive reinforcement, you can motivate an employee to want to perform in a way that will bring more praise. The sense of accomplishment the person experiences will provide an additional reward. The employee may also come to define their own mastery goals. Positive reinforcement results in the general sense that you can impact your own circumstances.

HOW TO USE COMPETENCE MOTIVATION IN THE WORKPLACE

Research suggests that when teachers emphasize meaning and individual development in the classroom, children's competence motivation is increased. The same applies to employees in the

workplace. Here are a few ways you can use competence motivation in the workplace right away:

1. Assign tasks that are personally interesting to employees
2. Provide the right kind of feedback
3. Assign tasks that are moderately and appropriately challenging
4. Encourage mastery, skill development and the learning process
5. Encourage challenging but achievable goals
6. Give praise when earned

1. ASSIGN TASKS THAT ARE PERSONALLY INTERESTING TO EMPLOYEES

Employees will be more interested in pursuing mastery of an area if they are personally interested in the topic or task. This will create a kind of peak involvement, where the employee isn't thinking about objectives, rewards or anything else extrinsic. And by being wholly involved in learning, the employee should be more likely to achieve competency in the subject.

2. PROVIDE THE RIGHT KIND OF FEEDBACK

Managers or team leaders can help employees feel in control of their learning and achievements by providing feedback that encourages them to recognize the power they have over what and how they learn. When giving feedback, talk about how far the employee has come since first trying the task. Focus on the process they are using to learn.

3. ASSIGN TASKS THAT ARE MODERATELY AND APPROPRIATELY CHALLENGING

Encourage employees to try tasks that are appropriately challenging for their skill levels. To do this successfully, encourage them to focus on mastery goals, which by nature are always just out of reach. Also, focus on the constructive value of failure and mistakes. This will help you achieve a healthy balance, providing both mental challenges as well as comfort in knowing that occasional errors are okay.

4. ENCOURAGE MASTERY, SKILL DEVELOPMENT AND THE LEARNING PROCESS

Unlike performance goals, which focus on a specific outcome, mastery goals are about mastering a task and being better each day than you were the day before. You never quite reach them because there is always room for improvement. By focusing on mastery, skill development and the learning process, employees in your workplace will be less likely to give up in difficult circumstances and more likely to persevere when experiencing setbacks.

5. ENCOURAGE CHALLENGING BUT ACHIEVABLE GOALS

According to the competence motivation theory, success or mastery of a task can lead to an overall increase in the perception of one's own competence. However, if the person is continually failing at a task or does not receive peer support, it can have the opposite effect. That is why it is essential to encourage challenging but achievable goals. If the goals are too easily achieved, the employee can become bored or even embarrassed by the simplicity of the tasks they are given. Challenging goals are important in a public setting like a workplace.

6. GIVE PRAISE WHEN EARNED

Giving employees praise for growth or increased mastery of a task or skill can help to create a high perception of competence. Praise employees for their hard work, rewarding success

publicly and praising exemplary work throughout your department or organization.

SELF-REGULATION

Self-regulation is the ability to monitor and manage your energy states, emotions, thoughts, and behaviors in ways that are acceptable and produce positive results such as well-being, loving relationships, and learning. It is how we deal with stressors and as such, lays the foundation for all other activity. Developing this ability requires self-awareness, emotional intelligence, efficient filtering of sensory stimulation, coping effectively with stress, relating well to others, and sustaining focus.

SELF-REGULATION AND CHILDHOOD DEVELOPMENT

It is one of the big developmental tasks of childhood. Sometimes, kids develop it naturally from being around self-regulating adults, from playing and exercising, from being in nature, eating healthy foods, and getting plenty of sleep. Other times, however, kids are over-stimulated, around adults who are stressed and/or dys-regulated, and are not getting enough exercise, time outside in nature, sleep, hydration, and healthy food. These kids struggle with attention, learning, impulse control and relationships.

SELF-REGULATION INVOLVES THE WHOLE PERSON/CHILD

What is self-regulation in terms of the whole person or child? This skill involves much more than simply self control. It involves the whole person including these 4 aspects: **Physical**: biology, temperament **Emotional**: personality, exposure to trauma, ability to inhibit impulses, **Mental**: focus, shift of focus, control, management of distractions & frustration **Social**: interpersonal interactions, empathy, values

SELF-REGULATION TAKES ENERGY.

When a child acts out or melts down, it is because s/he has no more fuel for managing stressors. That's why it's important to notice what stresses your children and what soothes them; to teach them mindfulness skills; to play with them; to make sure they get exercise and plenty of sleep. Dr. Stewart Shanker uses a car analogy to explain self-regulation, which is paraphrased below: Self-regulation is like maintaining a consistent rate of acceleration. If we want to go 25 mph, then we will need to adjust the pressure to the accelerator to allow for changes to the road, incline and wind. Driving requires constant changes depending on traffic conditions and speed zones, etc. Learning to accelerate, brake, and change gears smoothly takes time and practice. This is quite similar to children learning to self-regulate. Some children are always pushing too hard on the accelerator, while others jump between gears quickly, and some are slow to accelerate. Children need time and support to master the ability to find and sustain their optimum speed and level of arousal while dealing with a range of stimuli and stressors.

As children develop motor skills and process sensory information they start to understand how their body can move slow, fast and all the speeds in between. Over time, children begin to learn to self-regulate and determine their "just right" body state that is ready to learn. **Too Slow, Just Right or Too Fast – Visual Supports for Self-Regulation** digital document includes 11 visual supports to help children practice self-regulation skills. Use the visual supports to have children practice moving at different speeds to determine their "just right" state. If children have trouble processing sensory information, you can use the visual supports for them to respond and reflect on their current level of arousal.

FLOW THEORY IN PSYCHOLOGY

We all want to experience it. It's intense, exhilarating, and satisfying. When we're in the zone, or what researchers call 'flow,' we feel invisible. The theory behind flow is as popular as ever with researchers investigating its effects in several areas of our lives. They're looking at how flow affects us in sports, art, gaming, learning, and everyday athletics.

Mihaly Csikszentmihalyi (Me-high Cheek-sent-me-high), the researcher who coined the term 'flow' discovered that people who experience flow tend to describe it similarly. There's a feeling of timelessness. The task seems easy and things just "come together." He and his fellow researchers asked participants in their study to use pagers to communicate their thoughts and feelings at various times throughout their day. The initial study involved teenagers and while many reported unhappiness, Csikszentmihalyi noticed that when the teens were engaged in a challenging activity, their answers were more positive. \ This type of tracking is called the Experience Sampling Method in which participants answer a series of questions about their experience at the moment the pager beeps.

Here's how he explains flow and his research. To better understand Flow Theory, we need to know Csikszentmihalyi's perspective regarding consciousness. He believes that we need to control our consciousness which in psychology is defined as: "...the subjective experience of oneself and one's environment. This experience includes the awareness of one's feelings and emotions and the awareness of, and perceived control over, one's thoughts and behaviors." For those familiar with Daniel Kahneman's book, *Thinking Fast and Slow*, we can call this System 2 processing. As this happens, we formulate emotions and thoughts that eventually lead to action or inaction by our bodies. Without System 2, as Csikszentmihalyi (1990) points out, our instincts and reflexes (System 1) would take over.

Another way to look at this is, we need to control how we interpret the events that become a part of our conscious experience. If we do this successfully, then we are more likely to experience greater happiness, and therefore more flow. Researchers at Harvard (2016) believe they've located where consciousness is in our brains. While studying coma patients they discovered a connection between a small part of our brainstem and two cortical regions. When that portion of the brainstem is damaged, a disconnection occurs between the cortical regions. This is important because we need both arousal and awareness in order to experience consciousness. System 1 represents arousal and System 2 is awareness. Think of this as our internal "checks and balances" as we navigate our environment. Flow is the complete immersion in an activity that you deem enjoyable in some way. This doesn't mean that it's not challenging. In fact, the activity must challenge you just enough to push you. Your skills must be tested. Flow activities excite us, provide intrinsic rewards, and help us develop our skills. Flow is a feeling of exhilaration and bliss.

A key component of getting into flow is that we've voluntarily accepted the challenge we're attempting to solve. That's part of what makes it deeply enjoyable. In Csikszentmihalyi's (1990) first edition of **Flow: The psychology of optimal experience**, he identified 9 ways through which we can achieve flow.

- Our bodies: Sex, dancing, and singing are a few examples. Later, Csikszentmihalyi (2008) classifies these as pleasurable, but not necessarily leading to flow.
- Our minds: Pushing ourselves to accomplish a difficult task like solving a math problem leads to

satisfaction and enjoyment.

- Memories: Recalling enjoyable events allows us to relive our experience.
- Contemplating philosophical questions
- Communication: Conveying our thoughts to others and being understood can create a sense of profound enjoyment.
- Writing: This activity brings organization to our thoughts and is therefore enjoyable.
- Lifelong learning keeps us engaged in the activities we enjoy.
- A job: This works especially well if one is able to gamify one's job.
- Solitude: Being comfortable alone with our thoughts can lead to exciting discoveries about the topics we find most enjoyable.

We can experience flow throughout our day, or sadly not at all. It's a choice. That's the beauty of finding flow.

Czikszentmihalyi (2008) also describes the theory as involving nine major components. To experience flow is to experience a sense of euphoria.

THEY ARE:

- The task is just outside our grasp, but we believe we can reach it.
- We're able to focus all of our effort and attention on the task.
- Our goals are clearly defined.
- We receive immediate feedback (which includes course corrections.)
- Our time spent on the task seems effortless to us.
- We feel a sense of autonomy over our actions.
- Our focus isn't on ourselves.
- The experience is timeless.
- The experience is autotelic.

DIFFICULTY ACHIEVING FLOW

- People who have psychiatric disorders like schizophrenia have difficulty because they can't ignore distractions from external stimuli. They're unable to distinguish between relevant and irrelevant information.
- Self-conscious people may lack the confidence necessary to pursue a challenging task.
- Self-centered people may lack the intrinsic motivation needed to doggedly pursue a challenge to completion.
- People who behave in ways that go against their goals (known as alienation) may not establish clearly defined objectives for their tasks.
- People who experience an environment in which the norms aren't clearly defined may become confused.

WHO CAN ACHIEVE FLOW?

The short answer is almost everyone. Even many of the people mentioned above can learn to achieve flow. Czikszentmihalyi (1990) asserts that no one is permanently disadvantaged by their genetics. Young and old can achieve flow. Have you ever watched a child playing a new sport, bumbling about, but then she gets control of the ball and scores? Think of a time when you were focused on an activity you liked. It probably took 15–20 minutes for you to get into "your zone," but once you did, what happened? Maybe you were writing a short story or immersed in your favorite video game. Did you lose track of time? Did your writing come more easily to you? Were you able to

reach higher and higher levels more rapidly?

People who experience flow regularly tend to be able to ignore irrelevant stimuli in their environments and enjoy themselves in a variety of situations because of their ability to filter. They also have more control over their thoughts. These individuals pay close attention to details which often helps them identify opportunities to act, set goals, gain feedback, and go after bigger challenges

FLOW AND HAPPINESS

The connection of flow to happiness is an important one. In his book, Csikszentmihalyi sums it up this way: "One of the most frequently mentioned dimensions of the flow experience is that, while it lasts, one is able to forget all the unpleasant aspects of life." Mihaly Csikszentmihalyi, *Flow: The Psychology of Happiness* Rogatko (2009) studied positive affect (PA) in a group of undergraduate college students in Japan. The objective was to determine if a causal relationship existed between PA and flow. Students were assigned to either a low or high flow activity. The results support the theory that flow leads to PA. The pursuit of flow experiences is the pursuit of happiness, but this happiness is eudemonic in nature, not hedonic.

It's important to note that a single flow experience doesn't automatically lead to other flow experiences, but for someone who has a clearly defined goal it can. If the goal is challenging enough and other goals flow from it, then it's more likely that the person will have more flow experiences in various areas of her life. Csikszentmihalyi (1990) calls this a "unified flow experience." This means that the person is devoting all of her energy to acquiring the skills necessary to achieve the larger goal. This puts her thoughts, feelings, and actions into harmony. Everything she does fits into her larger goal whether it's in the present moment or upon review of past events, actions, and experiences.

FLOW AND POSITIVE PSYCHOLOGY

The study of flow falls within the area of happiness in Positive Psychology research. There are numerous topics covered in positive psychology including resilience, creativity, positive emotions, strengths, and mindfulness. The researcher's focus is driven by and concerned with how human beings thrive. Positive psychology researchers study how people lead meaningful and fulfilling lives.

Steven Kotler and Jamie Wheal are two men on a mission to explore the boundaries if there are any, of flow. They're immersing themselves in the subject and working with several organizations and businesses to study ultimate human performance.

10 EXAMPLES OF FLOW IN PSYCHOLOGY

The number of examples one could list is very long. Here are several to spark your thinking.

- A graphic artist creating a website illustration or logo
- A writer completing a 2000-word scene in an hour
- A musician composing a song while commuting to work on a subway
- A skier navigating a challenging downhill course seemingly effortlessly
- The creation of a soufflé by a chef
- Solving a Rubik's Cube
- A pool player performing trick shots
- A pool player sinking all of their balls before their opponent steps up to shoot
- An hapkidoist executing expert joint locks

- A student studying for finals wearing noise-canceling headphones

FLOW STATE IN SPORTS PSYCHOLOGY

This is perhaps one of the most widely studied areas in positive psychology. How and when do athletes get “in the zone?” Most research is conducted using self-report surveys and the Experience Sampling Method (ESM) mentioned earlier and originally developed by Csikszentmihalyi. Researchers have found a significant, positive relationship between intrinsic motivation and flow state among athletes. They’ve also learned that extrinsic motivation doesn’t significantly predict flow state (Kauffman, Soulliard, Perry, Montgomery, Hansen, Merz, & Ross, 2017).

Athletes and coaches want to find ways to get into flow faster and sustain the experience longer. This video provides useful information about flow, athletic performance, and a tool that could be used. (This isn’t an endorsement for their product. It’s simply an example of what could happen in the near future for athletes.)

MOTIVATION AND FLOW THEORY

Extrinsic motivation can be thought of as the “carrot and stick” approach to engagement in a task. Its effects are fleeting. As long as the person receives a reward and avoids a negative outcome, it works, but it does little to develop intrinsic motivation. A prerequisite of attaining flow is voluntary engagement in a task that the person finds enjoyable. For tasks that are neither completely voluntary or enjoyable, the person may only work for satisfaction derived from external rewards. When we’re in flow, we experience intrinsic motivation. We do whatever the task involves simply because it interests us, is enjoyable, provides a level of challenge that nearly matches our current skills, and for which we’re receiving immediate feedback.

Have you ever done a job and thought, “I’d do this even if they didn’t pay me?” You might be experiencing consistent and constant flow in that job. The satisfaction from doing the work motivates you to continue. You don’t need or care about recognition. It’s all about the work.

A LOOK AT FLOW THEORY IN EDUCATION

A survey conducted by **Youth Truth** between 2012-2017 that included 230,000 students in grades three through twelve, indicated that the majority of students feel engaged at school. Sixty-eight percent of students in small schools (200 middle school – 300 high school students) reported being engaged compared to fifty-seven percent in large schools (800 middle school – 1200+ high school). Smaller school size is associated with lower dropout rates, higher GPAs, better attendance, and higher graduation rates. While numbers varied depending on level (elementary students were most engaged and high school students least) this is great news for flow researchers. An engaged student population is likely to experience more moments of flow.

THE EFFECT OF FLOW ON LEARNING

The idea of overlearning a task relates to flow. If you recall from the video above, our brains love repetition. That’s essentially what overlearning a task is, and when we do a thing repeatedly for a period of time, we’re more likely to experience flow. Let’s return to those gaming researchers – rather than use the usual questionnaires and scales, some researchers are beginning to use EEG machines to objectively study what’s happening in the student’s brain while engaged in an educational gaming activity. This is because self-reports are subjective. One of the objectives of researchers in this field is to create a flow environment. They want to know if a student can be guided into a

flow experience. It's not simply to determine if students experience flow while playing the game. When we're in flow, our learning speeds up.

TAKE THIS EXAMPLE:

Researchers wanted to know the effect of flow on EFL learners' vocabulary acquisition. They used the "Flow Perceptions Questionnaire," to assess if a relationship existed. Their results indicated that flow existed in the classroom and that there was a significant relationship between the level of flow, and vocabulary retention in immediate and delayed measurements (Amini, Ayari, & Amini, 2016).

ARE OPEN-PLAN SCHOOLS HURTING STUDENTS' ABILITY TO ACHIEVE FLOW?

Given what research tells us about the negative effects of open-office designs, how does this affect students in a similar environment? Does flow become disrupted in open classroom designs, or does it encourage flow for students and teachers? There's been a resurgence of open-plan school designs in the past few years in the US and elsewhere. Proponents believe the closed classroom concept is archaic and that children need to be able to explore and learn at their own pace. Opponents point to research like what's been mentioned in this article that shows the detrimental effects of open floor plans. The most commonly studied issue is noise. Shield, Greenland, and Dockrell (2010) reviewed research spanning a 40-year period specifically related to this concern. The primary issue is noise coming from adjacent classes. They cite the need to install proper acoustic materials, the use of partitions, and coordinating with other teachers to minimize distraction.

WHAT IS EMOTIONS: PHYSIOLOGICAL CORRELATES THEORIES OF EMOTIONS: JAMES-LANGE, CANON-BARD, SCHACHTER AND SINGER, LAZARUS, LINDSLEY. EMOTION REGULATION?

EMOTIONS: PHYSIOLOGICAL CORRELATES THEORIES OF EMOTIONS: JAMES-LANGE, CANON-BARD, SCHACHTER AND SINGER, LAZARUS, LINDSLEY. EMOTION REGULATION

Emotions: Physiological correlates

According to most recent theories, human emotion is intrinsically tied to the concomitant activity of the autonomic nervous system. Empirical research has put forth an increasing number of indicators of physiological activity which are considered to be relevant for discriminating between specific subtypes of emotions (for a review, see Kreibig, 2010). One physiological indicator related to strong emotional experience is piloerection. In Charles Darwin's seminal work on "The Expression of the Emotions in Man and Animals" (1872), he already acknowledged that "hardly any expressive movement is so general as the involuntary erection of the hairs, feathers and other dermal appendages" (p. 95).

Piloerection, on the one hand, is known as a response to cold as a primary physical elicitor. In animals, the erection of coat hair or feathers serves to increase the isolation layer of air around the body. In humans, piloerection in response to cold is considered as a relic of the thermoregulatory response of our furred ancestors in evolution (Campbell, 1996). On the other hand, piloerection is also known as a response to strong psychological elicitors. In animals, it can be observed in states of anger or anxiety (Darwin, 1872), but it was also observed in the course of courtship of male chimpanzees (Nishida, 1997). In humans, the study of emotional piloerection (i.e., goose bumps) is tightly linked to the study of chills or thrills. While piloerection actually denotes the visible erection of body hair, the phenomenon of chills or thrills usually relates to a subjective experience.

This subjective experience is sometimes described by the sensation of 'shivers down the spine' and it was found to be a necessary but not sufficient concomitant of visible piloerection (Craig, 2005). However, it should be noted that piloerection and chills are sometimes also found to be used interchangeably in the scientific literature. Psychophysiological correlates of subjectively reported piloerection Music is also the most common stimulus in the study of psychophysiological correlates of piloerection-evoking experiences. Rickard (2004) compared emotionally powerful music (i.e., individually selected moving and personally meaningful music) to arousing music (i.e., music pre-selected to elicit high subjective and physiological arousal).

He showed that emotionally powerful music elicited more subjective responses of chills and higher skin conductance level (SCL), whereas the conditions did not differ significantly with respect to heart rate (HR) or skin temperature (ST). Craig (2005) found that music sections containing reports of chills were associated with higher skin conductance response (SCR) amplitudes than sections preceding or following chills, but not with changes in ST. Guhn et al. (2007) identified music passages apt to elicit chill responses and found that participants who actually reported experiencing chills showed higher SCR amplitudes than those who did not; the groups did however not differ with respect to HR. Grewe et al. (2009) found that music episodes which elicited subjective reports of chills were associated with increases in SCR amplitude, SCL, and HR but with no difference in respiratory rate (RR). In a similar study, Salimpoor et al. (2009) showed that music episodes which elicited subjective reports of chills resulted in higher SCL, HR, RR, and lower blood volume pulse amplitude and ST as compared to matched neutral episodes. In a positron emission tomography (PET) study, Subject-Selected music, which reliably elicited subjective reports of chills, was compared to music that elicited chills in others (Blood and Zatorre, 2001). Chill music was associated with higher HR and RR but with no significant difference in electrodermal measures or ST. Moreover, cerebral blood flow related to chill intensity showed a pattern typical for processes involved in reward, euphoria and arousal, including ventral striatum, midbrain, amygdala, orbitofrontal cortex, and ventral medial prefrontal cortex.

COGNITIVE THEORIES OF EMOTIONS:

Two-Factor Theory The two-factor theory of emotion states that emotions are interactions of

- (1) physiological arousal and
- (2) the cognitive label that we apply to explain the arousal.

To demonstrate the two-factor theory, Schachter and Singer gave participants an injection of epinephrine that increases blood pressure, heart rate, blood flow to the brain, blood sugar levels and respirations. This was an artificial physiological arousal. Participants were given one of three explanations about the injection.

- correctly informed of the effects, or
- some were misinformed of the effects, or
- some were not informed at all.

All participants had a change in physiological arousal. What label do people ascribe to this arousal?

- Those who were informed about the injection would understand their physiological changes and need not explain this arousal with an emotional response.
- Those who had no explanation (the misinformed and uninformed group) for their physiological changes would use environmental cues to understand their arousal and explain it with an emotional response (e.g. happiness)

Misattribution of Emotional States According to the two-factor theory, when we are physiologically aroused, we try to understand the arousal and attribute it to emotions. In some instances, we misidentify the source and cause of our emotions. This process is unconscious and automatic. When people are physiologically aroused while riding an exercise bike, or

- o They find attractive people more attractive
- o Annoying people more annoying
- o Funny cartoons funnier

When people were physiologically aroused by walking over a bridge high above the ground (left panel), an interviewer they encountered was rated as more attractive compared to a bridge closer to the ground (right panel).

SITUATIONAL DETERMINANTS OF AGGRESSION:

Heat Media Violence Violent video games There are higher rates of violent crimes, but not non-violent crimes, as the number of days above 90 degrees Fahrenheit increase. This relationship still held when you took into account unemployment rates, per capita income and average age of the residents.

EXAMPLES OF SCARCITY:

- When Dade county banned phosphate based soaps, citizens smuggled phosphate soaps in from neighboring counties. They claimed that the phosphate based soaps cleaned their laundry better, and made their clothes smell fresher.
- Music by Kurt Cobain, Elvis, The Doors is valued more after their deaths.
- Paintings by Van Gogh, Monet, Picasso are valuable because they are scarce.
- Fantastic Four #1, X-men #94 or Spider-Man #1 are more expensive comic books because there are very few copies of them compared to later issues.
- The subjective value of Cabbage Patch dolls, Tickle me Elmo, and Play Station 2, Wii were inflated when the demand was high and the availability is low.
- In the Scientific American Frontiers video Fat and Happy, children are more likely to binge on junk food when they are provided the opportunity if they are restricted at home.
- A person who sells a used car, stereo, refrigerator, etc. can make the item appear "scarce" by scheduling people to view the item at the same time.

STUDENT EXAMPLES OF SCARCITY

I have a friend who finds he only wants to date women that are already married or have a serious boyfriend. It is like he becomes obsessed with trying to go out with them. Every once and a while a woman will break up with her boyfriend and start to date him, but then he finds them unappealing; there is no longer a challenge for him. They become too convenient.

THE CANNON-BARD THEORY OF EMOTION

The Cannon-Bard theory of emotion, also known as the Thalamic theory of emotion, is a physiological explanation of emotion developed by Walter Cannon and Philip Bard. Cannon-Bard theory states that we feel emotions and experience physiological reactions such as sweating, trembling, and muscle tension simultaneously.

HOW THE CANNON-BARD THEORY WORKS

More specifically, it is suggested that emotions result when the thalamus sends a message to the brain in response to a stimulus, resulting in a physiological reaction.¹ For example: I see a snake --> I am afraid, and I begin to tremble. According to the Cannon-Bard theory of emotion, we react to a stimulus and experience the associated emotion at the same time. The physical reactions are not dependent upon the emotional reaction, or vice versa.² When an event occurs, the thalamus transmits a signal to the amygdala. The amygdala is a small, oval-shaped structure in the brain that plays an important role in emotional processing, including emotions such as fear and anger. The thalamus also sends signals to the autonomic nervous system, resulting in physical reactions such as muscle tension, shaking, and sweating.

EXAMPLES

You can see how the Cannon-Bard theory might be applied by looking at any experience where you have an emotional reaction. While you might immediately think of negative emotional responses, it also applies to positive emotions as well.

A FRIGHTENING EXPERIENCE

For example, imagine that you are walking to your car through a darkened parking garage. You hear the sounds of footsteps trailing behind you, and spot a shadowy figure slowly following you as you make your way to your car. According to the Cannon-Bard theory of emotion, you will experience feelings of fear and physical reaction at the same time. You will begin to feel fearful, and your heart will begin to race. You rush to your car, lock the doors behind you, and rush out of the parking garage to head home.

A NEW JOB

Imagine that you are starting a new job. Your first day can be stressful. You'll be meeting new co-workers, making first impressions, learning more about your role, and participating in training or meetings. Cannon-Bard theory suggests that you would experience both physical and emotional signs of stress simultaneously. You might feel nervous and experience an upset stomach.

A DATE

Imagine that you are going on a date with someone you recently met. You really like this person and are excited to spend time with them. You experience both physical and emotional responses, including feelings of happiness and excitement as well as sweaty palms and a rapid heartbeat.

JAMES-LANGE THEORY

Cannon-Bard theory was formulated as a reaction to the James-Lange theory of emotion. Where James-Lange theory represented a physiological explanation for emotions, the Cannon-Bard theory represents a neurobiological approach. William James's theory suggested that people first experience a physiological reaction in response to a stimulus in the environment. People then experience some sort of physiological reaction to this stimulus which is then labeled as an emotion. For example, if you encounter a growling dog, you might begin to breathe rapidly and tremble. James-Lange theory would then suggest that you would label those feelings as fear.

Cannon's work instead suggested that emotions could be experienced even when the body does not reveal a physiological reaction. In other cases, he noted, physiological reactions to different

emotions can be extremely similar. Cannon and Bard instead suggested that the experience of emotion was not dependent upon interpreting the body's physiological reactions. Instead, they believed that the emotion and the physical response occur simultaneously and that one was not dependent upon the other.

SCHACTER-SINGER THEORY

Another more recent theory is the Schacter-Singer theory of emotion (also known as two-factor) theory, which takes a cognitive approach. The Schacter-Singer theory draws on elements of both James-Lange theory and Cannon-Bard theory, proposing that physiological arousal occurs first but that such reactions are often similar for different emotions. The theory suggests that the physiological reactions must be cognitively labeled and interpreted as a particular emotion.

CRITICISMS

Criticisms suggest that Cannon-Bard theory places too much emphasis on the role that the thalamus plays in emotions while largely ignoring other parts of the brain. The thalamus is part of the limbic system and does play an important part in the experience of emotions, but more recent research suggests that the process is more complex than the Cannon-Bard theory suggests. The basic assumption of Cannon-Bard theory, that physical reactions do not lead to emotions, has been refuted by a number of studies. Research has shown that when people are asked to make a particular facial expression, such as frowning or smiling, they are more likely to also experience an emotion connected to that expression.

KEY TAKEAWAYS

Key Points

- The appraisal theory of emotion proposes that emotions are extracted from our “appraisals” (i.e., our evaluations, interpretations, and explanations) of events. These appraisals lead to different specific reactions in different people.
- Psychologist Magda Arnold made early advancements in appraisal theory, proposing that an initial appraisal begins the emotional sequence by arousing both the appropriate physiological reactions and the emotional experience itself.
- In 1991, psychologist Richard Lazarus built on appraisal theory to develop cognitive-mediation theory. This theory still asserts that our emotions are determined by our appraisal of the stimulus, but it suggests that immediate, unconscious appraisals mediate between the stimulus and the emotional response.
- Lazarus also distinguished between primary appraisal, which seeks to establish the significance or meaning of an event, and secondary appraisal, which assesses the ability of the individual to cope with the consequences of the event.

RICHARD LAZARUS

Psychologist Richard Lazarus (1991) adapted Arnold's work slightly in the development of his cognitive-mediation theory, which asserts our emotions are determined by our appraisals of stimuli. This appraisal mediates between the stimulus and the emotional response, and it is immediate and often unconscious. In contrast to the Schacter-Singer theory of emotions, which views emotion as an outcome of the interaction between physiological arousal and cognition, Lazarus argued that the appraisal precedes cognitive labeling, simultaneously stimulating both the physiological arousal and the emotional experience itself.

Lazarus argued that the cognitive activity involved in interpreting emotional context could be conscious or unconscious and may or may not take the form of conceptual processing. He stressed that the quality and intensity of emotions are controlled through cognitive processes, which mediate the relationship between the person and the environment through coping strategies, which in turn are the basis of the emotional reaction.

In his research, Lazarus specified two major types of appraisal methods: 1) primary appraisal, which seeks to establish the significance or meaning of an event, and 2) secondary appraisal, which assesses the ability of the individual to cope with the consequences of the event. In the specific context of emotion and stress, Lazarus described primary appraisals as judgments about the degree of potential harm or threat to well-being that a stressor might introduce. The perception of a threat then triggers this secondary appraisal—judgment of the options available to cope with the stressor—as well as perceptions of how effective such options will be.

EMOTION REGULATION

While there are many ways to influence one's emotional state for the better, emotion regulation often involves what experts call "down-regulation," or reducing the intensity of emotions. A grieving person might down-regulate his sadness by recalling something amusing. An anxious person may cope by distracting herself from the thought that is causing her anxiety. Emotion regulation can also include "up-regulation," or amping up one's emotions, which can be useful when an imminent danger or challenge calls for a healthy dose of anxiety or excitement. The process model of emotion regulation proposed by psychologist James Gross emphasizes that people can act to control their emotions at different points in time—including before they feel an emotion ("antecedent-focused emotion regulation") and after they have already begun to react emotionally ("response-focused emotion regulation").

EMOTION REGULATION IS IMPORTANT

Unlike small children, adults are expected to be able to manage their emotions—especially anxiety and anger—in a manner that is socially acceptable. When emotional control fails, people often say or do things they later regret and wish they had been able to keep their emotions in check. Emotion dysregulation is a component of certain forms of mental illness. Over time, it could have a negative impact on one's personal well-being and social relationships.

EMOTION DYSREGULATION

"Emotion dysregulation" is the term used to describe an inability to regularly use healthy strategies to diffuse or moderate negative emotions. While all people occasionally use less than ideal emotion regulation strategies, individuals who regularly experience what feels like overwhelming, intense negative emotions are much more likely to rely on unhealthy strategies, like self-injury. What causes emotions to feel so overwhelming? It is really important to note that the experience of an emotion per se is not what leads to difficulties. It is the interpretation of this emotion that tends to ratchet up feelings and a sense of not being able to tolerate them. We call this a "vicious emotional cycle." Emotions, thoughts, and our behavior are all linked together.

For instance, consider this common scenario: A friend walks right past you in the hallway without acknowledging you and you immediately have a rapid fire set of feelings, like confusion or disappointment or self-doubt or anger, that turns quickly into a series of thoughts about that event (e.g., "What did I do wrong?" "I'll bet that she is mad at me for that thing that happened a few weeks

ago...""I am sure it was nothing, I am being oversensitive, she was probably in a hurry somewhere. But still..."). This initial cascade can lead to intense or acute feelings (e.g., frustration, panic, insecurity) and you may have a strong desire to not be feeling the negative feelings coming up. This desire turns into action: you do something (e.g., go home and dwell on it; stop communicating with your friend; get a tasty treat to make you feel better or take your mind off it). Sounds familiar?

This cycle can become vicious and/or a typical go-to pattern over time. Unless something is done to change the cycle, continued avoidance of the feelings associated with that friend or event may lead to additional negative thoughts and feelings about that person. This further supports one's initial interpretation of the event and can then lead to even more negative thoughts and feelings (e.g. "Our friendship is ending; she never really liked me anyway. What will happen if she shares what she knows about me to others? Will I lose more friends?? Oh no, it is all happening again!"). It is easy to see how even a small event can cascade into something hugely triggering. This cycle can be even more intense when the events that occur are more serious or somehow tie into earlier negative experiences, like trauma or abuse.

WHAT IS CONFLICTS: SOURCES AND TYPES

Stress and Coping: Concept, Models, Type A, B, C, D behaviors, Stress management strategies [Biofeedback, Music therapy, Breathing exercises, Progressive Muscular Relaxation, Guided Imagery, Mindfulness, Meditation, Yogasana, Stress Inoculation Training]?

CONFLICTS: SOURCES AND TYPES

Stress and Coping: Concept, Models, Type A, B, C, D behaviors, Stress management strategies [Biofeedback, Music therapy, Breathing exercises, Progressive Muscular Relaxation, Guided Imagery, Mindfulness, Meditation, Yogasana, Stress Inoculation Training]

STRESS AND COPING: CONCEPT, MODELS, TYPE A, B, C, D BEHAVIORS,

Conflicts are natural in all walks of daily life – both at workplace and home. Thus, conflict is ever present and both charming and maddening. But conflict is a complex and big subject. There are many sources of conflict. Conflict occurs when individuals or groups are not obtaining what they need or want and are seeking their own self-interest. Sometimes the individual is not aware of the need and unconsciously starts to act out. Other times, the individual is very aware of what he or she wants and actively works at achieving the goal. It would be better to identify conflict at an early stage and come to an understanding.

The concept of conflict is controversial. Psychologists and sociologists have given different meanings. It is being defined as a process by few, an obstructive behavior, and goal incompatibility by others. Conflict can be expressed as: Conflict is a process, where perception (real or otherwise) leads to disruption of desirable state of harmony and stability in an interdependent world.

CHARACTERISTICS OF CONFLICT:

1. Conflict is a Process:

Conflict occurs in 'layers'. First layer is always misunderstanding. The other layers are differences of values, differences of viewpoint, differences of interest, and interpersonal differences. It is also called a process because it begins with one party perceiving the other to oppose or negatively affect its interests and ends with competing, collaborating, compromising or

avoiding.

2. CONFLICT IS INEVITABLE:

Conflict exists everywhere. No two persons are the same. Hence they may have individual differences. And the differences may be because of values or otherwise, lead to conflict. Although inevitable, conflict can be minimized, diverted and/or resolved. Conflict develops because we are dealing with people's lives, jobs, children, pride, self-concept, ego and sense of mission. Conflict is inevitable and often good, for example, good teams always go through a "form, storm, norm and perform" period.

3. CONFLICT IS A NORMAL PART OF LIFE:

Individuals, groups, and organisations have unlimited needs and different values but limited resources. Thus, this incompatibility is bound to lead to conflicts. The conflict is not a problem, but if it is poorly managed then it becomes a problem.

4. PERCEPTION:

It must be perceived by the parties to it, otherwise it does not exist. In interpersonal interaction, perception is more important than reality. What we perceive and think affects our behaviour, attitudes, and communication.

5. OPPOSITION:

One party to the conflict must be perceiving or doing something the other party does not like or want.

6. INTERDEPENDENCE AND INTERACTION:

There must be some kind of real or perceived interdependence. Without interdependence there can be no interaction. Conflict occurs only when some kind of interaction takes place.

7. EVERYONE IS INFLICTED WITH CONFLICT:

Conflict may occur within an individual, between two or more individuals, groups or between organisations.

8. CONFLICT IS NOT UNIDIMENSIONAL:

It comes into different ways in accordance with degree of seriousness and capacity. At times, it may improve even a difficult situation.

CONCEPT OF CONFLICT MANAGEMENT:

'Conflict management is the principle that all conflicts cannot necessarily be resolved, but learning how to manage conflicts can decrease the odds of non-productive escalation. Conflict management involves acquiring skills related to conflict resolution, self-awareness about conflict modes, conflict communication skills, and establishing a structure for management of conflict in your environment.' All members of every organisation need to have ways of keeping conflict to a minimum – and of solving problems caused by conflict, before conflict becomes a major obstacle to your work.

TYPES OF CONFLICT:

Conflicts can be of different types as described below: On the basis of involvement:

Conflicts may be intrapersonal (conflict with self), interpersonal (between two persons) and

organisational. Organizational conflict, whether real or perceived, is of two types -intraorganizational and interorganizational. Interorganizational conflict occurs between two or more organizations.

Different businesses competing against each other are a good example of interorganizational conflict. Intraorganizational conflict is the conflict within an organization, and can be examined based upon level (e.g. department, work team, individual), and can be classified as interpersonal, intragroup and intergroup.

Interpersonal conflict- once again- whether it is substantive or affective, refers to conflict between two or more individuals (not representing the group of which they are a part of) of the same or different group at the same or different level, in an organization. Interpersonal conflict can be divided into intergroup and intragroup conflict. While the former— intragroup- occurs between members of a group (or between subgroups within a group), intergroup- occurs between groups or units in an organization.

ON THE BASIS OF SCOPE:

Conflicts may be substantive and Affective. A substantive conflict is associated with the job, not individuals, while an affective conflict is drawn from emotions. Substantive conflicts may be over the facts of a situation, the method or means of achieving a solution to the problem, ends or goals, and values. Thus it includes task conflict and process conflict in its scope. Procedural conflicts can include disagreements about factors such as meeting dates and times, individual task assignments, group organization and leadership, and methods of resolving disagreements. Unresolved procedural conflicts can prevent work on collaborative projects. Substantive conflict can enhance collaborative decision-making. Substantive conflict is also called performance, task, issue, or active conflict.

On the other hand, an affective conflict (also called as relationship or opposite of agreeable conflict) deals with interpersonal relationships or incompatibilities and centres on emotions and frustration between parties. Affective conflicts can be very destructive to the organisation, if remains unresolved. Relationship conflict comes under the scope of affective conflicts. An affective conflict is nearly always disruptive to collaborative decision-making. The conflict causes members to be negative, irritable, suspicious, and resentful. For example, when collaborators disagree on the recognition and solution to a task problem because of personal prejudices (e.g. prejudices stemming from strong social, political, economic, racial, religious, ethnic, philosophical, or interpersonal biases) they are seldom able to focus on the task.

ON THE BASIS OF RESULTS:

Conflict can be Constructive or Destructive, creative or restricting, and positive or negative. Destructive conflicts are also known as dysfunctional conflicts, because such conflicts prevent a group from attaining its goals. Conflict is destructive when it takes attention away from other important activities, undermines morale or self-concept, polarises people and groups, reduces cooperation, increases or sharpens difference, and leads to irresponsible and harmful behaviour, such as fighting, name-calling.

On the other hand, constructive conflicts are also known as functional conflicts, because they support the group goals and help in improving performance. Conflict is constructive when it results in clarification of important problems and issues, results in solutions to problems, involves people in resolving issues important to them, causes authentic communication, helps release emotion,

anxiety, and stress, builds cooperation among people through learning more about each other; joining in resolving the conflict, and helps individuals develop understanding and skills.

ON THE BASIS OF SHARING BY GROUPS:

Conflicts may be Distributive and Integrative. Distributive conflict is approached as a distribution of a fixed amount of positive outcomes or resources, where one side will end up winning and the other losing, even if they do win some concessions. On the other hand, integrative – Groups utilizing the integrative model see conflict as a chance to integrate the needs and concerns of both groups and make the best outcome possible. This type of conflict has a greater emphasis on compromise than the distributive conflict. It has been found that the integrative conflict results in consistently better task related outcomes than the distributive conflict.

ON THE BASIS OF STRATEGY:

Conflicts may be competitive and cooperative. Competitive conflict is accumulative. The original issue that began the conflict becomes irrelevant. The original issue is more of a pretext than a cause of the conflict. Competitive conflict is marked by the desire to win the fight or argument, even if winning costs more and causes more pain than not fighting at all. Costs do not matter in competitive conflict, and therefore, irrationality remains its main mark. Competitive conflict is characterized by fear, which is one of the important ingredients in a conflict becoming irrational. If one is personally invested in the outcome, this too leads to irrational conclusions, especially if issues of self-esteem, whether personal or national, are involved.

Competitive conflict can either begin by, or be rationalized by, conflicts of ideology or principle. Even more, when the desire to win overtakes any specific reason for the conflict, irrationally develops. Importantly in history, when powers are roughly equal, such as the World War I alliances were, conflict that becomes competitive and irrational nearly always develops. In economic competition customers are the winners and the firms may be at risk. But in sports competition is encouraged. In a cooperative situation the goals are so linked that everybody 'sinks or swims' together, while in the competitive situation if one swims, the other must sink. A cooperative approach aligns with the process of interest-based or integrative bargaining, which leads parties to seek win-win solutions. Disputants that work cooperatively to negotiate a solution are more likely to develop a relationship of trust and come up with mutually beneficial options for settlement.

ON THE BASIS OF RIGHTS AND INTERESTS:

Conflict of rights means where people are granted certain rights by law or by contract or by previous agreement or by established practice. If such a right is denied, it will lead to conflict. Such a conflict is settled by legal decision or arbitration, not negotiation. On the other hand conflict of interests means where a person or group demands certain privileges, but there is no law or right in existence. Such a dispute can be settled only through negotiation or collective bargaining.

STAGES OF CONFLICT:

A manager must know various stages of conflict to handle it. The solution to conflict becomes easy before it becomes serious, if he knows of the real issue behind the conflict and how the conflict developed. Normally a conflict passes through the following stages:

- a. People recognise lack of resources, diversity of language or culture. Sensitiveness may possibly result in conflict.

- b. If there are serious differences between two or among more than two groups, the latent conflict in a competitive situation may turn into conflict.
- c. An incident may trigger a latent conflict into an open conflict
- d. Once a problem has been solved, the potential for conflict still remains in the aftermath. In fact the potential is bigger than before, if one party perceives that the resolution has resulted into win-lose situation.

ARE CONFLICTS BAD AND UNDESIRABLE?

There are three viewpoints. The traditionalists view conflict as bad and be avoided. In most of the cultures, this is what is being taught – ‘If you cannot speak well, keep mum,’ don’t fight with anyone’, and alike. The followers of human relations school opine that conflict is natural and can be functional at sometime and dysfunctional at other time. According to them, conflict provides an avenue to know of opinions and an opportunity for creativity and persuasion. Thus, it calls for an open approach to conflict. The integrationists view conflict as inevitable and stimulating conflict to some extent is helpful. Conflict is viewed as a positive force except that when it is misdiagnosed, mismanaged, or improperly avoided. We are of the opinion that conflicts are inevitable, not always bad or the same as discomfort, but key to them is proper diagnosis and their resolution. Conflict is often needed as it-

- a. Helps to raise and address problems,
- b. Energizes work to be on the most appropriate issues,
- c. Helps people “be real”, for example, it motivates them to participate, and
- d. Helps people learn how to recognize and benefit from their differences.

CONFLICT BECOMES A PROBLEM WHEN IT:

- a. Hampers productivity,
- b. Lowers morale,
- c. Causes more and continued conflicts, and
- d. Causes inappropriate behaviours.

CONFLICT INDICATORS:

- a. Body language
- b. Colleagues not speaking to each other or ignoring each other
- c. Deliberately undermining or not co-operating with each other, to the downfall of the team
- d. contradicting and bad-mouthing one another
- e. Disagreements, regardless of issue
- f. Withholding bad news
- g. Surprises
- h. Strong public statements
- i. Airing disagreements through media
- j. Conflicts in value system
- k. Desire for power
- l. Increasing lack of respect

- m. Open disagreement
- n. Lack of candour on budget problems or other sensitive issues
- o. Lack of clear goals
- p. No discussion of progress, failure relative to goals, failure to evaluate the superintendent fairly, thoroughly or at all
- q. Factions meeting to discuss issues separately, when they affect the whole organisation
- r. One group being left out of organising an event which should include everybody
- s. Groups using threatening slogans or symbols to show that their group is right and the others are wrong.

CAUSES/ REASONS/SOURCES OF CONFLICTS:

Conflicts may be caused by any one or more of the following reasons:

COGNITIVE (RECOGNITION AND UNDERSTANDING) DISSONANCE (DIFFERENCE OF OPINION):

It is a conflict between convergent (ability to narrow the number of possible solutions to a problem by applying logic and knowledge) and divergent thinking (thinking outwards instead of inward).

STATUS:

Status is a state, condition, or situation. When there is a need for status and a "wrong" person is promoted.

INCONGRUENCE:

A party is required to engage in an activity that is incongruent with his or her needs or interests.

INCOMPATIBILITY:

A party holds behavioural preferences like attitudes, values, skills, goals, and perceptions, the satisfaction of which is incompatible with another person's implementation of his or her preferences.
Economics: Insufficient remuneration to employees.

STRESS:

Conflicts from stress from external sources; i.e., functional or dysfunctional situations.
Poor or Inadequate Organisational Structure and Lack of Teamwork.

SEEKING POWER:

Often a conflict for power struggle takes place when everyone wants to be a leader and nobody wants to be a follower.

WEAK LEADERSHIP:

Conflict is bound to result if someone of less stature leads a more qualified and experienced worker.
Arbitrary interpretation and application of rules and policies: Lack of transparency and openness creates dissatisfaction among the affected people.

DIFFERING VIEWPOINTS AMONG COLLEAGUES ABOUT EACH OTHER:

In case of joint action two parties may have partially exclusive behavioural preferences.

MANAGERIAL ACTIONS:

Poor communication (employees being not informed of new decisions, programmes etc., not involved in decision making, and rumor mongering allowed); insufficient resources (Disagreement on allotment of work, stress from inadequate financial, equipment, facilities, and other resources and privileges); absence of personal chemistry between managers and employees (both sides having rigidity, dislike for absence of self- traits); lack of clarity in roles and responsibilities, arbitrariness in employees' performance appraisal; weak leadership, and inconsistent, too-strong, or uninformed leadership (lack of openness, buck-passing with little follow-through, lingering on issues, first-line managers failing to understand their subordinates' jobs). All these factors cause dissatisfaction.

CONFLICT MANAGEMENT STYLES:

Conflict management must aim at minimizing affective conflicts at all levels, attain and maintain a moderate amount of substantive conflict, and also to match the status and concerns of the two parties in conflict. Many styles of conflict management behavior have been researched in the past century. Mary Parker Follett described them as domination, compromise, and integration (involves openness, exchanging information, looking for alternatives, and examining differences to solve the problem in a manner that is acceptable to both parties).

STRESS: COPING WITH LIFE'S

Coping usually involves adjusting to or tolerating negative events or realities while attempting to maintain your positive self-image and emotional equilibrium. Coping occurs in the context of life changes that are perceived to be stressful. Psychological stress is usually associated with negative life changes, such as losing a job or loved one. However, because all changes require some sort of adaptation, even positive changes, such as getting married or having a child, can be stressful. Changes are stressful because changes require us to adjust and to adapt. Experiencing too many changes within a brief time period often creates a perception that we are not in control of important events. This perception contributes to low self-esteem and may even contribute to the development of anxiety or depression. In some cases, physical illnesses may develop or be exacerbated when a person's capacity to adapt to change is overwhelmed by too much change.

Coping involves adjusting to unusual demands, or stressors, and thus requires the mobilization of greater effort and the use of greater energy than is required by the daily routines of life. Prolonged mobilization of effort can contribute to elevated levels of stress-related hormones and to eventual physical breakdown and illness. Stressors that require coping may be acute, such as a change in residence or onset of marital problems. Stressors also occur that are of longer duration, such as chronic pain, chronic illness, or enduring financial problems. The effect of many acute stressors that occur within a relatively brief period of time may be cumulative and profound. Thus, the individual who experiences a marital separation, the death of an aging parent, and a change in his or her job within a brief period of time may find himself or herself struggling to adjust to maintain his or her physical and emotional health.

WHAT ARE SOME COMMON COPING STRATEGIES?

Some common coping mechanisms include:

- Lowering your expectations

- Asking others to help or assist you
- Taking responsibility for the situation
- Engaging in problem solving
- Maintaining emotionally supportive relationships
- Maintaining emotional composure or, alternatively, expressing distressing emotions
- Challenging previously held beliefs that are no longer adaptive
- Directly attempting to change the source of stress
- Distancing yourself from the source of stress
- Viewing the problem through a religious perspective

Experts agree that coping is a process rather than an event. Thus, an individual may alternate between several of the above coping strategies in order to cope with a stressful event. Individuals differ in particular styles of coping or preferences for using certain coping strategies over others. These differences in coping styles are usually reflective of differences in personality. Rigidity in coping is less likely to produce a desirable outcome than is flexibility in coping, or being able to fit the most appropriate coping strategy to the demands of different situations. It should be noted, however, that some situations that require coping are likely to elicit similar coping responses from most people. For example, work-related stressors are more likely to elicit problem-solving strategies. Stressors that are perceived to be changeable are more likely to elicit problem-solving strategies while stressors perceived to be unchangeable are more likely to elicit social support seeking and emotion-focused strategies. What can we do to protect ourselves against stress and therefore enhance our prospects for successful coping? Perhaps the most important strategy is to maintain emotionally supportive relationships with others. A vast field of research demonstrates that emotional support buffers individuals against the negative impact of stress.

It is especially important to evaluate your overall lifestyle when encountering significant stress. Engaging in stress-reducing activities can also be a helpful overall approach to coping with stressors. Examples include:

- Getting enough good quality sleep
- Eating a well-balanced diet
- Exercising on a regular basis
- Taking brief rest periods during the day to relax
- Taking vacations away from home and work
- Engaging in pleasurable or fun activities every day
- Practicing relaxation exercises such as yoga, prayer, meditation, or progressive muscle relaxation
- Avoiding use of caffeine and alcohol

COPING SKILLS

The transactional **model** of stress and coping developed by Lazarus and Folkman (1987) explained coping as a phenomenon that involves both cognitive and behavioral responses that individuals use in an attempt to manage internal and/or external stressors perceived to exceed their personal resources. It is safe to say that coping with stressful and anxiety-provoking situations is first on the list of an athlete's job description; and failure to do so will most likely result in subpar athletic performance. Omar-Fauzee, Daud, Abdullah, and Rashid (2009) observed that athletes at various levels of sport participation made use of a variety of effective coping strategies to help

deal with the multiple stressors they encounter.

The Athletic Coping Skills Inventory (ACSI-28) developed by Smith, Schultz, Smoll, and Ptacek (1995) is a popular self-report measure used to assess the various coping techniques implemented by athletes. The ACSI-28 measures the following domains: Coping with Adversity, Peaking Under Pressure, Goal Setting and Mental Preparation, Concentration, Freedom from Worry, Confidence and Achievement Motivation, and Coachability. Spieler et al. (2007) studied coping differences between starters and non-starting collegiate varsity football players and concluded that when combined with other factors such as size of high school when growing up as well as age, athletes who were part of the starting line-up scored higher on the Coping with Adversity domain.

THE EFFECT OF PERSONALITY TYPES ON INDIVIDUALS WORK-RELATED BEHAVIORS

In literature, it is seen that personality psychologists are interested in human wholeness, and attempt to reveal out the complexity of human behaviors (Esmaeilpour et al., 2013: 405). Because personality is considered as a crucial component underlying human behaviors, researchers have focused on personality traits. Personality traits affect individuals' perceptions, appraisal of the environment, their emotional responses and attitudes. However, it is suggested that personality traits are examined as an important determinant of individuals' workplace behaviors (Kozako et al., 2013: 182).

For instance, whereas some people have positive and strong personality traits, others may have negative and weak traits which lead them to exhibit some favorable or undesirable work-related behaviors. Accordingly, this study aims to present some effects of Type A, B, C and D personalities on positive and negative work-related behaviors. Further, it purposes a classification as to which personality type results in negative or positive behaviors in workplaces. Type A individuals are often regarded "workaholics" as they take over multi-tasks and are strongly motivated to do extra work and to achieve success (Radsepehr et al., 2016: 2).

Related to these characteristics of Type A, it is possible to express that they experience increased performance and increased job satisfaction. However, even several researchers have examined the relationship between Type A and job satisfaction, results have been inconsistent and controversial. For example, the studies by Al-Mashaan (2001) and; Yazici and Altun (2013) found a positive correlation between Type A and job satisfaction. On the other hand, Jamal and Baba (2001); Kirkcaldy et al., (2002) and Bockhaus et al., (2012) report that Type A individuals have lower levels of job satisfaction. In addition, as Type A's have a competitive and ambitious nature, they are expected to exhibit aggressive behaviors in interpersonal relations at work (Batıgün and Şahin, 2006: 2). Vera-Villarreal et al. (2004); Faunce et al. (2004) and Mohan and Singh (2016) asserted that Type A personality characteristics are positively related to aggressive and hostile behaviors. In consideration of positive work behaviors, Sameen and Burhan (2014) and Hussein (2014) have indicated that Type A individuals tend to exhibit creative behaviors than others.

Due to Type A individuals prefer undertaking excessive responsibilities and new challenges, working under time pressure and have a greater commitment to their roles, it is expected that these individuals engage to their works (Baka and Derbis, 2012: 134). Studies of Hallberg et al., (2007); Moodley (2010); Baka and Derbis (2012) suggest that there is a positive relationship between Type A characteristics and work engagement. Consequently, it can be said that Type A individuals may exhibit both positive and negative work behaviors.

Type B individuals are considered easygoing and moderate thanks to their personality characteristics. For example, it can be said that Type B individuals are more flexible and can easily adapt to changing conditions easily (Radsepehr et al., 2016: 3). However, Type B's are regarded as the opposite of Type A individuals. In other words, they have a desire to be successful, but they are not excessively ambitious or competitive as Type A individuals are. Due to their fondness for being comfortable, they do their work at the last minutes, and even procrastinate. It can be expressed that Type B individuals exhibit procrastination behaviors more often in their worklife (Hussein, 2014: 2). Therefore, it can be inferred that Type B individuals use their time poorly and can not make efficient time schedules (Hisam et al., 2014: 1305). Type B individuals have better communication skills than Type A's, so they can easily communicate with others (Tokat elal., 2013: 1978). Thanks to Type B's good communication skills, they are supported others and are more likely to express their feelings. Moreover, as Type B's have no eyes on greater success, high positions and extreme gains, they are expected to be satisfied with their jobs (Darshani, 2014: 2).

On the other hand, because Type B individuals pay no attention to the time scheduling, they may spend more hours in their workplace for their co-workers and companies. In other words, they tend to participate in non-compulsory activities or roles and tend to display non-discretionary behaviors. Type C personality is regarded as a part of negative personality traits based on the individuals' some characteristics like incapability, non-assertiveness and passiveness. However, Type C individuals possess some positive traits such as dedicated focus on other people, exhibit cooperative behaviors and tendency to comply with external environment (Denollet, 1998: 981). Type C's seem kind, obedient, well-mannered, pragmatic and normative people who are preferred by others in work and social life (Durai, 2010: 390). On the other hand, these individuals considered as introvert and intelligent people who are interested in details, like to discover new things and are eager to achieve a successful career in the professional life (Ansari et al., 2013: 1004).

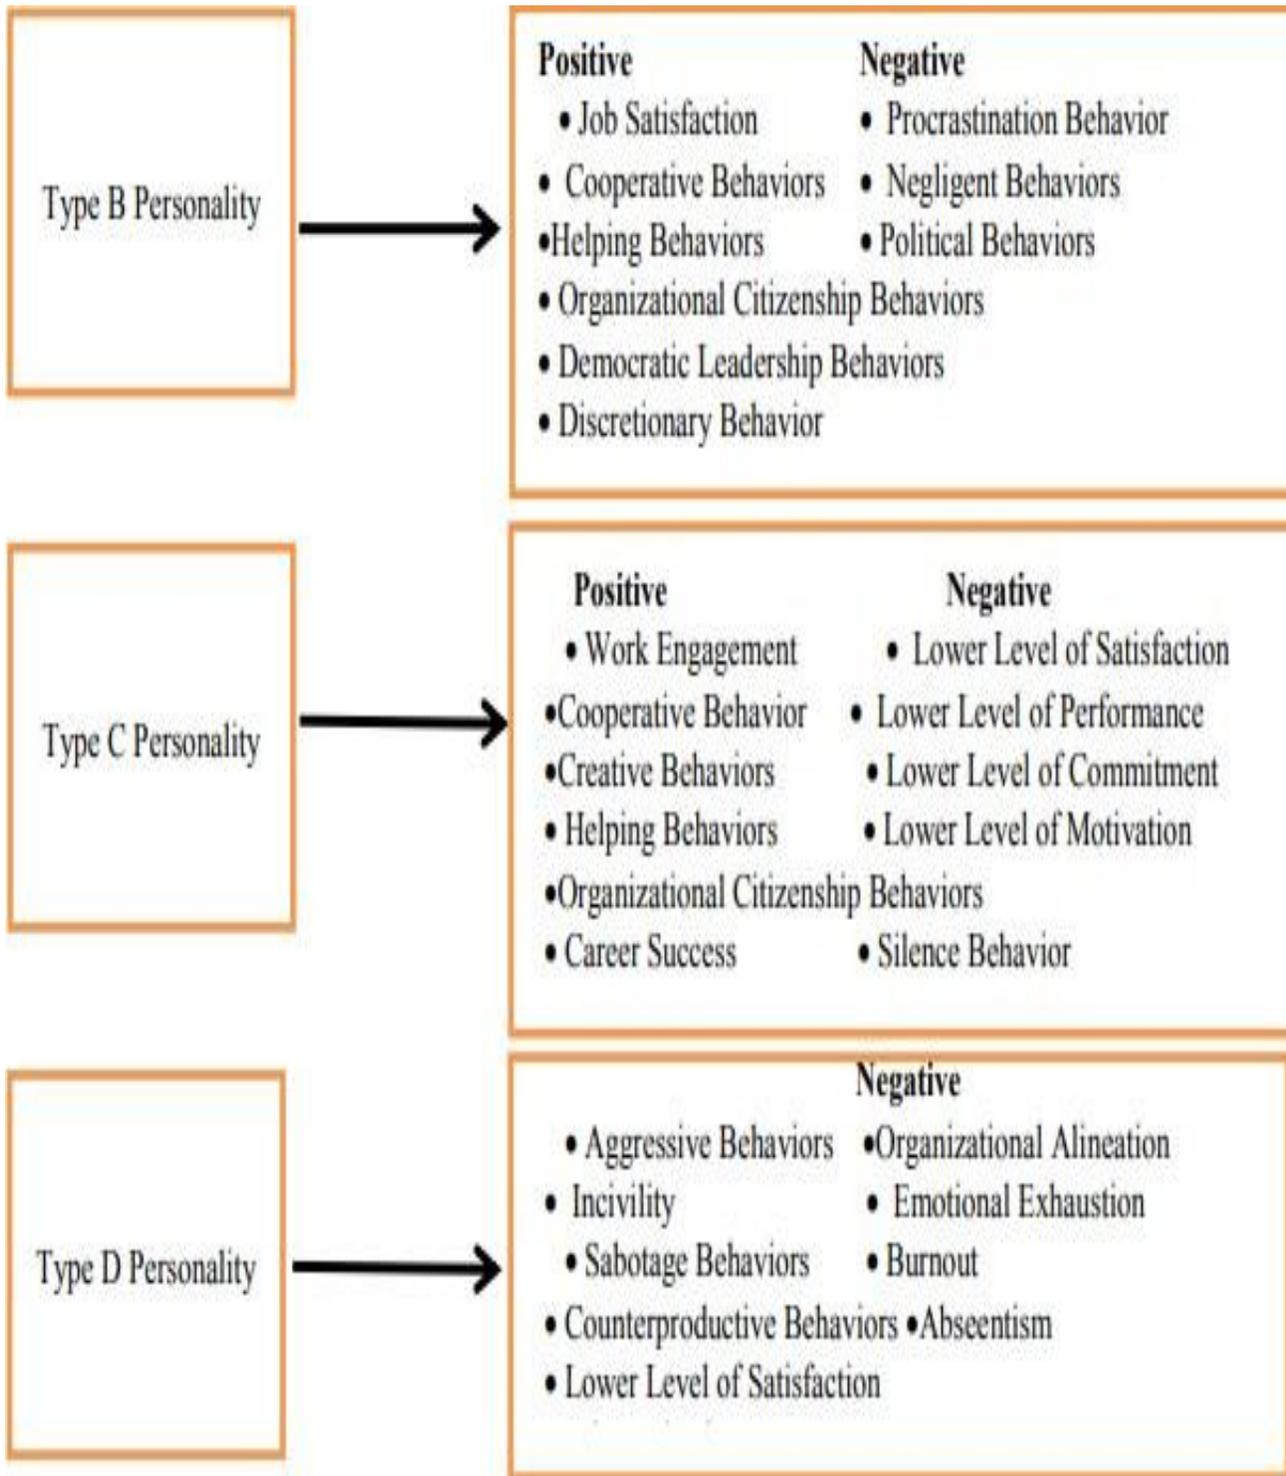

Moreover, type C individuals are obsessed with making visionary dreams come true and regarded as creative people (Atchity, 2012: 16). Therefore, it can be expressed that due to their altruistic and sensitive side, Type C's may display helping behaviors, cooperative and organizational citizenship behaviors and feel engaged in their work roles more than the others in the working environment. In addition, these individuals have more dispositions to exhibit creative behaviors thanks to their imaginations. From the pessimistic perspective, it is possible to infer that because of their negative emotions, type C's easily get unhappy and dissatisfied with their jobs. Thus, it is expected that their job performance, motivation and commitment levels decrease.

Type D or distressed personality examined in the extent of other negative personality traits due to the characteristics of negative and pessimistic view in all field of life, feeling of anxious, unsatisfying and always experience negative emotions. Owing to these characteristics lead Type D individuals build fewer friendly relationships, have fewer friends and feel uncomfortable with strangers in work and social life (Radsepehr et al., 2016: 3- 4). Depending on these fewer social relationships, they perceive lower levels of social support from others in their professional lives (Tekin et al., 2017: 173). However, Type D individuals feel tense and insecure in the working environment which causes them to keep other people at a distance. In the literature, studies suggest that.

Type D individuals suffer from higher levels of social alienation from their family members, friends and working colleagues (Ginting et al., 2016: 728). In addition, researchers assert that Type D

individuals get exhausted much more quickly than others and feel disengaged to their work. Therefore, it can be concluded that Type D individuals experience adverse work-related outcomes such as higher burnout, higher work-related stress and substantial problems in interacting with co-workers and managers (Reid, 2013: 9). Besides, it is asserted that Type D's are more absent from their works due to the physical and psychological illness, show a lower sense of personal accomplishment and perceive adverse working conditions (Mols and Denollet, 2010: 4- 6).

Besides, it can be noted that Type D individuals are expected to display some negative work-related behaviors such as absenteeism, incivility, sabotage and aggressive behaviors and counterproductive behaviors (Kanten et al., 2017: 605). When the literature has been reviewed, it can be said that personality types cause some positive and negative work-related outcomes.

Accordingly, this study aims to explain Type A, B, C, D personality's positive and negative effects on employees' attitudes and behaviors.

STRESS MANAGEMENT TIPS

People can learn to manage stress and lead happier, healthier lives. Here are some tips to help you

keep stress at bay.

- Keep a positive attitude.
- Accept that there are events that you cannot control.
- Be assertive instead of aggressive. Assert your feelings, opinions, or beliefs instead of becoming angry, defensive, or passive.
- Learn and practice relaxation techniques; try meditation, yoga, or tai-chi for stress management.
- Exercise regularly. Your body can fight stress better when it is fit.
- Eat healthy, well-balanced meals.
- Learn to manage your time more effectively.
- Set limits appropriately and learn to say no to requests that would create excessive stress in your life.
- Make time for hobbies, interests, and relaxation.
- Get enough rest and sleep. Your body needs time to recover from stressful events.
- Don't rely on alcohol, drugs, or compulsive behaviors to reduce stress.
- Seek out social support. Spend enough time with those you enjoy.
- Seek treatment with a psychologist or other mental health professional trained in stress management or biofeedback techniques to learn healthy ways of dealing with the stress in your life.

BIOFEEDBACK

Biofeedback is a mind-body technique that involves using visual or auditory feedback to gain control over involuntary bodily functions such as blood flow, blood pressure, and heart rate. This technique may be used to help alleviate symptoms of conditions including high blood pressure, chronic stress, headaches, pain, and anxiety. The goal of biofeedback is often to make subtle changes to the body that result in a desired effect. This might include relaxing certain muscles slowing heart rate or reducing feelings of pain. Some of the functions that people can learn to control include:

- Blood flow
- Blood pressure
- Heart rate
- Muscle tension
- Pain perception

By doing this, people are often able to improve their physical, emotional, and mental health. For example, biofeedback can also be used to help people better manage the symptoms of a condition. The Association for Applied Psychophysiology and Biofeedback defines biofeedback as a process that allows people to alter their physiological activity in order to improve health or performance.¹ Utilizing precise measurement instruments, information about the body's functions are provided to the user.

TYPES OF BIOFEEDBACK

There are many different types of biofeedback. The specific approach you choose to utilize might depend upon what you hope to accomplish and what your therapist or physician recommends. Some of the available options include:

BREATHING

Respiratory biofeedback involves wearing sensor bands around the chest and abdomen to monitor

breathing rates and patterns. With training, people can learn to have greater control over their breathing rates which can help in a variety of situations including when people experience anxiety.

HEART RATE

This type is known as heart rate variability biofeedback and there is some evidence that it might possibly be useful for a number of different disorders including asthma and depression.² Patients using this type of biofeedback wear a device connected to sensors in either the ears or fingers or sensors placed on the wrists, chest, or torso.

GALVANIC SKIN RESPONSE

This type of biofeedback involves measuring the amount of sweat on the surface of the skin. Galvanic skin response, also known as skin conductance, is a useful marker for detecting levels of emotional arousal. Aside from the obvious thermoregulatory function of sweat, emotional stimulation can also easily trigger sweating. The more strongly people are aroused, the stronger their skin conductance will be.

BLOOD PRESSURE

This type of biofeedback involves wearing a device that measures blood pressure. These devices provide information about the patient's blood pressure and often guide the user through relaxation techniques that may rely on visual cues, breathing exercises, or music.

While such devices have gained popularity, one study reviewing eight previous trials did not find convincing evidence that this type of biofeedback has any lasting long-term impact on hypertension.³

SKIN TEMPERATURE

In this form of biofeedback, patients wear sensors that detect blood flow to the skin. Because people often experience a drop in body temperature during times of stress, such devices can help people better detect when they are starting to feel distressed. A low reading on one of these monitors can indicate a need to utilize some stress management techniques.

BRAIN WAVES

This type of biofeedback, often referred to as neurofeedback, involves utilizing electroencephalography (EEG) to measure brain wave activity. Scalp sensors are connected to an EEG device. Neurofeedback is sometimes used as a non-invasive treatment for ADHD, pain, addiction, anxiety, depression, and other disorders. **Muscle Tension** In this type of biofeedback, sensors are placed at various points on the body and connected to an electromyography (EMG) device. This device detects changes in muscle tension over time by monitoring electrical activity that results in muscle contractions.

USES

Biofeedback has been used for a range of applications, including:⁴

- ADHD
- Anxiety
- Brain injuries
- Depression
- Digestive disorders such as irritable bowel syndrome
- High and low blood pressure

- Mental health conditions
- Migraines
- Pain
- Physical reactions to stress
- Post-traumatic stress disorder (PTSD)
- Relaxation and stress management
- Tension headaches

BIOFEEDBACK WORK?

Biofeedback teaches people to recognize the physical signs and symptoms of stress and anxiety such as increased heart rate, body temperature, and muscle tension. Scientists believe that it is often the stress response, the body's tendency to go into a state of "fight- or-flight" in order to deal with potential threats, that often exacerbate certain conditions.

DURING A TYPICAL BIOFEEDBACK SESSION:

- Electrical sensors will be connected to specific areas of your body, depending upon the type of response being measured.
- These sensors will be connected to a measurement device that will provide feedback on your physical responses.
- During your session, your therapist will guide you through different mental exercises that may involve visualization, meditation, breathing, or relaxation techniques.
- As you perform these activities, you will receive information on your physical response from the measurement device.

EFFECTIVENESS

Biofeedback is often considered a type of training rather than a treatment. With training and practice, biofeedback can be used to help people develop new skills that may help them to better cope or perform.

BIOFEEDBACK DEVICES

Biofeedback devices fall into two different categories. The first are those used by medical and mental health professionals. The second are those available on the consumer market for personal use.

CLINICAL BIOFEEDBACK DEVICES

Biofeedback devices utilized for clinical purposes are regulated by the U.S. Food and Drug Administration. These devices are often available through a biofeedback therapist's office or the office of another health practitioner.

PERSONAL USE BIOFEEDBACK DEVICES

A number of biofeedback devices can be purchased for personal, in-home use from various online retailers. Such devices often involve wearing sensors that record information and can then be plugged into a computer. Other wearable devices utilize sensors that then provide information via an app on your mobile device. These devices include wearable instruments ranging from muscle sensors to skin response units to brain wave monitors. Such devices make a variety of claims and target a number of different ailments such as migraines, pelvic floor weakness, snoring, depression,

ADHD, autism, and sleep disruptions.

REASONS TO USE BIOFEEDBACK

Like other approaches to treatment, biofeedback has both its own set of upsides and downsides. It may not be right for everyone, so it is important to consider the benefits and risks before you determine if it the best choice for your situation. So what are some of the reasons why you might consider using biofeedback?

IT CAN COMPLEMENT OTHER TREATMENTS

Biofeedback may appeal in situations where other treatments have not been effective or where people are unable to take certain medications. Because biofeedback is non-invasive, patients may prefer it in situations where other treatments may be more invasive or disrupting. Biofeedback training can also be used as one part of a treatment approach. People often choose to utilize biofeedback to augment other treatments.

YOU WANT TO BETTER MANAGE YOUR STRESS

Biofeedback also teaches people how to control their own responses in stressful situations, which can help people feel more in control. This can help people better manage the stress they may face in their daily life, cope with feelings of anxiety, or handle stress that results from another health condition.

THERE MAY BE OTHER BENEFITS

In addition to helping people better manage stress and other conditions, biofeedback can also have additional mental health benefits. The training process can help people learn new techniques for managing their anxiety and emotional responses.

MUSIC THERAPY

Music therapy—a type of expressive arts therapy that uses music to improve and maintain the physical, psychological, and social well-being of individuals—involves a broad range of activities, such as listening to music, singing, and playing a musical instrument. This type of therapy is facilitated by a trained therapist and is often used in hospitals, rehabilitation centers, schools, correctional facilities, nursing homes, and hospices.

HISTORY OF MUSIC THERAPY

Music has been used as a therapeutic tool for centuries and has been shown to affect many areas of the brain, including the regions involved in emotion, cognition, sensation, and movement. This fact, combined with the engaging nature of music and the diversity of music forms, makes music uniquely effective in the treatment of a wide array of physical and mental problems, including depression, anxiety, and hypertension. When traveling music groups played for hospitalized veterans during and after both World Wars, doctors and clinicians began to realize the powerful effects that music has on the healing process and requested that professional musicians be hired by the hospitals. This created a need for specialized training in the appropriate delivery of music as a therapeutic method.

Gradually, colleges and universities began to include music therapy as part of their curriculum, beginning with Michigan State University in 1944. In 1950, the first major professional organization for music therapists was formed, and it became known as the National Association for Music

Therapy (NAMT). In 1998, the American Music Therapy Association (AMTA) was formed out of a merger between the NAMT and the American Association for Music Therapy. The AMTA focuses on increasing awareness of and access to music therapy services while promoting the advancement of education, training, professional standards, and research in the field of music therapy.

WHO CAN BENEFIT FROM MUSIC THERAPY?

Music therapy can benefit many individuals. The diverse nature of music means it can be applied in the treatment of concerns both physical and psychological. In some instances, the therapeutic use of music has been able to help people in ways that other forms of therapy have not, as it can sometimes elicit responses that may not appear through more traditional forms of treatment. When people find it difficult to express themselves verbally, they may display a greater degree of interest and engagement in music therapy than they would in a more traditional form of therapy. No background in music is required for a person to benefit from this approach. Because music can evoke positive emotions and stimulate reward centers in the brain, music therapy is often able to alleviate symptoms of mental health concerns such as:

- Depression
- Mood-related concerns
- Anxiety
- Schizophrenia
- Substance dependency
- Autism
- Personality issues
- Insomnia
- Dementia

Music therapy can both assess and enhance cognitive, social, emotional, and motor functioning, and studies have shown positive results among individuals who have intellectual or physical difficulties, brain injuries, or Alzheimer's. This type of therapy has also been used in the treatment of physical ailments such as cancer and hypertension. The positive effects of music therapy are not limited to those coping with severe or long-lasting physical and psychological problems, and this therapy can benefit people in a variety of situations. Music is frequently used to reduce stress levels and pain perception among mothers in labor and has been associated with improvements in self-esteem, self-concept, verbal communication, prosocial behavior, socialization skills, group cohesion, and coping skills.

WHAT HAPPENS IN A MUSIC THERAPY SESSION?

The intervention methods employed in music therapy can be roughly divided into active and receptive techniques. When a person is making music, whether by singing, chanting, playing musical instruments, composing, or improvising music, that person is using active techniques. Receptive techniques, on the other hand, involve listening to and responding to music, such as through dance or the analysis of lyrics. Active and receptive techniques are often combined during treatment, and both are used as starting points for the discussion of feelings, values, and goals.

Music therapy can be conducted with individuals or in groups, and the music may be chosen by the

therapist or by the person in therapy. A music therapist will generally ensure the type and mode of the chosen form of music, as well as the timing of the music intervention, are appropriate for meeting the needs and goals of the individual in therapy. When introducing music, therapists often base their selections on the Iso principle, which states music is more likely to have influence if it matches an individual's current condition. Therapists therefore try to ensure the lyrics and melody of a selected piece of music are well matched with the mood and psychological state of the person in therapy.

Songwriting is commonly used in music therapy and may involve writing original songs or modifying existing ones, with the latter being a more structured approach to writing. A person might modify a song by changing some of the words or lines, adding new verses, or writing entirely new lyrics to match the existing tune. In cases when songs are freely composed, the therapist may provide an emotion or topic to serve as a starting point.

MUSIC THERAPY CAN BE USED IN A VARIETY OF WAYS:

- When a person experiences difficulty communicating after a stroke, singing words or short phrases set to a simple melody can often enhance speech production and fluency.
- A person with impaired motor skills might improve fine motor skills by playing simple melodies on a piano or tapping out a rhythm on drum pads. Listening to a rhythmic stimulus, such as a metronome, can also help a person initiate, coordinate, and time their movements.
- A therapist might play a piece of music for children with autism who have limited social skills and ask them to imagine the emotional state of the person who created the music or the person who is playing it. Doing so can help a person with autism develop or strengthen the ability to consider the emotions others are experiencing.
- Group drumming circles have been used to induce relaxation, provide an outlet for feelings, and foster social connectedness among members of a group. Group members might sit in a circle with a hand drum while the therapist leads them in drumming activities that may involve group members drumming one at a time or all at once. Those who are part of the circle may be asked to express how they feel by playing a rhythm on their drum or the group might be asked to improvise music as a means of increasing group cohesiveness.
- Music might be incorporated into guided imagery or progressive muscle relaxation techniques to enhance the effectiveness of these methods.

TRAINING FOR MUSIC THERAPISTS

Those wishing to become a music therapist must have at least a bachelor's degree in music therapy from an institution approved by the American Music Therapy Association (AMTA). Music therapy programs involve coursework as well as an internship in an educational and/or health care facility. After successfully completing one of the AMTA-approved programs, individuals must take the national examination offered by the Certification Board for Music Therapists (CBMT). If they are successful in the examination, they receive the credential Music Therapist-Board Certified (MT-BC), which is required for professional practice. Board certification is renewed every five years, and in order to maintain this credential, music therapists must retake the CBMT examination or complete 100 recertification credits within each five-year period.

LIMITATIONS OF MUSIC THERAPY

Music therapy generally produces positive results, but it is not recommended as a stand-alone

treatment for serious medical and psychiatric issues. While music may help to alleviate some of the symptoms of these conditions, other forms of treatment such as medication, physical therapy, or psychotherapy may also be necessary.

BREATHING TECHNIQUES

Take a deep breath in. Now let it out. You may notice a difference in how you feel already. Your breath is a powerful tool to ease stress and make you feel less anxious. Some simple breathing exercises can make a big difference if you make them part of your regular routine.

Before you get started, keep these tips in mind:

- Choose a place to do your breathing exercise. It could be in your bed, on your living room floor, or in a comfortable chair.
- Don't force it. This can make you feel more stressed.
- Try to do it at the same time once or twice a day.
- Wear comfortable clothes.

Many breathing exercises take only a few minutes. When you have more time, you can do them for 10 minutes or more to get even greater benefits. Most people take short, shallow breaths into their chest. It can make you feel anxious and zap your energy. With this technique, you'll learn how to take bigger breaths, all the way into your belly.

1. Get comfortable. You can lie on your back in bed or on the floor with a pillow under your head and knees. Or you can sit in a chair with your shoulders, head, and neck supported against the back of the chair.
2. Breathe in through your nose. Let your belly fill with air.
3. Breathe out through your nose.
4. Place one hand on your belly. Place the other hand on your chest.
5. As you breathe in, feel your belly rise. As you breathe out, feel your belly lower. The hand on your belly should move more than the one that's on your chest.
6. Take three more full, deep breaths. Breathe fully into your belly as it rises and falls with your breath.

BREATH FOCUS

While you do deep breathing, use a picture in your mind and a word or phrase to help you feel more relaxed.

1. Close your eyes if they're open.
2. Take a few big, deep breaths.
3. Breathe in. As you do that, imagine that the air is filled with a sense of peace and calm. Try to feel it throughout your body.
4. Breathe out. While you're doing it, imagine that the air leaves with your stress and tension.
5. Now use a word or phrase with your breath. As you breathe in, say in your mind, "I breathe in peace and calm."
6. As you breathe out, say in your mind, "I breathe out stress and tension."
7. Continue for 10 to 20 minutes.

EQUAL TIME FOR BREATHING IN AND BREATHING OUT

In this exercise, you'll match how long you breathe in with how long you breathe out. Over time, you'll

increase how long you're able to breathe in and out at a time.

1. Sit comfortably on the floor or in a chair.
2. Breathe in through your nose. As you do it, count to five.
3. Breathe out through your nose to the count of five.
4. Repeat several times.

Once you feel comfortable with breaths that last five counts, increase how long you breathe in and breathe out. You can work up to breaths that last up to 10 counts.

PROGRESSIVE MUSCLE RELAXATION

In this technique, you breathe in as you tense a muscle group and breathe out as you release it. Progressive muscle relaxation helps you relax physically and mentally.

1. Lie comfortably on the floor.
2. Take a few deep breaths to relax.
3. Breathe in. Tense the muscles of your feet.
4. Breathe out. Release the tension in your feet.
5. Breathe in. Tense your calf muscles.
6. Breathe out. Release the tension in your calves.
7. Work your way up your body. Tense each muscle group. This includes your legs, belly, chest, fingers, arms, shoulders, neck, and face.

MODIFIED LION'S BREATH

As you do this exercise, imagine that you're a lion. Let all of your breath out with a big, open mouth.

1. Sit comfortably on the floor or in a chair.
2. Breathe in through your nose. Fill your belly all the way up with air.
3. When you can't breathe in any more, open your mouth as wide as you can. Breathe out with a "HA" sound.
4. Repeat several times.

PROGRESSIVE MUSCULAR RELAXATION

Have you ever had an aching back or pain in your neck when you were anxious or stressed? When you have anxiety or stress in your life, one of the ways your body responds is with muscle tension. Progressive muscle relaxation is a method that helps relieve that tension.

- In progressive muscle relaxation, you tense a group of muscles as you breathe in, and you relax them as you breathe out. You work on your muscle groups in a certain order.
- When your body is physically relaxed, you cannot feel anxious. Practicing progressive muscle relaxation for a few weeks will help you get better at this skill, and in time you will be able to use this method to relieve stress.
- When you first start, it may help to use an audio recording until you learn all the muscle groups in order. Check your local library or a bookstore for progressive muscle relaxation audio recordings.
- If you have trouble falling asleep, this method may also help with your sleep problems.

THE PROCEDURE

You can use an audio recording to help you focus on each muscle group, or you can learn the order

of muscle groups and do the exercises from memory. Choose a place where you won't be interrupted and where you can lie down on your back and stretch out comfortably, such as a carpeted floor.

1. Breathe in, and tense the first muscle group (hard but not to the point of pain or cramping) for 4 to 10 seconds.
2. Breathe out, and suddenly and completely relax the muscle group (do not relax it gradually).
3. Relax for 10 to 20 seconds before you work on the next muscle group. Notice the difference between how the muscles feel when they are tense and how they feel when they are relaxed.
4. When you are finished with all of the muscle groups, count backward from 5 to 1 to bring your focus back to the present.

After you have learned how to tense and relax each muscle group, here's something else to try. When you have a very tense muscle, you can practice tensing and relaxing that muscle area without going through the whole routine.

THE MUSCLE GROUPS

The following is a list of the muscle groups in order and how to tense them. Remember to lie down when you do this. Remember to lie down when you do this.

Muscle group	What to do
Hands	Clench them.
Wrists and forearms	Extend them, and bend your hands back at the wrist.
Biceps and upper arms	Clench your hands into fists, bend your arms at the elbows, and flex your biceps.
Shoulders	Shrug them (raise toward your ears).
Forehead	Wrinkle it into a deep frown.
Around the eyes and bridge of the nose	Close your eyes as tightly as you can. (Remove contact lenses before you start the exercise.)
Cheeks and jaws	Smile as widely as you can.
Around the mouth	Press your lips together tightly. (Check your face for tension. You just want to use your lips.)
Back of the neck	Press the back of your head against the floor or chair
Front of the neck	Touch your chin to your chest. (Try not to create tension in your neck and head.)
Chest	Take a deep breath, and hold it for 4 to 10 seconds.
Back	Arch your back up and away from the floor or chair.
Stomach	Suck it into a tight knot. (Check your chest and stomach for tension.)
Hips and buttocks	Press your buttocks together tightly.
Thighs	Clench them hard.
Lower legs	Point your toes toward your face. Then point your toes away, and curl them downward at the same time. (Check the area from your waist down for tension.)

GUIDED IMAGERY FOR RELAXATION

You may have heard of guided imagery as a stress management technique, but do you know how it works, why it's useful, and how it measures up against other stress relievers? Guided imagery is widely used for Guided imagery is an effective stress management technique and has remained popular for several reasons. It can quickly calm your body and simultaneously relax your mind. It's pleasant to practice, and not overly difficult or intimidating to learn. And it can help you to de-stress in minutes, but can also be a useful strategy for maintaining resilience toward stress during difficult times. If this sounds like something you can use in your life, read more about when guided imagery is used, and how it may be a useful go-to stress reliever for you. Guided Imagery is a convenient and simple relaxation technique that can help you quickly and easily manage stress and reduce tension in your body. It's virtually as easy as indulging in a vivid daydream and, with practice, this technique can help you to better access your inner wisdom.

There are a few different ways to practice using guided imagery, including taking a class where you are "guided" by an instructor, using audio recordings, creating your own recordings, or using your inner voice and imagination. Here we'll examine the benefits and drawbacks of this simple and engaging stress management technique and explore how it compares to other methods so you can determine how guided imagery may fit into your life. Then we'll delve into the practice of guided imagery and the different ways of using it. We'll look at methods of using your own thoughts, simply because this takes the least amount of preparation and expense; however, you can also explore guided imagery at many yoga studios, with recordings, and through an experienced therapist. You can also record your own guided imagery tapes. First, let's take a closer look at the practice itself.

GUIDED IMAGERY'S EFFECTS ON THE BODY

Guided imagery has been found to provide significant stress reduction benefits, including physically relaxing the body quickly and efficiently and even helping participants get in touch with deeper levels of wisdom (held on a subconscious level) that would help them better manage their lives in ways that would reduce stress. The studies demonstrating the health benefits of imagery are so numerous that many hospitals are incorporating imagery as an option to help with treatment. Fortunately, it's a simple enough technique that it can be used at home as well, with positive results.

WHAT'S INVOLVED?

With the help of a guided imagery recording, a professional helper, or just one's own imagination, those who practice guided imagery get into a deeply relaxed state and envision, with great detail relating to all of the senses, a relaxing scene. This scene may be something in the natural world like a beautiful waterfall in Hawaii with sparkling and refreshing water at the bottom or a cool and dense forest where you may take a calming walk in your imagination. It could also be a relaxing or happy event such as a vividly-imagined scene where you discover a \$50 bill on the sidewalk and eat a delicious meal in a restaurant by the beach, or win the lottery and buy whatever you want. Those who use guided imagery for stress relief may also imagine a wise 'guide' with them, answering their questions and asking them questions that they must ponder in order to get to a better place in their lives. (This 'guide' is a representation of their subconscious mind that they aren't generally able to access.)

PRACTICING GUIDED IMAGERY:

Now that you understand the basics of this stress management tool, let's get into how you can practice it. The following are general guidelines to help you understand the process of guided imagery,

and be able to practice it on your own. Here's how to make guided imagery practice work for you.

GET COMFORTABLE

Get into a relaxed position, like the one you would use for meditation or self-hypnosis. If a lying-down position would likely put you to sleep, opt for a cross-legged position or recline in a comfortable chair. Try to position yourself in a way where your physical comfort won't be a distraction. Breathe From Your Belly Use diaphragmic deep breathing and close your eyes, focusing on "breathing in peace and breathing out stress." This means letting your belly expand and contract with your breath—if you find your shoulders rising and falling, you are likely carrying tension in your body and not breathing in the most relaxed way.

CHOOSE A SCENE AND VIVIDLY IMAGINE IT

Once you get to a relaxed state, begin to envision yourself in the midst of the most relaxing environment you can imagine. For some, this would be floating in the cool, clear waters off of a remote tropical island, where attractive people bring drinks and smooth music plays in the background. For others, this might be sitting by a fire in a secluded snow cabin, deep in the woods, sipping hot cocoa and reading the latest bestseller while wrapped in a plush blanket and fuzzy slippers. You may want to remember a time and place when you felt wonderful and relaxed (a "happy place" in your memory), a vividly-described scene from a book you love, or the way you imagine a place you've always wanted to visit.

RELAX

Stay here for as long as you like. Enjoy your 'surroundings', and let yourself be far from what stresses you. When you're ready to come back to reality, count back from ten or twenty, and tell yourself that when you get to 'one', you'll feel serene and alert, and enjoy the rest of your day. When you return, you'll feel calmer and refreshed, like returning from a mini-vacation, but you won't have left the room!

TIPS

1. You may want to use ambient sounds that compliment your imagery. This way, you feel more immersed in your 'environment', plus the sounds of real-life will be obscured.
2. You may also want to set an alarm, just in case you lose track of time or fall asleep. This way, you'll be more able to relax and let go, knowing that your schedule won't be in jeopardy.
3. As you get more practiced, you'll be able to go more deeply and quickly. You may also want to communicate with your subconscious mind, with the help of a tape you record for yourself or purchase, or a therapist.

MINDFULNESS

You may have heard that mindfulness — the ability to be fully present in the moment — can have numerous benefits, everything from decreased stress and sadness to increased levels focus and happiness, according to general mindfulness research. But what exactly is mindfulness? And, how can you recognize it and reap its many benefits? Mindfulness meditation practice is one way to truly experience the current moment and integrate that awareness into your everyday life. Here's everything you need to know to get started.

First, it's helpful to become familiar with the meaning of mindfulness, as well as how it relates to meditation. Mindfulness is the quality of being present and fully engaged with whatever we're doing at the moment — free from distraction or judgment, and aware of our thoughts and feelings

without getting caught up in them. We train in this moment-to-moment awareness through meditation, allowing us to build the skill of mindfulness so that we can then apply it to everyday life. In teaching the mind to be present, we are teaching ourselves to be live more mindfully – in the present, taking a breath, not beholden to reactive thoughts and feelings – which is particularly helpful when faced with challenging circumstances or difficult situations.

Wondering how many times a day you're in a mindful state? There's actually a 15-item questionnaire researchers use to measure mindfulness called the Mindful Attention Awareness Score (MAAS), that you can take to see where you stand – the higher the score, the greater your ability to be mindful. Scored lower than you'd like? Don't sweat it! It's simply a sign that you may benefit from some mindfulness meditation practice.

THE DIFFERENCE BETWEEN MINDFULNESS AND MEDITATION

Here's the thing that many people find confusing about mindfulness: it's not a temporary state of mind that is present during meditation and then vanishes for the rest of the day. Rather, mindfulness is a way of living in which – when we remember – we are able to step back and be in the present moment in any situation. Mindfulness doesn't eliminate stress or other difficulties; instead, by becoming aware of unpleasant thoughts and emotions that arise because of challenging situations, we have more choice in how to handle them in the moment – and a better chance of reacting calmly and empathetically when faced with stress or challenges. Of course, practicing mindfulness does not mean we never get angry – rather it allows us to be more thoughtful in how we want to respond, whether that's calmly and empathetically or perhaps, occasionally with measured anger. Meditation is the training ground for learning mindfulness. At first, we meditate to become familiar with the here and now for a limited period of time. Over time, however, regularly practicing mindfulness helps us develop the ability to be present throughout the day, every day.

HOW MINDFULNESS MEDITATION WORKS

Mindfulness meditation doesn't only change our mindset and perspective, it actually can change the shape of our brains. Generalized neuroimaging meditation studies found that 8 weeks of mindfulness meditation also changes our brains, rewiring them towards more positive thoughts and emotions. For starters, meditation allows us to move from high-frequency brainwaves to a lower frequency, which activates (and, potentially even more importantly, deactivates) certain areas of the brain. For example, it can decrease neurological connections to the medial prefrontal cortex, or the "me center," diminishing traits such as fear, stress, and anxiety. In turn, meditation can also build new pathways to the parts of the brain responsible for traits like focus and decision-making. And that's not all: mindfulness meditation can actually change the shape of the brain as well, a process known as neuroplasticity. Research shows that gray matter – the area of the brain responsible for emotional regulation, planning, and problem-solving – as well as the cortical thickness – responsible for learning and memory – both increase with regular meditation practice. Alternatively, the amygdala, which regulates how we feel stress, fear, and anxiety, decreases in size.

THE BENEFITS OF MINDFULNESS

The hype around mindfulness meditation is real. People who incorporate it into their lives often report heightened levels of happiness, patience, acceptance, and compassion, as well as lower levels of stress, frustration, and sadness. There's plenty of research, too: Separate studies conducted by Northeastern University found that 3 weeks of Headspace increased compassion by 23% and reduced aggression by 57%. What's more, another study with students found that 10 days of

Headspace increased positivity and well-being. And yet another — an internal study that was published in top mindfulness journal PLOS ONE — found that 10 days of Headspace reduced stress by 14%.

PRACTICING MINDFULNESS MEDITATION

Practicing mindfulness meditation can be a great way to manage stress and boost compassion, focus, empathy, patience, energy, and ultimately, happiness. If you're just beginning a practice, a guided mindfulness meditation — led by a teacher in person or via the Headspace app — might be a good place to start. Having a trusted, experienced teacher guide you through the basic steps can be key to getting the most out of the experience. Most guided mindfulness meditations follow a similar format: the teacher explains how the mind behaves during meditation, leads you through a particular meditation technique, and suggests how to integrate this technique into your everyday life.

Though there are countless mindfulness techniques — each rooted in a different tradition and with a unique focus — most have one thing in common: they're aimed at cultivating two essential components, **calm** and **clarity**, with the intention to remain focused and hone a natural quality of awareness.

8 MEDITATION TECHNIQUES THAT CULTIVATE MINDFULNESS

Here's a breakdown of eight of the more popular mindfulness techniques — all of which are used in the Headspace app. Some will sound intriguing, while others may not be your cup of tea. See which ones work best for you.

- 1. Focused Attention:** Likely the most common form of meditation, this technique uses the breath to anchor the mind and maintain awareness. Focus your attention on the breath — specifically the rise and fall of the chest — and return to the breath whenever you get distracted or notice your mind starting to wander.
- 2. Body Scan:** This technique, which uses meditation to connect with the body, involves scanning your body from head to toe and being aware of any discomfort, sensations, or aches that exist (which could be indicators of stress and anxiety).
- 3. Noting:** This is a mindfulness technique in which you “note” a particular thought or feeling when you become distracted during meditation. The practice of noting helps to create space and learn more about our habits, tendencies, and conditioning.
- 4. Loving Kindness:** Instead of focusing on the breath, this technique involves focusing on the image of different people: people we know, people we don't; people we like, people we don't. We direct well-wishes and goodwill first to ourselves, and then, as a ripple effect, to others, which helps us let go of unhappy feelings we may be experiencing.
- 5. Skillful Compassion:** Similar to the loving kindness meditation technique, this one involves focusing on a person you know or love and paying attention to the sensations arising from the heart. It's aptly named because it's thought to be helpful in opening our hearts and minds for the benefit of other people, which in turn fosters a feeling of happiness in our own mind.
- 6. Visualization:** This technique uses visualization, to focus on a person or something more abstract, to hold attention. The idea here is that the familiar image will help create and maintain a relaxed focus.
- 7. Resting Awareness:** Rather than focusing on the breath or a visualization, this technique

involves letting the mind rest; thoughts may enter, but instead of distracting you and pulling you away from the present moment, they simply leave.

- 8. Reflection:** For this technique, ask yourself a question, for example, “What are you most grateful for?” (Note that asking yourself a question using the second person – you – will discourage the intellectual mind from trying to answer it rationally.) Be aware of the feelings, not the thoughts, that arise when you focus on the question.

PRACTICING MINDFULNESS POST-MEDITATION

Whichever technique you choose, know that experiencing moments of mindfulness during meditation is a great first step. After meditation, while our minds will likely experience distractions throughout the day, the more our mindfulness practice is honed and developed, the more we are able to catch ourselves being distracted and the more we are able to bring our focus back to the present moment. After all, that’s the whole point of practicing mindfulness meditation – to make us more mindful and less distracted throughout the day. So how do you remember to be mindful when you’re not meditating? At the end of your meditation, try to recognize how your mind feels and then make an intention to carry that feeling into the rest of your day. Some people find it helpful to form a clear idea of what they are going to do next – maybe take a shower or get a cup of coffee – and perform their next task with the same level of awareness they experienced during meditation. It doesn’t matter what you do after meditation, as long as you look for opportunities throughout your day in which to recognize the space and mindfulness you experienced during your practice.

MINDFULNESS FOR BEGINNERS

If you’re looking for a beginner’s guide to mindfulness, Headspace offers a 10-day beginner’s course on the essentials of meditation that will help you develop mindfulness – available for free – which is an ideal way to start building the foundation for a life-changing daily meditation practice. From there, once you gain more experience and confidence, you can explore the whole library of content, featuring hundreds of guided mindfulness meditations on a wide array of topics from stress and compassion, to sleep and focus.

YOGASANA

Tada means palm tree or mountain. This asana teaches one to attain stability and firmness and forms the base for all the standing asana.

TECHNIQUE

Tada means palm tree or mountain. This asana teaches one to attain stability and firmness and forms the base for all the standing asana.

TECHNIQUE

- Stand with feet 2 inches apart.
- Interlock the fingers, and turn the wrist outwards. Now inhale, raise the arms up and bring them in line with the shoulders.
- Raise the heels off the floor and balance on the toes. Stay in this position for 10 -15 seconds.
- Exhale, bring the heels down
- Release the interlock of the fingers and bring the arms down parallel to the trunk, and come back to standing posture.

BENEFITS

- This asana brings stability in the body, helps to clear up congestion of the spinal nerves, corrects faulty posture.
- Helps to increase height up to a certain age.

A WORD OF CAUTION

- Avoid lifting the toes in case of acute cardiac problems, varicose veins and vertigo. Vrksasana (The Tree Posture) Vṛkṣa means tree. The final position of this asana resembles the shape of a tree, hence the name. Techniq

- Stand
- with feet 2 inches apart
- Focus on a point in front.
- Exhale, bend the right leg and place the foot on the inside of the left thigh. The heel should be touching the perineum.
- Inhale and extend the arms up and join the palms.
- Stay in the position for 10 to 30 seconds and breathe normally.
- Exhale and bring the arms and right foot down.
- Relax and repeat the asana by bending the left leg.

BENEFITS

- Improves neuro-muscular coordination, balance, endurance and alertness.
- It tones up the leg muscles and rejuvenates the ligaments also.

A WORD OF CAUTION

- Please avoid this practice in case of arthritis, vertigo and obesity. Pada-Hastasana (The Hands to Feet Posture) Pada means feet, hasta means hands. Therefore, Pada Hastasana means taking the palms down towards the feet. This is also referred as Uttanasana.

Techniq

Stand with feet 2 inches apart

- Inhale slowly and raise the arms up.
- Stretch up the body from the waist.
Exhale and bend forward until the trunk is parallel to the ground
- Exhale, and bend forward until the entire palm rests on the ground.
- Maintain this final posture for 10-30 seconds.
- Those who are having stiff back should bend according to their capacity.
- Now inhale, come up slowly to the vertical position and stretch the arms above the head.
- Exhale and slowly return to the starting position in reverse order.
- Relax in Tadasana.

BENEFITS

- Makes the spine flexible, improves digestions, and prevents constipation and menstrual problems.

A WORD OF CAUTION

- Please avoid this practice in case of cardiac or back problems, abdominal inflammation, hernia and ulcers, high myopia, vertigo and during pregnancy.
- Those with vertebral and disc disorders should also avoid this practice.

Ardha Çakrasana (The Half Wheel Posture)

Ardha means half. Çakra means wheel. In this posture, as the body takes the shape of a half wheel, hence it is called Ardha Çakrasana.

TECHNIQ

- Support the back at the waist with all the fingers together pointing forward or downward.
- Drop the head backwards and stretching the neck muscles. As you inhale, bend backwards from the lumbar region; exhale and relax.

- Stay here for 10-30 seconds with normal breathing.
- Inhale and slowly come up.

BENEFI

- Ardha Çakrasana makes the spine flexible and strengthens thespinal nerves.
- Strengthens the neck muscles, and improves breathingcapacity.
- Helps in cervical spondylitis.

A WORD OF CAUTION

- Avoid this posture in case of vertigo or a tendency to giddiness.
- Hypertensive patients shall bend with care. Trikonasana (The Triangle Posture)
Trikoṇa means triangle. Tri means three and kona is an angle. As the asana resembles three arms triangles made by the trunk and the limbs, it has been named Trikoṇasana.

TECHNIQ

Stand with your feet comfortably apart.
Slowly raise both the arms sideways till they are horizontal

- Exhale, slowly bend to the right side and place the right hand just behind the right foot.
- The left arm is straight up, in line with the right arm.
- Turn the left palm forward.
- Turn your head and gaze at the tip of the left middle finger.
- Remain in the posture for 10-30 seconds with normal breathing.
- As you inhale slowly come up.
- Repeat for the left side.

BENEFITS

- Prevents flat foot.
- Strengthens calf, thigh and waist muscles
- Makes the spine flexible, improves lungs capacity.

A WORD OF CAUTION

- Avoid this posture in case of slipped disc, sciatica, and after undergoing abdominal surgery.
- Do not do beyond limits and overdo the lateral stretch.
- If one cannot touch the feet, one can reach for the knees instead.

SITTING POSTURES

Bhadrasana (The Firm/ Auspicious Posture)

Sthiti: Long sitting posture (**Vişramasan**

TECHNIQ

- Sit erect with the legs stretched out straight in the front.
- Keep the hands beside the hips. This is **Dandasana**.
- Now put the soles of your feet together.
- Exhale and clasp your hands together over your toes. Pull your heels as close as possible up to perineum region.
- If your thighs are not touching or are not close to the floor, place a soft cushion underneath the knees for support. This is the final position.
- Stay here for some time

BENEFITS

- Keeps the body firm and stabilize the mind.
- Keeps the knees and hip joints healthy.
Helps to relieve knee pain
- Acts on the abdominal organs and releases any tension in the abdomen.
- Benefits women by relieving abdominal pain often experienced during menstruation.

A WORD OF CAUTION

- Avoid this practice in case of severe arthritis and sciatica. Vajrāsana (Thunderbolt Posture)
This can be considered as a meditative posture. While practicing it for meditative purposes, one should close his/her eyes at the final stage.

TECHNIQUE

Sit with extended legs together, hands by the side of the body, palm resting on the ground, fingers pointing forward

- Fold the right leg at the knee and place the foot under the right

buttock.

- Similarly folding the left leg, place left foot under the left buttock
- Place both the heels so that the big toes overlap each other.
Position of the buttocks in the space between the heels
- Keep hands on respective knees.
- Keep the spine erect, gaze in front or close the eyes.
- While returning to the original position, bend a little towards right side, take out your left leg and extend it.
- Similarly extend your right leg and return to the original position.

BENEFITS

- This āsana strengthens thigh muscles and calf muscles.
- This āsana is good for digestion.
- It provides firm base to the spine and keeps the spine erect.

A WORD OF CAUTION

- Persons suffering from piles should not practise this āsana.
 - Those who are suffering from knee pain and ankle injury should avoid this practice.
- Ardha Ustrasana (The Half Camel Posture) **Sthiti:** Long sitting posture (Viśramasana) Ustra means camel. The final version of this āsana resembles the hump of a camel. In this version, only the first stage (half) of the āsana is being practiced.
- Techniq

- Sit in Viśramasana.
- Come to Dandasana.
- Fold your legs and sit on your heels.
- Keep the thighs close and big toes touching.
- Place the hands on the knees.
- The head and back should be straight.
- This is Vajrasana
- Stand on your knees.
- Place the hands on the waist with fingers pointing downward.
- Keep the elbows and shoulders parallel
- Bend the head back and stretch the neck muscles; inhale and bend the trunk backwards as much as possible. As you exhale, relax.
- Keep the thighs perpendicular to the ground

- Remain in the posture for 10-30 seconds with normal breathing.
- Return with inhalation; sit in Vajrasana.
- Relax in Viśrāmāsana.

Note: If you can reach the heels, you can place your hands on them and bend backwards. This is called Uṣṭrasana.

BENEFITS

- Relieves constipation and back pain.
- Increases blood circulation to the head and cardiac region.

A WORD OF CAUTION

- In case of hernia and abdominal injuries, arthritis, vertigo and pregnancy, please avoid doing this asana.
Ustrasana (Camel Posture) Ustra means camel. The body in this posture resembles the posture of a camel, hence the name.

TECHNIQ

- Kneel down on the floor. Keep your thighs and feet together, toes pointing back and resting

on the floor.

- Bring the knees and the feet about one foot apart and stand on the knees.
- While inhaling bend backward.
- Be careful not to jerk the neck while bending backward.
- With exhalation place the right palm on right heel and left palm on left heel.
- In final position, thighs will be vertical to the floor and head tilted backward.
- Weight of the body should be evenly supported by the arms and legs.
- This āsana should be practiced after Sarvangasana as a counter pose to enhance the benefits of Sarvangasana.

BENEFITS

- Ustrāsana is extremely useful for defective eyesight.
- This is useful in relieving back pain and neck pain.
- It helps to reduce fat over the abdomen and hips.
- It is helpful in digestive problems.

A WORD OF CAUTION

- Those suffering from high blood pressure, heart disease, hernia should not practice it.

SASANKASANA (THE HARE POSTURE)

- Sit in Vajrasana.
- Spread both the knees wide apart, keep the big toes touching.
- Keep the palms between the knees.
- Exhale and slowly stretch them full length.
- Bend forward and place the chin on the ground.
- Keep the arms parallel.

- Look in front and maintain the posture.
- Inhale and come up.
- Exhale and come back to Vajrasana.
- Stretch your legs back to Visramasan.

BENEFITS

- It helps to reduce stress, anger etc.
- It tones up reproductive organs, relieves constipation, improves digestion and relieves back pain.

A WORD OF CAUTION

- Please avoid this posture in case of acute backache.
- Patients with osteoarthritis of the knees should exercise with caution or avoid Vajrasana.

Uttāna Mandūkāsana (Stretched up-frog posture)

Uttāna means upright and Mandūka means frog. The final position of Uttāna Mandukasana resembles an upright frog, hence the name. In Uttāna Mandūkāsana, the head is held by the elbows.

TECHNIQUE

SIT

in Vajrāsa

- Spread both the knees wide, apart while toes remaining together.
- Raise your right arm, fold it and take it backward from above the right shoulder and place the palm below the left shoulder.
- Now fold left arm similarly and place the palm from the above level at below right shoulder.
- Maintain the position for a while, then coming back slowly to remove the left arm and then the right arm; bring the knees together as in the initial position.

BENEFITS

- This asana is helpful in backache and cervical pain.
- It helps in improving the diaphragmatic movements and helpsto improve lungs capacity.
-

A WORD OF CAUTION

Person with severe knee joint pain should not perform it. Vakrasana (The Spinal Twist Posture)

Sthiti:Dandasana**Techniq**

- Bend the right leg, and place the right foot beside the left knee.
- As you exhale, twist the body to the right.
- Bring the left arm around the right knee and clasp the right bigtoe or place the palm beside right foot.
- Take the right arm back and keep the palm on the ground withthe back straight.
- Remain in the posture for 10-30 seconds with normalbreathing and relax.
- Take out your hands with exhalation and relax
- Repeat the same on the other side.
- Inhale and come up.

BENEFITS

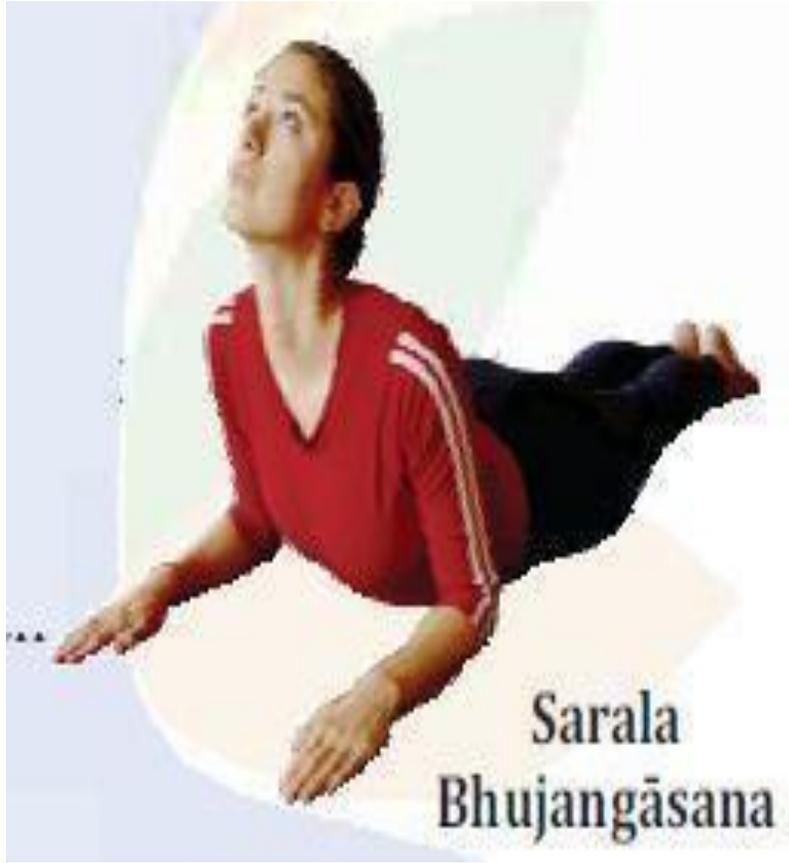

- Increases flexibility of the spine.
Helps to overcome constipation, dyspepsi
- Stimulates pancreas and helps in the management of diabetes.

A WORD OF CAUTION

- Please avoid this posture in case of severe back pain, vertebral and disc disorders, after abdominal surgery and during menstruation.

PRONE POSTURES

Bhujangasana (The Cobra Posture)**Sthiti:**Prone posture or Makarasana**Technique**

Lie down on your stomach, rest your head on your hands and relax the body.

- Now join your legs and stretch your arms
- Keep the forehead on the ground.
- Now place your hands just beside the body; keep palms and elbows on the ground.
- As you inhale slowly, lift the chin and chest come up to navel region.

STAY THERE COMFORTABLE

- This is called **Sarala Bhujangasana**.
 - Now come back and place your forehead on the ground.
 - Keep your palms besides the chest where your elbows were and raise the elbows.
 - Inhale; slowly lift the chin and chest up to navel region.
 - Exhale, rest your forehead on the ground and place your palms and rest your head on the palms and spread your legs and relax.
- Note:** Keep the legs firm so that no load or strain is felt on the lumbar spine.

BENEFITS

- This āsana is best for stress management.
- It reduces abdominal fat and alleviates constipation.

- It also helps to remove backache and bronchial problems.

A WORD OF CAUTION

- Those who have undergone abdominal surgery should avoid this asana for 2-3 months.
 - Those who suffer from hernia, ulcers should not practice this asana.
- Salabhasana(The Locust Posture)**Sthiti:**Prone posture; Makarasana**Techniq**

- Lie down on your stomach in Makarasana.
- Rest the chin on the floor; keep both hands beside the body; palms facing upwards
- Inhale, raise the legs off the floor as much as you can without bending the knees.
- Extend the arms and legs well to ease the lift of the body off the floor.
- Stay in this position for 10-20 seconds breathing normally.
- Exhale, bring the legs down towards the floor.
- Rest for a few seconds in Makarasana.

Note: Pull up the knee caps and squeeze the buttocks to improve the posture. This āsana is more beneficial when performed after Bhujangasana Benefi

- Helps in sciatica and lower backache.
- Tones the hip muscles and those in the kidney region.
- Reduces fat on the thighs and buttocks; good in weight management.
- Helps the abdominal organs aiding digestion

A WORD OF CAUTION

- Cardiac patients should avoid this posture. Please proceed cautiously in case of severe lower back pain.
- People with high blood pressure, peptic ulcers and hernia should also avoid this posture.

MAKARASANA (THE CROCODILE POSTURE)

In Sanskrit, Makara means crocodile. In this āsana, the body resembles a crocodile.

Sthiti: Prone relaxation posture Techniq

Lie down on your stomach with the feet wide apart, feet pointing outward.

- Bend both the arms and place the right hand on the left hand.
- Place the forehead on your hands.
- Keep the eyes closed. This is **Makarasana**.
- This asana is practiced for relaxation in all prone postures.

BENEFITS

Promotes relaxation of the lower bac

- Helps in recovery of back problems.
- Indicated for all orthopedic ailments.
- Indicated to counter stress and anxiety.

A WORD OF CAUTION

- Avoid this practice in case of low blood pressure, severe cardiac problems and pregnancy.

Supine Postures

SETUBANDHASANA (THE BRIDGE POSTURE)

Setubandha means formation of bridge. In this posture, the body is positioned like a bridge, hence the name. This is also called as Çatuşpadasana. **Sthiti:**Supine lying; Savasana. Techniq

- Bend both the legs at the knees and bring the heels near the buttocks.
- Hold both the ankles firmly; keep the knees and feet in one straight line.
- Inhale; slowly raise your buttocks and trunk up as much as you can to form bridge.
- Remain in this position breathing. For 10-30 seconds, with normal
- Exhale, slowly return to Savasana. The original position and relax in

Note: In the final position, the shoulders and head remain in contact with the floor and if required, in the final position, you can support your body at the waist with your hands.

BENEFITS

- Relieves depression and anxiety. Strengthens lower back muscles.
- Stretches abdominal organs, improves digestion and helps to relieve constipation.

A WORD OF CAUTION

- People suffering from ulcers and hernia, and women in advanced stages of pregnancy should not practice this asana.

UTTĀNA PĀDĀSANA (RAISED FEET POSTURE)

Uttāna in this context mean raised-upward and Pāda means leg. In this āsana, the legs are raised upward in supine position, hence, the name. Techniq

- Lie comfortably on the ground with legs stretched out. Hands should be placed by the sides.
- While inhaling, slowly raise both the legs without bending them at the knees and bring them to 90° angle.
- Maintain the position with normal breathing.
- Exhale and slowly bring both the legs down and place them on the ground.
- Repeat it one more time.

BENEFITS

- It balances the navel centre (Nabhimanipuracakra)
- It is helpful in relieving abdominal pain, flatulence, indigestion and diarrhea. It builds up the abdominal muscle
- It is also effective in overcoming the nervousness and anxiety.
- Helps to improve breathing and lungs capacity

A WORD OF CAUTION

- People with hypertension shall practice it with one leg alternatively without holding the breath. Ardha Halāsana (Half plough posture) 'Ardha' means half and 'Hala' means plough. This posture is known as Ardha Halāsana because in its final position, the body resembles half the shape of an Indian plough.

TECHNIQUE

- Take supine position; keep hands by the sides of thighs, palms resting on the ground
- Slowly raise your legs together without bending at knees and stop at 30° angle.
- After few seconds raise your legs further up to 60° angle and maintain the position.
- Now slowly raise the legs at 90° angle. This is the final position of the Ardha Halāsana.
- The body from hip to shoulder should be kept straight.
- Maintain this position as long as comfortable.
- Slowly lower legs at 90° angle and then on the ground without lifting the head.

BENEFITS

- This āsana is beneficial for dyspepsia and constipation
- The practice of this asana is useful in cases of diabetes, piles and throat related disorders.
- This is very beneficial for Hypertensive patients but needs to practice with care.

A WORD OF CAUTION

- Those who have lumbosacral (lower back) pain should not perform with both legs together. Avoid this practice in case of abdominal injuries, hernia etc. Pavanmuktasana (The Wind Releasing Posture)

Pavan means wind and mukta means to release or to make free. As the name suggests, this asana is useful in removing wind or flatulence from the stomach and intestines.

Sthiti: Savasana **Technique**

- Lie down flat on the back.
- Bend both the knees and bring the thighs to the chest.
- Interlock the fingers and clasp the shin below knees.
- Exhale; rise the head till your chin touches the knees and relax.
- This is Pawanmuktasana.
- Bring the head back to the ground.

WHILE EXHALING, LOWER THE LEGS TO THE FLOOR

- Rest in Savasana

Note: Synchronise your breathing with the leg movement and while touching the knee with the nose/ forehead, you should be able to feel the lumbar region stretch; keep the eyes closed and focus your attention on the lumbar region.

BENEFITS

- Removes constipation; gives relief from flatulence, decreases the bloating sensation in the abdomen and aids digestion.
- Helps in recovery of back problems.
- Offers deep internal pressure, massage and stretching of the highly complicated network of muscles, ligaments and tendons in the pelvis and waist region.
- It tones up the back muscles and spinal nerves.

A WORD OF CAUTION

- Please avoid this practice in case of abdominal injuries, hernia, sciatica or severe back pain and during pregnancy.

SAVASANA (THE DEAD BODY POSTURE)

Sava means dead body. The final position in this āsana resembles a dead body.

Sthiti:Supine Relaxation Posture

TECHNIQUE

- Lie down on your back with arms and legs comfortably apart. Palms facing upward; eyes close
- Relax the whole body consciously

- Become aware of natural breath and allow it to become rhythmic and slow.
- Remain in the position till you feel refresh and relax.

BENEFITS

- Helps to relieve all kinds of tensions and gives rest to both body and mind.
- Relaxes the whole psycho-physiological system.

The mind, which is constantly attracted to the outer world, takes a U-turn and moves inwards, thus gradually getting absorbed; as the mind turns quiet and absorbed, the practitioner remains undisturbed by the external environment

- It is found very beneficial in the management of stress and its consequences.

STRESS INOCULATION TRAINING

Stress Inoculation Training (SIT) is a multifaceted type of cognitive- behavioral therapy designed to help individuals cope with stress. It was initially developed by psychologist Donald Meichenbaum in the 1980s and has been employed to mitigate the sequelae of stress in a variety of situations. The essence of SIT is that by exposing people to increasing levels of perceived stress, they

practice employing different coping skills and eventually develop increased tolerance or immunity to a particular stimulus.

1. **Conceptualization** – This phase is designed to achieve two specific goals. First, it builds a relationship between the therapist, coach, or trainer. Second, it educates an individual, increasing their understanding and awareness of his or her stress response and existing coping skills. According to Meichenbaum, is it preferable for this phase to be less didactic and more Socratic in nature. He suggests using “curious questions” to promote an individual’s processing and discovery.

Skills Acquisition and Consolidation – This phase is all about developing and practicing individual psychological tools and cognitive restructuring techniques (breathing techniques, relaxation techniques, negative thought stopping, etc.). The goal is build the coping techniques to they can be applied in the next phase to regulate negative emotions and increase control over physiological responses. They are discovered, nurtured, and strengthened in collaborative manner with a trainer or therapist.

2. **Application and Follow-through** – This phase is, in essence, the phase of inoculation. On a graduated basis, an individual is exposed to increasing levels of a particular stressor and practices applying the skills they have developed to mitigate his or her stress response.

MODIFICATIONS OF STRESS INOCULATION TRAINING: STRESS EXPOSURE TRAINING

It is important to recognize that Meichenbaum’s intention was really to help individuals cope with physical pain, anxiety, anger, and fear as a result of traumatic experiences. This was a clinical intervention designed to treat pathological psychiatric conditions. However, various organizations and individuals saw the potential benefit of instituting this technique prophylactically. Organizations, like the military and NASA, began to adapt the traditional structure of SIT in demonstrated substantial improvements in performance.^{7,8,9,10,11,12}

One adaptation of SIT is Stress Exposure Training (SET). SET, originally proposed by Driskell and Johnston, takes a slightly different approach.¹¹ Its general structure is similar to Meichenbaum’s cognitive behavioral approach. It is divided into three analogous phases:

Information provision – This phase provides information on the human stress response, conditions participants should expect to encounter, and other preparatory information

1. **Skills acquisition** – This phase is designed to develop and refine behavioral, technical, and cognitive skills
2. **Application and practice** – This phase includes practicing skills under conditions that approximate the operational environment and that gradually attain the level of stress expected. SET is different in that, quite simply, it takes a proactive approach. It provides prophylaxis. It prepares individuals without psychiatric pathology for potential stressors and situations that are likely to encounter.

INFORMATION PROVISION

Before we even approached the edge of the water, our instructors told us what to expect. They

said it was normal to be anxious; it was normal to be uncomfortable with your hands and legs tied together. Furthermore, it was a normal physiologic response to experience an elevated heart rate, physical discomfort, and a general unease having to hold our breath. They also explained why it would be important to relax and reduce our bodies' oxygen consumption as much as possible. In the first phase, preparatory information is provided to trainees. They are taught about the physiological response to stress normally and how these natural physiological mechanisms can interfere with the specific cognitive processes and technical skills during resuscitation. It ensures that everyone understands this deterioration in their faculties is normal. Furthermore, it generates accurate predictions of how they will respond. As it turns out, this is critical. Just by having more precise expectations, people perform better under stress. Another important part of this phase is making it clear that providers aren't helpless in the face of this hard-wired response. The belief that people have the capacity to exert control over their behavior is critical. This understanding of self-efficacy has been linked to improved performance in different domains.^{15,16} It also allows you to predict potential areas of weakness and motivate individuals to obtain the necessary skills to improve their response under stress.^{17,18}

PHASE 2 – SKILLS ACQUISITION

We practiced drown-proofing every day for months. Everybody developed tricks and methods to help keep calm, manage their anxiety, and prepare to address various challenges that arose during the exercise. Some people developed a mantra they would repeat to themselves to build confidence. Others sung songs in their heads to calm them down. Still others practiced muscle relaxation techniques whenever possible under water.

The crux of Phase 2 is to develop the host of technical and non-technical skills needed to perform in the resuscitation environment without the addition of stressful stimuli. The goal is to learn and develop constructive coping mechanisms and to develop effective performance habits. The fundamental technical skills of emergency medical care must be established **in conjunction with** various cognitive and behavioral techniques. Precisely what medical skills need to be acquired and how they are to be taught depends on an individual's role and level of experience. I will leave these recommendations to experts in the field of emergency medicine and critical care.

As far as the cognitive and behavioral skills go, I will attempt to outline some key techniques. I would hasten to add that these, too, need to be adapted to different settings. Also, at least in my opinion, they need to be individualized. Some people have an easier time with certain techniques than others. That's fine. Develop a habit of using the various psychological tools that work best for you. It is also worth pointing out that I developed the concepts of Performance Enhancing Psychological Skills (PEPS) and also the components of "Beat The Stress Fool" or BTSF (for more on this check out the post on Enhancing Human Performance in Resuscitation) from the following list of evidence-based techniques:

COGNITIVE CONTROL TECHNIQUES

The foundation of evidenced-based cognitive behavioral therapy in psychiatry is the fact that there is a fundamental connection between what a person thinks, what they feel, and how they act. Cognitive control techniques are designed to provide control over distracting or stress-inducing thoughts. At its core, this is essentially a metacognitive process. The individual is taught to recognize deleterious or distracting thought processes and stopping them. Then negative thoughts are replaced with positive, task-focused thoughts. Say, for example, that a patient presents to you in

respiratory failure. At first glance, just based on preliminary information you immediately think “Oh crap! That looks like a difficult airway. I haven’t had one of these in a while.” You feel your heart rate start to increase and you start to experience feelings of doubt or anxiety. A cognitive control strategy might be to tell yourself... “It might be difficult, but I can take care of this. I have been trained to manage difficult airways and I have managed them before. I know the various steps I can take to optimize oxygenation and maximize chance of first pass success. I have a great team to support me. I can do this.” You could even make it even more specific. It could, perhaps, be made even more task specific by including individual steps. Regarding patient preoxygenation, you could invoke the words of airway master, Dr. Richard Levitan, and say “Sit the patient up, jaw forward, O’s through the nose.” These thoughts or self-suggestions are positive, self-affirming, and task specific. They not only use thoughts to change emotional condition (decrease fear or anxiety),¹⁹ but they also hone attention on the task at hand. Both are important aspects of dealing with stress and improving performance in this situation.^{20,21}

PHYSIOLOGICAL CONTROL TECHNIQUES

These strategies are aimed at controlling specific physiological parameters. Certain physiological responses, such as tachycardia and hyperventilation, magnify the effects of anxiety and contribute to the unfavorable effects of stress on fine motor control, visual acuity, and cognition. Some effective techniques include progressive relaxation or biofeedback.^{22,23} However, these techniques are not always feasible when suddenly presented with a decompensating patient. One method that shows great promise and could easily be applied in resuscitation is controlled breathing. Different techniques of breathing have been used in diverse fields: from yoga, meditation, and martial arts to public speaking and athletics.

Personality, Motivation, emotion, stress and coping MCQ

- 1- Mismatch between personality and organization may lead(s) to
 - (A) Confusion and chaos
 - (B) Loss of interest by members in organization
 - (C) Low morale and job satisfaction
 - (D) All of the aboveAns. D

- 2- A__ person has a cause and an ideology to fight for achieving the set goal.
 - (A) Self-actualized
 - (B) Self-confident
 - (C) Self-driven
 - (D) Self-disciplinedAns. A

- 3- The techniques such as interviews, questionnaires, etc. are used in the__stage related to management of change.
 - (A) Training
 - (B) Diagnosis

- (C) Recruitment
(D) All of the aboveAns. B
- 4- The team whose members collaborate through use of various information technologies is known as team.
- (A) Virtual
(B) Ideal
(C) Real
(D) None of the aboveAns. A
- 5- Which personality theories give recognition to continuity of personalities?
- (A) Humanistic
(B) Integrative
(C) Trait
(D) None of the aboveAns. C
- 6- Major determinants of personality
- (A) Biological
(B) Situation
(C) Both (A) and (B)
(D) None of the aboveAns. C
- 7- Caused by travails of life to meet deadlines
- (A) Hyper work stress
(B) Eustress
(C) Distress
(D) All of the aboveAns. A
- 8- Caused by less than optimum activity
- (A) Distress
(B) Eustress
(C) Hypo stress
(D) None of the aboveAns. C
- 9- Identify the process influence personality development.
- (A) Socialization process
(B) Identification process
(C) Both (A) and (B)
(D) None of the aboveAns. C

- 10- Roger's defines the_ as an organized, consistent, conceptualgestalt composed of perceptions of the characteristics of the 'I' or 'me'.
- (A) The self concept
 - (B) The work concept
 - (C) The team concept
 - (D) None of the aboveAns. A
- 11- Identify the primary level(s) of conflict(s) (A) Intrapersonal
- (B) Interpersonal
 - (C) Intergroup
 - (D) All of the aboveAns. D
- 12- State the reason(s) for individualresistance
- (A) Personal reasons
 - (B) Economic reasons
 - (C) Social reasons
 - (D) All of the aboveAns. D
- 13- Fiedler has described situationalfavorableness in terms of three empirically derived dimensions, viz:-
- (A) The leader member relationship,The degree of task structure, The leader's positional power
 - (B) The leader member relationship, The degree of organization structure, The leader's positional power
 - (C) The leader member relationship,The degree of task structure, The leader's positional level
 - (D) The leader member relationship, The degree of organization structure,The leader's positional level Ans. A
- 14- Identify the main reason(s) forresistance to change, as advocatedby Keith Davis
- (A) Obsolescence of skills
 - (B) Fear of unknown
 - (C) Preference for status quo
 - (D) All of the aboveAns. D
- 15- _is the science of humanbehavior.
- (A) Psychology
 - (B) Philosophy
 - (C) Sociology
 - (D) None of the aboveAns. A
- 16- Identify the key principle(s) for integrative (win-win) negotiations (A), Invent options for mutual

gains

- (B) Focus on interests and not positions
 - (C) Insist on using objective criteria
 - (D) All of the above
- Ans. D

17- _____ is caused because of the modern life and anxiety to cope with them.

- (A) Depression
 - (B) Distress
 - (C) Eustress
 - (D) None of the above
- Ans. B

18- A person of lower than normal intelligence is less bored by _____ work.

- (A) Repetitive
 - (B) Continuous
 - (C) Daily
 - (D) All of the above
- Ans. A

19- What is the other name for vertical job loading?

- (A) Job satisfaction
 - (B) Job enlargement
 - (C) Job enrichment
 - (D) None of the above
- Ans. C

20- John and Peter are members of the Six-sigma team. What factor(s) may give rise to conflict between these two qualified members?

- (A) John and Peter have incompatible needs
 - (B) Limited availability of resources
 - (C) Perception relating to the concerned issue
 - (D) All of the above
- Ans. D

21- The conflict management style which refers to cooperative but unassertive behavior is known as _____.

- (A) Accommodating style
 - (B) Working style
 - (C) Cooperative style
 - (D) None of the above
- Ans. A

22- According to Freud the human mind is composed of

- (A) Preconscious mind
- (B) Conscious mind

- (C) Unconscious mind
- (D) All of the aboveAns. D

- 23- Behavioral scientists are focusing their attention on
- (A) Relationship of organizational structure to human behavior
 - (B) Organizational adaptability
 - (C) Decision making
 - (D) All of the aboveAns. D

- 24- The process by which a third party helps two or more other parties to resolve their conflicts is known as_.
- (A) Mediation
 - (B) Cooperation
 - (C) Mutation
 - (D) None of the aboveAns. A

- 25- Ego controls
- (A) The gateway of actions
 - (B) Select the feature of environment
 - (C) Decides what instincts will be satisfied
 - (D) All of the aboveAns. D

- 26- The relationship in which one person influences others to work together willingly on related tasks is known as_.
- (A) Delegation
 - (B) Leadership
 - (C) Management
 - (D) None of the aboveAns. B

- 27- Desire to be accepted by others
- (A) Affiliation motive
 - (B) Achievement motive
 - (C) Primary motive
 - (D) Power motiveAns. A

- 28- Desire to be successful
- (A) Achievement motive
 - (B) Affiliation motive
 - (C) Primary motive
 - (D) Power motiveAns. A

- 29-** Avoidance of pain
(A) Achievement motive
(B) Affiliation motive
(C) Primary motive
(D) Power motive
Ans. C
- 30-** Desire to control others
(A) Achievement motive
(B) Affiliation motive
(C) Power motive
(D) Primary motive
Ans. C
- 31-** Good match between individual personality and organization is essential because of
(A) Some people have passion for bureaucracy
(B) Some people prefer autonomy flexibility in operation
(C) Both (A) and (B)
(D) None of the above
Ans. C
- 32-** Ego reduces tension by performing task of
(A) Perceiving outside world
(B) Remembering experience with outside world
(C) Acting to satisfy the instinctual wishes
(D) All of the above
Ans. D
- 33-** Following is the specific characteristic(s) of high achiever
(A) Moderate risk taker
(B) Satisfied with his accomplishment
(C) Need for immediate feedback
(D) All of the above
Ans. D
- 34-** Organizational socialization includes
(A) Developing competencies
(B) Developing organizational values
(C) Developing social and working relationship
(D) All of the above
Ans. D
- 35-** According to Vroom's theory,
_is the result of multiplication of valence and expectancy.
(A) Motivation
(B) Management

- (C) Delegation
- (D) OrganizationAns. A

36- Which type of motivator(s) is (are) involved in granting additional authority to an employee in his activity?

- (A) Responsibility
- (B) Recognition
- (C) Both (A) and (B)
- (D) None of the aboveAns. C

37- An individual can cope with stress through_.

- (A) Regular exercise
- (B) The self concept
- (C) Self control
- (D) Self motivationAns. A

38- In order to understand the Rogers' theory one needs to understand which of the following?

- (A) The self concept
- (B) The organism
- (C) The development of self
- (D) All of the aboveAns. D

39- _is an event which leads to creation of a life stressor.

- (A) Festival
- (B) Marriage
- (C) Conference
- (D) WorkshopAns. B

40- Personality is affected by which of the following factor(s)?

- (A) Heredity
- (B) Culture
- (C) Family
- (D) All of the aboveAns. D

41- Trait theories

- (A) Allport, Cattell and Sheldon
- (B) Likert's scale
- (C) Sigmund Freud
- (D) Carl RogersAns. A

- 42-** Summed rating measure
(A) Allport, Cattell and Sheldon
(B) Likert's scale
(C) Sigmund Freud
(D) Carl Rogers
Ans. B
- 43-** Self theory
(A) Allport, Cattell and Sheldon
(B) Likert's scale
(C) Sigmund Freud
(D) Carl Rogers
Ans. D
- 44-** Intrapsychic theory
(A) Allport, Cattell and Sheldon
(B) Likert's scale
(C) Sigmund Freud
(D) Carl Rogers
Ans. C
- 45-** Manager's role changed from that of a leader to that of partner in a type of organization.
(A) Collegial
(B) Autocratic
(C) Custodial
(D) Supportive
Ans. A
- 46-** Identify the situation(s) which reflect upward communication
(A) Suggestion boxes kept in the worker's canteen
(B) Performance reports of workers
(C) Employee attitude surveys
(D) All of the above
Ans. D
- 47-** The blue print of human behavior at work is represented by
(A) Procedures, Rules, Regulations
(B) Procedures, Rules, Coordination
(C) Procedures, Motivation, Regulations
(D) Procedures, Motivation, Coordination
Ans. A
- 48-** Select the factor(s) which is (are) helpful in understanding perceptual organization.
(A) Perceptual grouping
(B) Perceptual constancy
(C) Closure principle

(D) All of the aboveAns. D

49- Two factor theory of motivation

(A) Harold Kelley

(B) Douglas McGregor

(C) Herzberg

(D) J. Stacy AdamsAns. C

50- Commonalities and differences suggest in certain respects, every person is like

(A) All other people

(B) Some other people

(C) No other person

(D) All of the aboveAns. D

51. Some behavior patterns appear only after a specific developmental stage or time. This stage or time is called:

(a) Imprinting

(b) maturation

(c) Learning

(d) InstinctAns. B

52. The inherited behavior is called instincts:

(a) Imprinting

(b) Learning

(c) maturation

(d) InstinctAns. D

53. The change of behavior by life experiences is called:

(a) Instinct

(b) maturation

(c) Learning

(d) ImprintingAns. C

54. The decrease in response to repeated or continuous stimulation is called:

(a) Instinct

(b) maturation

(c) habituation

(d) Imprinting Ans. C

55. The uses cognitive or mental processes to associate experiences and solve problems are

called:

- (a) Instinct
- (b) maturation
- (c) habituation
- (d) insight Ans. D

56. The behavior in which one animal is aggressive or attacks another animal, the other responds by returning the aggression or submitting is called:

- (a) agnostic
- (b) Territory
- (c) Hierarchy
- (d) Altruism Ans. A

57. The organization of group of animals in such a way that some members of the group have greater access to resources like food or mates than others is called:

- (a) agnostic
- (b) Territory
- (c) Hierarchy
- (d) Altruism Ans. C

58. The site defended by territorial animal by agonistic behavior is:

- (a) Hierarchy
- (b) Altruism
- (c) agnostic
- (d) Territory Ans. D

59. The interaction in which an individual gives up or sacrifices some of its own reproductive potential to benefit another individual is called:

- (a) agnostic
- (b) Territory
- (c) Hierarchy
- (d) Altruism Ans: D

60. Each of our _____ consists of tightly coiled DNA.

- (a) chromosomes
- (b) cell proteins
- (c) nucleotides
- (d) amino acids Ans. A

61. Genes regulate protein synthesis by

- (a)** coding for the arrangement of ribosomes on DNA molecules.
- (b)** specifying which amino acids will be joined together, and in what order.
- (c)** regulating the influx of ions like sodium and potassium, which code for proteins.
- (d)** setting the cell's biological clock and controlling how and when a cell divides.

Ans. B

62. The fusion of your father's sperm and your mother's egg is referred to as

- (a)** gene expression.
- (b)** spermatization.
- (c)** fertilization.
- (d)** epigenetics.

Ans. C

63. Even though your body changes and you develop new physical and behavioral characteristics, your DNA never changes.

- (a)** archetype
- (b)** phenotype
- (c)** appearance
- (d)** genotype

Ans. D

64. How do gene mutations contribute to evolution?

- (a)** Beneficial mutations are passed on to several members of a generation, quickly taking hold in a population.
- (b)** Unfavorable mutations have a more significant effect on genes than do favorable mutations, so they are spread through the population.
- (c)** Natural selection favors beneficial mutations, so they survive and are passed on to future generations.
- (d)** Beneficial and unfavorable mutations take hold in the population equally over numerous generations.

Ans. C

65. The process by which a cell directs a gene to make a certain protein is called

- (a)** gene expression.
- (b)** DNA extraction.
- (c)** chromosome assembly.
- (d)** genetic modification.

Ans. A

66. Epigenetics is most concerned with
- (a) changes in a person's genotype resulting from environmental influences.
 - (b) the expression of a particular gene as influenced by external inputs.
 - (c) environmental influences on gene expression over experiential influences.
 - (d) the heritability of genotypes that have been altered over multiple generations. Ans. B
67. In the experiment with dull and bright rats, Cooper and Zubek demonstrated a gene–environment interaction by showing that when navigating the maze
- (a) dull rats raised in all environments always made more errors.
 - (b) bright rats raised in enriched environments sometimes made more errors.
 - (c) dull rats raised in enriched environments eventually performed as well as bright rats.
 - (d) dull rats raised in impoverished environments performed poorly. Ans. C
68. Why are dominant, yet harmful, alleles like the *huntingtin* gene so rare in our genomes?
- (a) Only a few harmful alleles affect the nervous system.
 - (b) The carrier does not survive long enough to pass on the allele.
 - (c) The alleles for disorders are not active until adulthood.
 - (d) The allele can be transmitted only to another dominant carrier. Ans. B
69. Before the mechanisms behind PKU were known to science, infants that inherited the genes for the disorder almost always
- (a) maintained a low bodyweight.
 - (b) developed mental impairments.
 - (c) grew to pass on the genes to offspring.
 - (d) died before the age of ten. Ans. B
70. The effects of PKU are epigenetic because
- (a) having two genes for PKU doubles the chances that phenylalanine will impact a child's brain development.
 - (b) a child inherits two genes for PKU only when environmental conditions are favorable.
 - (c) phenylalanine causes mental deficits even if a child inherits just one gene for PKU.
 - (d) PKU is harmful only if a child ingests significant amounts of phenylalanine. Ans. D
71. Which single gene effect do men display more often than women?
- (a) The inability to distinguish red from green
 - (b) The inability to distinguish different pitches
 - (c) A gradual decline in the ability to focus on distant objects

- (d) A gradual decline in the ability to hear. Ans. A
72. One reason dysfunctional alleles can have such specific effects on the workings of our sensory systems is that
- (a) only one allele has a significant effect on each system.
 - (b) the toxicity of dysfunctional alleles degrades the action of the entire brain.
 - (c) our sensory systems rely on the functioning of more than one protein.
 - (d) only a single allele needs to be dysfunctional to result in a deficit. Ans. C
73. Which statement best describes a valid gene– environment interaction on behavior?
- (a) Identical twins adopted by different families often display behaviors typical of their adoptive families.
 - (b) In rats, littermates reared by mothers of different strains display the same exploratory behavior as their biological siblings.
 - (c) Two people with the same phenotype may not share the same genotype.
 - (d) Shrews raised in a lab without their mother fail to nurture their young. Ans. A
74. Which confounding variable is teased out when psychologists study the traits of identical twins?
- (a) Similar environments shared by relatives
 - (b) Shared zygotes of monozygotic twins
 - (c) The influence of dysfunctional alleles
 - (d) The genetic influence of the *huntingtin* gene. Ans. A
75. Dizygotic twins
- (a) have identical DNA.
 - (b) appear to be identical.
 - (c) rarely resemble each other.
 - (d) grow from separate zygotes. Ans. D
76. Twins who do *not* share 100 percent of their genes are called
- (a) dizygotic.
 - (b) monozygotic.
 - (c) identical.
 - (d) discordant. Ans. A

77. Twins who share a certain physical or behavioral trait are *_____* for that trait.
- (a) discordant
 - (b) monozygotic
 - (c) dizygotic
 - (d) concordant
- Ans. D
78. Heritability estimates tell us
- (a) the degree to which variations in a population can be attributed to genetics.
 - (b) the rate at which people in a given population develop a particular disorder.
 - (c) the percentage of people who can pass on a specific gene to a child.
 - (d) the chance that any one person will carry a particular gene.
- Ans. A
79. What is the key difference between twin studies and adoption studies?
- (a) Twin studies involve identical twins, while adoption studies involve fraternal twins.
 - (b) In twin studies, the effects of the environment are not taken into consideration.
 - (c) In adoption studies, twins are separated at birth, adopted, and raised apart.
 - (d) Adoption studies involve non-twin biological siblings raised by different families.
- Ans. C
80. Twin studies of the heritability of schizophrenia generally show that
- (a) there is a 50 percent difference in the genomes between those with schizophrenia and those without it.
 - (b) 90 percent of twins who inherit genes for schizophrenia will develop symptoms.
 - (c) monozygotic twins tend not to inherit genes for schizophrenia.
 - (d) the heritability of schizophrenia is about 50 percent.
- Ans. D
81. Schizophrenia most often presents itself at what stage?
- (a) Early childhood, when parental influences are most significant
 - (b) Late childhood, when genetics and family environment have the greatest impact
 - (c) Early adulthood, when people begin to face the world on their own
 - (d) Late adulthood, when brain and body cells are more susceptible to breaking down
- Ans. C
82. In cases where only one of two identical twins develops schizophrenia, all of the following factors may be responsible *except*
- (a) birth weight.
 - (b) birth order.
 - (c) nutrition.

(d) nurturing. Ans. B

83. Which situation is most consistent with the results of twin studies of schizophrenia?

(a) When both twins carry the gene for schizophrenia, only one will develop symptoms.

(b) Schizophrenia is more likely to materialize in a twin who experiences extreme stress.

(c) Twins who inherit the gene for schizophrenia very rarely present symptoms of the disorder.

(d) Having a father with schizophrenia greatly increases the chance that male twins will develop the disorder. Ans. B

84. What do studies of maternal nurturing behavior in rats suggest about humans?

(a) Maternal nurturing causes children to release corticosterone, which reduces levels of stress and leads to more nurturing.

(b) People who are adequately nurtured early in life tend to be less nurturing when they have children of their own.

(c) Children with nurturing mothers develop fewer natural defenses to stress and are more likely to become suicidal.

(d) Maternal neglect early in life may have lasting impacts on a person's ability to cope with life's challenges. Ans. D

85. All the following are defense mechanisms of the ego, except:

A. Projection

B. Conversion

C. Reaction formation

D. Transference Ans. D

86. Operant condition with paradigm pain stimulus given to a child for behaviour therapy is:

A. Positive reinforcement

B. Negative reinforcement

C. Punishment

D. Negotiation Ans. C

87. Psychoanalysis was discovered by:

A. Alder

B. Bleuler

C. Morton

D. Sigmund Freud Ans. D

88. Appropriate management of phobias includes:

A. Systematic desensitization

B. Chlorpromazine

- C. Bio feed base
D. ECTAns. A
89. Mature defense mechanism is:
A. Denial
B. Anticipation
C. Projection
D. Reaction Other mature defenses are:Sublimation, suppression,humor, altruism, ascetism. Ans. B
90. Mature defense mechanism is seen in:
A. Regression
B. Altruism
C. Repression
D. None Other mature defenses:Ascetism AnticipationSublimationSuppressionHumor Ans. B
91. That part of the mind which is working on reality principle is:
A. Id
B. Ego
C. Super ego
D. Ego-idealAns. B
92. One of the important defense mechanism is:
A. Anticipation
B. Confabulation
C. Repression
D. SuppressionAns. C
93. Which of the following excludes painful stimuli from awareness?
A. Repression
B. Projection
C. Rationalism
D. Reaction formationAns. A
94. According to Sartre, existentialism is a doctrine intended strictly for:
(a) all people.
(b) specialists and philosophers.
(c) Europeans.

(d) atheists. Ans. B

95. What all existentialists have in common, according to Sartre, is the view that:

(a) God does not exist, and so everything is permitted.

(b) all humans share a common nature.

(c) existence precedes essence.

(d) essence precedes existence. Ans. C

96. In Sartre's view, when one chooses how to live one is choosing:

(a) only for oneself.

(b) for all of one's family.

(c) for all of one's friends.

(d) for all people. Ans. D

97. Sartre claims that when he speaks of *forlornness*, he means that:

(a) God does not exist and we must face all the consequences of this.

(b) we can never truly know another human being.

(c) we are not responsible for our passions.

(d) all of the above. Ans. A

98. According to Sartre, the existentialist finds the fact that God does not exist:

(a) liberating.

(b) clarifying.

(c) very distressing.

(d) unimportant. Ans. C

99. In Sartre's view, humans are responsible for:

(a) their actions.

(b) their passions.

(c) both a and b.

(d) neither a nor b. Ans. C

100. Sartre claims that the value of one's affection is determined by:

(a) the way one acts.

(b) the way one feels.

- (c) the way one thinks.
- (d) all of the above. Ans. A

101. Sartre claims that according to existentialism, there is no reality except in:

- (a) passion.
- (b) action.
- (c) contemplation.
- (d) appetite. Ans. B

102. Who defined "group mind" as under: "It (Group mind) consists of the same stuff as individual minds, its threads and parts lie within these minds but the parts in the several individual minds reciprocally imply and complement one another and make up the system which consists wholly of them",

- (a) Mc Dougall
- (b) J. B. Watson
- (c) J. S. Mill
- (d) William James. Ans. A

103. For Mc Dougall, the seat of conscious mental activity is:

- (a) Mind
- (b) Soul
- (c) Synapse
- (d) Libido. Ans. C

104. Who has rightly revealed that Behaviourism has reduced the person "to a large white rat or a slower computer"?

- (a) J. B. Watson
- (b) R. S. Woodworth
- (c) Bugental
- (d) Maslow. Ans. C

105. Who has rightly commented, "The study of 1 crippled, stunted, immature and unhealthy specimens can yield only a cripple psychology and cripple philosophy"?

- (a) Abraham Maslow
- (b) Carl Rogers
- (c) J. B. Watson
- (d) R. S. Woodworth. Ans. A

106. Who was considered as "Spiritual father of humanism in America"?

- (a) J.B. Watson

- (b)** Carl Rogers
- (c)** R. S. Woodworth
- (d)** Abraham Maslow 1Ans. D

107. Who assumed that every person has an inherent tendency to actualize his unique potential?

- (a)** Abraham Maslow
- (b)** Carl Rogers
- (c)** R. S. Woodworth 1
- (d)** J.B. WatsonAns. B

108. Abraham Maslow assumed a holistic approach to:

- (a)** Perception
- (b)** Motivation
- (c)** Learning
- (d)** IntelligenceAns. B

109. Maslow's self-actualization theory has been best explained in terms of:

- (a)** Perceptual Processes
- (b)** Intellectual Processes
- (c)** Creativity
- (d)** Motivational ProcessesAns. D

110. Alfred Adler's striving for superiority and Erik Erikson's need for mastery are similar to Maslow's concept of:

- (a)** Belongingness Need
- (b)** Esteem Needs
- (c)** Need for self-actualization
- (d)** Safety NeedsAns. B

111. Self-actualization refers to the desire for:

- (a)** Self-fulfillment
- (b)** Security
- (c)** Sex satisfaction
- (d)** Love and belongingnessAns. A

112. In framing the concept of "Self-actualization", Maslow (1970) has acknowledged his debt to:

- (a)** Kurt Lewin
- (b)** Kurt Goldstein
- (c)** Carl Rogers
- (d)** R. S. WoodworthAns. B

113. Need for self-actualization is an umbrella need that covers:

- (a)** 10 metaneeds or being values
 - (b)** 100 metaneeds or being values
 - (c)** 20 metaneeds or being values
 - (d)** 17 metaneeds or being values
- Ans. D

114. Abraham Maslow is well-known for his concept of:

- (a)** Hierarchical model of motivation
 - (b)** Topographical Psychology
 - (c)** Field Theory
 - (d)** Life Space
- Ans. A

115. Self-actualization need lies at the top of the hierarchy where only:

- (a)** 50% people reach
 - (b)** 10% people reach
 - (c)** 80% people reach
 - (d)** 100% people reach
- Ans. B

116. The existential Psychology is highly related to Humanistic Psychology. These two systems together constituted the:

- (a)** Third force in psychology
 - (b)** Fourth force in psychology
 - (c)** First force in psychology
 - (d)** Second force in psychology
- Ans. A

117. Existential Psychology deals with person as such who exists as:

- (a)** A being-in-the-world
 - (b)** An animal
 - (c)** A psychophysical entity
 - (d)** An environmental product
- Ans. A

118. The basic aim of existential psychology is to understand a person in his:

- (a)** Motivational cycle
 - (b)** Situational world
 - (c)** Environmental cycle
 - (d)** Existential reality
- Ans. D

119. Soren Kierkegard was a/an:

- (a)** American Philosopher

- (b)** Danish Philosopher
- (c)** English Philosopher
- (d)** Swiss PhilosopherAns. B

120. When a person meaningfully communicates with others, he is said to have:

- (a)** Existed
- (b)** Communicated
- (c)** Restricted
- (d)** PreferredAns. A

121. The very term “existential neurosis” was first explained by:

- (a)** Rollo may (1909)
- (b)** Maddi (1967)
- (c)** Martin Heidegger (1899)
- (d)** Karl Jaspers (1960)Ans. B

122. For cognitive psychologists, psychology is the study of:

- (a)** Experience
- (b)** Mind and Soul
- (c)** Behaviour
- (d)** Higher and mental processesAns. D

123. When the child is about two years old, he develops the ability to respond to even those objects that are not observable. This is called:

- (a)** Egocentrism
- (b)** Object permanence
- (c)** Semiotic function
- (d)** AnimismAns. B

124. In pre-operational stage, the “intuitive period” is also known as:

- (a)** Sensori-motor Period
- (b)** Perceptual Period
- (c)** Concrete Operational Period
- (d)** Formal Operational PeriodAns. B

125. “Childhood shows the man as morning ‘ hows the day”. – This quotation reveals the importance of:

- (a)** Early childhood influence on the development of personality
- (b)** The influence of environment on personality
- (c)** Childhood of important personalities

(d) Importance of childhood in our lives Ans. A

126. The holistic approach considers man as:

- (a)** Religious
- (b)** A unified organism
- (c)** A dualistic being
- (d)** An emotional being Ans. B

127. According to Jean Piaget, egocentrism is a major hindrance to:

- (a)** Memory
- (b)** Cognitive Development
- (c)** Learning
- (d)** Creativity Ans. B

128. In the development of language and thinking, the child tends to display:

- (a)** Egocentric attitudes and centration
- (b)** Abnormal behaviour
- (c)** Assimilation and accommodation
- (d)** Seriation and accommodation Ans. A

129. According to Piaget, during age 4 to 7, there is decrease of gross absurdity in thinking and reasoning. The child has now some ideas of classes or concepts. So he groups objects by:

- (a)** Proximity
- (b)** Similarity
- (c)** Proximity
- (d)** Closure Ans. B

130. The ability of the child to maintain equivalence in spite of change in the perceptual field is called:

- (a)** Reversibility
- (b)** Assimilation
- (c)** Seriation
- (d)** Centration Ans. A

131. For children, Piaget observed two types of speech which are very often used. These are:

- (a)** Egocentric and Socialized speech
- (b)** Haphazard and Distorted speech
- (c)** Symbolic and socialized speech
- (d)** Communicative and Distorted speech Ans. A

132. Jean Piaget stressed the educational significance of learning in a/an:

- (a)** Social context

- (b) Physical context
 - (c) Environmental context
 - (d) Psychophysical context
- Ans. A

133. When a child gives evidence of being fluent, flexible, original and elaborative, he is said to be:

- (a) Intelligent
 - (b) Creative
 - (c) Gifted
 - (d) Dull
- Ans. B

134. For the first time, who has introduced the technique of "BrainStorming"?

- (a) J. B. Watson
 - (b) Osborn
 - (c) Jean Piaget
 - (d) R. S. Woodworth
- Ans. B

135. Noam Chomsky's major contribution to cognitive psychology was his theory of:

- (a) Language
 - (b) Grammar
 - (c) Concept
 - (d) Equivalence Formation
- Ans. B

136. Chomsky has developed a psycholinguistic theory of language development having a/an:

- (a) Biological base
 - (b) Psychological base
 - (c) Psychophysical base
 - (d) Physiological base
- Ans. A

137. Chomsky has assumed some innate neurological mechanisms which facilitate child's acquisition of syntax. These mechanisms are called:

- (a) Language Acquisition Device (LAD)
 - (b) Surface Structure
 - (c) Transformational Rules
 - (d) Deep Structure
- Ans. A

138. Who viewed that the major problem in understanding a language is to derive deep structure from the surface structure of the sentences?

- (a) Noam Chomsky
- (b) B. F. Skinner

- (c) E. C. Tolman
- (d) J. B. WatsonAns. A

139. The “meaning” of the sentence is determined by:

- (a) Deep structure
- (b) Surface structure
- (c) Language acquisition Device
- (d) Productive aspect of LanguageAns. A

140. An attempt to explain something unknown in terms of already known principles is known as:

- (a) Model
- (b) Concept
- (c) Theory
- (d) HypothesisAns. A

141. Information-processing model attempts to explain cognition in terms of the principles of operation of:

- (a) Machines
- (b) Computers
- (c) Galvanometers
- (d) BarometersAns. B

142. The “Information Processing Model” has given birth to the concept of:

- (a) Artificial Intelligence
- (b) Abstract Intelligence
- (c) General Intelligence
- (d) Situational IntelligenceAns. A

143. Intellectual capacities of computers are called:

- (a) General Intelligence
- (b) Artificial Intelligence
- (c) Specific Intelligence
- (d) Abstract IntelligenceAns. B

144. Information Processing Model have given birth to the concept of “artificial intelligence” which is very important to study:

- (a) Memory
- (b) Intelligence
- (c) Learning
- (d) Problem solving BehaviourAns. D

145. Bandura has placed importance on:

- (a)** Instrumental Learning
- (b)** Insightful Learning
- (c)** Classical conditioning
- (d)** Modelling or Observational Learning Ans. D

146. Modern Psychology has been unduly influenced by:

- (a)** Information Processing Model
- (b)** Structuralism
- (c)** Functionalism
- (d)** Gestalt Psychology Ans. A

147. In ancient psychology of India, transformation and modification of mind are done through:

- (a)** Dharma
- (b)** Abhidharma
- (c)** Karma
- (d)** Yoga Ans. D

148. The First Indian Psychological laboratory was established in the University of:

- (a)** Madras in 1928
- (b)** Calcutta in 1915
- (c)** Utkal in 1958
- (d)** Patna in 1960 Ans. B

149. Who has established the "Psychoanalytic Society" in India in the year 1922?

- (a)** Prof. Girindra Sekhar Bose
- (b)** Prof. G. C. Mishra
- (c)** Dr. R. N. Rath
- (d)** Prof. Maithili Jha Ans. A

150. Indian Psychological Association was formed in the year:

- (a)** 1920
- (b)** 1930
- (c)** 1925
- (d)** 1950 Ans. C

151. The famous book "Origin of Species" deals with the theory of:

- (a)** Creativity
- (b)** Evolution

- (c) Intelligence
- (d) LibidoAns. B

152. Folk Psychology deals with:

- (a) Folk literature
- (b) Folk art
- (c) Folk behaviour
- (d) Folk mythologyAns. C

153. When and where did the first International Congress of Psychology meet?

- (a) In Vienna in 1897
- (b) In Paris in 11889
- (c) In New Delhi in 1909
- (d) In Kathmandu in 1990Ans. B

154. A system is based upon determinism, empiricism, reductionism and environmentalism. Name the system.

- (a) Gestalt Psychology
- (b) Behaviourism
- (c) Psychoanalysis
- (d) StructuralismAns. B

155. Behaviourism regards personality as the totality of:

- (a) Environmental products
- (b) Behavioural patterns
- (c) Cultural products
- (d) S-R connectionsAns. A

156. Who has perceived human behaviour as a result of the motion of a fluid from the sense organs to the brain along the nerves and back from the brain to nerve endings in the muscles?

- (a) Descartes
- (b) Wilhelm Wundt
- (c) J. S. Mill
- (d) J.B. WatsonAns. A

157. According to B.F. Skinner, the simple unit of behaviour is:

- (a) Neuron
- (b) Reflex
- (c) Nervous System
- (d) NervesAns. B

- 158.** Who viewed that whenever behaviour is correlated to specific eliciting stimuli, it is “respondent behaviour” and whenever no such stimuli are present it is called “operant behaviour”?
- (a) J. B. Watson
 - (b) B. F. Skinner
 - (c) Clark H. Hull
 - (d) E. C. Tolman
- Ans. B
- 159.** Kurt Goldstein’s psychological theory is based on the principles of constancy or equalization of:
- (a) Sources
 - (b) Energy
 - (c) Intelligence
 - (d) Response
- Ans. B
- 160.** The idea of pleasure and unpleasure are related to the mental economy of excitation. This concept was borrowed by Sigmund Freud from:
- (a) Weber
 - (b) Fechner
 - (c) Watson
 - (d) Pavlov
- Ans. B
- 161.** In 1895, Breuer and Freud have published a volume entitled “Studies in Hysteria”. These studies reported successful treatment of hysterical symptoms by a method called:
- (a) Observation
 - (b) Introspection
 - (c) Hypnotism
 - (d) Catharsis
- Ans. D
- 162.** The law of proximity in perception becomes a law of “temporal contiguity” in the:
- (a) Personality Theory
 - (b) Learning Theory
 - (c) Theory of Creativity
 - (d) Theory of Intelligence
- Ans. B
- 163.** In the “Oral Biting Period” of Psychosexual Development, the libido is fixated on the:
- (a) Physical Self
 - (b) Genital Organs
 - (c) Hands
 - (d) Heads
- Ans. A

- 164.** Who held that human beings only go through an oedipal phase probably due to two reasons – (i) Because of the close knit character of human family formation and the utter helplessness of children during their first few years and (ii) the ability of helpless little boys and girls to build fantasies and daydreams about sexuality including ideas about parental intercourse, to entertain fantastic hopes of possessing a loved parent and in most cases to recognise the anatomical roof of sex differences even though they may misinterpret its source?
- (a) Benedeck (1959)
 - (b) Cameron (1969)
 - (c) Rangell (1955)
 - (d) Otto rank (1929) Ans. B
- 165.** According to Rangell (1955), the preoedipal child enters his oedipal phase with only infantile precursors of a/an:
- (a) Super Ego
 - (b) Ego
 - (c) Id
 - (d) Unconscious Ans. A
- 166.** “It seems probable that the “Oedipal Phase” is biologically predetermined or atleast that given such a close knit unit as the human family in the Western Culture, it is biologically inevitable.” Who has given the above statement?
- (a) C.G. Jung (1919)
 - (b) Benedeck (1959)
 - (c) Cameron (1969)
 - (d) Rangell (1955) Ans. B
- 167.** The tendency of men to marry women resembling their mother and the tendency of girls to marry men resembling their father indicates the shadow of:
- (a) Electra Complex
 - (b) Oedipus Complex
 - (c) Narcissism
 - (d) Libido Ans. B
- 168.** Constipation is a common defence reaction against:
- (a) Elimination
 - (b) Fixation
 - (c) Repression
 - (d) Regression Ans. A
- 169.** Excessive fixation in the “analstage” may lead people to develop the tendency to be:

- (a) Doctors
- (b) Teachers
- (c) Military men
- (d) Industrialists Ans. B

170. A sexual attachment towards one of the parents (of the oppositesex) with a concomitant jealousy towards the other parents is popularly known as:

- (a) Fixation
- (b) Narcissism
- (c) Oedipus Complex
- (d) Libido Ans. C

171. Who has emphatically remarked in his theory, "Super ego is the heir to Oedipus Complex"?

- (a) Sigmund Freud
- (b) C. G. Jung
- (c) Alfred Adler
- (d) Otto Rank Ans. A

172. The therapy formulated by Maslow which emphasizes the work of each individual and his personal growth self-direction is popularly known as:

- (a) Behaviour Therapy
- (b) Group Therapy
- (c) Client-Centred Therapy
- (d) Humanistic Therapy Ans. D

173. The view that an organism can be understood only as a whole and not as a sum of its components is called:

- (a) Psychoanalytic
- (b) Holistic
- (c) Behaviouristic
- (d) Structuralistic Ans. B

174. The concept that needs arrange themselves in an order in terms of importance from the most basic biological needs to psychological needs is popularly known as:

- (a) Hierarchy of Needs
- (b) Homeostasis
- (c) Reminiscence
- (d) Imprinting Ans. A

175. The residence for ex-mentalpatients who are attempting to return to normal life activities is commonly known as:

- (a)** Asylum
 - (b)** Mental Hospital
 - (c)** Half-way house
 - (d)** Mental Clinics
- Ans. C

176. Which school of Psychology always emphasized whole patternsrather than elements?

- (a)** Behaviourism
 - (b)** Gestalt Psychology
 - (c)** Functionalism
 - (d)** Structuralism
- Ans. B

177. A view of human beings that emphasises the individual's responsibility for becoming the kind of person he should be is called:

- (a)** Behaviourism
 - (b)** Existentialism
 - (c)** Structuralism
 - (d)** Functionalism
- Ans. B

178. Repetition of another person'sactions or gestures is known as:

- (a)** Echolalia
 - (b)** Echopraxia
 - (c)** Enuresis
 - (d)** Estrangement
- Ans. B

179. The school of psychology whichconsiders overt behaviour as its fieldof study is popularly known as:

- (a)** Structuralism
 - (b)** Behaviourism
 - (c)** Functionalism
 - (d)** Gestalt Psychology
- Ans. B

180. A firm belief that everything isunreal, is otherwise known as:

- (a)** Abnormal Delusion
 - (b)** Delusion of persecution
 - (c)** Delusion of Grandure
 - (d)** Nihilistic Delusion
- Ans. D

181. An escape mechanism by whicha person avoids facing frustration bymoving from place to

place or job to job is popularly known as:

- (a) Rationalization
- (b) Nomadism
- (c) Sublimation
- (d) Reaction Formation Ans. B

182. A model or pattern used in the collection and interpretation of data is otherwise known as:

- (a) Control group
- (b) Experimental group
- (c) Paradigm
- (d) Population Ans. C

183. The process of treating abnormal psychological conditions by means of drugs is known as:

- (a) Psychosurgery
- (b) Psychotherapy
- (c) Psychopathology
- (d) Psychopharmacology Ans. D

184. The branch of Psychology which studies psychological aspects of teaching and upbringing is known as:

- (a) Educational Psychology
- (b) Pedagogic Psychology
- (c) School Psychology
- (d) Developmental Psychology Ans. B

185. The sequence of events in the evolution of groups of organisms is known as:

- (a) Phrenology
- (b) Phylogenesis
- (c) Physiognomy
- (d) Pictogram Ans. B

186. The famous doctrine advanced by Franz Gall that human or animal mental features are associated with the shape of the skull is known as:

- (a) Physiognomy
- (b) Phrenology
- (c) Phylogenesis
- (d) Pictogram Ans. B

187. A branch of "Special Psychology" which examines the mental development of the blind and people with poor eyesight is called:

- (a) Tropisms
- (b) Typhopsychology
- (c) Abnormal Psychology
- (d) Clinical PsychologyAns. B

188. E. C. Tolman's theory represents an eclectic approach towards:

- (a) Personality
- (b) Creativity
- (c) Learning
- (d) IntelligenceAns. A

189. In his theory, E. C. Tolman has revealed about a type of learning in which the learner has to identify and determine his own drive state and respond accordingly. Name the type of learning.

- (a) Drive Discrimination
- (b) Field Expectancy
- (c) Equivalence Beliefs
- (d) Field Cognition ModesAns. A

190. For Wilhelm Wundt, attention was a perception of a narrow region of:

- (a) Unconscious
- (b) Consciousness
- (c) Subconscious
- (d) Super egoAns. B

191. The idea of "Consolidation" in memory was depicted by:

- (a) G. E. Muller
- (b) E. B. Titchener
- (c) Wilhelm Wundt
- (d) J. B. WatsonAns. A

192. The concept of "Consolidation in memory" was helpful to explain the phenomenon of:

- (a) Emotion
- (b) Forgetting
- (c) Thinking
- (d) PersonalityAns. B

193. C. G. Lange was a/an:

- (a) American Physiologist
- (b) German Psychologist
- (c) English Psychologist

(d) Danish PhysiologistAns. D

194. According to Guthrie, Thorndike's concept of reward and punishment could also be replaced by:

(a) The law of Readiness

(b) Single trial learning

(c) The law of Effect

(d) The Principle of last responseAns. D

195. According to E.C. Tolman, cathexis is a type of learning in which the association appears to be formed between:

(a) Certain objects and certain drivestates

(b) Stimulus and Organism

(c) Stimulus and Response

(d) Response and OrganismAns. A

196. In which type of Tolman's learning, the motor patterns are associated with or conditioned by behaviour?

(a) Drive Discrimination

(b) Motor patterns

(c) Field cognition modes

(d) Field ExpectancyAns. B

197. E. C. Tolman's "Field Expectancy" learning is not the usualSR learning, rather it is :

(a) S-O-R learning

(b) S-S learning

(c) S-P learning

(d) S-G learningAns. B

198. Very often, a sub-goal like scoring of high grades provides the same motivation as might be provided by the main goal like winning love and appreciation etc.The learning performed in such a condition is said to be the:

(a) Equivalence Beliefs Learning

(b) Field Expectancy

(c) Field cognition modes

(d) Drive DiscriminationAns. A

199. In 1930, E. C. Tolman and his associate Charles Honzik performedan experiment to demonstrate:

(a) Latent Learning

(b) Insightful Learning

- (c) Trial and Error Learning
- (d) Classical Conditioning Ans. A

200. Psychology has a long past, but:

- (a) Short history
- (b) Has no scientific basis
- (c) No system
- (d) No theory Ans. A

201. Prior to 1879, psychology was a part of:

- (a) Sociology
- (b) Philosophy
- (c) Anthropology
- (d) Zoology Ans. B

202. What is the difference between nomothetic and idiographic approaches to personality?

- (a) nomothetic approaches seek to find generalized laws of behaviour that help us classify people in terms of their similarities, while idiographic approaches seek to find what makes people unique
- (b) nomothetic approaches view only the differences between people, while ideographic approaches seek to find similarities
- (c) ideographic approaches try to categorize people, while nomothetic approaches don't
- (d) None of these Answer: A

203. What is one of the main assumptions of the trait approach to personality?

- a. traits are not very stable across the lifespan and are therefore weak predictors of personality
- b. traits stay relatively stable across the lifespan
- c. traits change drastically around the age of 6 years, which has to be taken into account when predicting personality
- d. None of these Answer: B

204. Sophie is a 22-year-old psychology student. She loves reading books and is a great drawer. She does go to parties every now and then, but she prefers to meet her friends for a coffee, movies or cooking together. She does not like to be the centre of attention. How would Eysenck make use of biological explanations to describe Sophie's personality trait?

- (a) he would argue that Sophie has very low arousal levels in her ascending reticular activating system (ARAS)
- (b) he would argue that Sophie's autonomic nervous system is generally less aroused and therefore does not invoke a 'fight-or-flight' response in her
- (c) he would argue that Sophie has high arousal levels in her ascending reticular activating system (ARAS)

(d) None of these Answer: C

205. What are the five personality traits identified by the five-factor model (McCrae & Costa, 1997)?

(a) extraversion, neuroticism, introversion, liveliness and agreeableness

(b) agreeableness, openness to experience, introversion, neuroticism and conscientiousness

(c) extraversion, agreeableness, neuroticism, openness to experience and conscientiousness

(d) None of these Answer: C

206. Peter studies Psychology in his first year. His friends know him as a very keen and eager student. He always carries a book with him and, every free minute, he works on some kind of thinking task. He loves to borrow books from the library that are meant for third year students. What is the best way to describe Peter?

(a) he has a high need for cognition

(b) he has a high need for stimulation

(c) he has a high need for attention

(d) None of these Answer: A

207. Harold works for a big law firm in London. He is often confronted with challenging cases but manages to stay calm and does not stress out about it. He and his colleagues love to go bowling after work, and Harold is very good at it. Often, he wins, which makes him very happy, but he is just as happy when one of his colleagues takes the lead. Which type of personality best describes Harold?

(a) personality Type A

(b) personality Type B

(c) personality Type C

(d) None of these Answer: B

208. Which of the following is NOT given as a criticism of the Type A/B personality theory?

(a) most of the research on Type A personality is purely correlational

(b) there is a lack of cross-cultural research

(c) the questionnaires that claim to measure Type A personality have poor internal reliability scores

(d) None of these Answer: C

209. Allison is a very self-critical, restless and impatient person. She believes her personality can explain her stomach problems. What approach is she taking?

(a) specificity approach

(b) generality approach

(c) specificity approach and generality approach

(d) None of these Answer: A

210. Renee has just recently quit smoking, and she was surprised how easy it was for her compared to the experiences of her friends. What is most likely to be TRUE for her?

- (a) she has a high sense of self-efficacy
- (b) she has an internal locus of control
- (c) she has a high sense of self-efficacy and an internal locus of control
- (d) None of these Answer: C

211. What is meant by

'interactionism' in personality psychology?

- (a) the view that the interaction between people shapes their personalities
- (b) the view that there is reciprocal interaction between personality, situations and the environment
- (c) the view that children should interact with other children as much as possible to shape a personality that will benefit them in their later lives
- (d) None of these Answer: B

212. In a typical memory experiment, participants are asked to recall stimuli in which phase?

- (a) presentation
- (b) test
- (c) material
- (d) distinction Answer: B

213. Participants are NOT told that they will be tested on a list of words presented in an experiment. This provides evidence of

- (a) intentional learning
- (b) a practice effect
- (c) incidental learning
- (d) masked learning Answer: C

214. A test where participants are asked to retrieve in any order stimuli previously presented is

- (a) cued recall
- (b) implicit memory
- (c) explicit memory
- (d) free recall Answer: D

215. Participants take part in an experiment where they learn a number of words and are told that they will be tested later on what they have learned. This is a test of

- (a) explicit memory
- (b) recognition
- (c) implicit memory
- (d) interference Answer: A

216. Storage is

- (a) the stage of memory where information is interpreted and transferred

- (b) the stage of memory where information is committed
- (c) the stage of memory most affected by direct manipulation in experiments
- (d) the stage of memory between presentation of stimuli and before test Answer: D

217. Investigating what factors can affect memory storage can be done by

- (a) manipulating what happens before the test phase
- (b) informing people that they will be tested
- (c) providing recall cues
- (d) manipulating what happens at the presentation phase Answer: A

218. Which is NOT typically used to test memory retrieval?

- (a) dot probe task
- (b) word stem completion
- (c) cued recall
- (d) serial position effects Answer: A

219. With immediate testing, recall accuracy is poorest for items that occur in which position of a list?

- (a) beginning
- (b) middle
- (c) end
- (d) no difference Answer: B

220. Immediately testing recall can lead to greater recall for words at the end of a list. This is

- (a) recency effect
- (b) primacy effect
- (c) serial position effect
- (d) superiority effect Answer: A

221. The recency effect in memory retrieval can be reduced when

- (a) rehearsal is prevented
- (b) short- to long-term memory interference is introduced
- (c) a backwards masking task is used
- (d) retention interval is increased Answer: D

222. Which authors proposed the modal model of memory?

- (a) Lansdale and Baguley (2008)
- (b) Tulving and Thompson (1975)
- (c) Atkinson and Shiffrin (1968)
- (d) Craik and Lockhart (1972) Answer: C

- 223.** The modal model of memory was challenged on the grounds that
- (a) impaired short-term memory does not disrupt long-term memory
 - (b) Short-term memory has a limited capacity
 - (c) longer time in short-term memory predicts likelihood of long-term memory
 - (d) long-term memory has a limited capacity
- Answer: A
- 224.** According to levels of processing, which of the following leads to the deepest level of memory?
- (a) perceptual
 - (b) semantic
 - (c) associative
 - (d) cue dependent
- Answer: B
- 225.** A critical issue with the 'levels of processing' account of memory is
- (a) the distinction between perceptual and semantic processing
 - (b) it is not compatible with the modal model
 - (c) determining the level of processing
 - (d) it does not explain how information is retrieved
- Answer: C
- 226.** Retrieval cues can improve recall because of
- (a) overlap between memories at encoding
 - (b) interference or decay
 - (c) traces still in short-term memory
 - (d) greater storage capacity
- Answer: A
- 227.** 'Specific operations [...] determine what is stored, and what is stored determines what retrieval cues are effective' refers to what term?
- (a) context-dependent memory
 - (b) encoding specificity principle
 - (c) levels of processing
 - (d) forgetting function
- Answer: B
- 228.** Retroactive inhibition is a term of memory
- (a) decay
 - (b) delay
 - (c) retrieval
 - (d) interference
- Answer: D
- 229.** Having prior memory associations that make it difficult to form new memory associations is termed
- (a) proactive inhibition
 - (b) transfer appropriate processing

- (c) time-dependent decay
 - (d) encoding specificity
- Answer: A

230. Which of the following was proposed by Keppel (1968) to be most likely?

- (a) prior learning may interfere with new learning only when items are similar, but new learning interferes with all old learning
 - (b) old learning can interfere with new learning, but new learning interferes with all old learning
 - (c) all forgetting is caused by non-specific proactive inhibition
 - (d) old learning only interferes with new learning when encoded in the same modality
- Answer: A

231. What explains the mathematical forgetting curve?

- (a) retroactive inhibition
 - (b) serial position
 - (c) Jost's law
 - (d) consolidation theory
- Answer: C

232. Lansdale and Baguley (2008) predict that the probability of correct recall depends on

- (a) proportion of correct memory traces
 - (b) encoding specificity
 - (c) context-dependent recall
 - (d) retroactive inhibition
- Answer: A

233. Lansdale and Baguley (2008) argue that memory dilution occurs because

- (a) long-term memory capacity is limited
 - (b) the number of null traces decreases
 - (c) memories become indistinct from similar memories
 - (d) the memory becomes less temporally distinctive
- Answer: D

234. Which element was NOT found to alter accounts of the 'War of the Ghosts' story?

- (a) rationalizations
 - (b) distortions
 - (c) omissions
 - (d) intrusions
- Answer: C

235. The study of how the 'War of the Ghosts' story accounts became altered at recall was carried out by

- (a) Bartlett (1932)
 - (b) Godden and Baddeley (1975)
 - (c) Postman and Phillips (1965)
 - (d) Eysenck (1979)
- Answer: A

- 236.** Eyewitness testimonies are an example of what kind of memory experiment?
(a) intentional learning
(b) context-dependent learning
(c) incidental learning
(d) cue-dependent learning Answer: C
- 237.** Which key academic is involved in the study of memory as a reconstructive process?
(a) A. Baddeley
(b) H. Eysenck
(c) G. Hitch
(d) E. Loftus Answer: D
- 238.** The accuracy of eyewitness testimonies can be improved with
(a) recovered memories
(b) cognitive interviews
(c) noise reduction
(d) neurofeedback Answer: B
- 239.** What can help improve the accuracy of eye witness testimonies?
(a) serial position
(b) context reinstatement
(c) mnemonics
(d) distributed practice Answer: B
- 240.** Memory can be improved when information to be learnt is
(a) organized
(b) written
(c) spoken
(d) elaborated Answer: A
- 241.** Which is a good method of revision:
(a) intense sessions
(b) spaced learning
(c) 1 hour on/1 hour off
(d) late night sessions Answer: B
- 242.** Mood is defined as
(a) a short-lived feeling
(b) being depressed for more than 1 month
(c) a prevailing state of feeling

(d) a temporary depression Answer: C

243. Which of these supports the James-Lange theory of emotion?

- (a) emotion is a visceral response producing a behavioural response
- (b) artificial induction of visceral changes does not necessarily produce emotion
- (c) the viscera are 'insensitive structures'
- (d) visceral changes are the same in many emotions Answer: A

244. The direct emotional circuit controlling fear comprises

- (a) eye, thalamus, sensory cortex, hippocampus, prefrontal cortex
- (b) eye, thalamus, amygdala, hypothalamus
- (c) eye, hypothalamus, visual cortex, striatum
- (d) eye, geniculate nucleus, hippocampus, prefrontal cortex Answer: B

245. Which neurotransmitter is most commonly associated with depression?

- (a) serotonin
- (b) dopamine
- (c) septomin
- (d) glutamate Answer: A

246. Which of the following is NOT an example of an intrinsically motivated activity?

- (a) eating a pie because you like pie
- (b) playing with a toy for the fun of it
- (c) revising for an exam to get a good grade
- (d) reading a book because you enjoy the story Answer: C

247. According to Gray (1972), there are two types of personalities, specifically

- (a) those that are repelled by positive stimuli and those that are attracted to negative stimuli
- (b) those that are attracted to rewarding stimuli and those that tend to avoid aversive stimuli
- (c) those that are motivated by greed and those that are motivated by altruism
- (d) those that believe in simple binary divisions of personality and those that don't Answer: B

248. Which of the following are NOT TRUE of motivation?

- (a) it is the drive, incentive or interest to initiate, perform or maintain a behaviour
- (b) it is independent of emotion or cognition
- (c) it is a preparatory phase prior to action
- (d) it may be influenced by rewards and punishments Answer: B

249. According to the revised reinforcement sensitivity theory (Gray and McNaughton, 2000), the behavioural inhibition system (BIS)

- (a) detects goal conflict between reward and punishment
- (b) gives one a sensitivity to punishment
- (c) gives one a sensitivity to reward

(d) encourages inhibition of reward seeking Answer: A

250. Why do those with orbitofrontal cortex damage perform poorly on the Iowa gambling task?

(a) choices made are random

(b) inability to respond flexibly

(c) motivated by reward only (not losses)

(d) sensitive to punishment of loss Answer: C

251. According to the incentive sensitization theory of addiction (Robinson and Berridge, 1993), increased dopamine as a result of repeated drug use leads to

(a) sensitivity to the rewarding aspect of the drug

(b) neural adaptations in the mesolimbic dopamine system

(c) increased sensitivity seen as facial reactivity to pleasure in the rat

(d) tolerance of the rewarding effect of a drug Answer: B

252. Self-actualization is the process whereby individuals

(a) establish their concept of self

(b) become selfless

(c) reach their full potential

(d) realize their ideal self Answer: C

253. Matsuda et al. (2008) found that there appeared to be a cultural difference between Western and Japanese people's visual interpretations of emotion, specifically that

(a) Westerners seem less sensitive to the visual perception of emotion than Japanese people

(b) Japanese people tend to focus on the mouth, while Westerners seem to look at the eyes

(c) Westerners incorporate social context into emotional perception, while Japanese people tend to see emotions as individual feelings

(d) Japanese people tend to interpret emotions in a group context, while Westerners tend to view emotions in relation to only the individual Answer: D

254. Psychometric scales are

(a) tests used to measure a person's level of psychopathy

(b) an instrument to estimate the mass of a person's brain

(c) survey-type questions that can be used to establish a quantitative measure of a trait, emotion, mood, etc.

(d) questions that assess a person's level of latent psychic ability Answer: C

255. Which region of the brain appears to be responsible for the freeze response to a fear stimulus?

(a) the hypothalamus

(b) the periaqueductal grey matter

(c) the orbitofrontal cortex

(d) the anterior cingulate cortex Answer: B

- 256.** Which of the following brain regions has NOT been identified by researchers as being activated in response to pleasurable emotions
- (a) the anterior cingulate cortex
 - (b) the orbitofrontal cortex
 - (c) the insular cortex
 - (d) the medulla oblongata
- Answer: D
- 257.** A cognitive process that starts with simple processes and builds to the more-complex higher levels is known as
- a. bottom-up processing
 - b. lateral processing
 - c. internal processing
 - d. top-down processing
- Answer: A
- 258.** Deliberately reinterpreting an event with the intention of modifying the emotional response to it is known as
- (a) cognitive distortion
 - (b) cognitive suppression
 - (c) cognitive reappraisal
 - (d) cognitive control
- Answer: C
- 259.** The emotional processing explanation of post-traumatic stress disorder suggests that the patient
- (a) has a cognitive bias that the world is dangerous
 - (b) has a tendency to avoid situations that remind him/her of the trauma
 - (c) has repressed emotional responses
 - (d) has an inability to recognize fear in others
- Answer: A
- 260.** Which of the following best describes the concept of an emotion?
- (a) a response to an external or internal stimulus with the purpose of motivating an action or behaviour
 - (b) an enduring or recurrent state with no specific causes
 - (c) the mental representation of general feelings within an individual
 - (d) a highly illogical concept
- Answer: A
- 261.** TMS is a technique to manipulate activity in a particular brain region. TMS stands for
- (a) Transcranial melatonin stimulation
 - (b) Transatlantic motivation system
 - (c) Transorbital motor sensitization
 - (d) Transcranial magnetic stimulation
- Answer: D

- 262.** According to Tuckman (1965), which of the following is NOT a stage of the life cycle of a group:
- (a) performing
 - (b) norming
 - (c) reforming
 - (d) storming Answer: C
- 263.** The phenomenon whereby an individual in a group will tend to end up agreeing with a strong majority opinion in spite of their own judgement is known as
- (a) normative influence
 - (b) informative influence
 - (c) critical mass influence
 - (d) bullying influence Answer: A
- 264.** The idea that the degree to which you will be influenced by the opinion of another group member will depend on how much you identify with that person is known as
- (a) reactive intransigence influence
 - (b) referent informational influence
 - (c) reconciliation of internal influence
 - (d) reorganizational interest influence Answer: B
- 265.** Which of the following is NOT suggested as an explanation for poor group motivation?
- (a) lack of individual feedback
 - (b) lack of clear performance standards
 - (c) seeing that others aren't pulling their weight
 - (d) latent misanthropic enjoyment of group failure Answer: B
- 266.** The tendency whereby a group reaches a decision by trying to minimize conflict, neglecting to critically test and evaluate ideas, is termed
- (a) group compromise
 - (b) group consensus
 - (c) groupthink
 - (d) group cohesion Answer: C
- 267.** The process whereby the presence of others is suggested to lead to individuals losing their sense of personal identity is termed
- (a) deindividuation
 - (b) deindividualization
 - (c) individualization
 - (d) individuation Answer: A
- 268.** The tendency whereby groups make decisions that are more extreme than the individuals' opinions within the group is termed

- (a) group polarization
 - (b) group cohesion
 - (c) group deindividuation
 - (d) group extremism
- Answer: A

269. Steiner (1972) called losses in group productivity due to poor coordination

- (a) disorganization losses
 - (b) momentum losses
 - (c) process losses
 - (d) laziness losses
- Answer: C

270. Which of the following did Wilfred Bion (1961) NOT observe as a quality that was likely to be present in a group with 'good group spirit'?

- (a) flexibility of group membership
 - (b) the presence of distinct subgroups
 - (c) common purpose
 - (d) valuing of all group members
- Answer: B

271. The so-called 'Hawthorne effect' refers to which group-related phenomenon?

- (a) one person in a group usually does most of the work
 - (b) people in groups tend to try to get away with doing as little as possible
 - (c) people always perform better when they're being watched
 - (d) there is usually one person in a group who will try to argue against the majority
- Answer: C

272. Which of the following terms is used to refer to the potential negative effects of group identification that stem from processes like stigma and rejection?

- (a) the Social Curse
 - (b) the Exclusion Hypothesis
 - (c) the Norm-Violation Problem
 - (d) the Discrimination Dilemma
- Answer: A

273. The term 'groupthink' was coined by

- (a) Janis (1972)
 - (b) Jarvis (1972)
 - (c) Jager (1972)
 - (d) Jarratt (1972)
- Answer: A

274. Groupthink refers to the process by which, when making decisions, the group places more importance on

- (a) reaching a cohesive agreement
- (b) making a quality decision

- (c) reaching a speedy decision
- (d) reaching a well-evaluated decision Answer: A

275. Diener's (1980) explanation of deindividuation posited that deindividuation is the result of

- (a) decreased self-awareness
- (b) decreased responsibility
- (c) increased anonymity
- (d) increased group size Answer: A

276. Group polarization refers to the tendency whereby

- (a) groups make decisions that are more extreme than the individuals' opinions
- (b) conflict of individuals' extreme opinions causes the group to side with the majority
- (c) the opinions of the minority shift to the majority
- (d) groups make decisions that are less extreme than the individuals' opinions Answer: A

277. Which of the following is NOT a type of theory seeking to explain group polarization?

- (a) persuasive argument
- (b) social categorization processes
- (c) social comparison processes
- (d) social conformity processes Answer: D

278. Identification with social groups has been shown to lead to various psychological outcomes. Which of the following is NOT one of them?

- (a) self-esteem
- (b) distinctiveness
- (c) belonging
- (d) narcissism Answer: D

279. According to Tajfel and Turner (1979), which of the following is a primary reason for choosing to identify with a group?

- (a) to avoid loneliness
- (b) a fear of missing out
- (c) a desire to prove loyalty to a stereotype
- (d) to maintain a positive sense of self Answer: D

280. The Social Cure (Jetten et al. 2009 & 2012) refers to

- a. improvements in group cohesion as a result of socializing together
- b. improvements in health and well-being as a result of identification with a group
- c. improvements in social mobility resulting from free social care provision
- d. improvements in health and well-being as a result of socialism Answer: B

- 281.** According to Moscovici (1980), the best way for a minority to exert influence on the majority's opinion is to
- (a) maintain a consistent position over time
 - (b) express extreme opinions
 - (c) stress the importance of their opinion
 - (d) express creative opinions
- Answer: A
- 282.** Tajfel (1978) proposed that a group is
- (a) a set of people who feel that they are a group
 - (b) a set of people who outsiders see as a group
 - (c) a set of people with a common goal
 - (d) a set of people with shared beliefs
- Answer: A
- 283.** An unreasonable or unfair dislike of something, or more usually, someone, typically because they belong to a specific race, religion or group, is referred to as
- (a) stereotyping
 - (b) prejudice
 - (c) scapegoating
 - (d) discrimination
- Answer: B
- 284.** An oversimplified, generalized impression of someone or something is referred to as
- (a) a stereotype
 - (b) prejudice
 - (c) a scapegoat
 - (d) discrimination
- Answer: A
- 285.** The consideration or treatment of others based on general factors (e.g. their race, religion or some other grouping), rather than on individual merit, is termed
- (a) a stereotype
 - (b) prejudice
 - (c) scapegoating
 - (d) discrimination
- Answer: D
- 286.** Someone who is (often unfairly) made to take the blame for something is referred to as
- (a) a scapegoat
 - (b) prejudiced
 - (c) discriminated
 - (d) stereotyped
- Answer: A
- 287.** A stance in which an individual believes that their own race/ethnic group (or aspects of it, e.g. its culture) is superior to those of other groups is termed

- (a) ethnocentrism
 - (b) egocentrism
 - (c) ethnicentrism
 - (d) existentialism
- Answer: A

288. The 'FAH' refers to a tendency whereby individuals frustrated in pursuit of their goals become aggressive. 'FAH' stands for

- (a) frustration-aggression hypothesis
 - (b) frustration-aggravating hypothesis
 - (c) frustration-anger hypothesis
 - (d) frustration-antagonism hypothesis
- Answer: A

289. The social learning theory was put forward by

- (a) Bandura (1977)
 - (b) Freud (1939)
 - (c) Tajfel (1978)
 - (d) Allport (1954)
- Answer: A

290. Goals that different groups share but that can only be achieved by those groups working together are called

- (a) superordinate goals
 - (b) subdominant goals
 - (c) subsidiary goals
 - (d) subliminal goals
- Answer: A

291. According to the social identity theory, which one of our many social identities we adopt depends on:

- (a) an individual's mood
 - (b) social influences
 - (c) the context
 - (d) situational factors
- Answer: C

292. The early theorist who saw prejudice as resulting from inflexible and faulty cognitive processing was

- (a) Duckitt (1954)
 - (b) Allport (1954)
 - (c) Bandura (1954)
 - (d) Sherif (1954)
- Answer: B

293. Which authors investigated the accuracy of eye-witness testimony accounts?

- (a) Steele and Aronson (1995)

- (b) Boon and Davies (1987)
- (c) Blake and Mouton (1961)
- (d) Ferguson and Kelley (1964) Answer: B

294. The concept of ethnocentrism was introduced by

- (a) Sumner (1906)
- (b) Sommers (1906)
- (c) Summer (1906)
- (d) Sollman (1906) Answer: A

295. The restraint required to limit the expression of aggression, in line with the norms of society, is the basis of theories from which school of thought?

- (a) Freudian
- (b) gestaltis
- (c) humanistic
- (d) social learning theory Answer: A

296. The frustration–aggression hypothesis (FAH) was developed by

- (a) Dollard et al. (1939)
- (b) Deschamps and Doise (1978)
- (c) Boon and Davies (1987)
- (d) Hovland and Sears (1940) Answer: A

297. A healthy and restorative outpouring of built-up emotional energy is termed

- (a) catharsis
- (b) cataclysm
- (c) catabolism
- (d) catachresis Answer: A

298. The main finding of Hovland and Sears' (1940) study was

- (a) a positive correlation between the number of lynchings of black people and the price of cotton
- (b) a small, but not significant, relationship between the number of lynchings of black people and the price of cotton
- (c) no relationship between the number of lynchings of black people and the price of cotton
- (d) a negative correlation between the number of lynchings of black people and the price of cotton Answer: D

299. Bandura (1977) saw the expression of aggression as

- (a) a healthy outpouring of energy
- (b) a calming outpouring of energy
- (c) encouraging of future aggressive acts

(d) likely to increase frustration Answer: C

300. Adorno et al.'s (1950) post- World War II publication, which sought to understand the psychological dynamics involved in anti-Semitism and wider ethnocentrism, was entitled

(a) The Authoritarian Personality

(b) The Potential for Fascism

(c) Authoritarianism

(d) The Widening Circle of Covariation Answer: A

301. In Adorno et al.'s (1950) study of ethnocentrism, ethnocentrism was found to be related to the extent to which the person 'liked things as they are', which was termed

(a) political and economic conservatism

(b) ethnocentric traditionalism

(c) traditionalist conservatism

(d) social conservatism Answer: A

302. Altemeyer (1998) devised an instrument, termed the

(a) Right Wing Authoritarianism Scale

(b) The Authoritarian Personality Scale

(c) The Traditionalist Personality Scale

(d) The Ethnocentrism Scale Answer: A

303. Perrin (2005) found that authoritarian values and behaviour may increase in response to

(a) changes in social context, such as unemployment

(b) external threats, such as terrorism

(c) childhood experiences

(d) between-group conflict Answer: B

304. Sherif (1966) saw the psychological processes behind discrimination and prejudice of out-groups as following on from

(a) inter-group relations

(b) material relations

(c) conflict of beliefs

(d) conformity Answer: B

305. Which of the following was NOT an experimental stage under the first two studies of Sherif et al. (1966) on inter-group relations?

(a) friendship development

(b) group formation

(c) introduction of superordinate goals

(d) inter-group competition Answer: C

- 306.** In his theory of inter-group conflict, Sherif (1966) saw discrimination and prejudice of out-groups as mainly due to
- (a) competition for scarce resources
 - (b) differing group values
 - (c) extreme ideologies
 - (d) group idealization
- Answer: A
- 307.** Blake and Mouton (1961) replicated Sherif et al.'s (1966) findings in which group of people?
- (a) school children
 - (b) lecturers
 - (c) business executives
 - (d) medical professionals
- Answer: C
- 308.** Which of the following is NOT one of the four conditions suggested under Allport's (1954) initial contact hypothesis for contact between groups to be encouraged?
- (a) equal social conditions
 - (b) support of authorities within the group of contact
 - (c) common goals between the groups
 - (d) similar group size
- Answer: D
- 309.** Amir contributed to Allport's contact hypothesis, adding the condition for contact between groups to be
- (a) rewarding
 - (b) close
 - (c) for a sustained period
 - (d) equal
- Answer: A
- 310.** The concept of superordinate goals derives from
- (a) group conflict theory
 - (b) behavioural conflict theory
 - (c) realistic conflict theory
 - (d) social conflict theory
- Answer: C
- 311.** Which of the following is NOT listed as a predictor of collective action in van Zomeren, Postmes and Spears' social identity model of collective action (SIMCA)?
- (a) perceived injustice
 - (b) perceived efficacy
 - (c) a sense of social identity
 - (d) a sense of superiority
- Answer: C

UNIT - 8

SOCIAL PSYCHOLOGY

Social Psychology

WHAT IS NATURE, SCOPE AND HISTORY OF SOCIAL PSYCHOLOGY?

NATURE, SCOPE AND HISTORY OF SOCIAL PSYCHOLOGY

The last century witnessed the creation of new sciences and specialised branches for specific needs together with the technological developments that have changed the scenario of education and knowledge. New social realities generated new problems. Social psychology came into existence at the time when the world was undergoing a great upheaval. A significant number of facts in the fields of linguistics, anthropology, ethnography and archaeology needed interpretation for various facts.

This need manifested itself in the development of two sciences regarded as the parents of social psychology: psychology and sociology. Societies manifest themselves through the activities of people, through communication and interaction and in turn shape the behaviour of individuals.

The study of social psychology enable us to understand the dynamics of human behaviour in social situations and what effects do these situations exert on individuals and in what ways are these situations get changed by the behaviour of the individuals. Social psychology intrudes social life by providing practical recommendations in various areas.

The practical needs of the discipline have been increased by the increased demand for efficient management in the areas of industry, education, health, mass communication system, struggle against anti-social behaviour, public services and sports etc. In this unit we will discuss the concept and definition of social psychology, its background and developments and its relation to other social sciences. Floyd Allpor (1924) has defined social psychology as “the scientific study of the experience and behaviour of individuals in relation to other individuals, groups and culture”.

A similar definition by Gordon W. Allport (1968) states that social psychology is a discipline “that attempts to understand and explain how the thought, feeling and behaviour of an individual are influenced by the actual, imagined or implied presence of others.” The above definitions include the elements: scientific study, experience and behaviour, individual, group and culture that throw light upon the nature of the discipline. These elements are elaborated below:

Social Psychology is Scientific in Nature Social psychology is scientific in its approach to the range of topics it deals. One may find many common sense explanations and literary works that tell us about interpersonal relations, love, jealousy, aggression, altruism (helping behaviour) and the roles of individuals in groups. The difference lies in the approach that a social psychologist adopts. It adopts scientific methods which we will discuss later but in all the methods a three step basic process has been employed (McDavid and Harari, 1994):

- The collection of carefully made observations. Careful observation requires gathering of information about issues and processes of interest, plus an attitude of scepticism.
- The ordered integration of these observations and the statement of general principles.

The utilisation of these general principles to predict future observations. As an example we can take this statement, “When people try to dismiss those who ask the big public questions on being emotional, it is a strategy to avoid debate.”¹ How do we proceed to check the validity of the statement? First, we have to see the bi national or international issues, big in the sense they raise

problems of wider concern, like the displacement of inhabitants of a particular place due to some projects. After this we will have to select a representative sample population and get their opinions.

SCOPE OF SOCIAL PSYCHOLOGY Social psychology attempts to understand the relationship between minds, groups, and behaviors in three general ways:

1. It tries to see how the thoughts, feelings and behaviours of individuals are influenced by the actual, imagined, or implied presence of other(s). This includes social perception, social interaction, and the many kinds of social influence (like trust, power, and persuasion). It deals with questions like: How do small group dynamics impact cognition and emotional states? How do social groups control or contribute to behaviour, emotion, or attitudes of the individual members? How does the group impact the individual? How does the individual operate within the social group? It tries to understand the influence that individual perceptions and behaviours have upon the behaviour of groups. How does persuasion work to change group behaviour, emotion or attitudes?
2. Second, it tries to understand the influence that individual perceptions and behaviours have upon the behaviour of groups. This includes looking at things like group productivity in the workplace and group decision making. It looks at questions like: What are the reasons behind conformity, diversity, and deviance?

Third, and finally, social psychology tries to understand groups themselves as behavioural entities, and the relationships and influences that one group has upon another group. It asks questions like: What makes some groups hostile to one another, and others neutral or civil? Do groups behave in a different way than an individual outside the group? In European textbooks there is also a fourth level called the "ideological" level. It studies the societal forces that influence the human psyche.

HISTORICAL DEVELOPMENTS: THE EMERGENCE OF MODERN SOCIAL PSYCHOLOGY

To understand the contribution of social psychology and what is distinct about it, we need to know its historical origins. The formation of pre-conditions of social psychology is as a whole the same as the development of any other scientific discipline.

The socio-psychological ideas originally took shape within the realm of philosophy and then gradually branched off from the system of psychological knowledge.

First we will briefly discuss the social thought before the advent of social science and then discuss the second stage of the development of social psychology which is deemed to be "more productive."

SOCIAL THOUGHT BEFORE THE ADVENT OF SOCIAL SCIENCE

Two earlier forms of social thought over the centuries are Platonic and Aristotelian. Platonic thought emphasised the primacy of state over the individual who had to be educated to become truly social. Aristotelian thought states that human being is social by nature and nature can be trusted to enable individuals to live together and to enter personal relationships from which families, tribes and ultimately the state will naturally develop.

In modern times these two traditions of social thought have been known as socio centred approach and individual centred approach. Socio centred approach emphasises the determining function of social structures (systems, institutions and groups) for individual experience and behaviour. According to the individual centred approach social systems are said to be explicable in terms of

individual processes and functions. For Hegel (1770-1831), the German philosopher, the state is not only the ultimate form of society but the incarnation of the objective social mind of which individual minds are active participants. The notion of Group Mind derived from Hegel's supra-individual nature. Social psychology from its beginning has been defined as the scientific study of the individual in the social context. Individualism has been an inherent property of the discipline. Individualistic doctrine says that all the explanations of individual social phenomena are to be rejected unless they are expressed in terms of individual. Individualism in psychology has been characterised and criticised for the self centred denial of the other. Individualism has appeared in two forms in sociological thought: Hedonism: People act in order to secure and maintain pleasure and to avoid and reduce pain.

Utilitarianism: The doctrine that advocates the pursuit of the greatest happiness of the greatest number. For most modern theories of conditioning and of motivation, the underlying ideas of individual satisfaction (reinforcement, reward, reduction of stress, of dissonance, uncertainty) are variations of the pleasure or utility principle. Utility and satisfaction are important constructs involved in many social psychological theories.

From Machiavelli (1513) and Thomas Hobbes (1651) the concept of power and its role in social relationships returned in social psychology. The concept of social power (social influence) found its proper frame of reference in the field theory and social exchange theory. In Lewinian field theory 'power' became the term for the potential to influence others while control and influence refer to the power of action. Research areas where power has been studied are: aggression, conformity to group pressure and obedience to authority, and power in language.

Modern social psychology was also influenced by the developments in the nineteenth century in two major areas: sociology and theory of evolution. We will discuss these influences later under the titles: social psychology and other disciplines and the influence of evolutionary theory will be discussed in current trends in social psychology.

WHAT IS TRADITIONAL THEORETICAL PERSPECTIVES: FIELD THEORY, COGNITIVE DISSONANCE, SOCIOBIOLOGY, PSYCHODYNAMIC APPROACHES, SOCIAL COGNITION? TRADITIONAL THEORETICAL PERSPECTIVES: FIELD THEORY

At the outset I must point out that field can mean two things: a region of space (such as psychological, social, cultural, or linguistic spaces) within which things are located as a function of space-time coordinates or the area in which a force operates. The latter presupposes the former and adds to it the notion of forces spread continuously throughout the region.

I will call the former view a spatial theory and the latter a field theory. It is helpful to keep this distinction in mind when considering psychological and social science perspectives, approaches, and theories, for what is called a field is often meant as a particular space, as in Arthur Bentley's or in Pitirim Sorokin's work. In this and in subsequent chapters, I will limit my survey to self-professed field theories of humankind, or such applications, or studies clearly involving a field perspective. This will eliminate from consideration many spatial theories, such as those of Osgood, Sorokin, Parsons, Cattell, and Bentley, or theories of social gravity and of social distance, but not those spatial theories explicitly meant by their authors to be field theories, such as Quincy Wright's.

Perhaps we can most appropriately begin this discussion with psychological fields, particularly as proposed in Gestalt theory, and move to Kurt Lewin's work, with which field theory has become most

associated for social scientists, and then to his successors. Subsequently, I will consider sociocultural fields and Ushenko's field of power.

This review is not a comprehensive survey, as such¹ My purpose is to exemplify the use of "field" in our attempts to understand ourselves, particularly as these attempts create insight into the nature of our intentional field and its eventual bearing on violence and war. A picture is enhanced and its central figures better seen against a well-constructed background. These chapters in Part I of *The Dynamic Psychological Field* comprise such a background.

Field theory in the social sciences has become indelibly associated with Kurt Lewin's name. For this reason and because Lewin's work stands in ancestral line to the field orientation of this book, *The Dynamic Psychological Field*, and to that of subsequent field theorists, I will devote some time to his ideas. As a young man in Germany, Lewin was attracted to Gestalt psychology, perhaps partly due to his experiences as a soldier in World War I and his observations on how battlefield involvement affects perception, and perhaps partly because of his quantitative experiments and consequent disillusionment with the classic theory of association. Soon after the war, Lewin accepted an appointment at the Psychological Institute, University of Berlin, where the Gestaltists, Köhler and Wertheimer (who was director), were accomplishing their famous research.

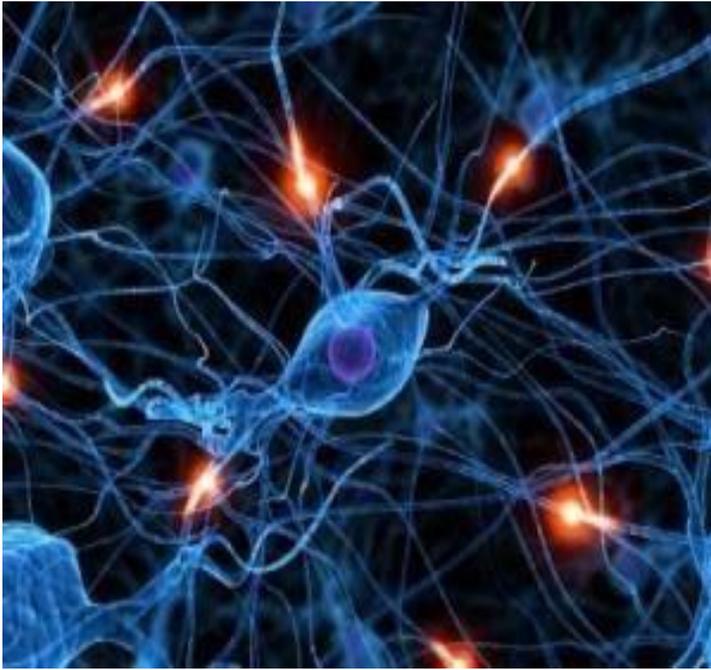

He remained there until Hitler's assumption of power caused Lewin (a Jew) to seek and accept a position in the United States. By then, through his students, research, and writings, he had developed a considerable reputation, and in his new homeland he continued to enhance it. By the time of his death in 1947, some psychologists were convinced that Lewin's name should rank with Freud's among those contributing the most to contemporary psychology.

COGNITIVE DISSONANCE

Cognitive Dissonance Theory Definition

Introduced by Leon Festinger in 1957—and since that time debated, refined, and debated again by psychologists—cognitive dissonance is defined as the aversive state of arousal that occurs when a person holds two or more cognitions that are inconsistent with each other. The concept of dissonance was once enormously controversial, but its support through five decades of research has made it one of the most widely accepted concepts in social psychology.

Cognitive dissonance theory can explain a variety of ordinary and extraordinary events in our social lives. Indeed, for a concept to have a long and active "shelf life" as dissonance, it must either help us see our social world differently, help us to understand why certain phenomena occur, or allow us to make (and confirm) interesting and nonobvious predictions about human nature. The theory of cognitive dissonance has accomplished all three.

To break the definition into its components, let us consider first what is meant by inconsistent cognitions, for it is the simultaneous holding of inconsistent cognitions that gives rise to the experience of dissonance. Festinger thought of a cognition as any piece of knowledge that we have. We can have knowledge about our beliefs, our behavior, our feelings, or about the state of the environment. We may have dozens of cognitions of which we are at least dimly aware at any moment in time and innumerable more of which we can become aware, once our attention or memory is set in motion. Most of the cognitions that we have are not related to each other in any obvious way. For example, my knowledge that I am hungry and my knowledge that the Earth travels around the Sun are two cognitions, but my hunger bears no relationship to the trajectory of the planets. However, some cognitions are directly related. My knowledge that I am hungry is very much related to my behavior at the local restaurant in which I am sitting. If I order a meal, the knowledge of that behavior is related to my knowledge that I'm hungry. In fact, it is quite consistent with my hunger. However, if I decide to forego the meal, or simply order a cup of coffee, my ordering behavior is again related to my hunger, but this time it is inconsistent.

Cognitive dissonance is all about the consequences of inconsistency. We prefer consistency to inconsistency and work hard to maintain (or restore) consistency among our cognitions. Failing to order food to allay my hunger at the restaurant, I may convince myself that I was not really that hungry, or that the restaurant's food was bad. In this way, the inconsistency between my knowledge of my hunger and the decision not to purchase food would seem more consistent. In many ways, the need to restore consistency is similar to the familiar concept of rationalization—indeed, rationalization is one way to deal with the dilemma posed by inconsistent cognitions.

Formally, the state of cognitive dissonance occurs when a person holds one cognition that follows from the obverse of another cognition. For example, not ordering food at the restaurant would follow from the obverse or opposite of being hungry. If I were full, I would not be expected to order food. But I was not full, and thus the decision to refrain from eating would follow from the obverse of my knowledge that I was hungry. The condition for dissonance is met.

How does cognitive dissonance feel? Dissonance is experienced as an unpleasant emotion, akin to feeling uncomfortable, bothered, or tense. In addition, dissonance is motivational. When we experience dissonance, we are motivated to reduce it, much like the way we are motivated to reduce physical drives such as hunger and thirst. The more dissonance we experience, the more we are motivated to find a way to reduce it. This need can lead to the kinds of rationalizing behaviors, such as those encountered in the restaurant scenario. Not ordering food when hungry creates a state of cognitive dissonance. Rationalizing, by convincing ourselves that we were not so hungry after all, reduces the inconsistency and thereby reduces the unpleasant state of dissonance.

THE HISTORY OF COGNITIVE DISSONANCE RESEARCH: PREDICTIONS AND FINDINGS

Choices, Choices

The occasions that cause us to experience dissonance are ubiquitous. Whenever we make a choice, there is the potential for dissonance. Imagine that you are purchasing an automobile. It is a tough choice with many alternatives from which to choose. Let's say you have narrowed the field to your two favorite options: a slightly used BMW and a brand-new Neon. **You** consider the pros and cons of each car. The BMW is fast, gorgeous, and attracts positive attention. The Neon is new, so you can get a full selection of colors and a multiyear warranty. On the other hand, the BMW, being old, is more likely to break down, the cost of repairs is high, and you must take it in green. The downside of the Neon, you believe, is that it is slow, less attractive, and handle sluggishly. You choose the BMW, satisfied that, on balance, it provided more of what you were looking for than the Neon.

But wait... you have now selected a car that has several negative features. What if it breaks down? What if your friends hate the color green? And what do you do about the features of the Neon that you are giving up? You liked the warranty, and now you don't have it. You liked the price, but you've now spent more money buying the BMW. All of these thoughts are inconsistent with your decision to buy the BMW. According to the theory of cognitive dissonance, you experience an unpleasant tension. Each time you think of a cognition that supported the Neon over the BMW, your tension rises. You are driven to reduce it. What can you do? Here are some possibilities: (a) You can increase the importance of some of the factors that caused you to like the BMW in the first place. Suddenly, speed seems like the most important dimension you can think of when it comes to buying a car. (b) You can reduce the importance of some of the good features of the Neon. For example, you decide that warranties are often deceptive and the parts of cars that break are usually not covered. (c) You can add cognitions that support your choice that you hadn't considered previously. You may think about how many more people will be friends with you when you drive the BMW or how many people would have thought you were dull if you had picked the Neon. In the end, you may perform any or all of the cognitive changes that help you reduce your dissonance. And there is a measurable consequence to these cognitive changes. When you made your choice, you liked the BMW a bit more than you liked the Neon. By the time you are finished with your rationalizations and distortions that have been at the service of reducing cognitive dissonance, you will like the BMW much better than the (now) boring little Neon.

The predictions in the automobile purchasing scenario were confirmed in the first reported laboratory research on cognitive dissonance. In his 1956 study, Jack W. Brehm asked consumers to rate a variety of household items such as blenders and toasters. He told the consumers that they would be able to take home one of two items from the longer list of products. To create a high degree

of dissonance, similar to the automobile example, Brehm asked the participants to choose between two highly attractive, closely related products. Brehm predicted that, just like the hypothetical BMW example, the consumers would rate the chosen product much more highly than they had rated it previously, and that they would downgrade the product that they did not choose. This is exactly what happened.

CHANGING YOUR ATTITUDES FOR LESS

Here is another “thought experiment”: Imagine that a researcher asks you to write an essay in which you argue that tuition rates at public and private colleges should increase. The researcher tells you that the Dean of your college is trying to understand the arguments in favor of and against tuition increases, and you have been asked to write in favor. You think to yourself that this would be difficult because you do not want to see tuition rates increase. The researcher tells you that you can decide whether or not to write the essay, but he would really appreciate your doing it. You think it over and then agree. Now, you have a cognitive dissonance dilemma. Writing an essay in favor of a tuition increase is discrepant with your negative attitude about tuition. But you agreed that you would write it. This scenario should arouse dissonance. What can you do? Among the alternatives at your disposal is to decide that you really are not against tuition increases after all. If you actually believe that it is okay to raise tuition rates, then there will not be any cognitive dissonance resulting from your writing the essay. Similarly, it may be that politicians who are cajoled to support an issue that they initially do not believe suffer the aversive state of dissonance and reduce it by coming to believe the position that they had just advocated— even though they did not believe it when they agreed to make the speech.

Once again, research in the laboratory demonstrated the truth of this prediction. Just as in the previous scenario, Festinger and his student, J. Merrill Carlsmith, showed that college students who agreed to make a speech with which they initially disagreed came to believe in the position they advocated following the speech. But there was more to this scenario: The students were given a monetary incentive to say what they did not believe. Would the magnitude of the incentive affect attitude change? Would speakers who received a large reward for making such a statement come to believe it more than students who received only a small token? Such a prediction may seem reasonable from what is known about the usual effects of rewards. Pigeons, rodents, and even humans have been shown to learn and act based on the magnitude of reward they receive for their behavior. However, dissonance theory makes a startling and nonobvious prediction—the lower the reward, the greater will be the attitude change. The magnitude of cognitive dissonance is increased by the magnitude and importance of the inconsistent cognitions a person holds, but it is reduced by the magnitude and importance of the consistent cognitions. Knowing that you made a speech that is contrary to your opinion is a cognition inconsistent with your opinion. On the other hand, receiving a bundle of money as a reward for the speech is a cognition quite consistent with giving the speech. The higher the reward is, the more important consistent cognition becomes. Therefore, making a counterattitudinal speech for a large reward results in less overall dissonance than making the same speech for a small reward. This is what Festinger and Carlsmith found: The lower the reward was for making the speech, the greater the attitude change was in favor of tuition increase. The notion that people change their attitude following counterattitudinal behavior has become known as the psychology of induced compliance. The finding that attitude change increases as the magnitude of the inducement decreases is perhaps the most telling signature that cognitive dissonance has been aroused.

TO SUFFER IS TO LOVE

Imagine that you have decided to join a sorority or fraternity at your college. You know that you have to undergo some form of pledging ritual to join. The pledging will not be fun and may be uncomfortable and embarrassing, but you decide to do it. Will the pledging affect your view of how attractive the sorority or fraternity is? The theory of cognitive dissonance makes another bold and nonobvious prediction: The greater is the suffering involved in the pledging, the more you will be motivated to like the club you are trying to enter. The knowledge that you chose to endure some degree of discomfort and unpleasantness is discrepant with your typical desire to have pleasant rather than difficult experiences. However, in this scenario, there is a reason that you engaged in a difficult, less-than-pleasant pledging ritual: You wanted to join the group. Wanting to be a member of the group is the cognition that makes your suffering seem to make sense. Any dissonance created by your decision to endure the pledging is explained or justified by how enjoyable it will be to participate in the group. The more uncomfortable the group's pledging procedure is, the more you need to find a reason for enduring it. And the justification can be made very compelling by distorting how good you think the group really is. Therefore, the prediction from cognitive dissonance theory is that the act of pledging will make the group seem attractive— and the more difficult or noxious the pledging is, the more attractive the group will seem. This phenomenon has been called effort justification.

Two social psychologists, Elliot Aronson and Judson Mills, tested the logic of effort justification in an experiment in which they had students undergo a screening test to join a group that was discussing the topic of sex. For some students, the screening was made avowedly difficult and embarrassing; for other students, the screening was less so. Although the group and the group members were precisely the same, those students who had the more embarrassing and difficult screening found the group discussion to be more interesting and the group members to be more attractive. By convincing themselves that the group was wonderful, the students were able to reduce the dissonance that had been aroused by their volunteering to engage in a difficult, embarrassing screening.

Volunteering to engage in difficult, effortful tasks happens frequently in our lives. Courses we choose to take may require a great deal of preparation, reading, and homework. Sports programs may require us to spend considerable amounts of time in training and in enduring the outbursts of demanding coaches. Yet, the very act of agreeing to participate in such effort has a positive consequence: It pushes us to like the activity for which we suffered.

COGNITIVE DISSONANCE AND SOCIAL LIFE

Cognitive dissonance is ubiquitous. We like to think of ourselves as psychologically consistent human beings—that we act in ways that are consistent with our attitudes and that our attitudes are typically consistent with each other. We like to think that we make good choices and act in our own best interests. However, life often throws us curves that create inconsistency. The choices we make often lead us to dilemmas in which we need to relinquish some aspects of a rejected alternative that we would really like or to accept aspects of our chosen alternative that we would rather not have to accept. Sometimes, we find ourselves engaged in effortful activities that make little sense or find that we have to say or do things that do not quite fit with our private attitudes. These occasions cause us to experience dissonance—that uncomfortable state of tension that Festinger introduced in 1957. We do not live with the tension; rather, we take action to reduce it. And that is what is so interesting about cognitive dissonance. In our effort to reduce dissonance, we come to distort our

choices to make them seem better, we come to like what we have suffered to attain, and we change our attitudes to fit our behaviors. Discovering and explaining the processes behind these occasions pervading our social life has been the hallmark of research on the theory of cognitive dissonance.

SOCIOBIOLOGY

In 1975, Harvard biologist Edward O. Wilson published *Sociobiology: The New Synthesis*, wherein he outlined a framework for investigating the biological basis of social behavior. As a branch of evolutionary biology, sociobiological theory aims to use demographic parameters (e.g., growth and mortality rates, gender and age distributions) and the genetic structure of populations to predict patterns of social organization across species. One of the conceptual tools sociobiology contributes to investigations of social behavior is an analysis of ultimate causation. Whereas proximate causal analyses focus on, for example, the behavioral, developmental, physiological, or neural mechanisms operating within an individual's lifetime to produce a particular phenotype, an ultimate causal analysis focuses on the selective forces that operated over generations and led to the evolution of the specific phenotype manifest in the individual.

In this way, proximate explanations answer the question of how mechanisms operate (e.g., the catalog of hormones, neurotransmitters, and brain regions governing behavior); ultimate explanations answer the question of why they were selected for (i.e., how a particular trait affected the probability of survival and reproduction).

Sociobiologists have made progress in understanding a wide range of behaviors, both their proximate mechanisms and ultimate functions, including altruism, patterns of communication, aggression, mating systems, and parental care of offspring. Such behaviors have been investigated in a wide range of species including ants, birds, frogs, and chimps. Wilson's volume sparked heated controversy regarding his last chapter, which extended the principles of evolutionary ultimate causation and population genetics to explain the social behavior of humans.

Among the many reasons for this controversy were

- a) misunderstandings about sociobiology and genetic determinism and,
- b) the long-held view in the social sciences that social behavior in humans is the product of cultural forces, rather than biological ones. Many opponents mistook sociobiology for arguing that social behaviors are genetically fixed and immutable when, in fact, much of sociobiology focuses on how evolved social behavior is capable of adapting to different environmental situations (e.g., morphological and behavioral change given particular environmental cues). Controversy also occurred because sociobiology ran counter to the prevailing view in the social sciences. Indeed, one goal of sociobiology is the reshaping of the humanities and social sciences to make them consistent with the principles of modern evolutionary biology.

Though based on many of the same principles, sociobiology is distinct from evolutionary psychology. Although both disciplines consider ultimate causal explanations, evolutionary psychology uses this level of analysis to construct models of the information processing circuitry (i.e., the cognitive programs) required to produce an adaptive response. In contrast, sociobiology steps from selective forces (e.g., limited resources) to social behavior (e.g., aggression) without making explicit the kinds of cognitive programs required to produce a particular behavior. So, though related, there exists a set of non-overlapping goals distinct to each field. Nevertheless, sociobiology

and its related disciplines take seriously the claim that principles derived from the modern synthesis, which united Darwin's theory of evolution and Mendelian genetics, can be used to explain the constellation of behaviors in humans and nonhumans alike.

PSYCHODYNAMIC APPROACHES

The psychodynamic theory is a psychological theory Sigmund Freud (1856-1939) and his later followers applied to explain the origins of human behavior.

The psychodynamic approach includes all the theories in psychology that see human functioning based upon the interaction of drives and forces within the person, particularly unconscious, and between the different structures of the personality.

Sigmund Freud's psychoanalysis was the original psychodynamic theory, but the psychodynamic approach as a whole includes all theories that were based on his ideas, e.g., Carl Jung (1912), Melanie Klein (1921), Alfred Adler (1927), Anna Freud (1936), and Erik Erikson (1950).

The words psychodynamic and psychoanalytic are often confused. Remember that Freud's theories were psychoanalytic, whereas the term 'psychodynamic' refers to both his theories and those of his followers. Freud's psychoanalysis is both a theory and therapy.

Sigmund Freud (writing between the 1890s and the 1930s) developed a collection of theories which have formed the basis of the psychodynamic approach to psychology.

His theories are clinically derived - i.e., based on what his patients told him during therapy. The psychodynamic therapist would usually be treating the patient for depression or anxiety related disorders.

BASIC ASSUMPTIONS

Our behavior and feelings are powerfully affected by unconscious motives:

The unconscious mind comprises mental processes that are inaccessible to consciousness but that influence judgments, feelings, or behavior (Wilson, 2002).

According to Freud (1915), the unconscious mind is the primary source of human behavior. Like an iceberg, the most important part of the mind is the part you cannot see.

- Our feelings, motives, and decisions are actually powerfully influenced by our past experiences, and stored in the unconscious.
- Our behavior and feelings as adults (including psychological problems) are rooted in our childhood experiences:
- Psychodynamic theory states that events in our childhood have a great influence on our adult lives, shaping our personality. Events that occur in childhood can remain in the unconscious, and cause problems as adults.
- Personality is shaped as the drives are modified by different conflicts at different times in childhood (during psychosexual development)
- All behavior has a cause (usually unconscious), even slips of the tongue. Therefore all behavior is determined:

- Psychodynamic theory is strongly determinist as it views our behavior as caused entirely by unconscious factors over which we have no control.
- Unconscious thoughts and feelings can transfer to the conscious mind in the form of parapraxes, popularly known as Freudian slips or slips of the tongue. We reveal what is really on our mind by saying something we didn't mean to.
- Freud believed that slips of the tongue provided an insight into the unconscious mind and that there were no accidents, every behavior (including slips of the tongue) was significant (i.e., all behavior is determined).
- Personality is made up of three parts (i.e., tripartite): the id, ego, and super-ego:
- The id is the primitive and instinctive component of personality. It consists of all the inherited (i.e., biological) components of personality present at birth, including the sex (life) instinct – Eros (which contains the libido), and the aggressive (death) instinct - Thanatos.
- The ego develops in order to mediate between the unrealistic id and the external real world. It is the decision making component of personality.
- The superego incorporates the values and morals of society which are learned from one's parents and others.
- Parts of the unconscious mind (the id and superego) are in constant conflict with the conscious part of the mind (the ego). This conflict
- creates anxiety, which could be dealt with by the ego's use of defense mechanisms.

SOCIAL COGNITION

How exactly do psychologists define social cognition? While there is no single definition, there are some common factors that many experts have identified as being important.

Social cognition involves:

- The processes involved in perceiving other people and how we come to know about the people in the world around us.
- The study of the mental processes that are involved in perceiving, remembering, thinking about, and attending to the other people in our social world.
- The reasons we attend to certain information about the social world, how this information is stored in memory, and how it is then used to interact with other people.

Social cognition is not simply a topic within social psychology—it is an approach to studying any subject with social psychology. Using a social- cognitive perspective, researchers can study a wide range of topics including attitudes, person-perception, prejudice, stereotypes, self- concept, discrimination, persuasion, decision-making, and other areas.

Examples

Imagine that you are getting ready to go on a blind date. Not only do you worry about the impression and signals that you are sending to the other person, but you are also concerned with interpreting the signal given by your date. How do you form an impression of this person? What meaning do you read into the other person's behavior?

This is just one example of how social cognition influences a single social interaction, but you can probably think of many more examples from your daily life. We spend a considerable portion of every day interacting with others, which is why an entire branch of psychology formed to help understand how we feel, think, and behave in social situations.

Development

Social cognition develops in childhood and adolescence. As children grow, they become more aware not only of their own feelings, thoughts, and motives but also of the emotions and mental states of others. Children become more adept at understanding how others feel, learning how to respond in social situations, engaging in prosocial behaviors, and taking the perspective of others.

While there are many different theories that look at how social cognition develops, one of the most popular focuses on the work of the psychologist Jean Piaget. According to Piaget, a child's cognitive development goes through a series of stages.

- During the earliest stages of development, children are very egocentric. They see the world from their own perspective and struggle to think about how other people may view the world.
- As children grow older, children become increasingly adept at perspective-taking and have an increased ability to think about how and why people act the way they do in social situations.
- More recently, research has provided evidence that children develop the ability to think about the perspectives of other people at an earlier age than Piaget previously believed. Even young preschoolers exhibit some ability to think about how other people might view a situation.

One of the most important developments in the early emergence of social cognition is the growth of a theory of mind. A theory of mind refers to a person's ability to understand and think about the mental states of other people.

It is the emergence of a theory of mind that is critical to being able to consider the thoughts, motives, desires, needs, feelings, and experiences that other people may have. Being able to think about how these mental states can influence how people act is critical to forming social impressions and explaining how and why people do the things that they do.

Cultural Differences

Social psychologists have also found that there are often important cultural differences in social cognition. When looking at a social situation, any two people may have wildly different interpretations. Each person brings a unique background of experiences, knowledge, social influences, feelings, and cultural variations.

Some researchers have found that there are also collective, cultural influences that can affect how people interpret social situations. The same social behavior in one cultural setting may have a very different meaning and interpretation if it was to take place or be observed in another culture.

As people interpret behavior, extract meaning from the interaction, and then act based upon their beliefs about the situation, they are then further reinforcing and reproducing the cultural norms that influence their social cognitions.

Research and Challenge

Research into social cognition is ongoing. But there are also challenges to some established theories.

Future Areas of Study

So what are some of the different questions related to social cognition that researchers are

interested in understanding? Our perceptions of others play such an important role in how we forge relationships, how we interact with others, how we treat others, and how others treat us.

Some of the topics that psychologists are interested in when it comes to social cognition include:

- How do we develop attitudes? What role do these attitudes play in our social lives?
- How do we interpret other people's feelings and emotions? How do we figure out what they are thinking or feeling? What cues or indicators do we use to make these assumptions?
- How is self-concept formed and how does it influence our relationships with others?
- What influence do our thoughts have on our feelings?
- What mental processes influence person perception, or how we form impressions of other people?

Challenges

One criticism of some of the research on social cognition suggests that it is too focused on individualistic behavior. Because the topic itself is so social, some suggest that many of the information-processing models that have traditionally been used to understand the cognitive processes behind social cognition are too limited. Focusing on the collective and interactive aspects of human thought may provide a better understanding of how people think about and understand social behavior.

WHAT IS SOCIAL PERCEPTION [COMMUNICATION, ATTRIBUTIONS]; ATTITUDE AND ITS CHANGE WITHIN CULTURAL CONTEXT; PROSOCIAL BEHAVIOR?

SOCIAL PERCEPTION [COMMUNICATION, ATTRIBUTIONS]; ATTITUDE AND ITS CHANGE WITHIN CULTURAL CONTEXT; PROSOCIAL BEHAVIOR

Social perception [Communication, Attributions];

Social Perception versus Faces

The Social Perception and Faces subtests both require processing facial information. When patients have low scores on Social Perception and Faces, they may have a general deficit in face processing that may be affecting their performance on the Social Perception test. In contrast, patients whose Social Perception scores are low and whose Faces scores are within normal limits are likely to have intact face processing, suggesting a specific deficit in emotion recognition or processing of emotional content. Lastly, low scores on Faces with Social Perception scores within normal limits suggest difficulties with face memory, but not necessarily with other aspects of face discrimination. Social Perception measures comprehension of social communication, including facial affect recognition and naming, affect recognition from prosody and facial expressions, and affect recognition from prosody and interaction between people. Three tasks comprise Social Perception: Affect Naming, Prosody-Face Matching, and Prosody-Pair Matching. In Affect Naming, the examinee is shown photographs of faces and selects an emotion from a card to describe the affect demonstrated in the photograph. In Prosody-Face Matching, the examinee hears an audio-recorded statement and selects one face from four choices that matches the emotion expressed in the recording.

In Prosody-Pair Matching, the examinee hears an audio-recorded statement and selects one photograph of interacting pairs of individuals from four choices that matches the meaning of the speaker's statement. For Prosody-Face Matching and Prosody-Pair Matching, the statement content may not match the emotion expressed. This intentional lack of matching allows for better

measurement of more subtle forms of communication, such as sarcasm. Available scores assess the examinee's overall performance, as well as the individual skills measured within and across the three tasks.

SOCIAL PERCEPTION

Social perception is typically partitioned into two categories, namely facial perception and vocal perception (Green et al., 2015). Vocal perception involves recognizing and discriminating acoustic properties of speech, and the affective information they convey, where facial perception is decoding affective information from others' facial expressions. Inherent in both categories is the ability to read others' emotional cues.

Generally speaking, there is evidence that individuals with schizotypy show mildly impaired performance on tasks of social perception, though the nature of these impairments has not replicated well across studies. For example, van't Wout, Aleman, Kessels, Larøi, and Kahn (2004) administered both the SPQ and a facial affect recognition task, and found that positive schizotypy correlated with misclassifying angry faces as happy, and the subscale of unusual perceptual experiences correlated with misclassifying happy faces as angry or fearful. Other studies have extended these findings and observed that negative schizotypy is also related to deficits in facial affect (e.g., Abbott & Green, 2013; Williams, Henry, & Green, 2007).

However, some studies do not replicate deficits in classifying facial emotion (e.g., Jahshan & Sergi, 2007; Shean, Bell, & Cameron, 2007), but these null findings are potentially limited by the emotion perception tasks used, which may be insufficiently sensitive. Brown and Cohen (2010) sought to use a more sensitive measure of facial emotion perception that included neutral stimuli, and found that people with schizotypy were worse at identifying emotions than controls, more likely to misclassify neutral faces as showing disgust, and that there was a relation between disorganized schizotypy and a systematic bias for classifying faces with a negative emotional valence. Individuals with schizotypy also show deficits in facial recognition, as demonstrated by Larøi, D'Argembeau, Brédart, and van der Linden (2007), who found that people higher in schizotypy traits endorsed greater difficulty recognizing themselves, and others they know, and also show perceptual distortion of faces, in comparison with people low in schizotypy. These difficulties and distortions were associated with positive and disorganized, but not negative, schizotypy. In sum, evidence suggests that there is a facial affect recognition negativity bias in people with schizotypy, and that kinds of schizotypy may differentially misread various emotions, which may be driven by a lack of ability to integrate facial cues more broadly.

These results are replicated in studies on emotion recognition from vocal information. Although there are significantly fewer studies overall, they consistently show deficits in vocal affect recognition, the ability to recognize emotions from speech, in schizotypy samples (Castro & Pearson, 2011), as well as in individuals diagnosed with schizotypal personality disorder (Baum & Nowicki, 1998; Wickline, Nowicki, Bollini, & Walker, 2012), and at ultra-high risk for psychosis (Amminger et al., 2012). One study partially extended this finding, with the specification that positive (particularly cognitive-perceptual) schizotypy was negatively related to vocal emotion recognition accuracy (Shean et al., 2007). Taken together, these studies and the studies of facial affect recognition show a deficit in social perception in schizotypy that mirrors the results of similar studies conducted in schizophrenia (Kohler et al., 2003; Tseng et al., 2013).

Some researchers have reported a negative correlation between ability to identify happy emotions and both negative and positive symptoms (Tseng et al., 2013). In contrast, Kohler et al. (2003) observed that facial affect recognition in schizophrenia was worse relative to controls for fearful, disgusted, and neutral faces, but not for happy or angry faces, and worse performance was connected specifically to negative symptoms. Similar to facial emotion recognition, there is a pattern of general deficit in social perception, but mixed results at the level of what kinds of perceptions are most difficult, and which symptom profiles are most closely connected.

Conclusion

Our knowledge of social perception was once limited to its downstream consequences, such as how categorization and perception influence stereotyping and behavior.^{40,152} The past decade has seen unprecedented progress in unveiling the processes underlying initial percepts. Such progress has been driven by an equally unprecedented integration between disciplines, including the anticipated wedding of social-cognitive and neural sciences,¹⁶²⁻¹⁶⁴ as well as social-cognitive and visual sciences.^{1,2,165}

Together, these perspectives have engendered productive theoretical accounts of social perception³⁶ and have galvanized research into its basis across levels of analysis. In this chapter, we have focused on the top-down influences in social perception, and importantly, the interesting and nuanced ways in which they interact with different levels of processing. Specifically, we have reviewed neuroscience research into top-down influences in social vision, a parsimonious account of these influences from the vision and neural sciences, and have discussed how these areas may inform one another and fit within current computational frameworks. We hope the current direction of this research forges a productive collaboration that informs each of the social, cognitive, and neural sciences.

COMMUNICATION AND PERCEPTION

Think back to the first day of classes. Did you plan ahead for what you were going to wear? Did you get the typical school supplies together? Did you try to find your classrooms ahead of time or look for the syllabus online? Did you look up your professors on an online professor evaluation site? Based on your answers to these questions, I could form an impression of who you are as a student. But would that perception be accurate? Would it match up with how you see yourself as a student? And perception, of course, is a two-way street. You also formed impressions about your professors based on their appearance, dress, organization, intelligence, and approachability. As a professor who teaches others how to teach, I instruct my student-teachers to really take the first day of class seriously. The impressions that both teacher and student make on the first day help set the tone for the rest of the semester.

As we go through our daily lives we perceive all sorts of people and objects, and we often make sense of these perceptions by using previous experiences to help filter and organize the information we take in. Sometimes we encounter new or contradictory information that changes the way we think about a person, group, or object. The perceptions that we make of others and that others make of us affect how we communicate and act. In this chapter, we will learn about the perception process, how we perceive others, how we perceive and present ourselves, and how we can improve our perceptions.

Perception is the process of selecting, organizing, and interpreting information. includes the

perception of select stimuli that pass throughour perceptual filters, are organized into our existing structures and patterns, and are then interpreted based on previous experiences. Although perception is a largely cognitive and psychological process, how we perceive the people and objects around us affects our communication. We respond differently to an object or person that we perceive favorably than we do to something we find unfavorable. But how do we filter through the mass amounts of incoming information, organize it, and make meaning from what makes it through our perceptual filters and into our social realities?

SELECTING INFORMATION

We take in information through all five of our senses, but our perceptual field (the world around us) includes so many stimuli that it impossible for our brains to process and make sense of it all. So, as information comes in through our senses, various factors influence what actually continues on through the perception process. Susan T. Fiske and Shelley E. Taylor, *Social Cognition*, 2nd ed. (New York, NY: McGraw Hill, 1991).

Selecting is the first part of the perception process, in which we focus our attention on certain incoming sensory information. Think about how, out of many other possible stimuli to pay attention to, you may hear a familiar voice in the hallway, see a pair of shoes you want to buy from across the mall, or smell something cooking for dinner when you get home from work.

VISUAL AND AURAL STIMULATION

It is probably not surprising to learn that visually and/or aurally stimulating things become salient in our perceptual field and get our attention. Creatures ranging from fish to hummingbirds are attracted to things like silver spinners on fishing poles or red and yellow bird feeders. Having our senses stimulated isn't always a positive thing though. Think about the couple that won't stop talking during the movie or the upstairs neighbor whose subwoofer shakes your ceiling at night. In short, stimuli can be attention-getting in a productive or distracting way. As communicators, we can use this knowledge to our benefit by minimizing distractions when we have something important to say. It's probably better to have a serious conversation with a significant other in a quiet place rather than a crowded food court.

As we will learn later altering the rate, volume, and pitch of your voice, known as vocal variety, can help keep your audience engaged, as can gestures and movement. Conversely, nonverbal adaptors, or nervous movements we do to relieve anxiety like pacing or twirling our hair, can be distracting. Aside from minimizing distractions and delivering our messages enthusiastically, the content of our communication also affects salience.

NEEDS AND INTERESTS

We tend to pay attention to information that we perceive to meet our needs or interests in some way. This type of selective attention can help us meet instrumental needs and get things done. When you need to speak with a financial aid officer about your scholarships and loans, you sit in the waiting room and listen for your name to be called. Paying close attention to whose name is called means you can be ready to start your meeting and hopefully get your business handled.

When we don't think certain messages meet our needs, stimuli that would normally get our attention may be completely lost. Imagine you are in the grocery store and you hear someone say your name.

You turnaround, only to hear that person say, "Finally! I said your name three times. I thought you forgot who I was!" A few seconds before, when you were focused on figuring out which kind of orange juice to get, you were attending to the various pulp options to the point that you tuned other stimuli out, even something as familiar as the sound of someone calling your name.

Again, as communicators, especially in persuasive contexts, we can use this to our advantage by making it clear how our message or proposition meets the needs of our audience members. Whether a sign helps us find the nearest gas station, the sound of a ringtone helps us find our missing cell phone, or a speaker tells us how avoiding processed foods will improve our health, we select and attend to information that meets our needs.

Expectation

The relationship between salience and expectations is a little more complex. Basically, we can find expected things salient and find things that are unexpected salient. While this may sound confusing, a couple examples should illustrate this point. If you are expecting a package to be delivered, you might pick up on the slightest noise of a truck engine or someone's footsteps approaching your front door. Since we expect something to happen, we may be extra tuned in to clues that it is coming. In terms of the unexpected, if you have a shy and soft-spoken friend who you overhear raising the volume and pitch of his voice while talking to another friend, you may pick up on that and assume that something out of the ordinary is going on. For something unexpected to become salient, it has to reach a certain threshold of difference.

If you walked into your regular class and there were one or two more students there than normal, you may not even notice. If you walked into your class and there was someone dressed up as a wizard, you would probably notice. So, if we expect to experience something out of the routine, like a package delivery, we will find stimuli related to that expectation salient. If we experience something that we weren't expecting and that is significantly different from our routine experiences, then we will likely find it salient. We can also apply this concept to our communication. I always encourage my students to include supporting material in their speeches that defies our expectations. You can help keep your audience engaged by employing good research skills to find such information. There is a middle area where slight deviations from routine experiences may go unnoticed because we aren't expecting them. To go back to the earlier example, if you aren't expecting a package, and you regularly hear vehicle engines and sidewalk foot traffic outside your house, those pretty routine sounds wouldn't be as likely to catch your attention, even if it were slightly more or less traffic than expected. This is because our expectations are often based on previous experience and patterns we have observed and internalized, which allows our brains to go on "autopilot" sometimes and fill in things that are missing or overlook extra things. Look at the following sentence and read it aloud: Percpetoin is bsaed on pateetrns, maening we often raech a cocnlsuion wituht cosnidreing ecah indiidaul elmenet.

This example illustrates a test of our expectation and an annoyance to every college student. We have all had the experience of getting a paper back with typos and spelling errors circled. This can be frustrating, especially if we actually took the time to proofread. When we first learned to read and write, we learned letter by letter. A teacher or parent would show us a card with A-P-P-L-E written on it, and we would sound it out.

Over time, we learned the patterns of letters and sounds and could see combinations of letters and

pronounce the word quickly. Since we know what to expect when we see a certain pattern of letters, and know what comes next in a sentence since we wrote the paper, we don't take the time to look at each letter as we proofread. This can lead us to overlook common typos and spelling errors, even if we proofread something multiple times. As a side note, I'll share two tips to help you avoid proofreading errors: First, have a friend proofread your paper. Since they didn't write it, they have fewer expectations regarding the content. Second, read your papers backward. Since patterns of speech aren't the same in reverse you have to stop and focus on each word. Now that we know how we select stimuli, let's turn our attention to how we organize the information we receive.

ORGANIZING INFORMATION

Organizing is the second part of the perception process, in which we sort and categorize information that we perceive based on innate and learned cognitive patterns. Three ways we sort things into patterns are by using proximity, similarity, and difference. Stanley Coren, "Principles of Perceptual Organization and Spatial Distortion: The Gestalt Illusions," *Journal of Experimental Psychology: Human Perception and Performance* 6, no. 3 (1980): 404–12. In terms of proximity, we tend to think that things that are close together go together. For example, have you ever been waiting to be helped in a business and the clerk assumes that you and the person standing beside you are together?

The slightly awkward moment usually ends when you and the other person in line look at each other, then back at the clerk, and one of you explains that you are not together. Even though you may have never met that other person in your life, the clerk used a basic perceptual organizing cue to group you together because you were standing in proximity to one another.

Social prescribing

Social prescribing is about expanding the range of options available to GP and patient as they grapple with a problem. Where that problem has its origins in socioeconomic deprivation or long-term psychosocial issues, it is easy for both patient and GP to feel overwhelmed and reluctant to open what could turn out to be a can of worms. Settling for a short-term medical fix may be pragmatic but can easily become a conspiracy of silence which confirms the underlying sense of defeat. Can or should we try to do more during the precious minutes of a GP consultation?

Where there are psychosocial issues GPs do suggest social avenues, such as visiting a Citizens Advice Bureau for financial problems, or a dance class for exercise and loneliness, but without a supportive framework this tends to be a token action. The big picture difficulty with leaving underlying psychosocial problems largely hidden in the consulting room is the medicalisation of society's ills. This ranges from using antidepressants for the misery of a difficult life, to the complex pharmaceutical regimes prescribed to patients with obesity and type 2 diabetes. This sort of medicalisation may help immediate problems (including driving the economy through jobs in the healthcare industries) but it is not enough if our society is to have a sustainable future.

Another way of looking at this is in terms of choice. The consumerist type of choice of provider beloved of the government, is what Canadian philosopher Charles Taylor calls 'weak evaluation'.¹ By this he means a utilitarian 'weighing-up' of generally short-term consequences of a choice. These choices represent 'second-order desires', such as to feel more cheerful, or to relieve a pain, or to have a good experience of hospitalisation. These do not involve the 'worth' of an action, but rather its expediency in terms of immediate outcome. Strong evaluations involve deeper values and

address first-order desires. In the present context, whether to grapple with a difficult psychosocial issue requires a strong evaluation because it is about the first-order desires of giving meaning to life, developing your potential as a person, and contributing to society.

SOCIAL PRESCRIBING?

As we have already said, social prescribing aims to expand the options available in a primary care consultation. This expansion is in the direction of strong choices – options that make available new life opportunities that can add meaning, form new relationships, or give the patient a chance to take responsibility or be creative. Usually these services need to be available locally and often within the voluntary, community, and social enterprise sector ('third sector'). Familiar examples are voluntary work agencies, further education, libraries social or lunch clubs, self-help groups, befriending organisations, hobby clubs, horticulture, sports clubs, nature conservation, book groups, art or dance classes – there is a huge array.

The multiplicity of options is one of the key challenges. The idea is simple but the reality is complex. How can busy GPs and others in primary care know what is available? How is it done? You can't write it on an NHS prescription.

THE PROCESS OF MAKING A SOCIAL PRESCRIPTION?

There are logistic challenges in making social prescribing work. Keeping track of the NHS is hard enough and community groups come and go even faster than statutory ones. Also, patients who are simply given information about an opportunity will not necessarily take it up without some hand-holding.

A workshop hosted by Bromley Primary Care Trust in 2002 ('Social prescribing: making it happen in Bromley') defined six models for overcoming these challenges. The most favoured among existing schemes involves the use of a 'facilitator' (or referral agent or navigator) coupled with personal support (often a volunteer) for the patient in actually taking up social opportunities.³⁻⁵ The facilitator is employed to act as a bridge between primary care professionals and the panoply of social opportunities. It is a challenging role requiring good listening skills and the ability to relate in an inspiring way to health professionals, the wide variety of people in the third sector and, of course, the patient who has been referred. There must also be a regularly updated and accessible database of opportunities.

In all cases, social prescribing is a formal means of making links to locally accessible opportunities for patients. Where there is nothing appropriate (especially in rural areas) it can provide a framework for getting something started. Once the facilitator and supporting network is in place, making the 'prescription' is quick and easy.

BELIEF AND ATTITUDE CHANGE

Although belief and attitude changes often follow technological innovation, environmental or economic changes, theories regarding attitude change tend to focus on intentional efforts to change attitudes with the anticipation that attitudinal change will translate into behavioral change or action. With widespread access to mass media, efforts to influence and change beliefs and attitudes rose to a higher level of intensity. Beliefs and attitudes must be communicated if they are to become known to others or influence the behaviors or actions of others.

Theory-informed communication programs have evolved from a monologic, prescriptive focus on individual behavioral change to dialogic, participatory involvement in social change. Beliefs and attitudes do change, a fact which allows us to hold out hope that the world community will embrace a new attitude, the attitude that G.H. Mead termed the “social attitude,” which would allow us to cherish cultural diversity even as we nourish the moral imperative of our shared humanity.

Introduction Belief and attitude change cannot be studied fruitfully in isolation from the constellation of factors that contribute to their formation, maintenance and reformation. While individually held, beliefs and attitudes are, with few exceptions, collectively shared. Eras, cultures, societies, communities and individuals are, in part, defined by the beliefs they espouse and the attitudes they hold. Beliefs and attitudes are neither static nor immutable, but are spatially and temporally variable. Theological, philosophical, phenomenological and empirical interpretations all attest to the variability of beliefs and attitudes, and contribute to our understanding of those concepts. Given that beliefs and attitudes are subject to modification, permutation, even transformation, it is important to explore both the roots and the ramifications of belief and attitude change. Perhaps since the dawning of human self-consciousness, individuals and collectivities have sought to identify and understand the ultimate causes of events, the forces that constrain or enable processes that lead to change. Over the centuries, the primary cause of change has been attributed to metaphysical providence, natural determination or the inner logic of history. Even when exceptional individuals were considered agents of change, it was their genetic endowment or accidental propensities that were cited as the cause of their contributions. In these instances, uniqueness rather than shared human characteristics was considered primary. The predominant view, however, held extrahuman factors to cause change.

THE ATTITUDE CONSTRUCT

An attitude is a psychological tendency or mental predisposition that is expressed by evaluating an object or entity with some degree of like or dislike, favor or disfavor. Attitudes are affective, reflecting emotions or feelings attached to categories or objects (people, things, places, issues, ideas, etc.). At one time it was common to find a tripartite division of attitudes into cognition, affect, and conation. Cognition was discussed in the preceding section. Conation denotes a person’s behavioral or action-oriented intentions with respect to or in the presence of an object; that is, the desire or volition to achieve an end. Affect refers to a person’s feelings toward and evaluation of a given object.

While cognition, affect and conation are all subsumed under the rubric ‘attitude’ by some social psychologists, in this paper attitude will be used to refer exclusively to the affective dimension of mental constructs. As defined above, the statement “This law is unjust” reflects a belief. An accompanying attitude could be “I am neither in favor of nor in agreement with this law.” Consonant with the notion that attitudes are of a tripartite nature is the idea that attitudes have three different types of antecedents -- cognitive, affective, and behavioral. Theorists who favor a cognitive base for attitude formation assume that beliefs are formed about the attitude object through a cognitive learning process.

As people gain information about the attitude object, new or altered beliefs may result as a result of that exposure. If altered or new beliefs develop, they will be followed by changed attitudes. The cognitive basis for attitude change implies that beliefs and attitudes are formulated through the process of reasoning. In contrast, theories that postulate either affective or behavioral antecedents to attitude formation give precedence to stimuli-response mechanisms over cognitive mechanisms

in explaining this process.

For theorists who postulate an affective or emotional experience as the formative base for attitudes, as was true of early theoretical accounts of classical conditioning, attitude is a result of the pairing of an attitude object with a stimulus that elicits an emotional response. The third alternative is to posit consistency between prior behavior and attitudes, arguing that individuals will express attitudes consistent with their memory of past behavior.

This approach contends that individuals are reluctant to report attitudes inconsistent with their own behavior, unless behavior is thought to have been compelled by forces beyond the individual's control, in which case attitudes are less likely to change. Increasingly, theorists recognize that different - even multiple - mechanisms influence the wide range of beliefs and attitudes that individuals or collectivities hold, though cognitive theories have been in the ascendancy since the 1970s among social psychologists.

THE BASICS OF PROSOCIAL BEHAVIOR

Prosocial behaviors are those intended to help other people. Prosocial behavior is characterized by a concern for the rights, feelings, and welfare of other people. Behaviors that can be described as prosocial include feeling empathy and concern for others and behaving in ways to help or benefit other people.

In *The Handbook of Social Psychology*, C. Daniel Batson explains that prosocial behaviors refer to "a broad range of actions intended to benefit one or more people other than oneself—behaviors such as helping, comforting, sharing and cooperation."

The term prosocial behavior originated during the 1970s and was introduced by social scientists as an antonym for the term antisocial behavior.

What Motivates Prosocial Behavior?

Prosocial behavior has long posed a challenge to social scientists seeking to understand why people engage in helping behaviors that are beneficial to others, but costly to the individual performing the action. In some cases, people will even put their own lives at risk in order to help other people, even those that are complete strangers. Why would people do something that benefits someone else but offers no immediate benefit to the doer?

Psychologists suggest that there are a number of reasons why people engage in prosocial behavior. In many cases, such behaviors are fostered during childhood and adolescence as adults encourage children to share, act kindly, and help others.

Evolutionary psychologists often explain prosocial behaviors in terms of the principles of natural selection. Obviously, putting your own safety in danger makes it less likely that you will survive to pass on your own genes. However, the idea of kin selection suggests that helping members of your own genetic family makes it more likely that your kin will survive and pass on genes to the future generations. Researchers have been able to produce some evidence that people are often more likely to help those to whom they are closely related.

The norm of reciprocity suggests that when people do something helpful for someone else, that

person feels compelled to help out in return. Essentially, helping others means that they might help us in return. This norm developed, evolutionary psychologists suggest because people who understood that helping others might lead to reciprocal kindness were more likely to survive and reproduce.

Prosocial behaviors are often seen as being compelled by a number of factors including egoistic reasons (doing things to improve one's self- image), reciprocal benefits (doing something nice for someone so that they may one day return the favor), and more altruistic reasons (performing actions purely out of empathy for another individual).

Situational Influences on Prosocial Behavior

Characteristics of the situation can also have a powerful impact on whether or not people engage in prosocial actions. The bystander effect is one of the most notable examples of how the situation can impact helping behaviors. The bystander effect refers to the tendency for people to become less likely to assist a person in distress when there are a number of other people also present.

For example, if you drop your purse and several items fall out on the ground, the likelihood that someone will stop and help you decreases if there are many other people present. This same sort of thing can happen in cases where someone is in serious danger, such as when someone is involved in a car accident. In some cases, witnesses might assume that since there are so many other people present, someone else will have surely already called for help.

The tragic murder of a young woman named Kitty Genovese was what spurred much of the interest and research on the bystander effect. In 1964, Genovese was attacked as she neared her apartment on her way home from work late one night. She was stabbed and left lying on the sidewalk. She called for help and reports later indicated that many of her neighbors heard her cries yet did not call for help or attempt to interfere with the attack that lasted approximately 30 minutes. A neighbor eventually called police, but Genovese died before reaching the hospital.

The story generated considerable interest in the bystander effect and in understanding why people help in some situations but not in others, and experts have discovered a number of different situational variables that contribute to (and sometimes interfere with) prosocial behaviors.

- First, the more people that are present decreases the amount of personal responsibility people feel in a situation. This is known as the diffusion of responsibility.
- People also tend to look to others for how to respond in such situations, particularly if the event contains some level of ambiguity. If no one else seems to be reacting, then individuals become less likely to respond as well.
- Fear of being judged by other members of the group also plays a role. People sometimes fear leaping to assistance, only to discover that their help was unwanted or unwarranted. In order to avoid being judged by other bystanders, people simply take no action.

Latané and Darley have suggested that five key things must happen in order for a person to take action. An individual must:

1. Notice what is happening
2. Interpret the event as an emergency
3. Experience feelings of responsibility

4. Believe that they have the skills to help
5. Make a conscious choice to offer assistance

Other factors that can help people overcome the bystander effect including having a personal relationship with the individual in need, having the skills and knowledge to provide assistance, and having empathy for those in need.

Prosocial Behavior Versus Altruism

Altruism is sometimes seen as a form of prosocial behavior, but some experts suggest that there are actually different concepts. While prosocial behavior is seen as a type of helping behavior that ultimately confers some benefits to the self, altruism is viewed as a pure form of helping motivated purely out of concern for the individual in need

GROUP AND SOCIAL INFLUENCE

Take-home Messages

- Social facilitation refers to the finding that people sometimes show an increased level of effort as a result of the real, imagined, or implied presence of others.
- The concept was first identified by Norman Triplett in 1898, when he noticed that cyclist's performance was facilitated (helped) when training as a group.
- Psychologist Floyd Allport labeled it social facilitation in 1920.
- There are two types of social facilitation: co-action effects and audience effect.
- Subsequent researchers found that performance improved as a result of the presence of others (social facilitation) whilst others found that it was impaired (social inhibition)
- Whether or not social facilitation occurs depends on the type of task: people tend to experience social facilitation when they are familiar with a task or for well-learned skills. However, social inhibition (decreased performance in the presence of others) occurs for difficult or novel tasks.
- Social facilitation is an improvement in the performance of a task in the presence of others (audience, competitor, co-actor) compared to their performance when alone.

6. References History and Origins **Co-action Effects**

Perhaps the first social psychology laboratory experiment was undertaken in this area by Norman Triplett in 1898. In his research on the speed records of cyclists, he noticed that racing against each

other rather than against the clock alone increased the cyclists' speeds.

He attempted to duplicate this under laboratory conditions using children and fishing reels. There were two conditions: the child alone and children in pairs but working alone. Their task was to wind in a given amount of fishing line and Triplett reports that many children worked faster in the presence of a partner doing the same task. Triplett's experiments demonstrate the co-action effect:

Co-action effects: A co-action effect refers to a phenomenon whereby increased task performance comes about by the mere presence of others doing the same task. An example would be running a 100 meter sprint against someone.

The co-action effect may come into operation if you find that you work well in a library in preference to working at home where it is equally quiet (and so on).

Other co-action effect studies include Chen (1937) who observed that worker ants will dig more than three times as much sand per ant when working (non-co-operatively) alongside other ants than when working alone.

Platt, Yaksh and Darby (1967) found that animals will eat more of their food if there are others of their species present.

AUDIENCE EFFECTS

Social facilitation occurs not only in the presence of a co-actor but also in the presence of a passive spectator/audience. This is known as the audience effect.

Dashiell (1935) found that the presence of an audience facilitated subjects' multiplication performance by increasing the number of simple multiplications completed.

Audience effects: An audience effect refers to a type of social facilitation in which an individual's performance is influenced by the presence of others (an audience), which causes an individual's dominant response to occur.

Travis (1925) found that well-trained subjects were better at a psychomotor task (pursuit rotor) in front of spectators. However, Pessin (1933) found an opposite audience effect, namely that subjects needed fewer trials at learning a list of nonsense words when on their own than when in front of an audience.

It seems, then, that the extent of social facilitation or inhibition depends upon the nature of the interaction between the task and the performer.

In some cases, the presence of co-actors/audience improved the quality of performance (Dashiell 1935) but in others it impaired the quality (Pessin, 1933).

What sorts of behaviors are improved by the presence of others and what sorts impaired? Whether or not social facilitation occurs depends on the type of task: people tend to experience social facilitation when they are familiar with a task or for well-learned skills.

However, social inhibition (decreased performance in the presence of others) occurs for difficult or novel tasks.

Social facilitation is thought to involve three factors:

COGNITIVE FACTORS (DISTRACTION CONFLICT AND ATTENTION)

Distraction Conflict (Barron, 1986) theory of social facilitation suggests that rather than the mere presence of others, it is the conflict between giving attention to a person and giving attention to a task which affects performance.

This attention conflict motivates a person to pay more attention to the task and therefore will increase performance for simple well-learned tasks

AFFECTIVE FACTORS (ANXIETY OF BEING EVALUATED)

According to Cottrell (1968), it's not the presence of other people that is important for social facilitation to occur but the apprehension about being evaluated by them. We know that approval and disapproval are often dependent on others' evaluations and so the presence of others triggers an acquired arousal drive based on evaluation anxiety.

We are aroused by audiences because we have learned that they evaluate our performance, they are not merely passive spectators, we believe. Such performance evaluation apprehension enhances drive/arousal

PHYSIOLOGICAL FACTORS (DRIVE AND AROUSAL)

According to Zajonc, behavior that is either instinctive or very well-learned/ highly practiced is improved whereas behaviour that is novel or complex is impaired.

Zajonc's (1966) fundamental claim is that "an audience impairs the acquisition of new responses and facilitates the emission of well learned responses". His crucial theoretical contribution was that the presence of others enhances the emission of dominant responses.

Zajonc's explanation is based upon Clark Hull's theory of motivation which states that a high level of arousal/drive will result in what is now called stress and will produce habitual behaviors (which are often incorrect).

The presence of others adds to arousal and when combined with the arousal arising from a difficult or unfamiliar task results in stress and consequent poor performance.

The extra arousal contributed by the presence of others takes us past our optimum level of arousal and result in the dominant response being something we can do easily, not something which is new or demanding. This is supported by the Yerkes-Dodson theory of optimal arousal. A dominant response is simply the response that is most likely to occur in the presence of the given array of stimuli. If a task is easy for the person, then the dominant response will be the correct one (i.e. most likely) and so the audience/co-actor helps elicit this. In a difficult task, the dominant response is the incorrect one(s) (i.e. the most likely again) and so the audience/co-actor helps elicit this.

SOCIAL FACILITATION AND SOCIAL LOAFING

However, there are instances where the presence of others has the opposite effect. That is, sometimes we don't work as hard in the presence of others as we do when we are alone, especially if our behavior is not under surveillance. This phenomenon is known as social loafing.

Psychologists have spent decades studying the power of **social influence**, and the way in which it manipulates people's opinions and behavior. Specifically, social influence refers to the way in which individuals change their ideas and actions to meet the demands of a social group, perceived authority, social role or a minority within a group wielding influence over the majority.

Most of us encounter social influence in its many forms on a regular basis. For example, a student may alter his or her behavior to match that of other students in a class. The majority-held opinions of a group of friends are likely to inform the views of new members to that social group. Furthermore, we are influenced by the requests of people who are seen as holding positions of authority. For instance, an employee will follow the orders of his supervisors in order to please them.

Why people accept social influence

There are a number of reasons why people allow social influences to affect their thoughts and behavior.

One reason is that we often conform to the norms of a group to gain **acceptance** of its members. Supporters of a football team voluntarily wear shirts of their teams to feel a part of the group. Friends may also wear similar clothing to their peers to experience a sense of belonging and to emphasise their shared ideas.

Group conformity can also encourage **cooperation** when attempting to achieve a shared goal. When an individual is able to exhibit a minority influence over a wider group, he or she can persuade that group to work collectively. For example, charity organizers recruiting new volunteers advocate improving their community (e.g. litter picking) in a way that cannot be achieved as easily by just one person acting alone.

However, cooperation can lead to a conformity of views, resulting in a phenomenon known as **groupthink**. When this occurs, team members adopt agreed views and actions in the pursuit of a given goal, but reject criticism from individuals who oppose or question the group's behavior. This lack of critical thinking can have a negative impact on a group's performance as its ability to evaluate its own behavior and adapt to changing conditions is impeded.

Additionally, group conformity enables a sense of **cohesion** within a society. Laws prohibiting violence and theft help to protect every individual within a community. However, such laws depend on people conforming to the norms of the wider group by acting as law-abiding citizens.

Whilst social influence can have a positive effect on behavior, its disadvantages have been a motivating factor behind research into conformity by psychologists such as Stanley Milgram. Conformity to a narrow set of behaviors and views can discourage the nurturing of new ideas which could improve the lives of a group. It can discourage its members from questioning and debating the beliefs and held by the majority of a group and its practises. This behavior has been observed in cults, where members are often reluctant to doubt the group's authority publically for fear of being

rejected by their peers.

Another form of social influence - minority influence - has also been used historically for malign purposes. The followers of leaders such as Adolf Hitler accepted and often internalized the Nazi leader's fascist views without question.

Following the Second World War, German officer Adolf Eichmann attempted to justify his participation in the Holocaust by claiming that he was merely 'following the orders' of perceived authority figures: in Eichmann's case, his commanders.

People tend to conform for one of two reasons: to act based on a more informed view (informative social influence) or to match the views and behavior of a social group (normative social influence):

INFORMATIVE SOCIAL INFLUENCE (OR SOCIAL PROOF)

People feel the need to be informed by accurate information, and when they lack confidence in their own knowledge, they turn to others in the hope that they will provide them with the correct information. By accepting this information, regardless of whether it is accurate, the person is subjected to social influence.

Social psychologist Muzafer Sherif demonstrated informative social influence in an experiment using the autokinetic effect.

Sherif (1935) placed participants in a darkened room, then projected a single, stationary light onto the wall facing them. In accordance with the autokinetic effect, when a person is unable to see another object to judge the light's relative position, the light appears to move.

One group of participants was then asked individually how far the light had moved. Based on their own perception alone, they reported that the light had shifted widely **varying distances**.

A second group was also asked how far the light had moved, but gave their answers **in front of other members of the group**.

Sherif found that participants who gave their answers in a group provided varying distances, but that the reported movement eventually fell into an **ever-smaller range**. In other words, when participants were unsure of the light's movement and information was available from other members of the group, they used their answers to inform their own opinions, leading to **conformity** amongst participants.

NORMATIVE SOCIAL INFLUENCE

A second type of conformity is normative social influence. People want to 'fit in' amongst friends and colleagues, and to be liked and respected by other members of their social group. They value the opinions of other members, and seek to maintain their standing within the group. Therefore, individuals will adjust their own attitudes and behavior to match the accepted norms of the group. This conformity with the majority may involve following the fashion trends that are popular amongst a group of friends, adopting the rituals of a religious group or watching a particular TV show because classmates at college talk about it.

SOCIAL INFLUENCE AND CONFORMITY

Social influence takes a number of forms. One type of such influence is **conformity**, when a person adopts the opinions or behaviors of others. This often occurs in groups, when an individual conforms to the social norms respected by a majority of the group's members.

An individual may conform to the opinions and values of a group. They express support for views accepted by the group and will withhold criticism of **group norms**. **Behavioral conformity** can also influence a group member's actions: a person will behave in a way that is similar to others in the group.

PUBLIC-VERSUS-PRIVATE CONFORMITY

When conforming to the social norms of a group, a person may disagree with the opinions that they express or the actions that they take, but nonetheless, they adopt the behavior that is expected of them.

- **Public conformity** involves matching one's behavior to meet the expectations of others, whilst privately holding a different view. For example, a student may express a liking for a rock band because all of his friends listen to it. Privately, however, he may dislike their music, but conforms in front of his friends to gain their acceptance.
- **Private conformity** occurs when a person **internalizes** the views of a group, and adopts a majority opinion as his or her own. For instance, the student listens to the music of a rock band that his friends like. Over time, he realises that he too enjoys this type of music. As his **private opinion** has changed, private conformity has occurred.

ASCH'S CONFORMITY EXPERIMENTS

One of the most-cited researchers into conformity was the Polish psychologist Solomon Asch (1907-1996). In the 1950s, he carried out a series of experiments known as the **Asch Paradigms** to understand the circumstances which led to people conforming to a majority influence.

In an experiment at Swarthmore College, Asch (**Asch and Guetzkow, 1951**) presented participants with a printed line of a given length, and a series of additional lines of varying lengths. One of the lines was the same length as in the initial image, whilst the other two were significantly different. In a group setting, participants were then asked to individually report which of the lines was the same length as the first. They were unaware that other members of the group were confederates who, in some of the trials, had been instructed to answer that a line which was clearly of a different length matched that of the original line.

Participants were torn between two options: did they report the answer which they had observed to be obviously correct but contradict other members of the group? Or, should they disregard their private opinion and report the answer that other group members were reporting?

Using this experimental design, Asch discounted the potential for informative influence to affect participants' answers. As the matching line length was obvious, they had no need to refer to other group members' opinions.

Even when the correct answer was obvious, Asch found that participants would conform to the group norm and report obviously inaccurate answers.

Asch's studies showed that social influence can lead subjects to doubt their own knowledge when

it is contradicted by the majority of their group's members, or to exhibit public conformity and avoid questioning group norms

IDENTIFICATION

Kelman (1958) distinguished between 3 types of conformity, including **identification**.

This occurs when an individual identifies with other members of a group and conforms to its opinions and behaviors. In doing so, they may seek to gain the favor of other members and to be accepted into the group.

When identifying with a group, a person does not internalise its norms. When they leave the group, they may assume their own beliefs and behaviors.

For example, an employee joining an office may go bowling as colleagues on her team like to visit the bowling alley once a week. Privately, however, she may dislike the pastime and prefer to spend it reading at home.

INTERNALIZATION

Internalization is a form of **opinion conformity**, whereby the opinions of a group, or minority within that group influence an individual's own opinions. The person may not only express the views of the group publicly, but also adopts these new views and regards them as being his or her own - a form of **private conformity**.

The internalization of new beliefs frequently occurs in religious groups, when members privately adopt the spiritual ideas expressed by the authority figures (e.g. a priest or other spiritual leader) as their own personal beliefs.

COMPLIANCE

Another form of conformity is achieved through **compliance**. This involves a request that an individual or group complies with the instructions of another. Unlike internalization, compliance **does not require private conformity**, as a person may reluctantly comply with a request whilst privately doubting it.

Compliance frequently occurs when a person is asked by an authority figure to meet a particular set of demands. For example, drivers comply with the directions given by traffic wardens, and students comply with the requests of their teacher, who they view as holding a position of **authority**.

Compliance may be achieved using a number of techniques known as **compliance strategies**. These are often used by salespeople to persuade potential customers to fulfill their request to place orders.

Compliance strategies include the **foot-in-the-door technique**, which involves a person making a small initial request in order to gain compliance with another question. Once a person has complied with a request, they are more likely to agree to a later, more significant, request. For example, a car sales representative may ask a prospective customer to agree to test-drive a new car. If the person agrees, they may be able to persuade them to extend their compliance by accepting a later request to buy the car.

The **door-in-the-face technique** is another compliance strategy which takes an opposite approach. An unreasonably large request is made initially, followed by the request that the subject is expected to comply with. A person will almost certainly reject the first request, but the second appears more reasonable when compared to it, and so they may be more inclined to comply with the second proposition.

Read more about compliance strategies here [Obedience](#)

Obedience is a form of public conformity which occurs when a person modifies their behavior to obey the directions of another, often in a position of authority. It does not require a subject to alter his or her private opinion.

Hierarchical relationships often involve one party obeying the orders of another. For instance, a son is expected to obey his parents, a teacher directs students to behave in class and a soldier takes orders from a superior officer. In each instance, the person in a subordinate position obeys the other, often for fear of the consequences of disobeying them.

In 1961, as the Nuremberg trials were taking place in Israel, the Nazi Adolf Eichmann gave testimony in his defense that he was merely following the orders of higher-ranking officials when he carried out war crimes leading to the Holocaust. American psychologist Stanley Milgram questioned how such people could obey the directions of others when such actions would lead to such atrocities.

Milgram (1963) conducted an experiment in which participants played the role of 'teacher'.

One participant, a confederate, was asked to learn a set of word pairs and the teacher would test his knowledge of these pairs. They were placed in adjacent rooms and the teacher was positioned in front of a set of controls to administer electric shocks to the learner. The teacher was instructed to punish the learner with a shock after each incorrect he gave (they were unaware that their compliance would not result in an actual shock to the confederate, who enacted responses to the punishments).

Milgram tested participants' willingness to obey by instructing the experimenters to administer higher shocks. When they displayed reluctance to injure the learner, further encouragement to continue the procedure were given.

The study found that all of the participants obeyed the order to shock the learner, but to varying degrees. His findings suggest that obedience to perceived authority figures can take precedence over one's own morals, and that **situational factors**, such as the setting participants found themselves in, can influence behavior even when **personality factors** (e.g. moral objections) oppose it.

Milgram (1974) proposed **agency theory** to explain the tendency to obey authority. He suggested that an individual may be in one of two states at any one time:

1. **Autonomous state** - when an individual's behavior is determined by his or her own independent beliefs and responsibility is taken for such actions. When a person regrets their actions, they experience feelings of guilt.
2. **Agentic state** - a person perceives another as being in a position of authority. They obey orders issued by the authority figure, acting as an 'agent' on their behalf. When this behavior is perceived to be a mistake, the person attributes responsibility to the authority that ordered it, rather than feeling guilt for their role in it.

When a person feels that an authority will take responsibility for the actions that they ask them to carry out, Miller believed that an **agentic shift** can occur from an autonomous to an agentic state.

FACTORS AFFECTING CONFORMITY

Conformity rates within a group vary depending upon a number of factors

The **size of a majority** can affect conformity rates within a group. **Asch (1956)** tested conformity rates whilst varying the number of confederates taking a common position. He found that conformity increased in line with the size of the majority, but that the most substantial increases occurred as the majority increased from 1 to 3.

Additionally, Asch found that group consensus and objecting members can affect conformity. **Unanimity** of opinion amongst members increased conformity, whilst dissenting voices encouraged other members to behave independently.

Cultural differences can also influence conformity. **Bond and Smith (1996)** found a correlation between conformity levels and societal attitudes in terms of **individualism-collectivism**. Conformity levels have been found to be lower in cultures where **individualism** is valued (particularly in Western countries such as the UK and US). In collectivist cultures, where individuals are expected to behave and work in a way that benefits society as a whole, conformity is often higher.

Furthermore, **task difficulty** can affect the extent to which an individual will consult the majority-held opinion when completing an activity. **Lucas et al (2006)** found that individuals' reduced confidence in one's own abilities to succeed at a task, or low self-efficacy, can increase his or her conformity.

SOCIAL ROLES

A further form of social influence is the **roles** in which people find themselves. Each role is associated with a set of attitudes and forms of behavior, and the role that a person is assigned can influence their actions and opinions.

Most of us are influenced by a number of roles at any one time. You may play a **professional role** - from doctor to wait-staff, naval officer to writer. Each profession is associated with different types of behavior. For example, people expect a doctor or naval officer to be more serious than a circus entertainer, and may try to fulfill this assumption when given a particular professional role. Other types of role, such as **gender, family** and **societal roles**, can also influence behavior.

Zimbardo et al (1973) conducted a well-known study to examine how social roles influence behavior. In the **Stanford prison experiment**, participants were assigned the role of either prisoner or prison officer, and were asked to play out their roles in a mock prison which Zimbardo had built in the basement of Stanford University, complete with cells for subjects.

During the study, Zimbardo himself assumed the role of prison officer in order to observe the behavior of participants.

He found that the behavior of those assigned to act as prison officers rapidly changed to meet their perceptions of the role. They would punish prisoners by asking them to perform push-ups and in one incident, sprayed a fire extinguisher in an attempt to quell a rebellion.

Similarly, prisoners themselves adopted a subservient role to the officers, treating them as authority figures and reporting on the 'misbehavior' of fellow prisoners.

Zimbardo found that assigned social roles led participants to behave in a way that they would not normally. Having eliminated participants from the experiment who were likely to behave in an offensive manner, he concluded that it was people's preconceptions of their assigned roles and the **experimental situation** in which they found themselves that influenced their actions.

Minority Influence

Whilst conformity usually occurs in response to the norms of a majority - other members in a social group - individuals or minorities of a group can also exhibit social influence. This is known as **minority influence**.

Minority influence occurs when an individual presents an opinion that is different to that held by the majority. As this opinion is novel and contrary to group norms, the attention of other members' is drawn to it, and they are led to consider the merits of the minority opinion.

As minority influence runs against the accepted beliefs of a group, it cannot rely upon normative influence to lead other members to comply: individuals tend towards a majority-held view to feel as though they are part of a group. Instead, a minority view usually needs to exert **informative influence**. By presenting new information (e.g. a key fact) as having been overlooked by the majority, a minority can persuade other members to reconsider their opinion. This process is known as **conversion**. If a minority influence is able to convert a sufficient number of members, the view will eventually become the opinion held by a majority of individuals within the group.

Many social and political movements, such as the civil rights movement in the United States, use minority influence to change the views of the wider population.

Minority influence is more effective when the person expressing the view displays **consistency**: **Moscovici et al (1969)** conducted an experiment in which a group was asked to identify the color shown on a series of slides. When a minority of confederates within the group consistently answered that slides were 'green', other participants were more likely to be influenced when giving their own answers than when the confederates were inconsistent in their responses.

SOCIAL LOAFING

Social loafing describes the tendency of individuals to put forth less effort when they are part of a group. Because all members of the group are pooling their effort to achieve a common goal, each member of the group contributes less than they would if they were individually responsible.¹

Overview

Imagine that your teacher assigned you to work on a class project with a group of 10 other students. If you were working on your own, you would have broken down the assignment into steps and started work right away. Since you are part of a group, however, the social loafing tendency makes it likely that you would put less effort into the project. Instead of assuming responsibility for certain tasks, you might just think that another group member will take care of it.

Or in some cases, the other members of your group assume that someone else will take care of their share of the work, and you end up getting stuck doing the entire assignment yourself.

Ringelmann's Rope-Pulling Experiments

One of the first experiments in social loafing was conducted by French agricultural engineer, Max Ringelmann in 1913.¹

He asked participants to pull on a rope both alone and in groups. He found that when people were part of a group, they made less of an effort to pull the rope than they did when working individually. A group of researchers replicated Ringelmann's experiment in 1974, with a few small changes.²

The first group was consistent with Ringelmann's original study and contained small groups of participants. The second panel consisted of only one real participant; the rest were confederates who merely pretended to pull the rope.

The researchers found that the groups containing all real participants experienced the largest declines in performance, suggesting the losses were linked to motivational factors rather than group coordination problems.

A 2005 study found that group size can have a powerful impact on group performance.³ In the study, half of the groups consisted of four people while the other half consisted of eight. Some groups worked at a table together, while distributed groups worked on the same problem communicating only through computers.

The researchers found that people exerted greater individual effort when they were in smaller groups in both the distributed and collocated situations. When placed in collocated groups, however, people felt greater pressure to look busy even when they were not, while those in the distributed groups were less likely to feel such pressure.

How Does Group Size Influence Problem Solving? Causes

If you have ever worked as part of a group toward a larger goal, then you have undoubtedly experienced this psychological phenomenon firsthand. And if you've ever led a group, then you have likely felt frustration at the lack of effort that group members sometimes put forth. Why does this sometimes aggravating malingering happen?

Psychologists have come up with a few possible explanations.¹

Motivation (or lack thereof): This can play an important role in determining whether social loafing takes place. People who are less motivated by a task are more likely to engage in social loafing when they are part of a group.

- **Diffusion of responsibility:** People are more likely to engage in social loafing if they feel less personally accountable for a task, and know their individual efforts have little impact on the overall outcome. This is often used to explain the bystander effect, or the tendency to be less likely to help a person in need when others are present.
- **Group size:** In small groups, people are more likely to feel their efforts are more important and will, therefore, contribute more. The larger the group, however, the less individual effort people will exert.
- **Expectations:** If you expect other people to slack off, you probably will as well since you don't

want to get stuck doing all of the work. On the other hand, if you are in a group of high-achievers who seem to be in control of everything, you might also be more likely to kick back and let them handle all the work.

HOW TO REDUCE SOCIAL LOAFING

Social loafing can have a serious impact on group performance and efficiency. However, there are some things that can be done to minimize the effects of social loafing.¹

- Assigning individual tasks and responsibilities
- Creating small groups and establishing individual accountability can help.
- Establishing clear standards and rules
- Evaluating individual and group performance
- Highlighting the achievements of individual member

CONFORMITY

Conformity is a type of social influence involving a change in belief or behavior in order to fit in with a group.

This change is in response to real (involving the physical presence of others) or imagined (involving the pressure of social norms / expectations) group pressure.

Conformity can also be simply defined as “yielding to group pressures” (Crutchfield, 1955). Group pressure may take different forms, for example bullying, persuasion, teasing, criticism, etc. Conformity is also known as majority influence (or group pressure).

The term conformity is often used to indicate an agreement to the majority position, brought about either by a desire to ‘fit in’ or be liked (normative) or because of a desire to be correct (informational), or simply to conform to a social role (identification).

Jenness (1932) was the first psychologist to study conformity. His experiment was an ambiguous situation involving a glass bottle filled with beans.

He asked participants individually to estimate how many beans the bottle contained. Jenness then put the group in a room with the bottle, and asked them to provide a group estimate through discussion.

Participants were then asked to estimate the number on their own again to find whether their initial estimates had altered based on the influence of the majority.

Jenness then interviewed the participants individually again, and asked if they would like to change their original estimates, or stay with the group's estimate. Almost all changed their individual guesses to be closer to the group estimate. However, perhaps the most famous conformity experiment was by Solomon Asch (1951) and his line judgment experiment.

Types of Conformity

Kelman (1958) distinguished between three different types of conformity:

Compliance (or group acceptance)

This occurs 'when an individual accepts influence because he hopes to achieve a favorable reaction from another person or group. He adopts the induced behavior because....he expects to gain specific rewards or approval and avoid specific punishment or disapproval by conformity' (Kelman, 1958, p. 53).

In other words, conforming to the majority (publicly), in spite of not really agreeing with them (privately). This is seen in Asch's line experiment.

Compliance stops when there are no group pressures to conform, and is therefore a temporary behavior change.

Internalization (genuine acceptance of group norms)

This occurs 'when an individual accepts influence because the content of the induced behavior - the ideas and actions of which it is composed - is intrinsically rewarding. He adopts the induced behavior because it is congruent [consistent] with his value system' (Kelman, 1958, p. 53).

Internalization always involves public and private conformity. A person publicly changes their behavior to fit in with the group, while also agreeing with them privately.

This is the deepest level of conformity where the beliefs of the group become part of the individual's own belief system. This means the change in behavior is permanent. This is seen in Sherif's autokinetic experiment.

This is most likely to occur when the majority have greater knowledge, and members of the minority have little knowledge to challenge the majority position.

IDENTIFICATION (OR GROUP MEMBERSHIP)

This occurs 'when an individual accepts influence because he wants to establish or maintain a satisfying self-defining relationship to another person or group' (Kelman, 1958, p. 53).

Individuals conform to the expectations of a social role, e.g. nurses, police officers. It is similar to compliance as there does not have to be a change in private opinion. A good example is Zimbardo's Prison Study.

Man (1969) identified an additional type of conformity: **Ingratiation**

This is when a person conforms to impress or gain favor/acceptance from other people.

It is similar to normative influence, but is motivated by the need for social rewards rather than the threat of rejection, i.e., group pressure does not enter the decision to conform.

EXPLANATIONS OF CONFORMITY

Deutsch and Gerrard (1955) identified two reasons why people conform:

Normative Conformity

- Yielding to group pressure because a person wants to fit in with the group. E.g. Asch Line Study.
- Conforming because the person is scared of being rejected by the group.
- This type of conformity usually involves compliance – where a person publicly accepts the views of a group but privately rejects them.

INFORMATIONAL CONFORMITY

- This usually occurs when a person lacks knowledge and looks to the group for guidance.

- Or when a person is in an ambiguous (i.e. unclear) situation and socially compares their behavior with the group. E.g. Sherif's Study.
- This type of conformity usually involves internalization – where a person accepts the views of the groups and adopts them as an individual.

SHERIF (1935) AUTOKINETIC EFFECT EXPERIMENT

Aim: Sherif (1935) conducted an experiment with the aim of demonstrating that people conform to group norms when they are put in an ambiguous (i.e. unclear) situation.

Method: Sherif used a lab experiment to study conformity. He used the autokinetic effect – this is where a small spot of light (projected onto a screen) in a dark room will appear to move, even though it is still (i.e. it is a visual illusion).

It was discovered that when participants were individually tested their estimates on how far the light moved varied considerably (e.g. from 20cm to 80cm) The participants were then tested in groups of three. Sherif manipulated the composition of the group by putting together two people whose estimate of the light movement when alone was very similar, and one person whose estimate was very different. Each person in the group had to say aloud how far they thought the light had moved.

Results: Sherif found that over numerous estimates (trials) of the movement of light, the group converged to a common estimate. The person whose estimate of movement was greatly different to the other two in the group conformed to the view of the other two.

Sherif said that this showed that people would always tend to conform. Rather than make individual judgments they tend to come to a group agreement.

Conclusion: The results show that when in an ambiguous situation (such as the autokinetic effect), a person will look to others (who know more / better) for guidance (i.e. adopt the group norm). They want to do the right thing, but may lack the appropriate information. Observing others can provide this information. This is known as informational conformity.

NON CONFORMITY

Not everyone conforms to social pressure. Indeed, there are many factors that contribute to an individual's desire to remain independent of the group.

For example, Smith and Bond (1998) discovered cultural differences in conformity between western and eastern countries. People from Western cultures (such as America and the UK) are more likely to be individualistic and don't want to be seen as being the same as everyone else. This means that they value being independent and self sufficient (the individual is more important than the group), and as such are more likely to participate in non conformity.

In contrast, eastern cultures (such as Asian countries) are more likely to value the needs of the family and other social groups before their own. They are known as collectivist cultures and are more likely to conform.

PEER PRESSURE

Heart pounding, Leah leaned against the store's unattended makeup display and slid two tubes of lipstick into her purse. She looked bored and detached as she followed her friends Suki and Jill out of the store, but inside she felt panicked.

"I can't believe you made me do that," Leah wailed.

"Relax," said Jill. "Everybody does it sometimes. And we didn't make you do it."

She said nothing, but Leah knew she wouldn't have done that on her own. She'd just had a big dose of peer pressure.

WHO ARE YOUR PEERS?

When you were a little kid, your parents usually chose your friends, putting you in play groups or arranging play dates with certain children they knew and liked. Now that you're older, you decide who your friends are and what groups you spend time with.

Your friends — your peers — are people your age or close to it who have experiences and interests similar to yours. You and your friends make dozens of decisions every day, and you influence each other's choices and behaviors. This is often positive — it's human nature to listen to and learn from other people in your age group.

As you become more independent, your peers naturally play a greater role in your life. As school and other activities take you away from home, you may spend more time with peers than you do with your parents and siblings. You'll probably develop close friendships with some of your peers, and you may feel so connected to them that they are like an extended family.

Besides close friends, your peers include other kids you know who are the same age — like people in your grade, church, sports team, or community. These peers also influence you by the way they dress and act, things they're involved in, and the attitudes they show.

It's natural for people to identify with and compare themselves to their peers as they consider how they wish to be (or think they should be), or what they want to achieve. People are influenced by peers because they want to fit in, be like peers they admire, do what others are doing, or have what others have.

PEER INFLUENCE ISN'T ALL BAD

You already know that the teen years can be tough. You're figuring out who you are, what you believe, what you're good at, what your responsibilities are, and what your place in the world is going to be. It's comforting to face those challenges with friends who are into the same things that you are. But you probably hear adults — parents, teachers, guidance counselors, etc. — talk about peer pressure more than the benefits of belonging to a peer group.

You might not hear a lot about it, but peers have a profoundly positive influence on each other and play important roles in each other's lives

- **Friendship.** Among peers you can find friendship and acceptance, and share experiences that can build lasting bonds.
- **Positive examples.** Peers set plenty of good examples for each other. Having peers who are committed to doing well in school or to doing their best in a sport can influence you to be more goal-oriented, too. Peers who are kind and loyal influence you to build these qualities in yourself. Even peers you've never met can be role models! For example, watching someone your age compete in the Olympics, give a piano concert, or spearhead a community project might inspire you to go after a dream of your own.

- **Feedback and advice.** Your friends listen and give you feedback as you try out new ideas, explore belief, and discuss problems. Peers can help you make decisions, too: what courses to take; whether to get your hair cut, let it grow, or dye it; how to handle a family argument. Peers often give each other good advice. Your friends will be quick to tell you when they think you're making a mistake or doing something risky.
- **Socializing.** Your peer group gives you opportunities to try out new social skills. Getting to know lots of different people – such as classmates or teammates – gives you a chance to learn how to expand your circle of friends, build relationships, and work out differences. You may have peers you agree or disagree with, compete with, or team with, peers you admire, and peers you don't want to be like.
- **Encouragement.** Peers encourage you to work hard to get the solo in the concert, help you study, listen and support you when you're upset or troubled, and empathize with you when they've experienced similar difficulties
- **New experiences.** Your peers might get you involved in clubs, sports, or religious groups. Your world would be far less rich without peers to encourage you try sushi for the first time, listen to a CD you've never heard before, or to offer moral support when you audition for the school play.

WHEN THE PRESSURE'S ON

Sometimes, though, the stresses in your life can actually come from your peers. They may pressure you into doing something you're uncomfortable with, such as shoplifting, doing drugs or drinking, taking dangerous risks when driving a car, or having sex before you feel ready.

This pressure may be expressed openly ("Oh, come on – it's just one beer, and everyone else is having one") or more indirectly – simply making beer available at a party, for instance.

Most peer pressure is less easy to define. Sometimes a group can make subtle signals without saying anything at all – letting you know that you must dress or talk a certain way or adopt particular attitudes toward school, other students, parents, and teachers in order to win acceptance and approval.

The pressure to conform (to do what others are doing) can be powerful and hard to resist. A person might feel pressure to do something just because others are doing it (or say they are). Peer pressure can influence a person to do something that is relatively harmless – or something that has more serious consequences. Giving in to the pressure to dress a certain way is one thing – going along with the crowd to drink or smoke is another.

People may feel pressure to conform so they fit in or are accepted, or so they don't feel awkward or uncomfortable. When people are unsure of what to do in a social situation, they naturally look to others for cues about what is and isn't acceptable.

The people who are most easily influenced will follow someone else's lead first. Then others may go along, too – so it can be easy to think, "It must be OK. Everyone else is doing it. They must know what they're doing." Before you know it, many people are going along with the crowd – perhaps on something they might not otherwise do.

Responding to peer pressure is part of human nature – but some people are more likely to give in, and others are better able to resist and stand their ground. People who are low on confidence and

those who tend to follow rather than lead could be more likely to seek their peers' approval by giving in to a risky challenge or suggestion. People who are unsure of themselves, new to the group, or inexperienced with peer pressure may also be more likely to give in.

Using alcohol or drugs increases anyone's chances of giving in to peer pressure. Substance use impairs judgment and interferes with the ability to make good decisions.

PRESSURE POINTERS

Nearly everyone ends up in a sticky peer pressure situation at some point. No matter how wisely you choose your friends, or how well you think you know them, sooner or later you'll have to make decisions that are difficult and could be unpopular. It may be something as simple as resisting the pressure to spend your hard-earned babysitting money on the latest MP3 player that "everybody" has. Or it may mean deciding to take a stand that makes you look uncool to your group.

But these situations can be opportunities to figure out what is right for you. There's no magic to standing up to peer pressure, but it does take courage – yours

- Listen to your gut. If you feel uncomfortable, even if your friends seem to be OK with what's going on, it means that something about the situation is wrong for you. This kind of decision-making is part of becoming self-reliant and learning more about who you are.
- Plan for possible pressure situations. If you'd like to go to a party but you believe you may be offered alcohol or drugs there, think ahead about how you'll handle this challenge. Decide ahead of time – and even rehearse – what you'll say and do. Learn a few tricks. If you're holding a bottle of water or a can of soda, for instance, you're less likely to be offered a drink you don't want.
- Arrange a "bail-out" code phrase you can use with your parents without losing face with your peers. You might call home from a party at which you're feeling pressured to drink alcohol and say, for instance, "Can you come and drive me home? I have a terrible earache."
- Learn to feel comfortable saying "no." With good friends you should never have to offer an explanation or apology. But if you feel you need an excuse for, say, turning down a drink or smoke, think up a few lines you can use casually. You can always say, "No, thanks, I've got a belt test in karate next week and I'm in training," or "No way – my uncle just died of cirrhosis and I'm not even looking at any booze." Hang with people who feel the same way you do. Choose friends who will speak up with you when you're in need of moral support, and be quick to speak up for a friend in the same way. If you're hearing that little voice telling you a situation's not right, chances are others hear it, too. Just having one other person stand with you against peer pressure makes it much easier for both people to resist.
- Blame your parents: "Are you kidding? If my mom found out, she'd kill me, and her spies are everywhere."
- If a situation seems dangerous, don't hesitate to get an adult's help.

It's not always easy to resist negative peer pressure, but when you do, it is easy to feel good about it afterward. And you may even be a positive influence on your peers who feel the same way – often it just takes one person to speak out or take a different action to change a situation. Your friends may follow if you have the courage to do something different or refuse to go along with the group. Consider yourself a leader, and know that you have the potential to make a difference.

SOCIAL POWER DEFINITION

Social power is the potential for social influence. The available tools one has to exert influence

over another can lead to a change in that person. Social power and social influence are separate and distinct concepts. Although social power is potential (which may or may not be used), social influence is an effect, an actual change (or deliberate maintenance) in the beliefs, attitudes, behavior, emotions, and so on, of someone because of the actions or presence of another. The person or group that is the source of influence is commonly known as the influencing agent, whereas the object of the attempted or successful influence attempt is commonly known as the target (of the influence). Thus, influencing agents have social power, which are the means they may use to influence targets.

Social Power Background and History

The ability of one person (or group) to get others to do his or her will, also known as social power, has long been of interest to social psychologists. Perhaps this is because so much of human interaction involves the change or the attempt to change the beliefs, attitudes, or behaviors of another. Because of the long-standing interest in the topic, several different investigations have used different definitions of social power and different ways of measuring power. However, an extensive survey has found that the approach most commonly used originally identified five distinct potential tactics one could use in an influence attempt. This approach was updated some years ago and now includes six distinct tactics that can be subdivided into 11 varieties. Of course, in an influence attempt multiple types of influence are often used at the same time. The types of social power are as follows:

- **Informational.** This type is the ability to rationally persuade someone.
- **Expert.** This social power is similar to informational power except that arguments are not necessary because the target trusts the influencing agent.
- **Referent.** The referent type is based on the target's identifying and liking the influencing agent and, because of this, wanting to comply with his or her requests.
- **Coercive power.** This type involves threat of punishment. These can be things such as monetary fines (impersonal) or simply personal disapproval (personal).
- **Reward power.** This social power type stems from the ability of the influencing agent to grant some kind of reward, either impersonal or personal
- **Legitimate power.** Based on what general society typically expects of us, this includes (a) the formal legitimate (or position) norm, which is the right to ask for something based simply on position or job title; (b) the reciprocity norm, whereby if someone does something for you, you owe him or her the favor in return; (c) the equity norm, the idea that one is expected to help others receive what they deserve, for example, if you work hard, you should get rewarded; and (d) social responsibility (or dependence), whereby people are obligated to help those who depend on them.

The type of social power used in an influence attempt often depends on a person's motivations. Sometimes people are consciously aware of their motivations, and sometimes they are not. Clever influencing agents often choose the kind of influence they use based on considerations of potential effectiveness and other factors. These factors can be quite varied. For example, some people are motivated by the desire to appear powerful. To feel powerful, an influencing agent may choose a type of influence strategy that makes him or her feel as though he or she is in control of the target of influence. If so, the influencing agent may choose to use coercion or reward in the influence attempt. Similarly, a desire to enhance one's sense of power in the eyes of others, status, security, role requirements, the desire to harm a target of influence, and self-esteem considerations might lead one to choose the more controlling, stronger, or harsher types of influence tactics (such as coercion). Others may wish to maintain a friendship or appear humble. In that case, they would rely

more on information.

When these stronger or harsher types of power are used effectively, they enhance the influencing agent's view of himself or herself because the influencing agent can attribute subsequent change in the target to himself or herself. When this occurs, the powerholder then tends to think less of the target of influence. It has been argued that simply through the continual exercise of successful influence, the powerholder's view of others and himself or herself changes in a harmful way. The powerholder begins to view himself or herself as superior to the person that over which he or she is exercising power, and because of this feeling of superiority, may treat the target of influence in a demeaning manner. This effect would be consistent with the common belief that power is a corrupting influence.

SOCIAL POWER EVIDENCE

Hundreds of studies published in respected scientific journals involving social power as described earlier have been conducted in several diverse fields, including health and medicine, family relations, gender relations, education, marketing and consumer psychology, social and organizational psychology, and examinations of confrontation between political figures. Studies have been conducted in the context simulations and questionnaires, strictly controlled laboratory settings using traditional experimental methods, real-world settings such as hospitals and other large organizations, and through historical case study analysis.

IMPORTANCE OF SOCIAL POWER

Much of what humans do as individuals and society involves influencing others. People want and need things from others, things such as affection, money, opportunity, work, and justice. How they get those things often depends on their abilities to influence others to grant their desires. In addition, people are also the constant targets of the influence attempts of others. Thus, it is important to understand what causes people to comply with others' wishes, and how the exercise of power affects both targets and influencing agents. The study of social power provides that knowledge.

PSYCHOLOGICAL REACTANCE

Almost 60 years have passed since Brehm presented a theory of psychological reactance as an answer to these questions. Reactance – the motivation to regain a freedom after it has been lost or threatened – leads people to resist the social influence of others. Since Brehm's first publication on reactance in 1966, the phenomenon has attracted attention in basic as well as applied research in areas such as health, marketing, politics, and education, and a wealth of reactance studies have been published. Forty years after Brehm's first publication, Miron and Brehm (2006) reviewed those areas they found especially relevant and pointed to several gaps in the research. Inspired by their review paper, we set out to explore the research addressing these gaps. About 50 years after the theory was first proposed, it is much clearer what reactance is and what role it plays when freedoms are threatened. However, there are still unanswered but important questions for psychology to clarify.

REACTANCE THEORY

In general, people are convinced that they possess certain freedoms to engage in so-called free behaviors. Yet there are times when they cannot, or at least feel that they cannot, do so. Being persuaded to buy a specific product in the grocery store, being forced to pay tuition fees, being prohibited from using a mobile phone in school, and being instructed to perform work for the boss

are all examples of threats to the freedom to act as desired, and this is where reactance comes into play. Reactance is an unpleasant motivational arousal that emerges when people experience a threat to or loss of their free behaviors. It serves as a motivator to restore one's freedom. The amount of reactance depends on the importance of the threatened freedom and the perceived magnitude of the threat. Internal threats are self-imposed threats arising from choosing specific alternatives and rejecting others. External threats arise either from impersonal situational factors that by happenstance create a barrier to an individual's freedom or from social influence attempts targeting a specific individual (Brehm, 1966; Brehm & Brehm, 1981; Clee & Wicklund, 1980). The unpleasant motivational state of reactance results in behavioral and cognitive efforts to reestablish one's freedom, accompanied by the experience of emotion.

Can Reactance Be Measured?

In their review paper, already provided some answers and further suggestions to the question of how to measure reactance. For measuring reactance as a trait they specify measurements such as the Hong' Psychological Reactance Scale (HPRS; e.g.,) which is still the most commonly used instrument. It has been translated into many languages and is used in countries around the world (However, research still does not agree on the factor structure. While , (reduced the original 18-item scale to a one-factor measure comprising 10 items, suggested a two-factor structure comprising an affective and a cognitive dimension.

Measurements of the state of reactance are rare, possibly because Brehm conceptualized reactance as "an intervening, hypothetical variable" that cannot be measured directly (; see also). However, in 2006 Miron and Brehm suggested that "reactance could be directly assessed through measurement of the subjective experience (feeling) that accompanies the urge to restore freedom"). The authors suggest that future studies should explore what people feel if they experience threats to their freedom. Over the last 10 years the question of how to measure the experience of reactance has attracted increasing attention.

Exploring persuasive messages, developed four items to assess people's perceived threat to freedom with regard to the message.¹ They demonstrated that a message that is perceived as highly threatening to one's freedom arouses reactance, which they conceptualized as a latent variable intermingling anger affect and negative cognition. To measure anger affect, Dillard and Shen asked their participants to indicate how irritated, angry, annoyed, and aggravated they were with regard to a freedom-threatening message. Further, they instructed participants to write down whatever came to mind after reading the message. Independent raters coded the thoughts as supportive, neutral, or negative. They found that anger and negative cognitions in the form of counterarguments mediated the relationship between the freedom-threatening message and people's attitudes toward the message. This attitude guided people's behavioral intentions to follow or not follow the advice of the message. But did affect and cognition have separate or combined effects on people's responses to the message? To test this, the authors compared four structural equation models: a single-process cognitive model, a single-process affective model, a dual-process model in which affective and cognitive reactions had unique effects on people's responses to the persuasive message, and an intertwined model in which affect and cognition were considered an alloy that could not be disentangled. In two studies they found the best fit for the intertwined model. In a meta-analytic review of 20 studies, Rains (2013) confirmed that the intertwined model was superior to the alternative models.

In a line of research on cross-cultural reactance (also see the section Reactance, Culture, and the Self), Jonas and colleagues used a different approach to measure the experience of reactance. They combined items assessing people's perception of threat to their freedom with items assessing people's emotional experience.² This measure has been shown to mediate the effect of freedom threat on behavioral intentions (e.g., the intention to help, J, Study 4). It has since been used in several studies investigating reactance in the context of change situations (e.g., personal change or political reforms), vicarious threats, and culture, and it has been shown to mediate cognitive and behavioral outcome variables such as attitude, intended and real resistance behavior, and performance. They validated these items together with items assessing aggressive behavioral intentions as well as negative evaluations and propose a new state reactance measure, the so-called Salzburger State Reactance Scale.

Also suggested that another way of directly assessing reactance would be to use physiological measures. research has demonstrated that freedom threats affect people's physiological arousal. Whereas in the previous study (Baum et al., 1986) arousal level increased when people were confronted with an uncontrollable event, such as a threat to their freedom, in the more recent studies (Sittenthaler, Jonas, et al., 2015; Sittenthaler, Steindl, et al., 2015) merely imagining being restricted from visiting a flat they might have wanted to rent was sufficient to increase people's heart rate. Interestingly, there was a difference between the heart rate increase following an illegitimate restriction (unexpected and inappropriate) and a legitimate restriction (unexpected but appropriate, i.e., when people were given reasons for not being allowed to visit the flat). When confronted with an illegitimate restriction, people's heart rate increased immediately. Heart rate also increased following a legitimate restriction, but only after a time delay. This finding led us to assume that different processes might be involved when people are confronted with different kinds of threats to their freedom. Whereas some threats (e.g., illegitimate threats) seem to follow a more emotional process leading to immediate arousal, others might induce people to reflect upon the situation before getting into an arousal state (Sittenthaler, Steindl, et al., 2015; see also Sittenthaler, Jonas, et al., 2015, for similar processes when confronted with self-experienced vs. vicarious reactance, on which we elaborate in more detail below). These findings suggest that dual processes in the form of more automatic, impulsive affect-driven versus more cognitive dominated reflective information processing appear to be important when looking at reactance processes following different kinds of threats. Affect and motivational arousal seem to be involved in both types of reactance responses, but occurring a bit later for the more reflective, cognitively oriented responses. These findings allow us to connect this line of research with Dillard and Shen's (2005) intertwined model, which conceptualizes reactance as a latent variable intermingling affect and cognition (see also Rains, 2013). Even if people first reflect on the restriction to their freedom (cognition), the experience of reactance seems to be also characterized by affect.

Different lines of research all suggest that one important component of reactance is the experience of anger. Anger is typically understood as a negative emotion but is also related to motivation, namely, approach motivation (Harmon-Jones, 2003, 2004; Harmon-Jones & Allen, 1998; Harmon-Jones, Harmon-Jones, Abramson, & Peterson, 2009). Approach motivation – the motivation to move toward something – is a force that determines human behavior and affect (Gray, 1982, 1990). It contrasts with avoidance motivation, which motivates people to withdraw (Harmon-Jones, Harmon-Jones, & Price, 2013). In a theoretical overview on reactance, Chadee (2011) even proposed that approach motivation is the necessary prerequisite for reactance to emerge. Feeling able to resolve a threatening event (i.e., to cope with a situation) has been shown to evoke approach motivation

(Harmon-Jones, Lueck, Fearn, & Harmon-Jones, 2006; Harmon-Jones, Sigelman, Bohlig, & Harmon-Jones, 2003). Because people experiencing reactance are striving to restore their freedom (i.e., they seem able to cope with the threat), reactance should be associated with approach motivation. Steindl, Jonas, Klackl, and Sittenthaler (2015) used electroencephalography (EEG) and found that reactance was associated with heightened left frontal alpha asymmetry, which is thought to be an indicator of approach motivation (Harmon-Jones, 2003; Harmon-Jones & Allen, 1998).

In summary, recent research suggests that reactance can indeed be measured. It is possible to assess people's experience of a threatening situation, the cognitive and affective processes that are activated by it, and the physiological arousal and activity in the brain that accompany the attempt to restore freedom. However, the extent to which people are affected by threats to their freedom and the resulting motivation to restore their freedom strongly depend on a person's self being involved in the reactance process.

REACTANCE, CULTURE, AND THE SELF

Miron and Brehm (2006) proposed that different cultures, such as individualistic and collectivistic, react to different threats and in different ways to restore their freedom. They suggested that it might be crucial whether a threat comes from individuals inside or outside one's group. They cited research showing that individualists and collectivists differ in their expectations of control and choice and thus in their self-construal, making them more or less sensitive to threats (Iyengar & Lepper, 1999). Assessing people's experience of reactance by measuring perceived threat and emotional experience, Jonas et al. (2009) showed that individualists or people with an independent self-construal are more affected by threats to their individual, personal freedom (e.g., doing another person a favor by lending him/her one's business car), in contrast to collectivists or people with an interdependent self-construal, who are more affected by threats to their collective freedom, that is, threats affecting not only themselves but also their group (e.g., doing another branch a favor by lending them a pool of business cars). The same results were obtained when independent versus interdependent values were primed by describing the differences versus similarities between themselves and their close others (see Trafimov, Triandis, & Goto, 1991). This suggests that people's experience of reactance strongly depends on the goals and values most accessible when the threat occurs. In these cultural studies, whether the values were group or individual was the key factor causing the differences in reactance. Thus, the experience of reactance as a mix of perceived threat and emotions seems to be motivational in nature. Only if people's values are affected do they seem to be energized to strive for a restoration of their freedom.

Graupmann, Jonas, Meier, Hawelka, and Aichhorn (2012) found that a threat to freedom of choice coming from one's ingroup aroused more reactance in individualistic than in collectivistic people. Individualists indicated a higher increase of attractiveness of the eliminated option when the threat originated in the ingroup versus an outgroup. In contrast, collectivists indicated a higher increase in attractiveness of the eliminated option when the threat originated in an outgroup versus the ingroup. This again seems to be because individualists highly value their individual freedom and distinctiveness from their ingroup (Markus & Kitayama, 1991). Thus, they are highly threatened by decisions coming from the ingroup. Collectivists, by contrast, highly value their connectedness with their ingroup (Markus & Kitayama, 1991) and thus, do not feel threatened by decisions coming from the ingroup.

Further evidence illustrating the motivational character of reactance comes from Laurin, Kay, and

Fitzsimons (2012). They explained the contradictory effect that some people may endorse a decision even though they are not in favor of it. Two factors determining the reaction to restrictions are the absoluteness of a restriction and self-relevance. If the threat is absolute, that is, sure to come into effect, people rationalize it. If it is nonabsolute, that is, it may not come into effect, people respond with reactance. Both effects, rationalization and reactance, were strongest if the restriction was self-relevant.

The differences in reactance processes that are due to one's self being involved in the threat raise the issue of vicarious reactance, in which a person experiences reactance to a threat to another individual or group, even if the threat does not have any implications for the person's own freedom of choice (Miron & Brehm, 2006). Is it possible to experience reactance on behalf of another person? What happens when people observe the restriction of another person?

VICARIOUS REACTANCE

Two distinct views of vicarious reactance exist: (a) It occurs as a consequence of people cognitively taking the role of the restricted person and asking themselves what the restricted person might experience tested female participants who observed an actor being excluded from a decision-making process and found that the participants themselves showed vicarious reactance by rating the attractiveness of the discussion topics higher when the actor was restricted versus not restricted. The authors concluded that "reactance can be aroused by the mere observance of a threat to another's freedom, without the perception of one's own freedom being potentially directly threatened" (p. 767).

Whereas measured reactance only in the form of cognitive changes in the attractiveness of an option, Sittenthaler and colleagues (Sittenthaler, Traut-Mattausch, et al., 2015) assessed the subjective experience of vicarious reactance. They found that people experienced strong reactance as a mix of perceived threat and emotions if they observed or read about a freedom threat to another person. These vicarious reactions to freedom threats, however, were moderated by people's self-construal. People with a more interdependent self-construal or a collectivistic cultural background (e.g., coming from Bosnia or Croatia) experienced more vicarious reactance (especially for an in-group member) compared to people with a more independent self-construal or an individualistic cultural background (e.g., coming from Germany or Austria). Furthermore, people with a more independent self-construal or an individualistic cultural background indicated stronger reactance when restricted themselves rather than being vicariously restricted. Other cross-cultural studies on vicarious reactance among collectivists from the Philippines and Eastern European countries (e.g., the Czech Republic, Romania, Russia; replicated those findings).

People respond to both kinds of freedom restrictions (self- and vicariously experienced), but Sittenthaler and colleagues presented evidence that the process underlying vicarious threats is different from the process of self-experienced threats. Before experiencing the motivational arousal state of reactance, people observing a restriction first seem to need to think about the restriction of the other person. This was demonstrated by looking at threatened people's cardiovascular responses (Study 2): While there was an immediate increase in physiological arousal (e.g., heart rate) after self-restrictions the increase after vicarious restrictions was delayed. Further evidence revealed that vicarious reactance is associated with a more reflective, cognitive process and self-experienced reactance with a more impulsive, emotional process (Studies 3 and 4). This was shown by using a cognitive load task (memorizing a 7-digit number), which diminished people's experience

of vicarious reactance, and an emotionally distracting task (think about the nicest day of last summer), which only diminished self-experienced reactance.

In a nutshell, research in the cultural context has shown that reactance is a state that (a) is influenced by people's cultural self-construal and (b) can also be experienced vicariously. Only if the freedom threat affects aspects that are important to the self do people show reactance. This illuminates that reactance is motivational in nature. The motivational nature of reactance also becomes evident in the different reactance processes we described before – people's responses to self-experienced and illegitimate threats appear to be more impulsive, whereas the responses to vicarious and legitimate threats seem to be more reflective. Similar different processes can also be found in the persuasion context.

PERSUASION AND RESISTANCE TO CHANGE

If persuasion poses a threat to a person's free behaviors, reactance in the form of negative cognitions, such as counterarguing and anger affect, leads to more negative attitudes toward the message and consequently to less intention to behave according to the message. Counterarguing and anger as an intertwined reactance process have been shown to mediate the effect of perceived freedom threat on reactance effects such as disagreeing with the message. Persuasive messages arouse reactance especially by using forceful and controlling language, such as the terms should, ought, must, and need.

This language has been shown to be perceived as more threatening and as eliciting more reactance than noncontrolling language, such as the terms consider, can, could, and may (Miller, Lane, Deatrick, Young, & Potts, 2007; Quick & Stephenson, 2008). For example, in a study on convincing members of a fitness club to participate in special exercises, people who had been given a forceful message such as "you have to do it" compared to a nonforceful message such as "consider it" experienced more threat, which elicited more reactance (negative cognitions and anger), and consequently, people were less convinced (Quick & Considine, 2008). Additionally, how threatening controlling messages are perceived to be depends on the level of social agency. Social agency is the extent to which a social agent is "perceived as being capable of social behavior that resembles human-human interaction" (Roubroeks, Ham, & Midden, 2011, p. 157). Roubroeks et al. showed their participants low- or high-control advice about energy conservation in the form of a text only, a text with a picture of a robotic agent, or a text with a brief film clip of the agent (Roubroeks et al., 2011; Roubroeks, Midden, & Ham, 2009). Both studies confirmed that the stronger the social agency of persuasive messages, the higher people's perceived threat and thus the higher their reactance (negative cognitions and anger).

With regard to the reactance process in the context of persuasion, research by Silvia (2006) showed that threats to freedom through persuasive messages can elicit disagreement through different paths and that these paths have different consequences. If freedom was threatened at the end of a persuasive message, people directly disagreed with the message. If freedom was threatened at the beginning of the persuasive message, negative cognitions such as counterarguing and perceiving the source as low in credibility mediated the effect on people's disagreement with the message. While disagreement that originated directly from the threat at the end of the message decreased over time, disagreement that originated in negative cognitions was stable over time. Thus a reflective reactance process, in which cognitions affect subsequent reactions, is a more stable reactance process. Research by Ziegler, Schlett, and Aydinly (2013) furthermore suggests that in this state,

people also seem to react very sensitively to the weakness of arguments when confronted with a highly threatening message. However, when they are in a state of positive or negative mood, the strength of the arguments plays a less important role in predicting their reaction toward the freedom threat. Interestingly, in a different line of research only people with sufficient cognitive resources showed reactance in the form of a negative attitude toward a restriction; without sufficient resources they even justified the restriction (Laurin, Kay, Proudfoot, & Fitzsimons, 2013).

So far, affect and cognition seem to be central elements if we want to understand the nature of reactance processes. This is most clearly expressed in the intertwined model of reactance (Dillard & Shen, 2005; Rains, 2013), but seems to be also supported by other research lines. However, even if reactance can be conceptualized as a latent variable intermingling anger affect and negative cognition, we can distinguish further between more affect-driven impulsive processes and more cognition-driven reflective reactance processes. In some situations, these different processes might be driven by both cognition and affect in an intermingling manner. However, in other situations, they might be distinguishable from each other. The latter becomes apparent if we look at shorter persuasive messages where there is less room for counterarguing.

For short messages, it has been found that the framing of the message as loss (e.g., "When you do not use sun protection you will pay costs.") led to a significantly stronger perception of threat than a gain frame (e.g., "When you use sun protection you will gain benefits.") and that the perceived threat was positively correlated with anger but not with negative cognitions (Cho & Sands, 2011). The authors speculated that "different types of messages create differences in the process of reactance" (Cho & Sands, 2011, p. 315).

The influence of different types of threats that rely on simple cues has also been explored in the context of political reforms. Citizens' reactions are influenced by the way politicians communicate reforms. Focusing on limitations that will result from the change has been shown to evoke more experience of reactance (using Jonas et al.'s, 2009, combined measure of an experience of perceived threat and negative affect) and thus more negative attitudes toward the reform than focusing on improvements that will result (Traut-Mattausch et al., 2008). Furthermore, a study by Förg, Jonas, Traut-Mattausch, Heinemann, and Frey (2007) demonstrated that experts communicating the reform to citizens aroused more experience of reactance and consequently a more negative attitude toward the reform than when laypeople delivered the message. Likewise, in the context of communicating changes, Niesta Kayser et al. (2015) used the same measurement (Jonas et al., 2009) and found that presenting a change message within an approach (focusing on possible positive outcomes) versus an avoidance (avoidance of possible negative outcomes) frame led to differences in people's experienced reactance. Changes presented as avoidance of negative outcomes aroused more experience of reactance, which mediated the effect of avoidance on people's lower agreement with the change. Avoidance resulted in more counterarguing and less positive perceptions of the communicator and the change message.

To summarize, in the context of persuasion, most of the recent research has been conducted in the tradition of Dillard and Shen' (2005) intertwined model, according to which people receiving persuasive messages perceive them as threats to their freedom, which further elicit an experience of reactance in the form of counterarguments that are accompanied by anger affect. When attempts are made to persuade people by using a forceful message, this message motivates people to present arguments against the persuasive attempt (counterarguing). This is a cognitive-reflective

process leading to negative attitudes toward the message and finally results in lower behavioral intention to follow the aim of the message. Research that indirectly manipulated threat through framing has found reactance to be a combination of perceived threat and negative affect (Traut-Mattusch et al., 2008). In these studies it seems that certain cues elicit an affective-impulsive process, which further leads to negative cognitions and a behavioral intention to restore one's freedom. This might be comparable to dual-process models and their distinction between more impulsive and more reflective processes of social behavior (e.g., Strack & Deutsch, 2004; for an overview, see Gawronski & Creighton, 2013). On the one hand, Dillard and Shen (2005) and Rains (2013) tested a dual-process model and rejected it. Yet, on the other hand, as described earlier, Sittenthaler and colleagues have shown in two contexts that depending on the threat (legitimate vs. illegitimate threats; self-experienced vs. vicarious threats), people either react immediately or after a time delay with an increased physiological arousal that can be seen as an indicator of motivation (Baum et al., 1986; Wright, 2008; Zanna & Cooper, 1974). Results showing that reactance can emerge automatically also come from studies on the implicit activation of reactance.

Priming Reactance

As mentioned by Miron and Brehm (2006), people do not react only to obvious, direct threats. Reactance can also be aroused in subtle way and even outside of conscious awareness. In a study by Wellman and Geers (2009), participants were primed with modified items of the Therapeutic Reactance Scale. Additionally, they were given a pill and told that it either did or did not improve performance on accuracy tasks. Results indicated that participants who were primed with reactance and who were given an explicit expectation that they should be good at the task committed the most errors, contrary to the experimenter's expectation.

showed that even subliminal primes can arouse reactance. They subliminally primed participants with the name of a controlling significant other person who wanted them to work hard versus a significant other who wanted them to have fun. Results reflected that participants primed with the controlling person's name opposed the person's wishes by answering fewer anagrams correctly than participants primed with the noncontrolling person's name.³ Thus, it is possible to arouse reactance with stimuli not consciously perceived, and relatively automatic processes can produce immediate reactance effects.

However, this is not always the case. found in a study on stereotype threat and negotiation that only an explicit expectation of behavior led to the exact opposite behavior. While an implicit activation of the stereotype that men are better in negotiating led to lower performance in women, an explicit activation led to higher performance in women.

Reactance as Motivation

Reactance theory, following the tradition of dissonance theory, is a theory of motivation. Using Brehm's description of reactance, it is "a motivational state and as such is assumed to have energizing and behavior-directing properties. This contrasts with the concept of learned helplessness, which is a state of passively enduring a threat or even withdrawing from it). Helpless individuals usually do not feel capable of changing an unpleasant situation. Reactant individuals, in contrast, feel capable of changing the current situation, that is, the freedom threat). Consistent with these analyses, in Kravitz study of "stereotype reactance," such reactance occurred only if women had sufficient power to act, which supports the idea that reactance develops only if people feel capable of restoring their freedom. Thus reactance possesses energizing and behavior-directing properties

when something to restore the freedom can be done .

Although the intertwined model addresses anger, which is a motivational state, it refers to anger only as affect. However, as demonstrated by EEG studies, anger is approach motivational). Thus, reactance is a state possessing a tremendous motivational force that induces undesirable outcomes such as disagreement or devaluation. Interestingly, most of the presented studies viewed reactance primarily as an undesirable factor that has to be eliminated or at least reduced. Several methods to reduce or prevent reactance have already been tested. For example, to perceive a message as less threatening, a restoration postscript telling participants that they are free to decide for themselves what is good for them can help. Moreover, if the threatened person takes the perspective of the threatening person or if state empathy is induced by a persuasive message, reactance is lower(). Another method is inoculation, which forewarns people of a potential threat. This strategy reduces the experienced threat and, consequently, reactance effects. However, in other cases, one could even make use of the motivational force of reactance. Paradoxical interventions, for example, use reactance to successfully reduce symptoms such as procrastination (for an overview see).

Furthermore, reactance can produce both undesirable and desirable outcomes. It has been found, for example, that the experience of reactance can elicit heightened achievement motivation . Recent studies have also shown that the experience of reactance can be associated not just with negative feelings, such as anger, but also with activating positive affect, such as feeling strong and determined . We invite future research to investigate the desirable motivational side of reactance in order to make use of its energizing probabilities.

Implications and Suggestions for Future Research

About 50 years of research has provided many answers regarding the determinants of reactance, the subjective experience of reactance, the processes involved, and its consequences. Although stated that reactance cannot be measured directly, research has found a way to do so. idea of assessing the affective, cognitive, and physiological aspects of experiencing reactance. Neuroscientific studies using EEG and functional magnetic resonance imaging (fMRI) have contributed to an even better grasp of the reactance phenomenon .

These studies showed us that reactance is a state consisting of affective, cognitive, and motivational components. One affective as well as motivational facet of the experience is anger. As anger is typically understood as a negative emotion emerging when people are kept from reaching a desired goal (for an overview , one might wonder if reactance is the same as anger. Although anger is an important component of reactance and has used fMRI techniques to compare conditions in which participants read about reactance-arousing, anger- arousing, or neutral situations. During reactance-arousing compared to anger-arousing situations, the middle temporal lobe, the temporal poles, and the gyrus rectus were active. These regions have been shown to be involved in mentalizing processes in which people are drawing inferences about the mental states of others.

This suggests one basis for distinguishing reactance processes from more pure anger processes, an issue that should be explored more carefully in future research.

Another interesting question for future research would be whether reactance motivation will always

lead to efforts to restore freedom. According to motivational intensity theory the emerging effort people expend to restore their freedom depends on the difficulty of the required behavior. The more difficult the behavior, the more effort is invested, up to the point where it seems impossible to restore freedom. What happens to reactance arousal and striving if one cannot restore an eliminated freedom is an open question. suggested, more research is needed to better understand the role of perceived difficulty of freedom restoration in reactance striving.

In the context of persuasion, the intertwined model describing reactance as a combination of anger and negative cognition that further affect people's attitudes seems to be an important model for understanding the reactance process. However, it is unclear if this model generalizes to all reactance situations, that is, also to those outside the persuasion context. Studies using framing, vicarious, or legitimate freedom threats for eliciting reactance indicate two processes of reactance, a more impulsive emotional and a more reflective cognitive process. People seem to either react to the threat immediately or after a time delay with intermediary cognition examining the process of reactance induced by guilt appeals found that in the context of guilt that the affective and cognitive reactance component did not correlate, which is in contrast to the intertwined model. However, in accordance with the intertwined model, both variables affected people's reactions to the perceived freedom threat. Yet, they did this via different routes. Whereas guilt directly affected the affective component of reactance (anger), it only indirectly affected the cognitive component of reactance (negative cognitions) via people's awareness that the message was a guilt appeal. The question of when and how different reactance models (dual-process vs. intertwined) apply seems to be a recent interest in reactance research and should further be explored in future studies.

Similar to the investigation of guilt, it would also be interesting for future research to take a closer look at the relation between reactance and other negative (and positive) emotions, like fear looked at reactance processes resulting from fear appeals from a within subjects perspective and interestingly found that the presentation of humorous information can mitigate reactance and therefore improve the persuasiveness of a message provide more evidence that reactance threat can also result from perceived threats to one's groups and social identities. Specifically, they show that examples of stereotypic women arouse some reactance response in feminist women and examples of counterstereotypic women arouse reactance in more traditional women. Interventions in the context of health behaviors can also elicit reactance which might contribute to the often missing effects in the long term.

Furthermore, how do cognition and affect combine in different types of freedom threats? Is there a difference between restricting a freedom versus imposing an alternative, and if so, how does this difference affect emotional experience, cognition, motivation, and physiological arousal? Although it is difficult to explore these processes in real-world phenomena, it would be enormously enriching for reactance research.

As people are often threatened by other people, reactance plays a crucial role in interaction processes. In any social interaction, one person's reaction influences the other person's experience, behavior, and cognition, which in turn affects the first person, and so on (Steindl & Jonas, in press). Freedom threats are probably common in many social interactions. Customers may feel restricted by salespeople. Service providers may feel controlled by those they serve. Patients may feel constrained by doctors and therapists. Marital partners may perceive threats to their freedoms from their spouses. Future research might consider the dynamics of these reactance processes in a wide

range of social contexts, to reach an understanding of how people's reactions to freedom threats mutually affect each other. The papers in the present volume hopefully both address these new questions and will serve to stimulate further efforts to do so.

CONCLUSION

Since Miron and Brehm's (2006) review paper, research on psychological reactance has continued. Although our knowledge about this fascinating phenomenon has grown, the puzzle of reactance is not yet complete. As Miron and Brehm (2006) so aptly put it, we further "hope that future research will consider the various implications of the theory for real

AGGRESSION AGGRESSION DEFINITION

In sports and in business, the term aggressive is frequently used when the term assertive, enthusiastic, or confident would be more accurate. For example, an aggressive salesperson is one who tries really hard to sell you something. Within psychology, the term aggression means something different. Most social psychologists define human aggression as any behavior that is intended to harm another person who wants to avoid the harm. This definition includes three important features. First, aggression is a behavior. You can see it. For example, you can see a person shoot, stab, hit, slap, or curse someone. Aggression is not an emotion that occurs inside a person, such as feeling angry. Aggression is not a thought that occurs inside someone's brain, such as mentally rehearsing a murder one is about to commit. Aggression is a behavior you can see. Second, aggression is intentional. Aggression is not accidental, such as when a drunk driver accidentally runs over a child on a tricycle. In addition, not all intentional behaviors that hurt others are aggressive behaviors. For example, a dentist might intentionally give a patient a shot of novocaine (and the shot hurts!), but the goal is to help rather than hurt the patient. Third, the victim wants to avoid the harm. Thus, again, the dental patient is excluded, because the patient is not seeking to avoid the harm (in fact, the patient probably booked the appointment weeks in advance and paid to have it done!). Suicide would also be excluded, because the person who commits suicide does not want to avoid the harm. Sadomasochism would likewise be excluded, because the masochist enjoys being harmed by the sadist.

The motives for aggression might differ. Consider two examples. In the first example, a husband finds his wife and her lover together in bed. He takes his hunting rifle from a closet and shoots and kills both individuals. In the second example, a "hitman" uses a rifle to kill another person for money. The motives appear quite different in these two examples. In the first example, the man appears to be motivated by anger. He is enraged when he finds his wife making love to another man, so he shoots both of them. In the second example, the hitman appears to be motivated by money. The hitman probably does not hate his victim. He might not even know his victim, but he kills that person anyway for the money. To capture different types of aggression based on different motives, psychologists have made a distinction between hostile aggression (also called affective, angry, impulsive, reactive, or retaliatory aggression) and instrumental aggression (also called proactive aggression). Hostile aggression is "hot," impulsive, angry behavior that is motivated by a desire to harm someone. Instrumental aggression is "cold," premeditated, calculated behavior that is motivated by some other goal (e.g., obtain money, restore one's image, restore justice).

One difficulty with the distinction between hostile and instrumental aggression is that the motives for aggression are often mixed. Consider the following example. On April 20, 1999, the 110th anniversary of Adolf Hitler's birthday, Eric Harris and Dylan Klebold entered their high school in

Littleton, Colorado (United States), with weapons and ammunition. They murdered 13 students and wounded 23 others before turning the guns on themselves. Harris and Klebold were repeatedly angered and provoked by the athletes in their school. However, they planned the massacre more than a year in advance, did research on weapons and explosives, made drawings of their plans, and conducted rehearsals. Was this an act of hostile or instrumental aggression? It is hard to say. That is why some social psychologists have argued that it is time to get rid of the distinction between hostile and instrumental aggression.

Another distinction is between displaced and direct aggression. Displaced aggression (also called the “kicking the dog” effect) involves substituting the target of aggression: The person has an impulse to attack one person but attacks someone else instead. Direct aggression involves attacking the person who provoked you. People displace aggression for several reasons. Directly aggressing against the source of provocation may be unfeasible because the source is unavailable (e.g. the provoker has left the situation) or because the source is an intangible entity (e.g., hot temperature, loud noise, foul odor). Fear of retaliation or punishment from the provoker may also inhibit direct aggression. For example, an employee who is reprimanded by his boss may be reluctant to retaliate because he does not want to lose his job.

Violence is aggression that has extreme physical harm as its goal, such as injury or death. For example, one child intentionally pushing another off a tricycle is an act of aggression but is not an act of violence. One person intentionally hitting, kicking, shooting, or stabbing another person is an act of violence. Thus, all violent acts are aggressive acts, but not all aggressive acts are violent; only the extreme ones are.

Is Aggression Innate or Learned?

For decades, psychologists have debated whether aggression is innate or learned. Instinct theories propose that the causes of aggression are internal, whereas learning theories propose that the causes of aggression are external. Sigmund Freud argued that human motivational forces such as sex and aggression are based on instincts. In his early writings, Freud proposed the drive for sensory and sexual gratification as the primary human instinct, which he called *eros*. After witnessing the horrors of World War I, however, Freud proposed that humans also have a destructive, death instinct, which he called *thanatos*.

According to Konrad Lorenz, a Nobel Prize-winning scientist, aggressive behavior in both humans and nonhumans comes from an aggressive instinct. This aggressive instinct presumably developed during the course of evolution because it promoted survival of the human species. Because fighting is closely linked to mating, the aggressive instinct helped ensure that only the strongest individuals would pass on their genes to future generations.

Other psychologists have proposed that aggression is not an innate drive, like hunger, in search of gratification. According to Albert Bandura’s social learning theory, people learn aggressive behaviors the same ways they learn other social behaviors—by direct experience and by observing others. When people observe and copy the behavior of others, this is called modeling. Modeling can weaken or strengthen aggressive responding. If the model is rewarded for behaving aggressively, aggressive responding is strengthened in observers. If the model is punished for behaving aggressively, aggressive responding is weakened in observers.

This nature versus nurture debate has frequently generated more heat than light. Many experts on aggression favor a middle ground in this debate. There is clearly a role for learning, and people can learn how to behave aggressively. Given the universality of aggression and some of its features (e.g., young men are always the most violent individuals), and recent findings from heritability studies, there may be an innate basis for aggression as well.

SOME FACTORS RELATED TO AGGRESSION FRUSTRATION AND OTHER UNPLEASANT EVENTS

In 1939, a group of psychologists from Yale University published a book titled *Frustration and Aggression*. In this book, they proposed the frustration-aggression hypothesis, which they summarized on the first page of their book with these two statements: (1) "The occurrence of aggressive behavior always presupposes the existence of frustration" and (2) "the existence of frustration always leads to some form of aggression." They defined frustration as blocking goal-directed behavior, such as when someone crowds in front of you while you are waiting in a long line. Although they were wrong in their use of the word always, there is no denying the basic truth that aggression is increased by frustration.

Fifty years later, Leonard Berkowitz modified the frustration-aggression hypothesis by proposing that all unpleasant events—instead of only frustration—deserve to be recognized as causes of aggression. Other examples of unpleasant events include hot temperatures, crowded conditions, foul odors, secondhand smoke, air pollution, loud noises, provocations, and even pain (e.g., hitting your thumb with a hammer).

All of these unpleasant environmental factors probably increase aggression because they make people feel bad and grumpy. But why should being in a bad mood increase aggression? One possible explanation is that angry people aggress because they think it will make them feel better. Because many people believe that venting is a healthy way to reduce anger and aggression, they might vent by lashing out at others to improve their mood. However, research has consistently shown that venting anger actually increases anger and aggression.

It is important to point out that like frustration, being in a bad mood is neither a necessary nor a sufficient condition for aggression. All people in a bad mood do not behave aggressively, and all aggressive people are not in a bad mood.

AGGRESSIVE CUES

Weapons. Obviously using a weapon can increase aggression and violence, but can just seeing a weapon increase aggression? The answer is yes. Research has shown that the mere presence of a weapon increases aggression, an effect called the weapons effect.

Violent Media. Content analyses show that violence is a common theme in many types of media, including television programs, films, and video games. Children are exposed to approximately 10,000 violent crimes in the media per year. The results from hundreds of studies have shown that violent media increase aggression. The magnitude of the effect of violent media on aggression is not trivial either. The correlation between TV violence and aggression is only slightly smaller than that correlation between smoking and lung cancer. Smoking provides a useful analogy for thinking about media violence effects. Not everyone who smokes gets lung cancer, and not everyone who gets lung cancer is a smoker. Smoking is not the only factor that causes lung cancer, but it is an

important factor. Similarly, not everyone who consumes violent media becomes aggressive, and not everyone who is aggressive consumes violent media. Media violence is not the only factor that causes aggression, but it is an important factor. Like the first cigarette, the first violent movie seen can make a person nauseous. After repeated exposure, however, the person craves more and more. The effects of smoking and viewing violence are cumulative. Smoking one cigarette probably will not cause lung cancer. Likewise, seeing one violent movie probably will not make a person more aggressive. But repeated exposure to both cigarettes and media violence can have harmful long-term consequences.

CHEMICAL INFLUENCES

Numerous chemicals have been shown to influence aggression, including testosterone, cortisol, serotonin, and alcohol.

Testosterone. Testosterone is the male sex hormone. Both males and females have testosterone, but males have a lot more of it. Testosterone has been linked to aggression. Robert Sapolsky, author of *The Trouble With Testosterone*, wrote, "Remove the source of testosterone in species after species and levels of aggression typically plummet. Reinstating normal testosterone levels afterward with injections of synthetic testosterone, and aggression returns."

Cortisol. A second hormone that is important to aggression is cortisol. Cortisol is the human stress hormone. Aggressive people have low cortisol levels, which suggests that they experience low levels of stress. How can this explain aggression? People who have low cortisol levels do not fear the negative consequences of their behavior, so they might be more likely to engage in aggressive behavior. Also, people who have low cortisol become easily bored, which might lead to sensation-seeking behavior such as aggression.

Serotonin. Another chemical influence is serotonin. In the brain, information is communicated between neurons (nerve cells) by the movement of chemicals across a small gap called the synapse. The chemical messengers are called neurotransmitters. Serotonin is one of these neurotransmitters. It has been called the "feel good" neurotransmitter. Low levels of serotonin have been linked to aggression in both animals and humans. For example, violent criminals have a serotonin deficit.

Alcohol. Alcohol has long been associated with violent and aggressive behavior. Well over half of violent crimes are committed by individuals who are intoxicated. Does all of this mean that aggression is somehow contained in alcohol? No. Alcohol increases rather than causes violent or aggressive tendencies. Factors that normally increase aggression, such as provocation, frustration, aggressive cues, and violent media, have a much stronger effect on intoxicated people than on sober people.

Self and Culture

Norms and Values. Amok is one of the few Indonesian words used in the English language. The term dates back to 1665, and describes a violent, uncontrollable frenzy. Running amok roughly translated means "going berserk." A young Malay man who had suffered some loss of face or other setback would run amok, recklessly performing violent acts. The Malays believed it was impossible for young men to restrain their wild, aggressive actions under those circumstances. However, when the British colonial administration disapproved of the practice and began to hold the young men responsible for their actions, including punishing them for the harm they did, most

Malays stopped running amok.

The history of running amok thus reveals three important points about aggression. First, it shows the influence of culture: The violence was accepted in one culture and prohibited in others, and when the local culture changed, the practice died out. Second, it shows that cultures can promote violence without placing a positive value on it. There is no sign that the Malays approved of running amok or thought it was a good, socially desirable form of action, but positive value wasn't necessary. All that was needed was for the culture to believe that it was normal for people to lose control under some circumstances and act violently as a result. Third, it shows that when people believe their aggression is beyond control, they are often mistaken—the supposedly uncontrollable pattern of running amok died out when the British cracked down on it. The influence of culture was thus mediated through self-control.

Self-Control. In 1990, two criminologists published a book called *A General Theory of Crime*. Such a flamboyant title was bound to stir controversy. After all, there are many crimes and many causes, and so even the idea of putting forward a single theory as the main explanation was pretty bold. What would their theory feature: Poverty? Frustration? Genetics? Media violence? Bad parenting? As it turned out, their main theory boiled down to poor self-control. The authors provided plenty of data to back up their theory. For one thing, criminals seem to be impulsive individuals who simply don't show much respect for norms, rules, and standards of behavior. If self-control is a general capacity for bringing one's behavior into line with rules and standards, criminals lack it. Another sign is that the lives of criminals show low self-control even in behaviors that are not against the law (e.g., smoking cigarettes).

Social psychology has found many causes of violence, including frustration, anger or insult, alcohol intoxication, violence in the media, and hot temperatures. This raises the question of why there isn't more violence than there is. After all, who hasn't experienced frustration, anger, insult, alcohol, media violence, or hot weather in the past year? Yet most people do not hurt or kill anyone. These factors may give rise to violent impulses, but most people restrain themselves. Violence starts when self-control stops.

Culture of Honor. The southern United States has long been associated with greater levels of violent attitudes and behaviors than the northern United States. In comparison to northern states, southern states have more homicides per capita, have fewer restrictions on gun ownership, allow people to shoot assailants and burglars without retreating first, are more accepting of corporal punishment of children at home and in schools, and are more supportive of any wars involving U.S. troops.

Social psychologist Richard Nisbett hypothesized that these regional differences are caused by a southern culture of honor, which calls for violent response to threats to one's honor. This culture apparently dates back to the Europeans who first came to the United States. The northern United States was settled by English and Dutch farmers, whereas the southern United States was settled by Scottish and Irish herders. A thief could become rich quick by stealing another person's herd. The same was not true of agricultural crops in the North. It is difficult to quickly steal 50 acres of corn. Men had to be ready to protect their herds with a violent response. A similar culture of violence exists in the western United States, or the so-called Wild West, where a cowboy could also lose his wealth quickly by not protecting his herd. (Cowboys herded cows, hence the name.) This violent culture isn't confined to the southern and western United States; cultural anthropologists have observed that

herding cultures throughout the world tend to be more violent than agricultural cultures.

Humiliation appears to be the primary cause of violence and aggression in cultures of honor. Humiliation is a state of disgrace or loss of self-respect (or of respect from others). It is closely related to the concept of shame. Research shows that feelings of shame frequently lead to violent and aggressive behavior. In cultures of honor there is nothing worse than being humiliated, and the appropriate response to humiliation is swift and intense retaliation.

Age and Aggression

Research has shown that the most aggressive human beings are toddlers, children 1 to 3 years old. Researchers observing toddlers in daycare settings have found that about 25% of the interactions involve some kind of physical aggression (e.g., one child pushes another child out of the way and takes that child's toy). High aggression rates in toddlers are most likely due to the fact that they still lack the means to communicate in more constructive ways. No adult group, not even violent youth gangs or hardened criminals, resorts to physical aggression 25% of the time.

Young children do not commit many violent crimes, especially as compared to young men. This is most likely due to the fact that young children can't do much physical damage, because they are smaller and weaker. Longitudinal studies show that serious aggressive and violent behavior peaks just past the age of puberty. After the age of 19, aggressive behaviors begin to decline. However, a relatively small subgroup of people continue their aggressive behavior after adolescence. These "career criminals" typically started violent offending in early life. The earlier the onset of aggressive or violent behavior is, the greater is the likelihood that it will continue later in life.

GENDER AND AGGRESSION

In all known societies, young men just past the age of puberty commit most of the violent crimes. Rarely women. Rarely older men. Rarely young children. Research shows that males are more physically aggressive than females, but this difference shrinks when people are provoked. Males are also more verbally aggressive than females, although the difference is much smaller. Females are often taught to be less direct in expressing aggression, so they often resort to more indirect forms of aggression. When it comes to relational aggression, for example, females are more aggressive than males. Relational aggression is defined as intentionally harming someone's relationships with others. Some examples of relational aggression include saying bad things about people behind their backs, withdrawing affection to get what you want, and excluding others from your circle of friends. Thus, rather than simply stating that males are more aggressive than females, it is more accurate to state that both sexes can behave aggressively, but they tend to engage in different types of aggression.

Aggression and Biased Social Information Processing

People do not passively respond to the things happening around them, but they actively try to perceive, understand, and attach meaning to these events. For example, when someone bumps a shopping cart into your knee in the local supermarket, you will likely do more than just feel the pain and take another carton of milk from the shelf. Instead, you will try to make sense of what happened to you (often this occurs automatically and so fast that you're not even aware of it): Why did this person bump me? Was it an accident or was it intentional?

According to the social information processing model, the way people process information in a

situation can have a strong influence on how they behave. In aggressive people, the processing of social information takes a different course than in nonaggressive people. For example, aggressive people have a hostile perception bias. They perceive social interactions as more aggressive than nonaggressive people do. Aggressive people pay too much attention to potentially hostile information and tend to overlook other types of information. They see the world as a hostile place. Aggressive people have a hostile expectation bias. They expect others to react to potential conflicts with aggression. Furthermore, aggressive people have a hostile attribution bias. They assume that others have hostile intentions. When people perceive ambiguous behaviors as stemming from hostile intentions, they are much more likely to behave aggressively than when they perceive the same behaviors as stemming from other intentions. Finally, aggressive people are more likely than others to believe that "aggression pays." In estimating the consequences of their behavior, they are overly focused on how to get what they want, and they do not focus much on maintaining good relationships with others. This is why aggressive people often choose aggressive solutions for interpersonal problems and ignore other solutions.

Intervening With Aggression and Violence

Most people are greatly concerned about the amount of aggression in society. Most likely, this is because aggression directly interferes with people's basic needs of safety and security. Accordingly, it is urgent to find ways to reduce aggression. Aggression has multiple causes. Unpleasant events, biased social information processing, violent media, and reduced self-control are just some of the factors that can increase aggression. The fact that there is no single cause for aggression makes it difficult to design effective interventions. A treatment that works for one individual may not work for another individual. One subgroup of extremely aggressive and violent people, psychopaths, is even believed to be untreatable. Indeed, many people have started to accept the fact that aggression and violence have become an inevitable, intrinsic part of society.

This being said, there certainly are things that can be done to reduce aggression and violence. Although aggression intervention strategies will not be discussed in detail here, there are two important general points to be made. First, successful interventions target as many causes of aggression as possible and attempt to tackle them collectively. Most often, these interventions are aimed at reducing factors that promote aggression in the direct social environment (family, friends), general living conditions (housing and neighborhood, health, financial resources), and occupation (school, work, spare time). Common interventions include social competence training, family therapy, parent management training (in children and juveniles), or a combination of these. Interventions that are narrowly focused at removing a single cause of aggression, however well conducted, are bound to fail.

Aggression is often stable over time, almost as stable as intelligence. If young children display excessive levels of aggression (often in the form of hitting, biting, or kicking), it places them at high risk for becoming violent adolescents and even violent adults. It is much more difficult to alter aggressive behaviors when they are part of an adult personality than when they are still in development. Thus, as a second general rule it is emphasized that aggressive behavior problems are best treated in early development, when they are still malleable. The more able professionals are to identify and treat early signs of aggression, the safer our communities will be.

DYNAMICS

In this article we will discuss about:- 1. Meaning and Definition of Group or Class 2. Types of Group

3. Group Guidance 4. Group Guidance Programmes 5. Leadership 6. Group Dynamics.

A collection of individuals forms a group whether there is interaction of the members or not. Without interaction the group is nearly an aggregation. Functional groups are characterised by common goals and inter stimulation and response among members, which serve as means for satisfying individual needs, and in which individuals enter into reciprocal relation with other group members, identify themselves with the group and are changed through membership in the group.

MEANING AND DEFINITION OF GROUP OR CLASS:

The class or group is a collection of individuals. The class may be regarded largely as an assemblage of individuals, each of whom be taught. It is also a social group, having a structure and an organization of forces which give it a measure of unity and coherence. The class may have a character of its own. The class has its norms of behaviour or performances. The class has a planned and well organized interaction. It has its own former leader i.e., teacher. The class as such may have a marked influence on its members.

THE GROUP HAS BEEN DEFINED AS FOLLOWS:

These definitions emphasize the following characteristics

1. It is an assemblage of individuals.
2. It has its own structure and organization of forces.
3. It has its own standard and norms of behaviour of performance.

TYPES OF GROUP:

Groups characterised by more or less continued intimate face-to-face association and cooperation are primary group, e.g., family; children's play groups, adolescent group, neighbourhood group.

1. SECONDARY GROUPS:

Secondary groups are special-interest groups, such as national, political religious, fraternal and professional groups. They don't depend upon face-to-face contact although there may be direct interaction among the members.

2. SOCIO & PSYCHO GROUPS:

In socio groups the purpose is largely impersonal, the members associating together to work on some common objective or problem. Labour union, editorial staff of a school year-book. The psycho group is more personal in nature and the members come together of their own accord primarily for the purpose of inter member association. The girls who meet regularly under the tree in the recess.

3. ORGANIZED AND UNORGANIZED GROUPS:

In the organized group the members play differentiated roles in relation to common goals. The degree of organisation may vary from loose, informal organization to a highly complex, formal one. But, if the group has a leader, it is an organization

In unorganized group each member functions more or less independently of the others. It is highly flexible, the members being free to develop their roles as they please.

4. IN GROUPS AND OUT GROUPS:

The groups to which an individual's belongs and toward which he feels a loyalty are in-groups. The ones toward which he feels neither loyalty nor sympathy and for which he may feel dislike, suspicion, opposition, fear, or even hatred are out-groups. A nation, race, religious sect, or neighbourhood group that is seen as inferior to one's and viewed with prejudice or hostility. SES, home and regional influences play an important part in the origin and propagation of such

prejudice.

GROUP GUIDANCE:

Guidance, whether on an individual or group basis, includes all those services that contribute to the individual understanding of himself—his attitudes, interests, abilities, his physical, mental and social maturity, and his personal and social needs for optimum development, achievement and life adjustment. It includes services that help each individual not only to gain self-understanding but also to develop skill in self-direction—

- a. in establishing suitable personal, educational and vocational goals,
- b. in planning desirable ways of pursuing these goals, and
- c. in developing standards of value consistent with his life-goals, so that he may be provided with criteria for the choice of experiences.

Group Guidance refers to any phase of guidance personal programme carried on with groups of individual rather than between counselor and counsellee or clinician and client in the face-to-face interview. It may include instruction in the classroom where the content is related to problems of self-appraisal, educational or vocational guidance, personal adjustment and interpersonal relationships. It includes many types of informal play or discussion groups, which often derive the double purpose of studying individuals in their interaction with others as well as helping them to work through certain difficulties and achieve new levels of adjustment.

GROUP GUIDANCE PROGRAMMES:

Group Guidance Programmes have been aimed at assistance in adjusting new school or college situations; improving study and learning methods; making new friends; improving social skills; learning to get along better with others; solving problems of interest and abilities and to make suitable educational and vocational plans meeting frustration wholesomely; and developing a workable philosophy of life-values to furnish criteria for the choice of life experiences.

THE PURPOSE OF GROUP GUIDANCE:

1. **To provide opportunities for learning essentials for self-direction with respect educational, vocational, and personal-social aspects of life through:**
 - a. Assistance in orientation in new school situations and in the best use of school opportunities.
 - b. Group study of problems of interpersonal relationships and assistance in choice of group experience in the school life that may modify both individual and group behaviour in socially acceptable ways.
 - c. Group study of problems of growing up, establishing adult adjustment and applying mental hygiene in living
 - d. Group study and application of sound methods of self-appraisal of attitudes, interests, abilities, personality and character trends and traits and personal-social adjustment.
 - e. Group study and application of efficiency methods in learning.
 - f. Group study about occasional life and problems of occasional adjustment and progress.
 - g. Assistance through groups in learning how to project suitable, long-range vocational plans.
 - h. Assistance through groups in learning how to project suitable, long-range educational plans.
 - i. Assistance in the development of discerning standards of value for making choices of experiences in various areas of living and the developing of growing philosophy of life.

2. TO PROVIDE OPPORTUNITY FOR THE THERAPEUTIC EFFECTS OF GROUP PROCEDURES THROUGH:

- a. The perspectives gained from the study of common human problem.
- b. The release of emotional tensions, increased insight into personality dynamics, and creative redirection of energy through group study of these common human problems in a permissive atmosphere.

3. To achieve some of the objectives of guidance more economically and some of more effectively than would be possible in a completely individualized approach.

To implement individual counselling to render it more effective through background study of common aspects of problems and the reduction or elimination of many emotional barriers to the discussion of unique aspects of common human problems

Guidance is a learning process for both the guidance worker and the individual, and this learning for both parties occurs through both counselling and group procedures.

LEADERSHIP IN A GROUP:

Effective leadership depends not so much upon specific qualities of personality as upon the working relationship of an individual within a group structure in which he acquires status through active participation and through demonstrating his capacity for helping the group to carry out cooperative tasks. Significant personal aspects of this capacity are intelligence, alertness to needs and motives of others, and insight into situations, further reinforced by such qualities as responsibility, initiative, persistence, and self-confidence.

The newer definition of leadership carries the implication that it may not be so much an attribute of individual as an aspect of organization, like authority, leadership appears to be determined by a system of inter-relationships and involves varying degrees of influence and responsibility. So, except in a completely authoritarian group, there would be varying degrees of influence and responsibility among members and therefore, varying degrees and kinds of leadership within the group.

One of the responsibilities of a guide is to work for the utilization by the group of its leadership potentials and to help all individuals to belong really to the group and to grow through contributing their best services to the group each member of a group can be helped to play both roles that is, of a leader and a follower, effectively.

Of course, some individuals will exert more influence on a group than others. Any member of a group exerts leadership to the extent that the stability of the group is modified by his presence. According to his viewpoint all member actions which help the group achieve its objectives are leadership functions in varying degrees, and it would be inconsistent to speak of the leader of a group. Sympathetic person and able to help members in a practical way who is intelligent relative to other group members; and who is consistent in performing his leadership functions.

Possession of particular traits is not enough to make a person a leader. He must be in a situation that permits him to make a contribution needed and perceived by the group as needed, and he must be perceived as being able to make such a contribution.

GROUP DYNAMICS:

In the field of group dynamics the term 'syntality' is used to describe for the group what is called personality for the individual. Syntality refers to all the interrelated attributes or independent variables by which a group may be defined. The terms used to describe this syntality of group are 'general ability', 'attitudes', 'performance' and 'morale'. Under morale we find such terms as 'synergy' referring to the sum total of the energy any group can command; 'doggedness' in meeting different situations and 'morality' and 'honesty'.

Synergy has two aspects- 'maintenance synergy' or the energy needed to keep the group intact; and 'effective synergy' or the energy available to move toward the achievement within the group goals. 'Group structure' refers to all the behaviour relationships within the group such as status gradients depending upon the varying roles of individual members * clique relationship.

According to Raymond Cattell "a group is a collection of organisms in which the existence of all (in their given relationship) is necessary to the satisfaction of certain individual needs in each". The term dynamics' as applied to groups refers to all the interacting forces within groups as they are organizing and operating to achieve their objectives which involve the whole field of sociometry and the nature of leadership.

The problem of first importance for the guidance leader is to study the group with a view to understanding its syntality and structure. This will involve studying the manners of the group both individually and collectively. Long range personal records of individual members of the group can be sought to answer many questions and also careful observation and study of the individual in action within the group and, of the total group in action.

To secure such information the teacher or guide must plan time for the study of personnel records and for the individual interviews. To study the individual and the groups in action, the leader must plan and initiate suitable activities at the start or be alert for suitable group initiative. These initial activities serve the double purpose of studying the individuals collectively and of helping to bring a real group with common interests and goals and an effective structure of inter-relationship into existence.

In many school programmes, the curriculum may provide for part areas of study in the guidance field at designated grade levels or in specific subject for example, educational or vocational planning, self-appraisal, understanding human behaviour, improving learning skills, getting along with others, or school citizenship.

Motion picture presentation of case studies, story-telling, individual or committee study, and reports on specific problems, dramatizations, lectures, informal discussion, and buzz sessions are among the multitude of possibilities at the command of a group leader. Such orienting activities, skillfully planned and executed, will create opportunities for the interaction of individuals in a way that will enable them to become acquainted with each other and will stimulate the development of a group structure of inter-relationship that can pave the way for real group organization and leadership.

Beyond these initial stages the guide should strive to be an integral part of a cohesive group with common interests in which each member senses that he has a respected place and a unique role to play in helping the group to reach its own group determined goals.

The behaviour of students in a class or in groups is the area of social psychology. This field of psychology deals the behaviour of an individual in groups. The concept of personality exists in the context of a group of social norms. The interpretation of behaviour of an individual is based on the norms. The norms are the average performance of the group. The standardization of psychological and educational tests is done by developing the norms of the concerned group.

THE SOCIAL PSYCHOLOGY MAY BE DEFINED AS:

1. "The social psychology is a scientific field that seeks to investigate the manner in which the behaviour, feelings or thoughts of an individual are influenced or determined by comparing with the group behaviours or the characteristics." -Baron and Byrne
2. "Educational psychology confines to the reactions of the learners or the student's classroom behaviours as a result of interaction with the teacher and among the students".

The social psychology is concerned with both type of group behaviours-positive or desirable behaviour and negative or undesirable behaviour of the individual. Educational psychology is concerned with the interaction of teacher and students mainly positive or desirable behaviour not the undesirable behaviour. The undesirable behaviour of the students are discouraged and desirable behaviours are reinforced or encouraged. The purpose is development of individual personality.

The standard or norms are development for the desirable behaviour of the group. A teacher has to deal usually a class or group of students. Therefore, it is very essential for a teacher to understand the group psychology rather than individual psychology. In planning and organizing his teaching he has to consider the norm of the group with regard to his level of teaching. The level of teaching is determined with help of class performance or level of students rather than individual level. The teacher must understand the dynamic of social behaviours of students to deal effectively.

Look no further than the headlines of any major newspaper to encounter the present difficulties, conflicts, and threats of human society. Modern humans are said to have socially evolved from more primitive life forms, yet we persist in the brutality of war, regularly experience or exhibit acts of intolerance, and sometimes whether unknowingly or as active participants, engage in many types of bias including gender and race discrimination. Despite this rather gloomy outlook, many continuously seek to achieve purpose through their personal lives and also through interactions with others. How might one achieve a sense of either when perceived threats, social dominance, and social identity are so intrinsically woven into our behavioral patterns? How do societal transgressions like racism or sexism persist in schools, neighborhoods, and workplaces? Behind these questions lies the fabric of social structures that manipulate motivational behavior in sometimes negative ways.

These social structures, when understood in the context of individual behavior in groups, may explain how one might be influenced by other to exhibit bias. The study of Intergroup Theories, which consist of Integrated Threat Theory, Social Identity Theory and Social Dominance Theory, serve to delineate these structures. By better understanding the research associated with these theories, their respective strengths and weaknesses, and their applications in the workplace, we can realize new methods of reducing both intra- and inter-organizational conflict and discrimination. If an individual takes the time to grasp these theories in concepts and gain a subsequent understanding

of the formation of these workplace groups it will help them do a better job and become a bigger asset to their employers, communities and families.

PERSONAL THREAT

Personal threat is when an individual believes his or her own resources or identity are under attack or risk and feel the need to protect. A personal threat can be triggered by something as simple as being categorized into a group (Ellemers et al., 2002; Hewstone, Rubin, & Willis, 2002). This type of threat is sometimes called "self-directed threat." For example, a person who received a negative review at work may quit as a way of protecting their personal identity from being attacked. Another example is when someone in a relationship does something wrong and decides to end the relationship in order to "save face" and protect their personal identity.

INTERGROUP THREAT

Intergroup threat is similar to personal threat, only the whole group is impacted rather than the individual. "As a general definition, intergroup threat occurs when one group's actions, beliefs, or characteristics challenge the goal attainment or well-being of another group" (Riek, Mania, & Gaertner, 2006). Intergroup threat has traditionally been depicted as competition for resources or status, but also occurs under conditions of social comparison (Brown, 1978; Shipley, 2008). The general idea is that members of one group perceive that another group will use up resources, and they will no longer be able to access those resources for themselves. These resources may be tangible, like money or material things or intangible like power or knowledge (Reik, Mania, & Gaertner, 2006). When resources are scarce, the group that feels threatened by the lack of resources finds itself motivated to compete for the resources in order to maintain its identity or to achieve its goals (Riek, Mania, & Gaertner, 2006). This competition promotes negative attitudes towards those in the group utilizing the resources (Aberson & Gaffney, 2008).

How does one determine which threat is applicable? Below are some characteristics that differentiate personal threats and intergroup threats.

NO THREAT

The absence of threat shows that an individual does not see any aspect of a situation as negative and does not react or act (Redmond, 2012). Without threat, individuals are not motivated to protect their resources. Instead they are motivated to engage in cooperative behaviors like gaining judgments that are more accurate of their group and contributing more efficient decision-making abilities (Redmond, 2012). These behaviors can be described as self-affirmation and group affirmation (Derks, Van Laar, & Ellemers, 2009). Self-affirmation is when the individual focuses on themselves rather than the group. Group affirmation is when the focus is on the group as a whole. Individuals from western cultures are more likely to engage in self-affirmation because in general, western cultures are more individualistic. Western cultures are more likely to focus on their personal identities rather than social identities (Redmond, 2012)

INTEGRATED THREAT THEORY COMPONENTS

There are several types of threats, which cause conflict between groups, including realistic threats, symbolic threats, intergroup anxiety and negative stereotyping. According to the Stephens, the Realistic and Symbolic threats both deal with threats to the interests of the group and "the degree [to which] you think your group's interests are being threatened, you will be prejudiced toward the other group" (Kendall, 1998). This differs from Intergroup Anxiety and Negative Stereotypes, which

enhance perceived threats by cultivating negative expectations and opinions of other groups (Redmond, 2012).

REALISTIC THREATS

These types of threats result from the perceptions held by the in-group, that the out-group "poses a risk to their safety, economy, politics, health or well-being" (Kendall, 1998). For example, when two groups within an organization are competing for the rights to complete a project for the president of the organization, and one group has more material resources than the other, the group with fewer resources will feel threatened because it feels there are barriers (the material resources), which will inhibit their ability to compete for the project.

Three studies were conducted to measure the antecedents of women's attitudes toward men using the integrated threat model. Four types of threats were hypothesized to produce negative attitudes toward men:

(1) realistic threat based on threats to women's political and economic power, (2) symbolic threat based on value differences, (3) intergroup anxiety experienced during social interaction with out-group members, and (4) negative stereotypes of men. Negative contact was hypothesized to increase the perception of all four threats as well as to affect attitudes directly. The findings suggest that symbolic threat, intergroup anxiety, and negative contact are the strongest predictors of negative attitudes toward men. Contrary to expectation, realistic threat may not be important to women's attitudes toward men.

The following graphic depicts the types of realistic threats as detailed by Kendall (1998).

SYMBOLIC THREATS

Symbolic threats refer to the beliefs and values of the group, which may be at risk. They primarily involve "perceived group differences in morals, values, standards, beliefs, and attitudes." (Oskamp, 2000, p.42) These threats affect the in-group paradigm, in that they affect the manner in which the group understands and interprets the world. The symbolic "threats arise, in part, because the in-group believes in the moral rightness of its system of values" (Oskamp, 2000, p.41). For example, if an in-group values a more protected approach to business, it might employ labor and materials purchased from its country of origin. As a result, a symbolic threat would involve competing firms that adopt a more global approach to business, especially if the costs of going global are substantially lower. This type of threat is found in many aspects of our lives; however, politics is the one that can be used to illustrate this threat the best. The different parties represent the different groups, and typically the major platforms the politicians run on are based on the morals, values and beliefs of that particular group.

THE CONSEQUENCES OF THREATS

Intergroup threats contribute to conflict because they influence behaviors, perceptions, and emotions. An appraisal of threat can evoke strong negative emotions, including that of fear, rage, anger, resentment, frustration, contempt and insecurity. In addition, perceptions of threat reduce emotional empathy for members of an out-group. The cognitive demands of dealing with threats causes a person to be in a sense preoccupied, in turn leading to poor decision-making. Intergroup threats can also influence the in-group's perception of themselves in comparison to the out-group. This perception can lead to believing that the once "powerful" in-group has now become vulnerable.

Negative intergroup perceptions and emotional biases contribute to the response in behavior towards a threat. The level of the behavioral response depends solely on the power of the threatened group. Higher power groups are not used to being threatened as their power generally isolates them from threat. Negative behavioral effects associated with these threats can impede peace and prolong reconciliation. When working in a group and threats and conflicts arise, communication comes to a screeching halt, and the group begins to lose focus of the goals that were initially set which can be detrimental. Communication is the key to all groups succeeding.

INTERGROUP ANXIETY

Intergroup anxiety refers to the "uneasiness and awkwardness in the presence of out-group members because of uncertainty about how to behave towards them" (Riek, Mania, & Gaertner, 2006, p. 341). This component of Integrated Threat Theory can be considered the strongest threat, as it deals with high emotions between groups. "People feel personally threatened in intergroup interactions because they are concerned about negative outcomes for the self, such as being embarrassed, rejected, or ridiculed" (Oskamp, 2000, p.40). The more anxiety the in-group feels towards the out-group, the more the in-group will anticipate a negative reaction from the out-group. The emotional anxiety can even occur in circumstances when the in-group incorrectly predicts the out-groups response to in-group values. The increased expectation of a negative reaction leads to a higher degree of prejudice and bias between members of the conflicting groups (Riek Mania, & Gaertner, 2006). Incidents that reinforce the negative feelings between groups can prolong and exacerbate the anxiety felt by both groups.

NEGATIVE STEREOTYPING

In the last component of Integrated Threat Theory, the in-group develops negative stereotypes about the out-group. Negative Stereotyping occurs when an individual's "beliefs about the characteristics of groups and the traits of group members" create "expectancies about the type of interactions that can be anticipated with out-group members" (Fiske, Gilbert, & Lindzey 2010). These stereotypes, like any other stereotypes, are based upon attributes the in-group believes the out-group to have (Kendall, 1998). These negative stereotypes towards the out-group are further enhanced as the degree of negative attitudes the in-group has towards the out-group increases (Reik, Mania, & Gaertner, 2006). Two reviews (Nguyen & Ryan, 2008; Walton & Cohen, 2003) concluded that people in the absence of threat make less stereotypical decisions and react in less biased ways in line with Ellemers et al.'s (2002) accuracy prediction.

The theory of accuracy in the absence of threat is supported by the theory of stereotype lift/boost. Stereotype lift/boost occurs when individuals perform better when they are reminded of a positive stereotype about themselves and their group membership (Walton & Cohen, 2003; Wraga, Duncan, Jacobs, Helt, & Church, 2006). When the performance threat is removed because the person is reminded of their stereotypical abilities, they perform at a higher level than when the stereotype is absent. An example of this is described as an Asian student performing well on a math exam compared to others when reminded of their ethnicity before taking the exam (Redmond, 2010)

RESEARCH SUPPORT ON INTEGRATED THREAT THEORY

Integrated threat theory is fairly new, and therefore does not have the extensive research that other motivational theories have. However, the field of research is growing, and of particular interest is its relevance to present societal issues. The research is valuable as it helps us understand the cognitive processes behind people's attitudes, beliefs, and behaviors. Some of the research topics the theory

can be applied to include:

- Religious intolerance
- Public attitudes toward immigration
- Racial profiling and stereotyping
- Public attitudes toward same gender relationships
- Support for feminist movements
- Diversity and a “national identity”
- Different motives in the workplace

Integrated Threat research has also shown its relevance with issues important to students. For example, one study looked at the cultural adjustment process required of students studying abroad (Fritz, M. V. et al 2008). This study examined the acculturation process of students living abroad and the effects of learning a new language, being separated from family and friends, and managing financial problems. The researchers looked at how Integrated Threat Theory addresses the issue of intergroup anxiety, where a student living abroad may experience feelings of being part of the “out” group.

Based on the study’s findings, the researchers were able to recommend specific program elements that would help foreign students adjust better to a new culture. More importantly, the study found that cultural sensitivity is the most important part of a successful program. A program designed to help Europeans adjust to studying in the U.S. would not be as helpful for a program designed for Asian students for example. Therefore, instead of grouping all foreign students together in a program to help them adjust, programs should be designed for specific cultural groups to help them adjust to their new environment.

One way to improve relations within a group experiencing conflict is to apply the Intergroup Contact Hypothesis, which was first proposed by Gordon Allport in 1954. His hypothesis suggests that under certain circumstances, having contact with members of different groups can reduce prejudice and intergroup conflict. However, the contact situation must include four major conditions in order to see positive effects. These conditions include equal status, intergroup cooperation, common goals, and support by social and institutional authorities. Research conducted in 1961, 1984, 1978, and 2007 has found positive contact has reduced prejudice against blacks, gays, the elderly, and the disabled. (The Inquisitive Mind, 2013)

Strengths and Weaknesses of Integrated Threat Theor

Condition	Meaning	Example	Evidence
Equal Status	Members of the contact situation should not have an unequal, hierarchical relationship.	Members should not have an employer/employee, or instructor/student relationship.	Evidence has documented that equal status is important both <i>prior</i> to (Brewer & Kramer, 1985) and <i>during</i> (Cohen & Lotan, 1995) the contact situation.
Cooperation	Members should work together in a non-competitive environment.	Students working together in a group project.	Aronson's 'jigsaw technique' structures classrooms so that students strive cooperatively (Aronson & Patnoe, 1967), and this technique has led to positive results in a variety of countries
Common Goals	Members must rely on each other to achieve their shared desired goal.	Members of a sports team.	hu and Griffey (1985) have shown the importance of common goals in interracial athletic teams who need to work together to achieve their goal.
Support by Social and Institutional Authorities	There should not be social or institutional authorities that explicitly or implicitly sanction contact, and there should be authorities that support positive contact.	There should not be official laws enforcing segregation.	Landis' (1984) work on the importance of institutional support in reducing prejudice in the military.

The student abroad study mentioned above is one example of Integrated Threat Theory's application to individual, but most research findings have focused on intergroup relationships and have found analyzing group conflict to be the theory's main strength. The original theory was found to have some weaknesses over the course of many studies and meta-analysis. First, there were problems inconceptualizing the types of threat and second, the number of antecedents and consequences was too limited.

To address these weaknesses the theory was revised in 2002 (Stephan& Renfro, 2002). The new theory now makes a distinction between threats to the in-group as a whole, and threats to individual members of the in-group, known as personal threats. In addition to this distinction, the antecedents of the theory were expanded upon. In the original theory there were four antecedents of threat; which included strong identification with the in-group, negative personal contact with the out-group, a history of conflict between the groups, and substantial disparities in status between groups.

In the revised theory, the following antecedents were added to the list: relations between groups, which factor in the size of the out-group relative to the in-group within the society, difference variable, including social dominance orientation and self esteem for factoring, cultural dimensions as this is a new domain of variables that can influence perceived threats and includes concepts like, individualism /collectivism, power distance, and uncertainty avoidance, and situational factors, which are variables that affect perceptions of threat like the setting, whether or not and how much the group interaction is structured or planned, and the nature of the interaction (cooperative vs. competitive)

The revised theory provides a much more comprehensive range of applications, but also requires more research to test and validate its concepts.

APPLICATION OF INTEGRATED THREAT THEORY IN THE WORKPLACE

Within an organization at any given time, many groups exist and may be in conflict with each other. An example of groups in conflict can include managers' priorities differing from employees' priorities. There will always be threats in workplaces because people will always have differing motives, needs, and ideas.

Organizational knowledge of Integrated Threat Theory and its implications on group interaction can be essential in preventing or minimizing group conflict. When managers and employees have differing priorities, knowledge of the integrated threats and understanding why groups feel threatened, will allow organizational leaders to recognize the conflict and then work with the two groups to set common goals and priorities to eliminate the competing priorities.

SOCIAL IDENTITY THEORY OVERVIEW

Social Identity Theory focuses on the relationship between self-concept and group behavior (Hogg & Terry, 2001). This theory explains that different aspects of individuals' personalities motivate them at different times, and that motivation from identity will be decided by the certain situation that the individual is in by relying on personal or social identity (PSU World Campus, L.8, 2012, p.5). Henri Tajfel proposed the Social Identity Theory as a result of work he had conducted in the 1970's concerning "categorization and social perception, intergroup behavior, and the pursuit of social psychological understanding of the causes of prejudice and intergroup conflict" (Abrams & Hogg, 1999). Tajfel et al (1971) attempted to identify the minimal conditions that would lead members of one group to discriminate in favor of the in-group to which they belonged and against another out-group.

Tajfel believed individuals were inconsistent when it came to how they behaved when they related to others in an intergroup setting, opposed to an interpersonal setting and sought to explain the behavior of people in-group situations (Abrams & Terry, 2001). Tajfel identified three components of social identity: self-conceptualization, group self-esteem, and commitment to the group, which when met, led a person to feel connected to their in-group. As a result, all other groups become out-groups and are rivals for status and resources as well as a source for comparison. This can lead to discrimination in favor of the in-group or against other out-groups, as well as stereotyping and prejudice when a perceived threat occurs (Redmond, 2009).

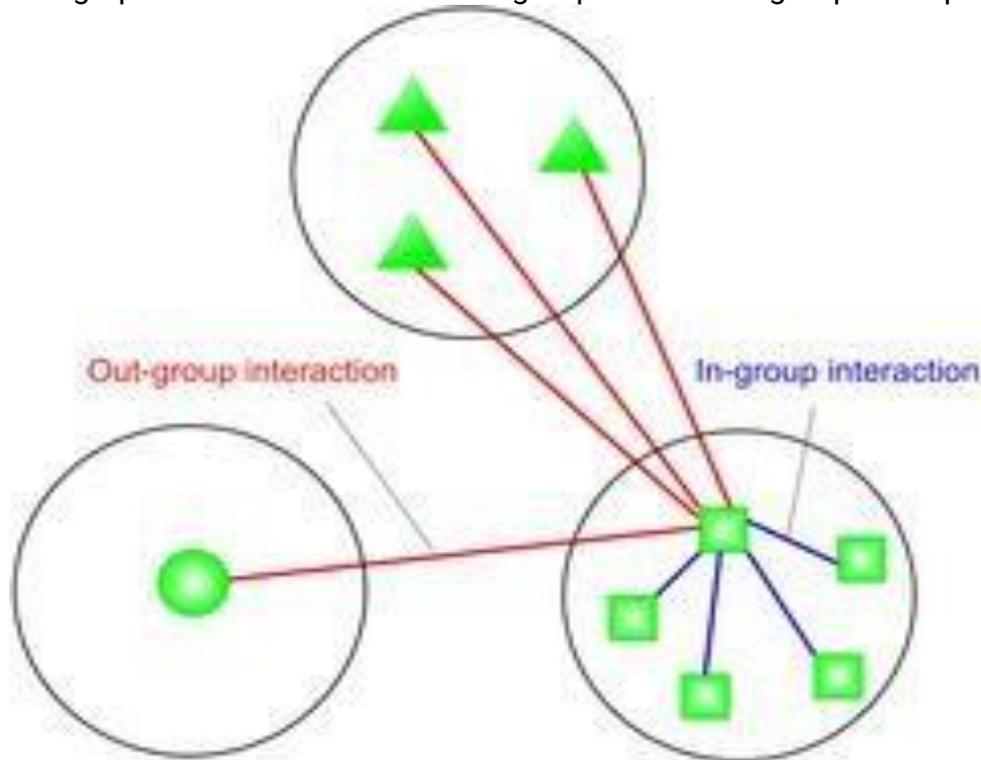

IN-GROUP FAVORITISM

An in-group can be described as the group of people with whom an individual categorizes

himself/herself. From a biological perspective, this behavior is inherent which means that people tend to help members from their own group rather than those from another. People can and will interact with out-groups, but use different strategies with both. Members of an in-group feel a sense of commitment to the group and gain greater esteem from their sense of belonging to the group (Redmond, 2012). In-group favoritism primarily exists to protect the group as individuals and as a group. By giving special treatment to group members, resources may be unavailable to other groups, and that group can maintain a higher status. Typically the larger the in-group, the more power they can impose on others. The overall idea is that members of the in-group stick together and give each other preferential treatment on professionally, financially, or socially

In-group favoritism can be explained through the average sports fan. Posten says "sports can work to increase self-esteem for a person by association and affiliation" (Posten, 1998, p.1). As a sports fan, you are extremely happy and proud after your team wins, as if you played the game yourself. Social Identity Theory also tells us that when our team loses, we will view that defeat positively so as to not defuse our self-esteem, since we have already identified with "our team" (Posten, 1998).

The graphic below illustrates the in-group and the out-group concept:

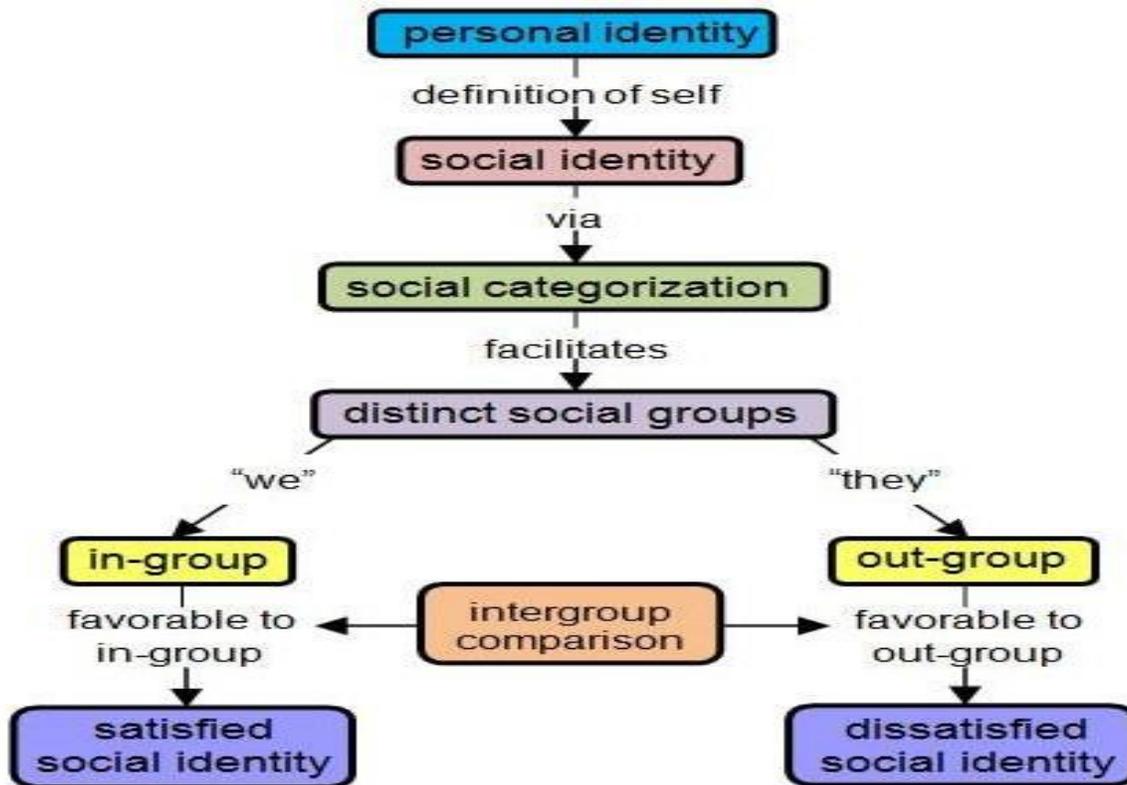

OUT-GROUP DEROGATION

An out-group can be described as any group outside of an individual's in-group and a group that can be a potential rival/competitor for resources (Redmond, 2012). Individuals in the out-group may be motivated to try and enter the in-group to gain access to limited or previously unavailable resources. Although once groups are formed, it can be hard to move to a new group and the person trying may face resentment from both groups. Members that are in the in-group can attempt to make members of the out-group look bad as to enhance their image and status.

Examples of In-Groups/Out-Groups Northern Ireland: Catholics/Protestants Rwanda: Hutus/ Tutsis Yugoslavia: Bosnians/ Serbs Germany: Jews/ Nazis Gender: Male/ Female Social Class: Upper /

Lower Class Social Identity Theory explains that every group has some type of social status that goes with its membership. This social status gives it value for the individuals that are members. Individual group members use the status from their membership in the group to gain and maintain self-esteem. The motivations to enhance self-esteem and gain status cause individuals to behave in ways that maintain the group and their memberships in the group. The better one's own group looks in comparison to other groups, the more status the group gains, and the more self-esteem it can provide for its members

SOCIAL IDENTITY THEORY COMPONENTS

According to Social Identity Theory, "social identity and intergroup behavior is guided by the pursuit of evaluative positive social identity through positive intergroup distinctiveness, which in turn is motivated by the need for positive self-esteem" (Hogg & Terry, 2001). In other words, their positive association with their in-group will affect a person's behavior when that association elevates their self-esteem and/or status. Furthermore, according to Michael Hogg (2006), social identity is motivated by self-enhancement and uncertainty reduction, which causes groups to "strive to be both better than and distinct from other groups" (pg. 120). Central to this theory are three components identified by Tajfel: self-categorization, group self-esteem, and group commitment.

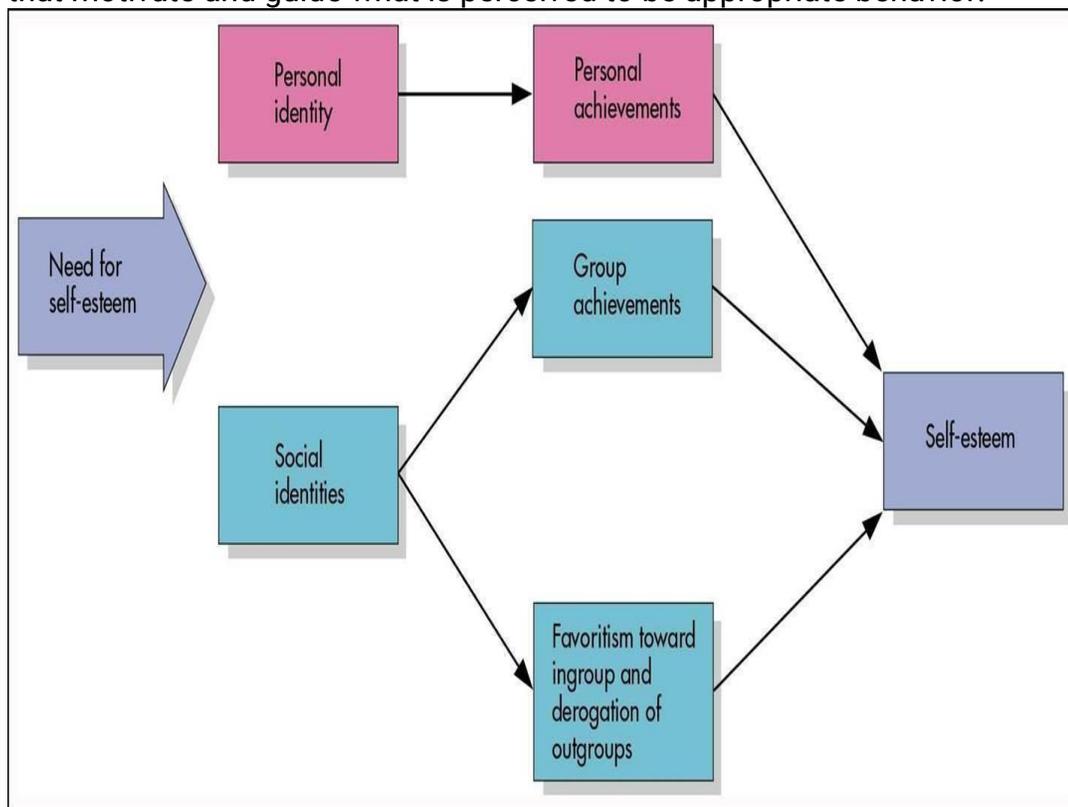

PERSONAL IDENTITY

Mayer, Greenbaum, Kuenzi, and Shteynberg (2009) state "personal identity consists of moral sensibility and conscience, and also a desire for achievement, mastery, and competence." Personal identity is the "combination of objective biosocial markers such as age, race, sex, and so on, and the personal life history of the individual" (Brewer & Gardner, 1996; Weigert et al., 1986). Personal identity is the aspects of one's self that make them unique and help define that individual (Brewer & Gardner, 1996). Individuals tend to be inconsistent when it comes to behavior in a social setting versus an individual setting. Social identity contrasts with personal identity because individuals will act

differently in social settings based on their perceived status within the group.

SELF-CATEGORIZATION

Social Identity Theory demonstrates that "the self is reflexive in that it can take itself as an object, and can categorize, classify, or name itself in particular ways in relation to other social categories or classifications" (Stets & Burke, 2000). This Identification process is known as self categorization and refers to a person's belief that they belong to a group. A person must categorize or identify him or herself as a member of a group in order to have their self-esteem elevated through association with the group. According to this theory, categorization "sharpens intergroup boundaries by producing group- distinctive stereotypical and normative perceptions and actions and assigns people, including self, to the contextually relevant category" (Hogg & Terry, 2001). In addition, self-categorization can reduce "uncertainty about themselves and others and about how they and others may or ought to behave in specific social contexts" (Hogg & Terry, 2001). In other words, we are able to find out specifics about ourselves and others as well as the appropriate behaviors associated with the group(s) in which we belong. "The core of an identity is the categorization of the self as the occupant of a role" (Stets & Burke, 2000). By assigning roles to individuals that are self-categorized as being part of a group, individuals can derive meanings and expectations associated with their roles, and as a result, are able to create value- based standards that motivate and guide what is perceived to be appropriate behavior.

Group Self-Esteem

Group self-esteem refers to the positive self-esteem or self-identity gained through membership in a group. "The relationship between intergroup differentiation and self-esteem should be assessed by using a measure of esteem at the level of the group or collective, rather than by using measures that address personal self-esteem" (De Cremer, Van Vugt, & Sharp, 1999). In order to categorize one's self as a member of a group, membership in the group must hold some value for the person such

as improvement in their status or positive personal identity through the association with the group. An example of this would be how memberships in sororities and fraternities constitute high social status among peers, and lifelong association with these groups produces additional personal identity benefits, including self-esteem.

The theory suggests that people have a need to "see themselves in a positive light in relation to relevant others" (Hogg & Terry, 2001) and that this can be achieved in a group context through "making comparisons between in-group and relevant out-groups in ways that favor the in-group" (Hogg & Terry, 2001). "The better one's group looks in comparison to other groups, the more status the group gains, and the more self-esteem it can provide for its members" (Morton, Postmes, Haslam, & Hornsey, 2009; Tajfel & Turner, 1979, 1986). "Self esteem and status are the main reasons that social identity is proposed to motivate individuals. But also remember that a person must also first describe him or herself as part of the group (self-categorization) and want to be part of the group (commitment)" (Redmond, 2010).

SOCIAL IDENTITY THEORY

Henri Tajfel's greatest contribution to psychology was social identity theory. Social identity is a person's sense of who they are based on their group membership(s) Tajfel (1979) proposed that the groups (e.g. social class, family, football team etc.) which people belonged to were an important source of pride and self-esteem. Groups give us a sense of social identity: a sense of belonging to the social world.

We divided the world into "them" and "us" based through a process of social categorization (i.e. we put people into social groups).

Henri Tajfel proposed that stereotyping (i.e. putting people into groups and categories) is based on a normal cognitive process: the tendency to group things together. In doing so we tend to exaggerate:

1. the differences between groups
2. the similarities of things in the same group.

This is known as in-group (us) and out-group (them). The central hypothesis of social identity theory is that group members of an in- group will seek to find negative aspects of an out-group, thus enhancing their self-image.

Prejudiced views between cultures may result in racism; in its extreme forms, racism may result in genocide, such as occurred in Germany with the Jews, in Rwanda between the Hutus and Tutsis and, more recently, in the former Yugoslavia between the Bosnians and Serbs.

Examples of In-groups and Out-groups

- Northern Ireland: Catholics – Protestants
- Rwanda: Hutus and Tutsis
- Yugoslavia: the Bosnians and Serbs
- Germany: Jews and the Nazis
- Politics: Labor and the Conservative
- Football: Liverpool and Man Utd
- Gender: Males and Females
- Social Class: Middle and Working Classes

SOCIAL IDENTITY THEORY STAGES

Tajfel and Turner (1979) proposed that there are three mental processes involved in evaluating others as “us” or “them” (i.e. “in-group” and “out-group”). These take place in a particular order.

CATEGORIZATION

The first is categorization. We categorize objects in order to understand them and identify them. In a very similar way we categorize people (including ourselves) in order to understand the social environment. We use social categories like black, white, Australian, Christian, Muslim, student, and bus driver because they are useful.

If we can assign people to a category then that tells us things about those people, and as we saw with the bus driver example, we couldn't function in a normal manner without using these categories; i.e. in the context of the bus.

Similarly, we find out things about ourselves by knowing what categories we belong to. We define appropriate behavior by reference to the norms of groups we belong to, but you can only do this if you can tell who belongs to your group. An individual can belong to many different groups.

Social Identification

In the second stage, social identification, we adopt the identity of the group we have categorized ourselves as belonging to. If for example you have categorized yourself as a student, the chances are you will adopt the identity of a student and begin to act in the ways you believe students act (and conform to the norms of the group).

There will be an emotional significance to your identification with a group, and your self-esteem will become bound up with group membership.

SOCIAL COMPARISON

The final stage is social comparison. Once we have categorized ourselves as part of a group and have identified with that group we then tend to compare that group with other groups. If our self-esteem is to be maintained our group needs to compare favorably with other groups.

This is critical to understanding prejudice, because once two groups identify themselves as rivals, they are forced to compete in order for the members to maintain their self-esteem.

Competition and hostility between groups is thus not only a matter of competing for resources (like in Sherif's Robbers Cave) like jobs but also the result of competing identities.

RELATIVE DEPRIVATION AND DEPRIVATION THEORY

Relative deprivation is formally defined as an actual or perceived lack of resources required to maintain the quality of life (e.g. diet, activities, material possessions) to which various socioeconomic groups or individuals within those groups have grown accustomed, or are considered to be the accepted norm within the group.

Key Takeaway

- Relative deprivation is the lack of resources (e.g. money, rights, social equality) necessary to maintain the quality of life considered typical within a given socioeconomic group.

- Relative deprivation often contributes to the rise of social change movements, such as the U.S. Civil Rights Movement.
- Absolute deprivation or absolute poverty is a potentially life-threatening situation that occurs when income falls below a level adequate to maintain food and shelter.

In simpler terms, relative deprivation is a feeling that you are generally “worse off” than the people you associate with and compare yourself to. For example, when you can only afford a compact economy car but your co-worker, while getting the same salary as you, drives a fancy luxury sedan, you may feel relatively deprived.

RELATIVE DEPRIVATION THEORY DEFINITION

As defined by social theorists and political scientists, relative deprivation theory suggests that people who feel they are being deprived of something considered essential in their society (e.g. money, rights, political voice, status) will organize or join social movements dedicated to obtaining the things of which they feel deprived. For example, relative deprivation has been cited as one of the causes of the U.S. Civil Rights Movement of the 1960s, which was rooted in Black Americans' struggle to gain social and legal equality with white Americans. Similarly, many gay people joined the same-sex marriage movement in order to acquire the same legal recognition of their marriages enjoyed by straight people.

In some cases, relative deprivation has been cited as a factor driving incidents of social disorder like rioting, looting, terrorism, and civil wars. In this nature, social movements and their associated disorderly act can often be attributed to the grievances of people who feel they are being denied resources to which they are entitled.

Relative Deprivation Theory History Development of the concept of relative deprivation is often attributed to American sociologist Robert K. Merton, whose study of American soldiers during World War II revealed that soldiers in the Military Police were far less satisfied with their opportunities for promotion than regular GIs.

In proposing one of the first formal definitions of relative deprivation, British statesman and sociologist Walter Runciman listed four required conditions:

- A person does not have something.
- That person knows other people who have the thing.
- That person wants to have the thing.
- That person believes they have a reasonable chance of getting the thing.

Runciman also drew a distinction between “egoistic” and “fraternalistic” relative deprivation. According to Runciman, egoistic relative deprivation is driven by an **individual's** feelings of being treated unfairly compared to others in their group. For example, an employee who feels they should have gotten a promotion that went to another employee may feel egoistically relatively deprived. Fraternalistic relative deprivation is more often associated with **massive group social movements** like the Civil Rights Movement.

Relative Versus Absolute Deprivation

Relative deprivation has a counterpart: absolute deprivation. Both of these are measures of poverty in a given country. Absolute deprivation describes a condition in which household income falls below a level needed to maintain the basic necessities of life, such as food and shelter.

Meanwhile, relative deprivation describes a level of poverty at which household income drops to a certain percentage below the country's median income. For example, a country's level of relative poverty could be set at 50 percent of its median income.

Absolute poverty can threaten one's very survival, while relative poverty may not but is likely to limit one's ability to participate fully in their society. In 2015, the World Bank Group set the worldwide absolute poverty level at \$1.90 per day per person based on purchasing power parities (PPP) rates.

CRITIQUES OF RELATIVE DEPRIVATION THEORY

Critics of relative deprivation theory have argued that it fails to explain why some people who, though deprived of rights or resources, fail to take part in social movements meant to attain those things. During the Civil Rights Movement, for example, Black people who refused to participate in the movement were derisively referred to as "Uncle Toms" by other Black people in reference to the excessively obedient enslaved person depicted in Harriet Beecher Stowe's 1852 novel "Uncle Tom's Cabin."

However, proponents of relative deprivation theory argue that many of these people simply want to avoid the conflicts and life difficulties they might encounter by joining the movement with no guarantee of a better life as a result.

Additionally, relative deprivation theory does not account for people who take part in movements that do not benefit them directly. Some examples include the animal rights movement, straight and cis gendered people who march alongside LGBTQ+ activists, and wealthy people who demonstrate against policies that perpetuate poverty or income inequality. In these cases, participants are believed to act more out of a sense of empathy or sympathy than feelings of relative deprivation.

REALISTIC CONFLICT THEORY

Definition and Examples of Realistic Conflict Theory

The **realistic conflict theory** states that whenever there are two or more groups that are seeking the same limited resources, this will lead to conflict, negative stereotypes and beliefs, and discrimination between the groups. The conflict can lead to increasing animosity toward the groups and can cause an ongoing feud to develop.

Conversely, conflict, negative stereotypes and beliefs, and discrimination between groups can potentially be reduced in situations where two or more groups are seeking to obtain some superordinate goals. **Superordinate goals** are mutually-desirable goals that cannot be obtained without the participation of two or more groups.

Because of its emphasis on group behaviors and conflict, the realistic conflict theory is also referred to as the **realistic group conflict theory**.

THE ROBBER'S CAVE EXPERIMENT

One of the earliest examples of realistic conflict theory is the Robber's Cave experiment conducted by social psychologist Muzafer Sherif in the 1950s. Sherif conducted a field experiment at Robber's Cave State Park in Oklahoma using 22 adolescent males. Each of the 22 participants was 12 years old, came from a 2-parent home, and was from a white middle-class background. None of the participants knew each other before the experiment. Sherif divided the males into two separate

groups: the Eagles and the Rattlers Neither of the groups was aware of the other's existence during the first stage of the experiment. During the first stage, the participants were involved in several activities with their group members such as hiking and swimming. These activities allowed participants to form attachments with their group and create their own group culture, norms, and expectations.

Once the participants had become attached to their own groups, Sherif introduced the groups to each other and arranged for competitive games and other conflicts between the groups. For example, one of the competitive games required the Eagles and the Rattlers to play each other in a baseball game. The winning group received a trophy and individual medals for the group members, while the losing group received nothing.

Sherif began to notice that the groups were calling each other names and teasing each other. However, as the competitive games continued, the groups became increasingly hostile. For example, the Eagles set the Rattlers' flag on fire and the Rattlers destroyed the Eagles' cabin. Eventually, the groups became so hostile with one another that they had to be physically separated.

Remember that the participants were 22 well-adjusted males. They were not criminals, nor did they have a history of aggressive or destructive behavior. However, once conflict and competition were introduced, their behaviors became discriminatory and hostile.

OTHER EXAMPLES OF REALISTIC CONFLICT THEORY

Suppose that the Eagles and Rattlers wanted to go on a hiking trip. The Eagles had all of the required hiking gear and the Rattlers had the required hiking maps and boots. The two groups would have to share their resources and cooperate with each other in order to make the hiking trip happen - a superordinate goal. Without cooperation, neither group would be able to go on the hiking trip. This cooperation might lead to positive communication between the two groups and could repair the relationship between the two.

ACTIVITY 1:

You read about the Robber's Cave experiment in the lesson. In this experiment, both groups consisted of 12-year-old Caucasian boys. The researcher was able to overcome inter-group conflict by presenting a superordinate goal. What do you think would happen if the groups were not equivalent to begin with? What if one group was boys and the other group was girls? What if one group was Hispanic teenagers and the other group was African American teenagers? Would the result have been the same as it was with two groups of Caucasian boys? Would a superordinate goal bring the groups together successfully as it did in the experiment? Write a two to three paragraph opinion paper discussing these issues.

ACTIVITY 2:

Think of a time that you have had to compete with a friend for a limited resource. For example, perhaps you competed for first place in a gymnastics or tennis competition. Did this competition affect your friendship? Did you disparage the other person in your head in terms of ability or personality? How were you able to get your friendship back on track after one person won the limited resource and the other person lost? Write a journal entry reflecting on your experience with limited resources against a friend.

ACTIVITY 3

The world is full of groups that are different in demonstrable ways. People have different skin colors, different religions, different languages, and different modes of dress. Prejudice and discrimination exist often due to a perceived competition for resources, or simply because sometimes people think that "different" means "wrong" or "worse." Do you think it is possible for a superordinate goal to bring all these disparate people together such that they feel unified in achieving a goal? To use an unrealistic and extreme example, what if aliens landed on earth, intending to harm humans? Would humans all come together to work to defeat the aliens, eliminating discrimination and prejudice, or is the superordinate goal not powerful enough to overcome deeply rooted differences between people? Write an essay describing the power or superordinate goals, or lack thereof, when it comes to making diverse people feel on the same "side."

BALANCE THEORY

Balance Theory Definition

Balance theory describes the structure of people's opinions about other individuals and objects as well as the perceived relation between them. The central notion of balance theory is that certain structures between individuals and objects are balanced, whereas other structures are imbalanced, and that balanced structures are generally preferred over imbalanced structures. Specifically, balance theory claims that unbalanced structures are associated with an uncomfortable feeling of negative affect, and that this negative feeling leads people to strive for balanced structures and to avoid imbalanced structures. An example for a balanced structure is when your best friend also likes your favorite rock band; an example for an imbalanced structure is when your best friend dislikes your favorite rock band. According to balance theory, the first case makes you feel good, whereas the second case creates an uncomfortable tension.

THEORETICAL ASSUMPTIONS

The original formulation of balance theory was designed to describe the pattern of relations between three individuals. Such relation patterns between three objects or individuals are often referred to as "triadic" relations. From a general perspective, a triadic relation between three individuals includes (a) the relation between a first person A and a second person O, (b) the relation between the second person O and a third person X, and (c) the relation between the first person A and the third person X (also described as A-O-X triad). In addition, it is assumed that the specific relations between two individuals can be positive (i.e., the two individuals like each other) or negative (i.e., the two individuals dislike each other). According to balance theory, a triad is balanced when it includes either no or an even number of negative relations. In contrast, a triad is imbalanced when it includes an odd number of negative relations. For example, the resulting triad of relations between Peter, John, and Paul would be balanced if (a) Peter likes John, John likes Paul, and Peter likes Paul; (b) Peter likes John, John dislikes Paul, and Peter dislikes Paul; (c) Peter dislikes John, John likes Paul, and Peter dislikes Paul; or (d) Peter dislikes John, John dislikes Paul, and Peter likes Paul. However, the resulting triad would be imbalanced if (a) Peter dislikes John, John likes Paul, and Peter likes Paul; (b) Peter likes John, John dislikes Paul, and Peter likes Paul; (c) Peter likes John, John likes Paul, and Peter dislikes Paul; or (d) Peter dislikes John, John dislikes Paul, and Peter dislikes Paul.

Even though balance theory was originally developed to explain patterns of interpersonal relations, it has also been applied to study attitudes and opinions about objects. For example, a triad including Sarah, Alice, and country music would be balanced if Sarah likes Alice, Alice likes country music, and Sarah also likes country music. However, the resulting triad would be imbalanced if Sarah

likes Alice, Alice likes country music, but Sarah dislikes country music.

Over and above these assumptions for personal sentiments, balance theory assumes that a positive relation can also result from the perception that two objects or individuals somehow belong together. Conversely, a negative relation can result from the perception that two objects or individuals do not belong together. Such kinds of relations are typically called "unit relations." Positive unit relations can result from any kind of closeness, similarity, or proximity, such as membership in the same soccer team, similar hair style, or same ethnic background. In contrast, negative unit relations can result from distance, dissimilarity, or distinctness, such as membership in different soccer teams, different hair style, or different ethnic background.

EVIDENCE

The distinction between balanced and imbalanced triads has been shown to have important implications for a variety of different domains. First, research has shown that the uncomfortable feeling associated with imbalanced patterns influences the formation of new attitudes. Specifically, it has been demonstrated that newly formed attitudes usually complete triadic relations in a manner such that the resulting triad is balanced rather than imbalanced. For example, if Sarah learns that a yet unknown individual is liked by her friend Alice, Sarah will form a positive attitude toward this individual. However, if Sarah learns that the same individual is disliked by her friend Alice, Sarah will form a negative attitude toward this individual.

Second, research has demonstrated a general superiority in memory for balanced as compared to imbalanced information. For instance, people show higher accuracy in recalling balanced patterns such as "Peter likes John, John dislikes Paul, and Peter dislikes Paul." However, people show lower accuracy in recalling imbalanced patterns such as "Peter likes John, John dislikes Paul, and Peter likes Paul." This difference in memory performance is even more pronounced when the triad includes the perceiver (e.g., "I like John, John dislikes Paul, and I dislike Paul").

Third, balance principles have been shown to have important implications for people's identity and the way people feel about themselves. Research in this area has shown that mental associations between the self and a particular group, evaluations of this group, and personal evaluations of oneself typically show patterns that can be described as balanced rather than imbalanced. For instance, if a Black person has a strong mental association between the self and the category Black, and in addition shows a positive evaluation of the category Black, this person will also exhibit a positive self-evaluation (i.e., "I'm Black, Black is good, therefore I'm good"). However, if a Black person has a strong mental association between the self and the category Black, but shows a negative evaluation of the category Black, this person will likely exhibit a negative self-evaluation (i.e., "I'm Black, Black is bad, therefore I'm bad"). According to balance theory, this transfer of evaluations is due to the inherent "unit" between the self and the category Black.

ADAMS' EQUITY THEORY

Adams' Equity Theory calls for a fair balance to be struck between an employee's inputs (hard work, skill level, acceptance, enthusiasm, and so on) and an employee's outputs (salary, benefits, intangibles such as recognition, and so on).

According to the theory, finding this fair balance serves to ensure a strong and productive relationship is achieved with the employee, with the overall result being contented, motivated

employees.

UNDERSTANDING THE THEORY

Adams' Equity Theory is named for John Stacey Adams, a workplace and behavioral psychologist, who developed his **job motivation theory** in 1963. Much like many of the more prevalent theories of motivation (such as **Maslow's Hierarchy of Needs** and **Herzberg's Two-Factor Theory**), Adams' Equity Theory acknowledges that subtle and variable factors affect an employee's assessment and perception of their relationship with their work and their employer.

The theory is built on the belief that employees become de-motivated, both in relation to their job and their employer, if they feel as though their inputs are greater than the outputs. Employees can be expected to respond to this in different ways, including de-motivation (generally to the extent the employee perceives the disparity between the inputs and the outputs exist), reduced effort, becoming disgruntled, or, in more extreme cases, perhaps even disruptive.

HOW TO APPLY THE ADAMS' EQUITY THEORY

It is important to also consider the Adams' Equity Theory factors when striving to improve an employee's job satisfaction, motivation level, etc., and what can be done to promote higher levels of each.

To do this, consider the balance or imbalance that currently exists between your employee's inputs and outputs, as follows:

Inputs typically include:

- Effort.
- Loyalty
- Hard work.
- Commitment.
- Skill.
- Ability.
- Adaptability.
- Flexibility.
- Acceptance of others.
- Determination.
- Enthusiasm.
- Trust in superiors.
- Support of colleagues.
- Personal sacrifice. Outputs typically include:
- Financial rewards (such as salary, benefits, perks).
- Intangibles that typically include:
 - Recognition.
 - Reputation.
 - Responsibility.
 - Sense of achievement.
 - Praise.
 - Stimulus.
- Sense of advancement/growth

- Job security.

-

While obviously many of these points can't be quantified and perfectly compared, the theory argues that managers should seek to find a fair balance between the inputs that an employee gives, and the outputs received.

And according to the theory, employees should be content where they perceive these to be in balance.

TIP:

This is similar to Frederick Herzberg's **Motivation/Hygiene Theory**. While Adams' Equity Theory obviously has a strong element of truth to it, it's probably fair to say that Herzberg's Motivation/Hygiene Theory has greater motivational significance.

KEY POINTS

Much like the five levels of needs determined by Maslow and the two factors of motivation as classified by Herzberg (intrinsic and extrinsic), the Adams' Equity Theory of motivation states that positive outcomes and high levels of motivation can be expected only when employees perceive their treatment to be fair. An employee's perception of this may include many factors (see outputs above). The idea behind Adams' Equity Theory is to strike a healthy balance here, with outputs on one side of the scale; inputs on the other – both weighing in a way that seems reasonably equal.

If the balance lies too far in favor of the employer, some employees may work to bring balance between inputs and outputs on their own, by asking for more compensation or recognition. Others will be demotivated, and still others will seek alternative employment.

SOCIAL EXCHANGE THEORY

Social exchange theory proposes that social behavior is the result of an exchange process. The purpose of this exchange is to maximize benefits and minimize costs. According to this theory, developed by sociologist George Homans, people weigh the potential benefits and risks of social relationships. When the risks outweigh the rewards, people will terminate or abandon that relationship.

Most relationships are made up of a certain amount of give-and-take, but this does not mean that they are always equal. Social exchange suggests that it is the valuing of the benefits and costs of each relationship that determine whether or not we choose to continue a social association.

COSTS VS. BENEFITS

Costs involve things that you see as negatives such as having to put money, time, and effort into a relationship. For example, if you have a friend that always has to borrow money from you, then this would be seen as a high cost.

The benefits are things that you get out of the relationship such as fun, friendship, companionship, and social support. Your friend might be a bit of a freeloader, but bring a lot of fun and excitement to your life. As you are determining the value of the friendship, you might decide that the benefits outweigh the potential costs.

Social exchange theory suggests that we essentially take the benefits and subtract the costs in order

to determine how much a relationship is worth. Positive relationships are those in which the benefits outweigh the costs while negative relationships occur when the costs are greater than the benefits. Expectations and Comparison Level

Cost-benefit analysis plays a major role in the social exchange process, but so do expectations. As people weigh benefits against the costs, they do so by establishing a comparison level that is often influenced by past experiences. If you have always had poor friendships, your comparison levels at the start of a relationship will be lower than a person who has always had supportive and caring friends.

For example, if your previous romantic partner showered you with displays of affection, your comparison level for your next relationship is going to be quite high when it comes to affection. If your next romantic partner tends to be more reserved and less emotional, that person might not measure up to your expectations.

EVALUATING THE ALTERNATIVES

Another aspect of the social exchange process involves looking at the possible alternatives. After analyzing the costs and benefits and contrasting these against your comparison levels, you might start to look at possible alternatives.

The relationship might not measure up to your comparison levels, but as you survey the potential alternatives, you might determine that the relationship is still better than anything else that is available. As a result, you might go back and reassess the relationship in terms of what may now be a somewhat lower comparison level.

THE HONEYMOON PHASE

The length of a friendship or romance can also play a role in the social exchange process. During the early weeks or months of a relationship, often referred to as the "honeymoon phase," people are more likely to ignore the social exchange balance. Things that would normally be viewed as high cost are dismissed, ignored, or minimized, while potential benefits are often exaggerated. When this honeymoon period finally comes to an end, there will often be a gradual evaluation of the exchange balance. Downsides will become more apparent and benefits will start to be seen more realistically. This recalibration of the exchange balance might also lead to the termination of the relationship if the balance is tipped too far toward the negative side.

APPLIED SOCIAL PSYCHOLOGY

Applied Social Psychology Definition

Applied social psychology can be defined as using social psychological theories, principles, research findings, and experimental methods to understand social issues and to offer real-world solutions for a variety of social problems. As a discipline, applied social psychology functions on the premise that social problems are, at their heart, caused by human behavior. To understand and change these problem behaviors, applied social psychologists conduct a scientific examination of individuals' thoughts, feelings, and behaviors as they pertain to a variety of social influences. Through their research, applied social psychologists hope to offer practical suggestions for improving human social behavior in areas ranging from workplace productivity to safer sexual activity.

APPLIED SOCIAL PSYCHOLOGY HISTORY AND BACKGROUND

While an earlier generation of psychologists had been predominantly interested in the structure and measurement of mental tasks in the laboratory, the 20th century saw a substantial increase in researchers advocating the application of theories outside the laboratory. In 1903, experimental psychologist Walter Dill Scott wrote *The Theory and Practice of Advertising*, suggesting that consumer habits could be influenced by emotional suggestions. In 1908, psychologist Hugo Munsterberg defined applied psychology as research adjusted to fit the problems encountered in everyday life. In works on industrial psychology, advertising, and education, Munsterberg, Scott, and others began exploring the possibilities of an applied psychology. In 1917, psychologist G. S. Hall founded the *Journal of Applied Psychology* to further explore the potential of this new field.

By the 1920s, there was an undeniable enthusiasm for applied research in the psychological community, despite its reputation as an “undignified” pursuit. In addition to the new challenges it presented, applied research was also attractive because private corporations often provided better salaries than did academic institutions. John B. Watson, former American Psychological Association president and one of the founders of modern behaviorism, began a successful career at the J. Walter Thompson advertising firm after being fired from Johns Hopkins University in 1920. Watson was able to put psychological principles into practice with such advertising industry standards as expert and celebrity testimonials and focus group research. He was promoted to vice president in only 4 years and was eventually honored for his achievements by the American Psychological Association. Even those psychologists who stayed in traditional laboratories found that it was easier to justify lab materials and costs if their research had the potential for application.

The work of Kurt Lewin (1890-1947) marks the beginning of modern applied social psychology. Lewin, best known for his field theory suggesting that behavior is a function of an individual's personality and his or her environment, proposed that social psychologists should engage in what he called action research. A social activist himself, Lewin believed that social issues should inspire social psychological research. This research could then be used to provide solutions for social problems. Lewin's action research sought to define a social problem, recommend countermeasures, and test the effectiveness of those countermeasures through community involvement, surveys, case studies, and controlled experiments. To this end, Lewin formed several organizations to engage in action research, including the Society for the Psychological Study of Social Issues, the Research Center for Group Dynamics, the Commission on Community Interrelations, and the National Training Laboratories. These groups studied interracial housing, ingroup loyalty, and leadership styles, establishing Lewin as one of the foremost proponents of combined applied and theoretical social psychology in the history of psychology.

As social psychology sought greater acceptance as a science in the 1950s and 1960s, action research in the field became less popular and was replaced by basic academic social psychology. It was not until the late 1960s and 1970s, while American society was undergoing radical transformations as a result of the civil rights movement, the Vietnam War, and the Watergate scandal, that social psychologists returned to the field in an attempt to understand and explain what was happening around them. Through the 1970s and 1980s, social psychologists debated if applied research could inform public policy. If so, many felt that the researchers themselves must present and explain their findings to policymakers or risk dangerous misinterpretation of their work.

Applied social psychology has been growing in prestige since the 1980s. With applications ranging from improving the criminal justice system to informing education and health issues, the last few decades have seen substantial increases in nontraditional funding sources. While applied social psychological research continues within academic institutions, private and government grants, as

well as full-time research positions within large corporations, have allowed researchers the flexibility and opportunity to study a diverse array of social phenomena

UNIQUE FEATURES OF APPLIED SOCIAL PSYCHOLOGY

While research in basic social psychology often begins with scientific curiosity, work in applied social psychology typically starts with the identification of a specific social problem, such as teen pregnancy or hate crimes. Applied social psychologists seek to understand and treat these social maladies through the application of the theories and methods of social psychology. While basic social psychologists attempt to isolate the causal relationships between a small number of specific variables that can be carefully controlled in the lab, applied social psychologists work to identify and predict large-scale effects that can be used to design and implement social programs. Real social issues rarely involve only one or two psychological variables. Therefore, it is often useful for applied social psychologists to consider broad combinations of psychological principles when attempting to understand a social issue. It is also common for applied social psychologists to adopt an interdisciplinary approach to their work, incorporating economic, sociological, and political perspectives.

Within the laboratory, social psychologists are generally able to conduct precise and carefully controlled experimental manipulations to test their hypotheses. Within communities and businesses, applied researchers often work in unpredictable and unrestricted environments, relying on less-precise research techniques such as surveys, self-reports, and rough “before and after” evaluations. Often at the mercy of corporate or government sponsors, applied social psychologists work under program deadlines, funding restrictions, and political pressures.

While laboratory effects need to reach statistical significance to support the hypothesis of the experimenter, implemented social programs need to show effects that are not only statistically significant but also large enough to have real-world consequences for the program’s sponsor. Applied social psychologists must also make quantitative estimates when designing an experimental social program to show that the program’s benefits will ultimately outweigh the initial costs.

WORKING IN APPLIED SOCIAL PSYCHOLOGY

To list all the areas to which social psychology is currently being applied would be almost impossible. Broadly, applied social psychologists are active in studying and improving educational programs, industrial and organizational productivity, environmental and health care issues, justice system reform, and all types of mass communication, including advertising, public relations, and politics. Some applied social psychologists conduct research for academic institutions, some for private foundations and corporations, and some for government organizations. Some evaluate the success or failure of a specific experimental social program while others work as internal consultants to government agencies and businesses, providing feedback on a variety of projects. Some applied social psychologists give policy advice to corporate or government managers from outside an organization while still others become managers themselves. Finally, some applied social psychologists become full-time advocates for social change, working with activist groups rather than from inside a government or corporate body.

CRITICISMS OF APPLIED SOCIAL PSYCHOLOGY

Criticisms of applied social psychology come from psychologists as well as from policymakers.

Laboratory psychologists question the methodology behind much of the applied social research. With no control groups, few experimental manipulations, and a heavy reliance on self-report and correlation, can applied social psychology really contribute to social psychological theories? After all, a successful social program will need to be tailored differently to every community in which it is implemented. Policymakers question whether the effects of experimental social programs are large enough (or cheap enough) to be widely implemented. Others argue that the large-scale behavior modification implied in some social psychological programs is unethical. Ultimately, there is a genuine tradeoff between conducting basic and applied social psychological research. In basic studies, researchers seek general principles that may not directly apply to more complicated real-world problems; in applied studies, researchers address specific problems, yet their conclusions may fail to generalize to other situations.

While both groups have valid critiques of an admittedly murky field, it is important to emphasize that applied social psychologists are actively engaged in the scientific study of social issues. While this problem-oriented approach does take some emphasis away from theory building, the plethora of field observations and unique program implementations essential to applied research will only serve to strengthen and refine current and future social psychological theories. Although the oversimplification of research findings could lead to the improper implementation of social programs, applied social psychologists seek to prevent such use by taking an active role in designing socially responsible policy.

A final issue to note is that the implied divide between applied and basic research ignores the contributions that basic social psychologists often make to areas of application. While applied social psychology refers to research with a problem-oriented focus, it is much more difficult to define who meets the definition of an applied social psychologist. Many psychologists primarily focused on basic laboratory research are also actively involved in the Society for the Psychological Study of Social Issues and other organizations committed to the application of social psychological principles.

TERRITORIALITY DEFINITION

Territoriality is a pattern of attitudes and behavior held by a person or group that is based on perceived, attempted, or actual control of a physical space, object, or idea, which may involve habitual occupation, defense, personalization, and marking of the territory. Marking means placing an object or substance in a space to indicate one's territorial intentions. Cafeteria diners leave coats or books on a chair or table. Prospectors stake claims. Personalization means marking in a manner that indicates one's identity. Many employees decorate their workspaces with pictures and mementoes. Some car owners purchase vanity license plates.

Territoriality usually is associated with the possession of some physical space, but it can also involve such processes as dominance, control, conflict, security, claim staking, vigilance, and identity. If a territory is important to a person, his or her sense of identity may be closely tied to it. Although it is sometimes associated with aggression, territoriality actually is much more responsible for the smooth operation of society because most people, most of the time, respect the territories of others.

TYPES OF TERRITORIES

Territoriality is extremely widespread. Once you recognize them, the signs of human territoriality are

everywhere: books spread out on a cafeteria table to save a place, nameplates, fences, locks, no-trespassing signs, even copyright notices. There are billions of territories in the world; some are large, others small, some are nested within others (such as a person's "own" chair within a home), and some are shared.

Primary territories are spaces owned by individuals or primary groups, controlled on a relatively permanent basis by them and central to their daily lives. Examples include your bedroom or a family's dwelling. The psychological importance of primary territories to their owners is always high. Secondary territories are less important to their occupiers than primary territories, but they do possess moderate significance to their occupants. A person's desk at work, favorite restaurant, locker in the gym, and home playing field are examples. Control of these territories is less essential to the occupant and is more likely to change, rotate, or be shared with strangers.

Public territories are areas open to anyone in good standing with the community. Beaches, sidewalks, and hotel lobbies are public territories. Occasionally, because of discrimination or unacceptable behavior, public territories are closed to some individuals. Retail stores, for example, are public territories open to anyone. However, someone who causes trouble may be banned from a particular store.

The physical self may be considered as a body territory. The boundary is at one's skin. Bodies may be entered with permission (as in surgery) or without permission (as in a knife attack). Some people mark and personalize their own bodies with makeup, jewelry, tattoos, piercings, and clothing, but they certainly defend and try to control access to their bodies by other people.

Two other types of territories exist, although they are not universally considered territories. Objects meet some of the criteria for territories—we mark, personalize, defend, and control our possessions. Ideas are also, in some ways, territories. We defend them through patents and copyrights. There are rules against plagiarism. Software authors and songwriters try to protect ownership of their programs and songs.

TERRITORIALITY INFRINGEMENTS

Even though territories usually work to keep society hassle-free, sometimes they are infringed upon. The most obvious form of infringement is invasion, in which an outsider physically enters someone else's territory, usually with the intention of taking it from its current owner. One obvious example is one country trying to take the territory of another.

The second form of infringement is violation, a temporary infringement of someone's territory. Usually, the goal is not ownership but annoyance or harm. Vandalism, hit-and-run attacks, and burglary fall into this category.

Sometimes a violation occurs out of ignorance, as when a boy who cannot yet read walks into a woman's wash-room. Other times the violation is deliberate, such as computer pranksters worming their way into others' machines. Violation may occur without the infringer personally entering the territory. Jamming radio waves and playing loud music are some examples.

The third form of infringement is contamination, in which the infringer fouls someone else's territory by putting something awful in the territory. Examples would be a chemical company leaving poisonous waste in the ground for later residents to deal with, a house-guest leaving the kitchen

filthy, or pesticide spray drifting into your yard.

Territoriality Defense

Just as there are three general ways to infringe on territories, there are three different types of defense. When someone uses a coat, sign, or fence to defend a territory, it is called a prevention defense. One anticipates infringement and acts to stop it before it occurs.

Reaction defenses, on the other hand, are responses to an infringement after it happens. Examples range from slamming a door in someone's face or physically striking the infringer to court actions for copyright violations.

The third type is the social boundary defense. Used at the edge of interactional territories, the social boundary defense consists of a ritual engaged in by hosts and visitors. For example, you need a password to enter many Web sites. Another example is the customs office at the national border. Social boundary defenses serve to separate wanted visitors from unwanted ones.

TERRITORIALITY IN EVERYDAY LIFE

One way territoriality has been used in everyday life involves defensible space theory, sometimes called crime prevention through environmental design. The theory proposes that certain design features, such as real or symbolic barriers to separate public territory from private territory and opportunities for territory owners to observe suspicious activity in their spaces, will increase residents' sense of security and make criminals feel uneasy. It has been used widely to reduce crime in residences, neighborhoods, and retail stores.

CROWDING DEFINITION

Environmental psychologists study how human behavior and the physical environment interrelate. Decision making and behavior make an impact on environmental quality—did you walk, bike, drive, or use public transit to get to school today? The physical environment also affects behavior. Crowding illustrates how the physical environment can affect human behavior.

Psychologists distinguish between crowding, a psychological construct wherein the amount of space available is less than desired, and purely physical indices of physical space such as density. Density is typically indexed as people per room or people per square foot. More external density measures like people per acre are less relevant for human well-being. The more immediate experience of the close presence of others, particularly in living and working spaces, matters most. The distinction between psychological and physical perspectives on crowding explains why a high-density social event (e.g., party) is fun, whereas a high-density living or work space can be negative. When you need more space and can't have it, you experience crowding.

The most common reaction to crowding is stress, particularly over time and in an important space like home. For example when it is crowded, people typically have negative feelings such as anxiety and frustration about restricted behavioral options. Our choices of what, where, and when we do things are constrained. If these restrictions are experienced repeatedly, crowding can also lead to feelings of helplessness wherein we start to question our own ability to effectively manage the environment. Studies in India and in the United States have found that children and adolescents who live in more crowded homes, independent of socioeconomic status, are less likely to persist on challenging puzzles, giving up sooner than those living under uncrowded conditions.

When people experience crowding, their social interactions change. Two results are common: They withdraw from others, creating more psychological space when physical space is limited, and they become more irritable and potentially aggressive. The natural tendency to cop with crowding by social withdrawal may become a characteristic way of interacting with others. For example, one study of college roommates found that when they initially moved in together, the number of people per room in their apartment was unrelated to how much social support they perceived from their housemates. But after 6 months of living together, more crowded undergraduates felt more withdrawn and less social support from their roommates. When these college students were brought into a laboratory to interact with a stranger, they exhibited this same more socially withdrawn style. Furthermore, when the stranger (who was really a confederate working with the experimenter) offered them some emotional support during a stressful experience, the higher the density of the apartment the student lived in, the less likely they were to accept the stranger's offer of support. Thus, even when in an uncrowded situation, students who had adapted to living under more crowded conditions were more withdrawn and less receptive to offers of social support. Parents in more crowded homes are also less responsive to their children.

One of the ways researchers mark whether a situation is stressful or not is to use physiological measures like blood pressure or stress hormones (e.g., cortisol, epinephrine). If crowding is a stressor, then it should affect these physiological measures. Both laboratory research, usually with college students, and community studies provide evidence that crowding can cause physiological stress. If you carefully observe yourself or others who are in a crowded situation, you can also see nonverbal indicators of stress. For example when it's crowded, people will fidget; adjust their clothes, hair, jewelry, and so on; and often avoid eye contact. Next time you are in a very crowded setting (e.g., elevator, train), see if you notice a link between how crowded the setting is and how much these behaviors occur

Will crowding make you seriously disturbed or damage your health? Will it ruin your grades and undermine your college experience because you are in a dorm room that isn't big enough? No, but it will probably lead to more distress and more social withdrawal, especially from your roommates. If you have an exam to study for or a difficult, challenging task, crowding could have some negative effects. Laboratory experiments show that crowding impairs complex, but not simple, task performance. If the task is demanding, requiring a lot of effort and attention to multiple components, it is likely to suffer under crowded conditions.

What about individual differences in sensitivity to crowding—does everyone respond the same way to a crowded situation? If you are studying and your friend is talking with his friends, crowding is likely to have drastically different effects on each of you. Men may react more physiologically to crowding, their blood pressure and stress hormones elevating more, whereas women (at least initially) try to get along with those around them when it's crowded. However, over time, if these attempts are unsuccessful, women may actually react more negatively because their attempts at affiliation prove futile. One study of tripled college dorm rooms designed for two people found more psychological distress in women than in men, but it took more time for this to occur in the females. The tripled-up men, but not the women, evidenced elevated stress hormones. How about culture or ethnicity? Some groups of people (e.g., Asian, Latin Americans) do indeed perceive high-density situations as less crowded than do others (e.g., White and Black North Americans). But their negative reactions to crowding are similar across cultures. The threshold to experience crowding may be

different, but once it happens, their reactions are parallel to one another.

One final topic worth brief mention is the potential role of architecture and design in crowding. Space is not simply area or volume. For example, in a study of elementary school children, the impacts of residential density were related to the type of housing. Children living in larger, multifamily residences, independently of social class, reacted more negatively to higher-density living spaces than did children living in single-family homes. There is also evidence that having some space in your home where you can at least temporarily be alone (refuge) can offset some of the negative impacts of crowding. Crowding is but one example of the many ways in which human behavior and the physical environment can influence one another.

Social Psychology MCQs

1. Who is best known for his research on conformity?

- a) Asch
- b) Rubin
- c) Schachter
- d) Zimbardo

Ans:- A

2. During the Stanford Prison study,

- a) guards did not take their roles seriously
- b) guards readily assumed their roles as agents of force
- c) the prisoners and the guards quickly became friendly towards one another
- d) three prisoners were so severely beaten they had to be hospitalized

Ans:- B

3. During research in a simulated prison situation

- a) three prisoners were so severely beaten they had to be hospitalized
- b) guards did not take their roles seriously
- c) prisoners quickly became passive and dehumanized
- d) the prisoners and the guards quickly became friendly towards one another

Ans:- C

4. The degree of attraction among group members relates to the dimension of

- a) Compatibility
- b) Structure
- c) Cohesiveness
- d) Conformity

Ans:- C

5. You are walking into a store when a man rudely cuts in front of you, almost shoving you, so that

he may enter the store first. "What a jerk!" you think to yourself. As you enter the store, you see the same man performing an emergency tracheotomy on a woman with a collapsed windpipe. You have just

- a) discounted a person's actions due to situational demands
- b) self-handicapped
- c) overemphasized the object in this action sequence
- d) made the fundamental attribution error

Ans:- D

6. According to evolutionary psychologists,

- a) women tend to be concerned with whether mates will devote time and resources to a relationship.
- b) men place less emphasis on physical attractiveness
- c) women place more emphasis on sexual fidelity
- d) men are biologically driven to have multiple partners

Ans:- A

7. Which statement about physical attractiveness is FALSE?

- a) Beauty is a factor mainly in initial acquaintances
- b) Looks are less related to dating frequency for men than for women
- c) For men, there is little relationship between attractiveness and the achievement of status
- d) For marriage partners there is a tendency for attractive men to be paired with highly educated women with high incomes

Ans:- D

8. Moderate self-disclosure typically leads to

- a) competence matching
- b) rejection
- c) romantic attraction
- d) reciprocity

Ans:- D

9. When subjects in Milgram's obedience experiments received their orders over the phone, they

- a) conformed more completely due to the formality of the telephoned instructions
- b) completely refused to participate
- c) were only slightly more obedient than they were in face-to-face conditions
- d) were far less obedient

Ans:- D

10. Solomon Asch's classic experiment (in which subjects judged a standard line and comparison lines) was arranged to test the limits of

- a) social perception
- b) indoctrination

- c) coercive power
- d) conformity

Ans:- D

11. The person who agrees to a small request initially is more likely later to comply with a larger demand. This describes the

- a) door-in-the-face-effect
- b) foot-in-the-door effect
- c) low-ball technique
- d) high-ball technique

Ans:- B

12. For most American adults, an invisible spatial envelope defining their most intimate space

- a) extends four feet from their body
- b) extends an "arm's reach" from their body
- c) is reserved for comfortable interactions with friends
- d) extends about 18 inches out from their body

Ans:- D

13. Which theory holds that a relationship must be profitable to endure?

- a) complementary need theory
- b) social exchange theory
- c) gain-loss theory
- d) social comparison theory

Ans:- B

14. You are asked by a close friend to outline a complete text to aid her studying for a final exam. You refuse to help. Later, your friend asks if you would at least outline two chapters. Feeling guilty, you now agree to help. Your behavior is predicted by the

- a) foot-in-the-face technique
- b) high-ball effect
- c) low-ball technique
- d) door-in-the-face effect

Ans:- D

15. Attachment style is marked by conflicting feelings of affection, anger, and emotional turmoil

- a) Mutual
- b) Secure
- c) Avoidant
- d) Ambivalent

Ans:- D

16. Zimbardo interpreted the results of his simulated prison study as an indication of the

- a) powerful influence of roles on people
- b) tendency to show compassion to people in need
- c) weakness of social pressure in some situations
- d) tendency to displace aggression

Ans:- A

17. Subjects in Milgram's experiment who gave large shocks rationalized that they were NOT personally responsible for their actions. This raises questions about our willingness to commit inhumane acts as a result of

- a) coercive power
- b) obedience to a legitimate authority
- c) expert power
- d) conformity to group pressure

Ans:- B

18. The process of changing your behavior to match that of others in a group is

- a) Norming
- b) forming a social contract
- c) conformity
- d) standardization

Ans:- C

19. If everyone leaves five minutes before the game is over to avoid a traffic jam, the resulting traffic jam would be an example of

- a) social impregnation
- b) a social trap
- c) groupthink
- d) self-handicapping

Ans:- B

20. People's invisible "spatial envelope" defines their _____, and extends "I" or "me" boundaries past the skin

- a) spatial role
- b) personal space
- c) ego location
- d) proximal location

Ans:- B

21. Physical proximity increases attraction because it

- a) increases frequency of contact
- b) enhances social comparisons
- c) establishes common norms
- d) reduces development of incompatible roles

Ans:- A

22. The study of unspoken rules for the use of interpersonal space is called

- a) Kinesics
- b) Psychoecology
- c) Proxemics
- d) Territoriality

Ans:- C

23. Someone asks you to bring dip to a party and you agree. Later the person asks you to also bring popcorn, chips, and sodas. The person has used which compliance strategy?

- a) the low-ball technique
- b) the over-commitment strategy
- c) the whole-part technique
- d) the passive obedience method

Ans:- A

24. The real danger of "groupthink" is that it

- a) is contagious
- b) occurs in cohesive groups
- c) disrupts coordinated efforts at group problem solving
- d) leads to a suspension of critical thinking

Ans:- D

25. The organization of roles, patterns of communication, and power in a group defines the group's

- a) Status
- b) Structure
- c) Cohesiveness
- d) Norms

Ans:- B

26. Those roles which one attains voluntarily are called

- a) ascribed roles
- b) achieved roles
- c) positions
- d) social selves

Ans:- B

27. Social traps can be dismantled by changing

- a) rewards and costs
- b) supply and demand
- c) compliance and assertiveness
- d) the tendency toward groupthink

Ans:- A

28. A learned disposition to respond to people, objects, or institutions in a positive or negative way defines

- a) cognitive dissonance
- b) socialization
- c) attitudes
- d) stereotypes

Ans:- C

29. In general, helping behavior in emergency situations is discouraged by

- a) the presence of a large number of persons
- b) low costs associated with helping
- c) smaller social distance between the helper and the victim
- d) fear of cognitive dissonance

Ans:- A

30. When a person with little or no authority makes a direct request to another person, the situation involves

- a) Compliance
- b) Obedience
- c) Coercion
- d) Conformity

Ans:- A

31. The fact that physically attractive people also tend to be rated more highly on traits such as intelligence and honesty is an example of

- a) social magnetism
- b) role modeling
- c) social comparisons
- d) the halo effect

Ans:- D

32. Negative attitudes that are tinged with fear, hatred, or suspicion is a definition of

- a) Prejudice
- b) Authoritarianism
- c) Discrimination
- d) Displaced aggression

Ans:- A

33. Interpersonal attraction is encouraged by which one of the following?

- a) personal space
- b) proxemics

- c) competition
- d) similarity

Ans:- D

34. Janis recommends ways to prevent groupthink, which include

- a) focusing on subjective evaluation and interpretation
- b) having the leader state personal preferences before discussion
- c) focusing on the decision, as opposed to the process
- d) encouraging someone to play devil's advocate

Ans:- D

35. In an experiment in which a "student" simulated a seizure, helping was inhibited by

- a) conditions employing smaller groups
- b) diffusion of responsibility
- c) group discussion
- d) reference cognitive dissonance

Ans:- B

36. Sharing your own private thoughts and feelings is called

- a) self-talk
- b) autonomy
- c) self-disclosure
- d) introspection

Ans:- C

37. Which of the following was a significant factor in determining the degree of obedience in Milgram's series of experiments?

- a) the tone of voice used by the experimenter
- b) whether the experimenter was male or female
- c) amount of complaining, shouting, and crying by the learner
- d) the setting in which the experiment was conducted

Ans:- D

38. You do not want a large, unattractive political sign in your yard. However, if you initially agree to put a small sign in your window, later you are more likely to allow the large sign in your yard. This course of events is described by the

- a) foot-in-the-face technique
- b) low-ball technique
- c) door-in-the-face effect
- d) foot-in-the-door effect

Ans:- D

39. In his classic studies of conformity, Asch demonstrated that

- a) size of the majority does not influence how many people will conform
 - b) a majority of one produces about as much conformity as a majority of eight
 - c) lack of unanimity greatly reduces the pressure to conform
 - d) obedience to authority was determined by the authority's perceived referent power
- Ans:- C

40. Expected behavior patterns associated with particular social positions are called

- a) Roles
- b) Culture
- c) Stereotypes
- d) Mannerisms

Ans:- A

41. As part of an experiment, two young women stroll down a busy sidewalk with their arms around each other. They get a variety of reactions from passersby, including disapproving looks and comments. These reactions demonstrate the existence of

- a) Norms
- b) ascribed roles
- c) group structures
- d) achieved roles

Ans:- A

42. How individuals are affected by the presence of others is the focus of study in the field of

- a) Sociology
- b) Social psychology
- c) Experimental psychology
- d) Sociobiology

Ans:- B

43. Groups reward members with _____ and _____ for conformity.

- a) unanimity; power
- b) power; authority
- c) legitimacy; power
- d) approval; acceptance

Ans:- D

44. Stanley Milgram's experiment in which a "teacher" gave shocks to a "learner" was designed to test the limits of

- a) expert power
- b) coercive power
- c) obedience
- d) conformity to a majority

Ans:- C

45. Milgram's shock study showed people to be surprisingly

- a)** Rebellious
- b)** Intelligent
- c)** Sexist
- d)** Obedient

Ans:- D

46. A reference group is

- a)** one with which a person has face-to-face contact
- b)** any group in which one plays an active role or has membership
- c)** any group outside one's social distance boundaries
- d)** any group whose values and attitudes are seen as relevant to one's own

Ans:- D

47. Studies of conformity indicate that people are more apt to be influenced by others if they

- a)** are concerned about the approval of others
- b)** have low needs for certainty and structure
- c)** are in temporary rather than established groups
- d)** are in very large groups

Ans:- A

48. In-group bias is the

- a)** Tendency to favor one's group and see this group as correct
- b)** Tendency to see other members of a group as similar
- c)** Tendency to perform worse when others are watching
- d)** Tendency to conform to the social harmony of a group

Ans:- A

49. People who are less likely to help someone because there are a lot of people present would be exhibiting:

- a)** Groupthink
- b)** Group polarization
- c)** Diffusion of responsibility
- d)** Mere exposure effect

Ans:- C

50. If you have a friend who is reluctant to help you clean your entire room, you may be successful through asking him to simply help you move one item in your room. This approach is referred to as:

- a)** Cognitive dissonance
- b)** Altruism
- c)** Foot-in-the-door

d) Door-in-the-foot

Ans:- C

51. Which of these is not a principle of great man theory?

- a) Leaders are born not made.**
- b) Great men rise up in times of crisis**
- c) We can learn from the biographies of great leaders**
- d) A great leader is only great in certain situations**

Ans:- D

52. In leadership trait theory what is a trait?

- a) A list of the things that make leaders different to everyone else**
- b) A list of the key things that a leader should do to be great**
- c) The list of key behaviours a leader exhibits**
- d) A list of key characteristics that makes a leader great**

Ans:- D

53. For the Ohio State leadership studies the perfect leader:

- a) Combines a focus on the task and the employee**
- b) Focuses on the task and getting things done**
- c) Inspires workers to aim higher and achieve more**
- d) Is concerned about the small details and how to increase productivity**

Ans:- A

54. Contingency theory is based on the assumption that the ideal leader:

- a) Shapes their leadership style depending on the situation**
- b) Provides clear instructions to the followers so that they know what they are doing**
- c) Knows what their strengths are and makes the most out of them**
- d) Spends time with their followers and therefore listens and responds to their needs**

Ans:- A

55. A transactional leader is one who:

- a) Inspires people and has strong interactions with them**
- b) Deals with people in order to get them to do things the leader wants**
- c) Is the ideal form of leadership**
- d) Works for long-term goals of the organization**

Ans:- B

56. What is a transformational leader?

- a) Someone who is involved in organizational change**
- b) A leader, like Taylor, who provided new ways of carrying out management**
- c) A leader who inspires the workers to new levels by offering them a vision of a better future**
- d) Leader who tries to transform their staff by giving them rewards for what they do**

Ans:- C

57.What is post-heroic leadership theory?

- a) A theory which states that there is too much emphasis on leaders and more attention should be placed on followers
- b) A theory looking beyond current leadership styles to new, more creative ways of leading
- c) A theory which tries to create new organizations which do not need leaders
- d) A theory which tries to find the ideal form of leadership

Ans:- A

58.What is the social construction of leadership?

- a) The view that all leadership is social and what matters is how leaders interact with others
- b) Leadership is a made up idea that therefore we should pay more attention to more significant aspects of the organization
- c) What counts as good leadership is a construction of the perceptions of the followers
- d) Leadership is something that the leader constructs as they meet with others

Ans:- C

59.What is the 'glass ceiling'?

- a) A barrier which prevents women from passing through to more senior positions in the company
- b) An old fashioned idea that suggests that women should not make it to the boardroom in organizations
- c) The effect where men can pass by women in women dominated professions
- d) An approach which seeks to get more women in senior positions in organizations

Ans:- A

60. Jimmy is very quiet at school, but later that night at a party Jimmy gets 'crazy' and starts to cut the rug on the dance floor. Jimmy's classmates are stunned at this displayed behavior. Jimmy is experiencing:

- a) Group polarization
- b) The power of SSRI's
- c) Deindividuation
- d) Groupthink

Ans:- C

61. _ set up an experiment, known as the Stanford Prison experiment, where people played the role of a prison guard. The goal was to observe if this authority position would cause them to act differently

- a) Stanley Milgram
- b) Philip Zimbardo
- c) Solomon Asch
- d) Muzafer Sherif

Ans:- B

62. Social Facilitation occurs:

- a) To the tendency for people to do less in a group setting
- b) To the tendency to keep personal opinions to themselves for fear of upsetting the group
- c) When the presence of other people watching improves a person's performance
- d) person's performance
- e) When the presence of other people watching hinders a person's performance

Ans:- C

63. Groupthink is defined as:

- a) When an attitude becomes stronger in group presence
- b) Thinking that revolves around keeping harmony within a group through not disagreeing with group opinion
- c) The tendency to do less in a group situation
- d) Improved performance when people are watching

Ans:- B

64. In Stanley Milgram's experiment on the role of obedience, the _____ was the person who worked with Milgram and played the part of an authority figure.

- a) Teacher
- b) Learner
- c) Experimenter
- d) Doctor

Ans:- C

65. According to Solomon Asch, in his experiment on conformity, _____% of the subjects gave the wrong answer because the group unanimously also gave the wrong answer.

- a) 76
- b) 48
- c) 32
- d) 89

Ans:- A

66. In Stanley Milgram's experiment on the role of obedience, the _____ was the subject who was being observed and did not know what the experiment was about or what was being studied.

- a) Learner
- b) Experimenter
- c) Teacher
- d) Milgram

Ans:- C

67. _____ is a change in behavior or belief as a result of group pressure.

- a) Cohesiveness
- b) Conformity
- c) Compliance

d) Obedience

Ans:- B

68. Publicly acting in accord with social pressure while privately disagreeing is called

a) Acceptance

b) Compliance

c) Reactance

d) Interaction

Ans:- B

69. Both acting and believing in accord with social pressure is called

a) Acceptance

b) Reactance

c) Compliance

d) Interaction

Ans:- A

70. An important difference between Asch's experiment in which participants judged the length of lines and Sherif's experiment in which participants judged the movement of light was that

a) Asch's participants were older than were Sherif's

b) there was an obviously correct answer in judging the length of lines but that was not so in judging the movement of light

c) Asch's participants made their judgments privately whereas Sherif's participants made their judgments publicly

d) Asch's participants were all male whereas Sherif's participants were both male and female

Ans:- B

71. In Asch's study of perceptual judgment involving the length of lines, naive participants conformed of the time to the false judgments of the confederates.

a) 10 percent

b) 37 percent

c) 68 percent

d) 92 percent

Ans:- B

72. Participants' tendencies to obey the experimenter's commands to shock a victim were highest when the experimenter was _____ and the victim was _____.

a) close; distant

b) close; close

c) distant; distant

d) distant; close

Ans:- A

73. To believe that Asch's compliant participants were particularly spineless people is to

- a) forget that behavior shapes belief
- b) overlook other personality characteristics that determine conformity
- c) make the fundamental attribution error
- d) ignore how the status of the experimenter shapes behavior

Ans:- C

74. How social pressure may lead us to perform immoral acts is best illustrated by studies of

- a) psychological reactance
- b) spontaneous self-concept
- c) obedience to authority
- d) informational influence

Ans:- C

75. The effect of group size on conformity has been explained by _____ theory.

- a) cognitive dissonance
- b) social norm
- c) psychological reactance
- d) social impact

Ans:- D

76. Milgram reported that a participant's tendency to obey the experimenter decreased dramatically

- a) when two other participants defied the experimenter
- b) when the participant could not hear the responses of the learner
- c) when the experimenter was a female
- d) when the experimenter was younger than the participant

Ans:- A

77. Philip hates to attend concerts but goes because his wife wants to. After three years Philip comes to genuinely enjoy concerts. This is an example of

- a. how acceptance can lead to compliance
- b. how compliance can lead to acceptance
- c. the "boomerang effect"
- d. how psychological reactance can lead to acceptance

Ans:- B

78. Commitment without intimacy or passion is

- a) Romantic love
- b) Empty love
- c) Non love
- d) Consummate love

Ans:- B

79.Decibel (dB) is the unit of

- a) Temperature
- b) Noise
- c) Pressure
- d) Density

Ans:- B

80.Depressive disorder connected to a specific season is

- a) Bipolar Disorder
- b) SAD
- c) Mania
- d) Hallucination

Ans:- B

81.A person's domicile is an example of _____territory

- a) Primary
- b) Secondary
- c) Tertiary
- d) None of the above

Ans:- A

82.Waiting room is a kind of _____territory

- a) Primary
- b) Secondary
- c) Tertiary
- d) None of the above

Ans:- C

83.One's preferred chair in a class is

- a) Primary territory
- b) Secondary territory
- c) Tertiary territory
- d) None of the above

Ans:- B

84.Crowding is a:

- a) Psychological phenomena
- b) Subjective feeling
- c) Potential source of stress
- d) All of the above

Ans:- D

85.Everyone has the right to access:

- a) Primary territory
- b) Secondary territory
- c) Tertiary territory
- d) Both b & c

Ans:- C

86.According to Hall, intimatedistance is

- a) 6 – 18 inches
- b) 1.5 – 4 feet
- c) 4 – 12 feet
- d) 12 – 25 feet

Ans:- A

87.Personal distance is

- a) 6 – 18 inches
- b) 1.5 – 4 feet
- c) 4 – 12 feet
- d) 12 – 25 feet

Ans:- B

88.Public distance can be

- a) 6 – 18 inches
- b) 1.5 – 4 feet
- c) 4 – 12 feet
- d) 12 – 25 feet

Ans:- D

89.A distance of _____ is social distance

- a) 6 – 18 inches
- b) 1.5 – 4 feet
- c) 4 – 12 feet
- d) 12 – 25 feet

Ans:- C

90.The highest level of physical distance is in _____

- a) Intimate relations
- b) Public relations
- c) Personal relations
- d) Social relations

Ans:- B

91.Personal space first defined by

- a) Hall

- b) Sommer**
 - c) Katz**
 - d) Sheriff**
- Ans:- C

92. Correct Sequence of prosocial behaviour

- a) Notice what is happening > Interpret the event as an emergency > Experience feelings of responsibility > Believe that they have the skills to help > Make a conscious choice to offer assistance**
- b) Interpret the event as an emergency > Notice what is happening > Experience feelings of responsibility > Believe that they have the skills to help > Make a conscious choice to offer assistance**
- c) Believe that they have the skills to help > Experience feelings of responsibility > Notice what is happening > Interpret the event as an emergency > Make a conscious choice to offer assistance**
- d) Experience feelings of responsibility > Believe that they have the skills to help > Notice what is happening > Interpret the event as an emergency > Make a conscious choice to offer assistance**

Ans:- A

93. Unselfish concern for other people is

- a) Prosocial behavior**
- b) Bystander effect**
- c) Altruism**
- d) Volunteering**

Ans:- C

94. The Negative Affect Escape Model explained by

- a) Baron**
- b) Baron & Bell**
- c) Bell**
- d) None of the above**

Ans:- B

95. Negative Affect Escape Model links to:

- a) Inverted S hypothesis**
- b) Inverted U hypothesis**
- c) Parabola**
- d) S curve**

Ans:- B

96. Population is effected by

- a) Birth & death**
- b) immigration**
- c) emigration**

d) all of the above

Ans:- D

97. Technical term used for the study of human population

a) Biography

b) Demography

c) Bibliography

d) Census

Ans:- B

98. Kin selection is an evolutionary theory that explains _____ of Altruism

a) Biological reasons

b) Neurological reasons

c) Cognitive reasons

d) Social norms

Ans:- A

99. Emergency observed -> Empathy aroused -> Help provided to the victim as it gave good feeling to the helper is;

a) Negative – state relief model

b) Genetic determinism mode

c) Empathy-altruism hypothesis

d) Empathy-joy hypothesis

Ans:- C

100. Who is more likely to help?

a) A person with a handicap

b) A person with an altruistic personality

c) A stranger to the victim

d) A person in a crowd of strangers

Ans:- B

101. Phrenologists tried to find out about personality by:

a. reading a person's horoscope

b. feeling a person's skull

c. looking at a person's hands

d. asking people questions

Ans:- B

102. A limitation of selective breeding studies is that they cannot:

a. tell us anything about the role of genes

b. be used to study human beings

c. provide information relevant to the nature/nurture debate

d. tell us anything about the role of the environment

Ans:- B

103. Which neo-Freudian challenged his ideas about penis envy?

a. Adler

b. Fromm

c. Jung

d. Horney

Ans:- D

104. Someone who feels as though they are not living up to expectations would be described by Adler as having:

a. low self-realization

b. an Adlerian complex

c. an inferiority complex

d. low actualization

Ans:- C

105. According to Freud, the mind's three components are:

a. ego, id, superego

b. unconscious, moral, immoral

c. oral, anal, phallic

d. primary, secondary, tertiary

Ans:- A

106. The idea that you can assess someone's personality by studying their face is called:

a. phrenology

b. physiology

c. somatology

d. physiognomy

Ans:- D

107. The ___ complex is to girls boys.

a. Electra, Oedipus

b. Oedipus, Electra

c. oral, phallic

d. phallic, oral

Ans:- A

108. The discovery that the heritability of the Big Five personality traits is around 40% – 50% suggests that:

a. the environment plays no role in personality

b. genes play no role in personality

- c. the environment plays an important role in personality
- d. the Big Five traits account for about half of our personality

Ans:- C

109. Humanistic psychologists embraced the idea of:

- a. repression
- b. free will
- c. unconscious drives
- d. the id

Ans:- B

110. According to Eysenck, extraverts seek to _____ their arousal while introverts seek to _____ their arousal.

- a. decrease, increase
- b. hide, reveal
- c. increase, decrease
- d. reveal, hide

Ans:- C

111. Allport believed that traits could be organized into three levels:

- a. primary, secondary, tertiary
- b. cognitive, emotional, physiological
- c. id, ego, superego
- d. cardinal, central, secondary

Ans:- D

112. The MMPI is used to measure:

- a. unconscious drives
- b. the Big Five traits
- c. personality and psychological disorders
- d. leadership potential

Ans:- C

113. Which of the following is NOT one of the Big Five traits?

- a. sense of humour
- b. openness to experience
- c. conscientiousness
- d. extraversion

Ans:- A

114. Freud founded the _____ approach to understanding human behaviour.

- a. palliative
- b. psychodynamic

- c. patronymic
- d. psychedelic

Ans:- B

115. The influence of parents on the personality of their children is:

- a. non-existent
- b. weakest in early childhood
- c. strongest in early childhood
- d. consistent across the lifespan

Ans:- C

116. What is special about “knockout” mice?

- a. they are very attractive
- b. their DNA has been modified
- c. they are easy to knock out
- d. they are unusually aggressive

Ans:- B

117. The aim of behavioural genetics is to learn about:

- a. the extent to which geneticists can modify people’s behaviour
- b. the possibility of eradicating behavioural problems in children
- c. the genetic and environmental influences on human behaviour
- d. the ability of animals to learn language

Ans:- C

118. Monozygotic is to _____ twins as dizygotic is to _____ twins.

- a. male, female,
- b. female, male
- c. fraternal, identical
- d. identical, fraternal

Ans:- D

119. Which of the following characteristics describe someone who, according to Maslow, is self-actualized?

- a. creativity
- b. confidence
- c. spontaneity
- d. all of the above

Ans:- D

120. According to Freud, children pass through 4 stages of psychosexual development. Which of the following shows the stages in the correct developmental order?

- a. oral, anal, phallic, latency

- b.** latency, oral, anal, phallic
- c.** phallic, anal, oral, latency
- d.** oral, phallic, latency, anal

Ans:- A

121. Projective tests claim to reveal information about:

- a.** career aptitude
- b.** intellectual attainment
- c.** unconscious processes
- d.** parenting style

Ans:- C

122. Traits are defined as:

- a.** physical characteristics that distinguish us from other people
- b.** relatively enduring characteristics that influence our behaviour across many situations
- c.** unconscious tendencies to act in different ways according to the situation
- d.** permanent personality tendencies that determine our behaviour in any situation

Ans:- B

123. Sheldon's theory that people with different body types have different personalities has been:

- a.** supported by research
- b.** discredited
- c.** shown to be accurate for thin people but not overweight people
- d.** shown to be accurate for women but not for men

Ans:- B

124. Which of the following is not a defence mechanism?

- a.** projection
- b.** regression
- c.** ingratiation
- d.** sublimation

Ans:- C

125. Rohan is self-disciplined, focused on achievement and keen to do his duty. He would be expected to score highly on:

- a.** neuroticism
- b.** agreeableness
- c.** extraversion
- d.** conscientiousness

Ans:- D

126. The Barnum effect helps to explain people's belief in:

- a.** fortune-telling

- b. astrology
- c. horoscopes
- d. all the above

Ans:- D

127. _____ are the basic biological units that transmit characteristics from one generation to the next:

- a. genes
- b. neurons
- c. glia
- d. instincts

Ans:- A

128. Which of the following would NOT be useful to a behavioural geneticist?

- a. family studies
- b. case studies
- c. adoption studies
- d. twin studies

Ans:- B

129. According to Freud, the id is to the _____ principle as the ego is to the _____ principle.

- a. aggressive, sexual
- b. sexual, aggressive
- c. pleasure, reality
- d. reality, pleasure

Ans:- C

130. Lana is friendly, always willing to help others and compassionate. We would expect Lana to score highly on:

- a. extraversion
- b. agreeableness
- c. neuroticism
- d. openness to experience

Ans:- B

131. Physically attractive people are usually perceived as:

- a. more intelligent than unattractive people
- b. more dominant than unattractive people
- c. more socially skilled than unattractive people
- d. all of the above

Ans:- D

132. Research has shown a positive correlation between aggression and the level of:

- a. acetylcholine
- b. testosterone
- c. estrogen
- d. GABA

Ans:- B

133. In Milgram's original study on obedience, what percentage of participants were willing to administer the maximum level of shock:

- a. 5%
- b. 30%
- c. 65%
- d. 95%

Ans:- C

134. People are more likely to help others if:

- a. they are in a bad mood
- b. they feel guilty about something
- c. someone else is already helping
- d. they are in a hurry

Ans:- A

135. Punching a wall or kicking a chair when you are angry at a co-worker are examples of:

- a. displaced aggression
- b. inanimate hostility
- c. repression
- d. avoidant attachment

Ans:- A

136. An advertiser who seeks to associate their product with something people already like (for example, a celebrity or a popular song) is making use of:

- a. classical conditioning principles
- b. pseudoscience
- c. operant conditioning principles
- d. sublimation

Ans:- D

137. According to Moreland and Beach, the more frequently we see a person the:

- a. less likely we are to recognize them
- b. less likely we are to trust them
- c. more likely we are to dislike them
- d. more likely we are to like them

Ans:- C

138. Having an audience typically _____ us if we are doing an easy task and _____ us if we are doing a difficult task.

- a. hinders, hinders
- b. helps, helps
- c. helps, hinders
- d. hinders, helps

Ans:- A

139. Groupthink is most likely when:

- a. there is time pressure
- b. group members feel no sense of group identity
- c. there is a weak leader
- d. group members are in frequent contact with people outside the group

Ans:- D

140. Stimulation of the amygdala is most likely to increase feelings of:

- a. happiness
- b. guilt
- c. shyness
- d. aggression

Ans:- B

141. Evolutionary theory predicts that we will be most likely to help:

- a. old people
- b. family members
- c. poor people
- d. strangers

Ans:- B

142. Research has shown that people are LESS willing to administer severe shocks in the Milgram paradigm if:

- a. they choose the level of shock themselves
- b. the person telling them to administer the shock is in another room
- c. they knew that other people had refused to administer severe shocks
- d. all of the above

Ans:- D

143. In terms of interpersonal attraction, research suggests that:

- a. opposites attract
- b. similarity breeds contempt
- c. birds of a feather flock together
- d. a stitch in time saves nine

Ans:- C

144. We tend to stereotype people on the basis of their:

- a. physical appearance
- b. age
- c. race
- d. all of the above

Ans:- D

145. People who are high in self-monitoring are _____ likely to act in ways consistent with their attitudes than people who are low in self-monitoring.

- a. more
- b. less
- c. neither more nor less
- d. more if they are angry, less if they are sad

Ans:- B

146. To be classed as "intimate", a relationship must be based on:

- a. passion
- b. acceptance
- c. social support
- d. all of the above

Ans:- D

147. Prejudice is to _____ as discrimination is to _____.

- a. thought, action
- b. race, age
- c. stereotype, categorization
- d. negative, positive

Ans:- A

148. The tendency to underestimate the role of situational factors when deciding why a stranger behaved in a particular way is known as the:

- a. self-serving bias
- b. fundamental attribution error
- c. situational exploitation bias
- d. causal explanation error

Ans:- B

149. If you want someone to be attracted to you, research suggests that you should:

- a. ask them about themselves
- b. argue with them
- c. talk only about yourself

d. all of the above

Ans:- A

150. The fact that as group size increases, group productivity tends to decrease is most likely explained by:

- a.** groupthink
- b.** stereotyping
- c.** social loafing
- d.** social facilitation

Ans:- C

151. According to the “foot in the door” technique, you are more likely to be able to change someone’s attitude if you:

- a.** visit them in their home
- b.** start by complimenting them on their choice of footwear
- c.** tell them how many celebrities hold the attitude you want them to adopt
- d.** get them to make a small change in attitude to start with

Ans:- D

152. Jill and John have been married for many years and rely on each other to meet important goals. This reliance reveals that they are:

- a.** passionate
- b.** interdependent
- c.** self-serving
- d.** all of the above

Ans:- B

153. Groups that set _____ and _____ goals are more likely to be effective than groups that don’t set these kind of goals.

- a.** easy, vague
- b.** vague, unreachable
- c.** specific, attainable
- d.** difficult, unattainable

Ans:- C

154. Which of the following best illustrates the concept of minority influence?

- a.** a union is successful in negotiating an improved benefits package for its members
- b.** three teenagers manage to persuade their school to adopt a new anti-litter policy
- c.** Shari is able to persuade her friend Ivy to give up smoking
- d.** the government passes a law requiring cyclists to wear helmets

Ans:- B

155. According to cognitive dissonance theory, we may be motivated to change our attitudes to:

- a.** reduce negative feelings

- b.** conform to the attitudes of high-status individuals
- c.** force others to do the same
- d.** increase our level of anxiety

Ans:- A

156. Another term for the fundamental attribution error is:

- a.** commitment
- b.** correspondence bias
- c.** cognitive dissonance
- d.** stereotype threat

Ans:- B

157. We are likely to make a _____ attribution to explain our success, and a ___tribution to explain our failure.

- a.** causal, correlational
- b.** correlational, causal
- c.** person, situation
- d.** situation, person

Ans:- C

158. Benjamin thinks that if he kick his car and swears at his computer he will release his anger and be less aggressive with his co-workers. Benjamin believes in:

- a.** the fundamental attribution error
- b.** social loafing
- c.** social facilitation
- d.** catharsis

Ans:- D

159. One likely explanation for why so many people ignored Kitty Genovese's situation is:

- a.** social facilitation
- b.** the social responsibility norm
- c.** diffusion of responsibility
- d.** groupthink

Ans:- C

160. The Implicit Association Test is designed to measure:

- a.** verbal ability
- b.** unconscious stereotyping
- c.** hidden mathematical ability
- d.** dream content

Ans:- B

161. How does naive psychology differ from phenomenology?

- a.** Phenomenology uses reaction-time methods

- b.** Phenomenology is not necessarily concerned with how people think about their own mental processes
 - c.** Phenomenology is no longer actively studied in the field
 - d.** Phenomenology uses people's self-reported ideas about their own cognitions and behaviors
- Answer: d. Phenomenology uses people's self-reported ideas about their own cognitions and behaviors

162. Social cognition is influenced heavily by _____ from _____ cognitive psychology.

- a.** Theory
- b.** Models
- c.** Methods
- d.** All of the above

Answer: c. Methods

163. Who proposed the configural and algebraic models of social cognition?

- a.** Solomon Asch
- b.** Kurt Lewin
- c.** Immanuel Kant
- d.** A and B

Answer: a. Solomon Asch

164. Asking people about their own thoughts and behaviors is a technique used by:

- a.** Behaviorists
- b.** Elementalists
- c.** Gestalt psychologists
- d.** B and C

Answer: d. B and C

165. According to Kurt Lewin, behavior is determined in part by:

- a.** Emotion
- b.** Experience
- c.** Motivation
- d.** A and C

Answer: d. A and C

166. Field theory is more consistent with:

- a.** An elemental approach
- b.** A holistic approach
- c.** A and B
- d.** Neither A nor B

Answer: b. A holistic approach

167. Why did researchers stop relying on introspection?

- a. Studying cognition was not important
- b. Results from introspection were not reproducible
- c. Research subjects behave differently in private than they do in public
- d. Introspection data were difficult to analyze

Answer: b. Results from introspection were not reproducible

168. During the 1960s, social psychology largely ceased to study:

- a. Behavior
- b. Cognition
- c. A and B
- d. Neither A nor B

Answer: d. Neither A nor B

169. Social and cognitive psychologists use computers for:

- a. Measuring cognition
- b. Simulating cognition
- c. Describing cognition
- d. All of the above

Answer: All of the above

170. If people are viewed as consistency-seekers, then their cognition is influenced by:

- a. Subjective inconsistency
- b. Objective inconsistency
- c. Attributional inconsistency
- d. A and C

Answer: a. Subjective inconsistency

171. "Errors and biases in our impressions of others are caused by motivations." This is true in what view of the social thinker?

- a. Naive scientist
- b. Cognitive miser
- c. A and B
- d. Neither A nor B

Answer: d. Neither A nor B

172. Which technique measures blood flow to different areas of the brain?

- a. EEG
- b. TMS
- c. fMRI
- d. A and C

Answer: c. fMRI

173. Neural evidence suggests that people can think about _____ as having intentions and personality:

- a. Geometric shapes
- b. Dogs
- c. Homeless people
- d. A and B

Answer: d. A and B

174. When people engage in social cognition, their mPFC responses are often:

- a. Much stronger than when they are resting
- b. Not very different from when they are resting
- c. Are different levels of analysis of the same social psychological phenomena
- d. Are not important to cognitive psychologists

Answer: c.

175. Brains and culture:

- A. Cannot be studied in the same experiment
- B. Are competing explanations for the same social psychological phenomena
- C. Are different levels of analysis of the same social psychological phenomena

- a. Influence
- b. Are influenced by
- c. A and B
- d. Neither A nor B

Answer: c. A and B

176. The choice between automatic and controlled processes is:

- a. Typically automatic
- b. Typically controlled
- c. Always automatic
- d. Always controlled

Answer: a. Typically automatic

177. Proceduralized judgments are:

- a. Developed without practice
- b. Preemptive over non-proceduralized judgments
- c. Slower than non-proceduralized judgments
- d. Deliberate and thoughtful

Answer: b. Preemptive over non-proceduralized judgments

178. Judgments about others' _____ are often automatic.

- a. Traits
- b. Behavior
- c. A and B

d. Neither A nor B

Answer: a. Traits

179. Automatic and controlled processes can be triggered by:

a. Subliminal primes

b. Supraliminal primes

c. A and B

d. Neither A nor B

Answer: c. A and B

180. An ironic rebound effect:

a. Occurs during the period of time when one is asked to suppress thoughts

b. Occurs when one is no longer attempting to suppress thoughts

c. Can be prevented by substituting different thoughts for the unwanted thoughts

d. B and C

Answer: a. Occurs when one is no longer attempting to suppress thoughts

181. Goal-directed automaticity is:

a. Adaptive

b. Maladaptive

c. A and B

d. Neither A nor B

Answer: c. A and B

182. The conscious will is an example of:

a. Automatic process

b. Controlled process

c. Intention

d. Behavior

Answer: b. Controlled process

183. First-order consciousness necessarily involves:

a. Being mindful

b. Having self-esteem

c. Thinking about one's own thoughts

d. Causing one's own behavior

Answer: a. Being mindful

184. Mind-wandering is an example of:

a. Stimulus-dependent thought

b. Stimulus-independent thought

c. Unconscious thought

d. Default network deactivation

Answer: b. Stimulus-independent thought

185. Trying to predict your roommate is an example of:

- a. Operant thought
- b. Respondent thought
- c. A and B
- d. Neither A nor B

Answer: a. Operant thought

186. _____ is a thought- sampling technique frequently used outside the laboratory:

- a. Experience sampling
- b. Think-aloud paradigm
- c. Videotaping
- d. A and C

Answer: a. Experience sampling

187. It is possible to study people's thoughts in a useful way when:

- a. People report on their thoughts while they are happening
- b. People report on the content of their thoughts
- c. People report on their thought processes
- d. A and B

Answer: d. A and B

188. The human need to belong preempts:

- a. The need for understanding
- b. The need for social control
- c. Controlled processes in social cognition
- d. All of the above

Answer: a. The need for understanding

189. The dual-process model and continuum model of impression formation:

- a. Do not depend on motivation
- b. Both propose stable cognitive representations at different stages of impression formation
- c. Both suggest distinct rules for proceeding to each stage of impression formation
- d. Both involve an interplay of automatic and controlled processes

Answer: d. Both involve an interplay of automatic and controlled processes

190. Does a person's self-concept typically change, or does it mostly stay the same?

- a. The self-concept remains constant for most people most of the time
- d. All of the above

Answer: d. All of the above

191. When we process information related to our own self-schemas, brain activity resembles _____ processes, but when we process information unrelated to our own self-schemas, brain activity resembles more _____ processes.

- a. Social judgment/non-social judgment
- b. Non-social judgment/social judgment
- c. Automatic/controlled
- d. Controlled/automatic

Answer:c. Automatic/controlled

192. The relation between individual self-esteem and life satisfaction is ___ in _____ interdependent cultures than it is in independent cultures.

- a. Higher
- b. Lower
- c. More stable
- d. The same

Answer: b. Lower

193. What is related to whether the Behavioral Activation System (BAS) or Behavioral Inhibition System (BIS) is activated?

- a. Different people tend to activate BAS or BIS more frequently
- b. Different situations lead to more BAS or BIS activation
- c. The left hemisphere is related to BAS and right hemisphere is related to BIS
- d. All of the above

Answer: d. All of the above

194. If a person notices a difference between the actual self and ideal self, what type of regulatory focus is activated?

- a. Promotion focus
- b. Prevention focus
- c. Self focus
- d. Other focus

Answer: a. Promotion focus

195. Researchers have shown that well-being depends in part on regulatory fit, in other words a match between _____ and _____

- a. Actual self/ideal self
- b. Actual self/ought self
- c. Ideal self/ought self
- d. Goals/regulatory focus

Answer: d. Goals/regulatory focus

196. What is one reason why people might drink alcohol or watch television after a bad day?

- a. Reduce prevention focus
- b. Reduce regulatory fit
- c. Reduce self-focus
- d. Reduce other-focus

Answer:c. Reduce self-focus

197. In order to regulate ourselves effectively, we depend on:

- a. Reasoned responses
- b. Hedonic emotions
- c. Self-conscious emotions
- d. Both A and C

Answer: d. Both A and C

198. Which needs are satisfied by holding positive illusions about the self?

- a. Self-verification
- b. Self-improvement
- c. Self-enhancement
- d. Accuracy

Answer: c. Self-enhancement

199. People who hold self-enhancing views tend to be:

- a. More receptive to negative feedback
- b. More defensive about negative feedback
- c. More dismissive of negative feedback
- d. Both B and C

Answer: d. Both B and C

200. Elevated cortisol levels indicate:

- a. Increased stress
- b. Increased self-esteem
- c. Increased attachment to close others
- d. Reduced heart rate

Answer:a. Increased stress

201. People who are motivated by self-enhancement seek a self- assessment that is:

- a. As realistic as possible
- b. As positive as possible
- c. Adequately positive
- d. Similar to others' assessments of them

Answer:c. Adequately positive

202. According to terror management theory, what acts as a buffer that reduces people's anxiety about death?

- a. Self-esteem
- b. Self-verification
- c. Endorsement of cultural views
- d. Both A and C

Answer: c. Endorsement of cultural views

203. What process does simulation theory describe?

- a. Inferring another person's mental state by imagining one's own mental state in that situation
- b. Inferring one's own mental state by imagining how another person might react to the situation
- c. Both A and B
- d. Neither A nor B

Answer: a. Inferring another person's mental state by imagining one's own mental state in that situation

204. In causal reasoning, when do we shift from more automatic processing to more thoughtful, controlled processing?

- a. When a result is unexpected
- b. When a result is negative
- c. When a result is ambiguous
- d. Both A and B

Answer: d. Both A and B

205. When trying to attribute the reasons for another person's actions, people most commonly implicate:

- a. The situation the person was in at the time of the action
- b. The person's enduring situation
- c. The person's disposition at the time of the action
- d. The person's enduring disposition

Answer: d. The person's enduring disposition

206. Forming dispositional attributions about others tends to be:

- a. Uncontrollable
- b. Very fast
- c. Automatic
- d. Both B and C

Answer: d. Both B and C

207. Why do people form attributions?

- a. They are motivated to predict future social events
- b. They are motivated to control future social events
- c. They are motivated to increase their own self-esteem
- d. Both A and B

Answer: d. Both A and B

208. What did Heider mean by "commonsense psychology?"

- a. The thought processes involved in everyday judgments
- b. How people understand their own thought processes
- c. How people's intuitions about psychology are most often correct
- d. None of the above

Answer: b. How people understand their own thought processes

209. What factors go into a person's capacity to complete an action?

- a. Ability
- b. Environmental forces
- c. Intentions
- d. Both A and B

Answer: d. Both A and B

210. According to Jones and Davis's Correspondent Inference Theory, we find a person's actions to be most informative about invariant dispositions when:

- a. The action depends on the person's situation
- b. The action is judged to be intentional
- c. The action seems to be caused by a consistent goal
- d. Both B and C

Answer: d. Both B and C

211. According to Correspondent Inference Theory, if a person's behavior is low in social desirability, then a social perceiver will:

- a. Attribute the behavior to the situation
- b. Attribute the behavior to the person's disposition
- c. Find the behavior uninformative
- d. Both A and C

Answer: b. Attribute the behavior to the person's disposition

212. According to Correspondent Inference Theory, people are more likely to form dispositional attributions about someone's choice when:

- a. There are more noncommon effects between the chosen and nonchosen alternatives
- b. There are fewer noncommon effects between the chosen and nonchosen alternatives
- c. The choice was hedonically irrelevant
- d. Both B and C

Answer: d. Both B and C

213. What type of model is Kelley's Covariation Model?

- a. A *positive* model: it describes how people actually form attributions in social situations based on distinctiveness, consistency and consensus
- b. A *normative* model: it describes an idealized set of rules for how people should form attributions when given optimal information about distinctiveness, consistency and consensus
- c. A *qualitative* model: it describes general tendencies but not quantitative predictions of how people might form attributions when given information about distinctiveness, consistency and consensus
- d. Both B and C

Answer: b. A *normative* model: it describes an idealized set of rules for how people should form attributions when given optimal information about distinctiveness, consistency and consensus

214. When forming attributions, which type of information do social perceivers rely on the *least*?

- a. Distinctiveness
- b. Consistency
- c. Consensus

d. None of the above

Answer: c. Consensus

215. Although findings about misattribution of arousal have turned out not to be strong enough to suggest clinical applications, these findings have been influential nonetheless. What did Schachter and Singer (1962) find in their study that began this line of research?

a. Participants who were given epinephrine and not given accurate information about the side effects reported feeling euphoric or angry

b. Participants who were given epinephrine and were given accurate information about the side effects reported feeling euphoric or angry

c. Participants who were not given epinephrine and were given accurate information about the side effects reported feeling euphoric or angry

d. None of the above

Answer: a. Participants who were given epinephrine and not given accurate information about the side effects reported feeling euphoric or angry

216. According to Bem's Self Perception Theory, if a person has a given job, under what circumstances will the person infer that they enjoy the job the most?

a. If they are paid very well for the job

b. If they are paid very poorly for the job

c. If their coworkers enjoy the job

d. Both B and C

Answer: b. If they are paid very poorly for the job

217. When people are cognitively busy, for example when they are busy self-regulating, how will this affect their attributions about others' behavior?

a. They will pay less attention to the context or situation

b. They will pay less attention to the person's actual behavior

c. They will make more dispositional attributions

d. Both A and C

Answer: b. Both A and C

218. When are people relatively less likely to exhibit the fundamental attribution error (or correspondence bias)?

a. When forming attributions about people they know well

b. When forming attributions about the self

c. Both A and B

d. Neither A nor B

Answer: c. Both A and B

219. Which of the following environmental law allows private rights to use a resource that is, groundwater, by viewing it as an attachment to the land?

A. Easement Act

B. Indian Fisheries Act

C. Factories Act

D. All of the above

Ans: A

220. Which environmental law establishes two sets of penal offences whereby the government can sue any person who uses dynamite or other explosive substance in any way (whether coastal or inland) with intent to catch or destroy any fish or poisonous fish in order to kill?

- A. Easement Act
- B. Indian Fisheries Act
- C. Factories Act
- D. Coastal Regulation Zone Notification

Ans: B

221. Consider the following statement (s) related to the Coastal Regulation Zone Notification.

- I. It puts regulations on various activities, including construction, are regulated.
- II. It gives some protection to the backwaters and estuaries.

Code:

- A. Only I
- B. Only II
- C. Both I & II
- D. Neither I nor II

Ans: C

222. Consider the following statement (s) related to the Water (Prevention and Control of Pollution) Act.

- I. It provides for the protection of birds and animals and for all matters that are connected to it whether it be their habitat or the waterhole or the forests that sustain them.
- II. It aims to deal with waste arising from ships along the coastal areas within a specified radius.

Code:

- A. Only I
- B. Only II
- C. Both I & II
- D. Neither I nor II

Ans: D

223. Which of the following environmental law empowers the central and state pollution control boards to meet with grave emergencies of air pollution?

- A. Air (Prevention and Control of Pollution) Amendment Act
- B. Environment (Protection) Act
- C. Air (Prevention and Control of Pollution) Rules
- D. Objective of Hazardous Waste (Management and Handling) Rules

Ans: A

224. Match the following

- a. National Environmental Tribunal Act 1. 1995

- b.** Public Liability Insurance Act and Rules 2. 1991
- c.** National Environment Appellate Authority Act 3. 1997
- d.** Biomedical waste (Management and Handling) Rules

Code:

a	b	c	d
A. 43	2	1	
B. 41	3	2	
C. 12	3	4	
D. 14	3	2	

Ans: C

225. Consider the following statement (s) related to the Biological Diversity Act.

I. This has been laid down for the regulation of production and consumption of ozone depleting substances.

II. It is an act to provide for the conservation of biological diversity, sustainable use of its components, and fair and equitable sharing of the benefits arising out of the use of biological resources and knowledge associated with it.

Code:

- A.** Only I
 - B.** Only II
 - C.** Both I & II
 - D.** Neither I nor II
- Ans: B

226. Which of the following act of environment and ecology is associated with 'law apply to every municipal authority responsible for the collection, segregation, storage, transportation, processing, and disposal of municipal solid wastes'?

- A.** Municipal Solid Wastes (Management and Handling) Rules
- B.** Environment (Siting for Industrial Projects) Rules
- C.** Ozone Depleting Substances (Regulation and Control) Rules
- D.** Batteries (Management and Handling) Rules

Ans: A

227. Consider the following statement (s) related to the Public Liability Insurance Act and Rules.

I. It was drawn up to provide for public liability insurance for the purpose of providing immediate relief to the persons affected by accident while handling any hazardous substance.

II. This law puts regulations on various activities, including construction, are regulated. It gives some protection to the backwaters and estuaries.

Code:

- A.** Only I
- B.** Only II
- C.** Both I & II
- D.** Neither I nor II

Ans: A

228. Which of the following is the oldest environmental law in India?

- A.** Wildlife Protection Act
- B.** River Board Act
- C.** Factories Act
- D.** Easement Act

Ans: D

229. The world as World Environmental day is celebrated on:

- (a)** December 1
- (b)** June 5
- (c)** November 14
- (d)** August 15

Ans: B

230. The provisions for environmental protection in the constitution were made in:

- (a)** 1976
- (b)** 1950
- (c)** 1982
- (d)** 1960

Ans: A

231. The provisions of environmental protection in the constitution were made under:

- (a)** Article 5-A
- (b)** Article 21-B
- (c)** Article 27-B (h)
- (d)** Article 48-A and Article 51-A (g)

Ans: D

232. The first of the major environmental protection act to be promulgated in India was:

- (a)** Water Act
- (b)** Air Act
- (c)** Environmental Act
- (d)** Noise Pollution Rule

Ans: A

233. The Forest (Conservation) Act was enacted in the year:

- (a)** 1986
- (b)** 1974
- (c)** 1980
- (d)** 1972

Ans: C

234. The Forest (Conservation) Act extends to the whole of India except:

- (a)** Uttar Pradesh

- (b) Karnataka
 - (c) Jammu and Kashmir
 - (d) Haryana
- Ans: C

235. Penalty for conservation of the provisions of the Forest Act is under:

- (a) Section 3A
- (b) Section 4A
- (c) Section 12A
- (d) Section 8A

Ans: A

236. Offences by the Authorities and Government Department in Forest Act is under:

- (a) Section 5B
- (b) Section 5A
- (c) Section 3B
- (d) Section 8A

Ans: C

237. The Wildlife (Protection) Act was enacted in the year:

- (a) 1986
- (b) 1974
- (c) 1994
- (d) 1972

Ans: D

238. The power to declare an area as a sanctuary or national park of central Government is Wildlife (Protection) Act is under:

- (a) Section 38
- (b) Section 39
- (c) Section 18
- (d) Section 27

Ans: A

239. The Wildlife (Protection) Act contains:

- (a) 7 Chapters
- (b) 6 Chapters
- (c) 5 Chapters
- (d) 8 Chapters

Ans: A

240. The Wildlife (Protection) Act contains:

- (a) 66 Sections

- (b)** 6 Sections
 - (c)** 7 Sections
 - (d)** 46 Sections
- Ans: A

241. The Water (Prevention and Control of Pollution) Act was enacted in the year:

- (a)** 1986
- (b)** 1974
- (c)** 1994
- (d)** 1975

Ans: B

242. The Water Act contains:

- (a)** 4 Chapters
- (b)** 5 Chapters
- (c)** 7 Chapters
- (d)** 8 Chapters

Ans: D

243. The Water Act have:

- (a)** 64 Sections
- (b)** 68 Sections
- (c)** 45 Sections
- (d)** 62 Sections

Ans: A

244. The functions of Central Board are given under:

- (a)** Section 16
- (b)** Section 19
- (c)** Section 25
- (d)** Section 24

Ans: A

245. The functions of State Board are given under:

- (a)** Section 16
- (b)** Section 17
- (c)** Section 21
- (d)** Section 45

Ans: B

246. Power to give directions are declared under:

- (a)** Section 16
- (b)** Section 17

(c) Section 18

(d) Section 25

Ans: C

247. In the Water Act the entire National Capital Territory of Delhi has been declared as water pollution prevention control area under:

(a) Section 21

(b) Section 23

(c) Section 19

(d) Section 24

Ans: C

248. The Air (Prevention and Control of Pollution) Act was enacted in the year:

(a) 1981

(b) 1996

(c) 2000

(d) 1974

Ans: A

249. The Air Act contains:

(a) 5 Chapters

(b) 6 Chapters

(c) 7 Chapters

(d) 8 Chapters

Ans: C

250. The Air Act have

(a) 56 Section

(b) 54 Section

(c) 58 Section

(d) 62 Section

Ans: B

251. Noise pollution has been inserted as pollution in the Air Act in:

(a) 1981

(b) 1987

(c) 1982

(d) 2000

Ans: B

252. The Environmental (Protection) Act was enacted in the year:

(a) 1986

(b) 1992

(c) 1984

(d) 1974

Ans: A

253. The EPA consists:

(a) 2 Chapters

(b) 4 Chapters

(c) 8 Chapters

(d) 7 Chapters

Ans: B

254. The EPA contains:

(a) 25 Sections

(b) 12 Sections

(c) 26 Sections

(d) 14 Sections

Ans: C

255. NGOs stands for:

(a) Non-Governmental Organization

(b) Nine-Governmental Organization

(c) Non-Gained Organizations

(d) National-Grade Organization

Ans: A

256. The Women's Population in the world is almost:

(a) Half

(b) One-fourth

(c) One-third

(d) One fifth

Ans: A

257. Literate women can help in:

(a) Reducing infant mortality rate

(b) Reducing population growth

(c) Promoting female children education

(d) All of the above

Ans: D

258. Which of the following is not the effect of modern agriculture?

(a) Nitrate pollution

(b) Eutrophication

(c) Biomagnification

(d) Ozone depletion

Ans: D

259. Housing affects:

- (a) Neighbourhood
- (b) Energy consumption
- (c) Water consumption
- (d) All of the above

Ans: D

260. The human activity, among the following, which causes maximum environmental pollution having regional and global impacts, is:

- (a) Urbanization
- (b) Industrialisation
- (c) Agriculture
- (d) Mining

Ans: B

261. Production, transformation and use of energy are the major problems of:

- (a) Industrial activity
- (b) Sustainable development
- (c) Global warming
- (d) Acid rain

Ans: A

262. A chemical industry is not a cause of:

- (a) Air pollution
- (b) Noise pollution
- (c) Water pollution
- (d) Nuclear pollution

Ans: D

263. Electronic waste is the adverse effect of:

- (a) Industry
- (b) Agriculture
- (c) Housing
- (d) Mining

Ans: A

264. Extraction of mineral and metal from the earth is:

- (a) Agriculture
- (b) Transportation
- (c) Mining
- (d) Sustainable development

Ans: C

265. Underground and open cast is the methods of:

- (a) Agriculture
- (b) Mining
- (c) Housing
- (d) Transportation

Ans: B

266. This is not the effect of transportation:

- (a) Air emission
- (b) Material consumption
- (c) Solid waste generation
- (d) Acid mine drainage

Ans: D

267. In EIA the decision to hold hearing has to be made within:

- (a) 5 days
- (b) 10 days
- (c) 20 days
- (d) 30 days

Ans: D

268. SPCB's are required to give notice in how many newspapers mentioning the date, time and place of public hearing:

- (a) 2
- (b) 4
- (c) 6
- (d) 8

Ans: A

269. 'Meeting the needs of the present without compromising the ability of future generation to meet their own need' is given by:

- (a) Brundtland
- (b) Mahatma Gandhi
- (c) Maathai
- (d) Sunderlal Bahugana

Ans: A

270. The idea of sustainable development was conceived in early: (a) 1950

- (b) 1960
- (c) 1970
- (d) 1980

Ans: D

271. How many agreement are therein Agenda – 21?

- (a) 4
- (b) 5
- (c) 6
- (d) 7

Ans: B

272. Sustainable development will not aim at:

- (a) Social economic development which optimise the economic and societal benefits available in the present, without spoiling the likely potential for similar benefits in the future
- (b) Reasonable and equitable distributed level of economic wellbeing that can be perpetuated continually
- (c) Development that meets the need of the present without compromising the ability of future generation to meet their own needs
- (d) Maximising the present day benefits through increased resource consumption

Ans: D

273. Which of the following statements in relation to sustainable development is not true?

- (a) Sustainable development is defined as the development that meets the needs of present without compromising the ability of our future generations to meet their own needs
- (b) Sustainability has the main objective of purely focussing on the natural environment
- (c) Sustainable development of various countries and the entire world is the only solution left with mankind to survive for a longer period on Earth
- (d) Sustainable development not only considers the protection of the environment but also the maintenance of economic viability as well as the social and ethical considerations

Ans: B

274. The maximum number of individuals that can be supported by a given environment is called

- (a) Biotic potential
- (b) Carrying capacity
- (c) Environmental resistance
- (d) Population size

Ans: B

275. Supporting capacity and assimilative capacity are the components of

- (a) Carrying capacity
- (b) Holding capacity
- (c) Containing capacity
- (d) Capturing capacity

Ans: A

276. Social, economical and ecological equity is the necessary condition for achieving

- (a) Social development
- (b) Economical development
- (c) Sustainable development
- (d) Ecological development

Ans: C

277. What type of appeal is more likely to elicit help from a stranger, according to the separate process view?

- a. Trying to make the stranger feel guilty about not helping
- b. Emphasizing the rewards of helping
- c. Both A and B
- d. Neither A nor B

Answer: b. Emphasizing the rewards of helping

278. A woman watches as a boy gives some money to a homeless person. The woman subsequently helps another person out of a general feeling of human goodness. Which hypothesis might predict this result?

- a. Social outlook
- b. Focus of attention
- c. Mood maintenance
- d. All of the above

Answer: a. Social outlook

279. What is true about people in a cheerful mood?

- a. They initiate fewer interactions
- b. They aggress against others less often
- c. They reward themselves more
- d. Both B and C

Answer: d. Both B and C

280. Why might happy people be more helpful?

- a. They want to stay in a happy mood
- b. They like others more when they are happy
- c. They are more optimistic when they are happy
- d. All of the above

Answer: d. All of the above

281. Mood-congruent memory effects are likely to be:

- a. Motivated
- b. Automatic
- c. Controlled
- d. All of the above

Answer: d. All of the above

282. Do negative events tend to be memorable?

- a. Mostly they tend not to be as memorable as positive events

- b. Yes, for people high in neuroticism
- c. Yes, for depressed people
- d. All of the above

Answer: d. All of the above

283. In the context of embodied cognition research, what does “offline cognition” mean?

- a. Unobtrusively manipulating facial expressions instead of mood states
- b. Recreating perception without the original targets
- c. Presenting stimuli in different sensory modalities
- d. All of the above

Answer: b. Recreating perception without the original targets

284. Which of the below is found to be universally disgusting?

- a. Vermin
- b. Bodily products
- c. Death
- d. None of the above

Answer: d. None of the above

285. Which brain area is NOT implicated in the neuroscience of emotion in decision-making?

- a. Amygdala
- b. vmPFC
- c. dlPFC
- d. None of the above

Answer: d. None of the above

286. Research on the effects of mood on persuasion shows many examples of:

- a. Classical conditioning
- b. Cognitive processes
- c. Automatic processes
- d. All of the above

Answer: d. All of the above

287. How can mood influence attitudes toward an argument?

- a. As an incidental cue
- b. As an influence on how the information is processed
- c. As an influence on the amount of information processed
- d. All of the above

Answer: d. All of the above

288. What kind of studies can support the idea that happiness causes success?

- a. Cross-sectional designs
- b. Longitudinal designs
- c. Both A and B
- d. Neither A nor B

Answer: b. Longitudinal designs

289. What types of stimuli are typically liked more after repeated presentation?

- a. Paintings
- b. Drawings
- c. Photographs
- d. All of the above

Answer: c. Photographs

290. Social judgments are often _____ social memory.

- a. Correlated with
- b. Uncorrelated with
- c. Based on
- d. Cues for

Answer: b. Uncorrelated with

291. This chapter is titled "From Affect to Social Cognition." What aspect of affect is particularly discussed regarding its influence on cognition?

- a. Preference.
- b. Emotion.
- c. Evaluation.
- d. Mood.

Answer: B

292. According to research on moods and helping, those in a positive mood will be encouraged to help others when _____ is/are salient. Those in negative moods will be encouraged to help others when _____ is/are salient.

- a. Rewards, guilt.
- b. Guilt, rewards.
- c. Other's good fortunes, one's own good fortunes.
- d. Both A and C.

Answer: A

293. Which of the following types of moods have been shown to most often facilitate helping behavior?

- a. Negative moods, likely because people will turn to helping behavior to make themselves feel better.
- b. Positive moods, likely because people want to maintain their positive mood by helping others.
- c. Neutral moods, likely because people are more attuned to the needs of others.
- d. All of the above.

Answer: D

294. Which of the following best describes objective self-awareness?

- a. People recalling positive material in positive moods and sometimes recalling negative material in negative moods.
- b. The experience of the self as the target of other's perceptions, often

experiencing the self as failing to live up to ideal standards.

c. One's understanding of who one should be.

d. People coping with threats to their self-worth by endorsing other, unrelated aspects of themselves, thereby addressing self-enhancement needs.

Answer: B

295. Tammy's father taught her the chords to his favorite feel-good song when she was in a bad mood one day. The next day, he asks her to play the song, and Tammy, who is still in a bad mood, cannot remember the chords. Her dad, a social psychologist, assures her that she will remember the chords when she is in a good mood. Her father's assumption aligns with which concept?

a. Mood state-dependent memory.

b. Mood-congruent memory.

c. The fundamental attribution error.

d. Negative state-relief hypothesis.

Answer: B

296. Which of the following demonstrates the mood manipulation in the Velten procedure?

a. Hypnosis.

b. Assuming positive or negative facial expressions.

c. Reading mood-relevant sentences.

d. Listening to mood-laden music.

Answer: C

297. In the affect infusion model, affect has little or no influence on which of the following processing modes?

a. Processing with direct access to prior judgment.

b. Substantive processing.

c. Motivated processing.

d. Both A and C.

Answer: D

298. Which of the following groups reliably demonstrates negative mood congruence?

a. Cheerful people.

b. Depressed people.

c. Extraverts.

d. All of the above.

Answer: B

299. Anna taught Joshua how to draw a horse one day when Joshua was sad. A few days later, Joshua can't recall how to recreate the drawing, but Anna suspects that the next time he is feeling sad, Josh will remember how to draw a horse. Anna's idea exemplifies which of the following memory phenomena:

a. Mood state-dependent memory.

b. Mood-congruent memory.

- c. The fundamental attribution error.
- d. Negative state-relief hypothesis.

Answer: A

300. Mood affects judgment, but even a person in a good mood will not have overly positive judgments:

- a. Of unattractive people.
- b. Of criminals.
- c. When they are highly involved in a situation.
- d. All of the above.

Answer: D

301. Which of the following offers an example of how negative mood affects judgment?

- a. People judge others according to positive applicable traits more when in a negative mood.
- b. Negative moods increase the perceived likelihood of future negative events.
- c. A negative mood can lead people to perceive themselves as having greater social support than they actually have.
- d. All of the above.

Answer: B

302. Which of the following emotions involves an approach orientation, optimism, risk seeking, relatively pleasant judgments when appraising the future, and a facilitation of automatic prejudices?

- a. Anger.
- b. Disgust.
- c. Fear.
- d. Sadness.

Answer: A

303. Research shows that for people high in _____, disgust leads to more severe moral judgments.

- a. Intuition.
- b. Private body consciousness (PBC).
- c. Offline cognition.
- d. Experimental demand.

Answer: B

304. The effects of mood on judgment are more reliably observed in adults than in children,

- a. True.
- b. False.

Answer: A

305. What is an illusory correlation?

- a. Simulations that increase the perceived likelihood of a potential outcome.
 - b. Simulations that reduce the perceived likelihood of a potential outcome.
 - c. Expecting a relationship between two variables when none actually exists.
 - d. The statistical fact that extreme events will, on average, be less extreme when reassessed later.
- Answer: C

306. Activation of which of the following brain areas is implicated with emotional-bodily states during decision-making activities (perhaps what we call “gut feelings”)?

- a. The amygdala.
- b. The insula.
- c. The cerebellum.
- d. The hippocampus.

Answer: B

307. What is a key factor described in the text that influences individual differences in emotional reactivity?

- a. Early life experiences.
- b. Later life experiences.
- c. Current friendships.
- d. All of the above.

Answer: A

308. Mood affects decision-making. According to research presented in the chapter, those in a positive mood are more likely to:

- a. Focus on details, neglecting the big picture.
- b. Correct their stereotypes when unmotivated.
- c. Take more risks if the possible losses are small.
- d. Both B and C.

Answer: C

309. Which of the following is most likely to facilitate creative thinking and rapid decision-making?

- a. Positive mood.
- b. Anger.
- c. Moral intuitions.
- d. Negative mood.

Answer: A

310. What does the affect-as-information approach posit?

- a. People sometimes demonstrate emotional responses to a person who resembles a significant other.
- b. Affective valence tells the self how it should evaluate a stimulus, even when the affect has an irrelevant source.
- c. One can fit a specific occasion, instance, or behavior to a more general prior concept.

d. People attempt to identify what factors give rise to what outcomes by inferring other people's dispositions and mental states from their behavior and its causes.

Answer: B

311. Troy is sitting outside of the library and sees Sam on his scooter far away near the next building. When Sam falls off his scooter, Troy thinks, "Sam is so clumsy, poor guy." But Troy doesn't realize that Sam hit a huge, indiscernible crack in the sidewalk, causing him to fall. Troy's thinking exemplifies:

- a.** The false consensus effect.
- b.** Affective transference.
- c.** The negative state-relief hypothesis.
- d.** The fundamental attribution error.

Answer: D

312. Mood's effect on persuasion varies depending on levels of the individual's:

- a.** Involvement.
- b.** Cognitive activity.
- c.** Entitativity.
- d.** Both A and B.

Answer: D

313. Which scholar proposed the separate-systems view of affect and cognition?

- a.** Joseph P. Forgas.
- b.** Klaus Fiedler.
- c.** Robert B. Zajonc.
- d.** Alice M. Isen.

Answer: C

314. Which of the following supports the separate-systems view?

- a.** The mere exposure effect.
- b.** People can know how they feel about an object before they can recognize it.

Answer: D

315. For which of the following does the mere exposure effect NOT occur reliably?

- a.** Meaningful words.
- b.** Drawings.
- c.** Polygons.
- d.** Photographs.

Answer: B

316. The mere exposure effect is stronger for supraliminal than for subliminal presentation.

- a.** True.
- b.** False.

Answer: B

317. An argument for the cognitive underpinnings of the mere exposure effect offers the mechanism of:

- a. Schema activation.
- b. Affective judgments.
- c. Evaluative content.
- d. All of the above.

Answer: A

318. One theory described in the text proposed two meanings of cognition: cognition1

- Affective judgments are difficult to _____, and verbalize.cognition2
- All of the above._____.

- a. Refers to heuristic processing, refers to substantive processing.
- b. Involves all mental activity, is intellectual knowledge acquisition.
- c. Is intellectual knowledge acquisition, involves all mental activity.
- d. Is intellectual knowledge acquisition, refers to heuristic processing.

Answer: C

319. Agricultural activity such as tilling, harvesting, heating and ventilation are direct consumers of:

- (a) Energy
- (b) Air
- (c) Sun
- (d) Heat

Ans: A

320. Compared to fear, anger makes people feel _____ about the future.

- a. Optimistic
- b. Neutral
- c. Risk-averse
- d. Pessimistic

Answer: a. Optimistic

UNIT – 9

HUMAN DEVELOPMENT AND INTERVENTIONS

Human Development and INTERVENTIONS

What is Developmental processes: Nature, Principles, Factors in development, Stages of Development. Successful aging. Theories of development: Psychoanalytical, Behavioristic, and Cognitive Various aspects of development: Sensory-motor, cognitive, language, emotional, social and moral?

DEVELOPMENTAL PROCESSES: NATURE, PRINCIPLES, FACTORS IN DEVELOPMENT, STAGES OF DEVELOPMENT. SUCCESSFUL AGING. THEORIES OF DEVELOPMENT: PSYCHOANALYTICAL, BEHAVIORISTIC, AND COGNITIVE VARIOUS ASPECTS OF DEVELOPMENT: SENSORY-MOTOR, COGNITIVE, LANGUAGE, EMOTIONAL, SOCIAL AND MORAL DEVELOPMENTAL PROCESSES: NATURE, PRINCIPLES, FACTORS IN DEVELOPMENT, STAGES OF DEVELOPMENT

AN DEVELOPMENTAL PSYCHOLOGY

Developmental psychology is the scientific study of changes that occur in human beings over the course of their lives. This field examines change and development across a broad range of topics, such as motor skills and other psycho-physiological processes; cognitive development involving areas like problem solving, moral and conceptual understanding; language acquisition; social, personality, and emotional development; and self-concept and identity formation. Developmental psychology explores the extent to which development is a result of gradual accumulation of knowledge or stage-like development, as well as the extent to which children are born with innate mental structures as opposed to learning through experience.

NATURE VERSUS NURTURE

A significant issue in developmental psychology is the relationship between the innateness of an attribute (whether it is part of our nature) and the environmental effects on that attribute (whether it is influenced by our environment, or nurture). This is often referred to as the nature vs. nurture debate, or nativism vs. empiricism. A nativist ("nature") account of development would argue that the processes in question are innate and influenced by an organism's genes. Natural human behavior is seen as the result of already-present biological factors, such as genetic code. An empiricist ("nurture") perspective would argue that these processes are acquired through interaction with the environment. Nurtured human behavior is seen as the result of environmental interaction, which can provoke changes in brain structure and chemistry. For example, situations of extreme stress can cause problems like depression. The nature vs. nurture debate seeks to understand how our personalities and traits are produced by our genetic makeup and biological factors, and how they are shaped by our environment, including our parents, peers, and culture. For instance, why do biological children sometimes act like their parents? Is it because of genetic similarity, or the result of the early childhood environment and what children learn from their parents?

INTERACTION OF GENES AND THE ENVIRONMENT

Today, developmental psychologists rarely take such polarized positions (either/or) with regard to most aspects of development; instead, they investigate the relationship between innate and environmental influences (both/and). Developmental psychologists will often use the biopsychosocial model to frame their research: this model states that biological, psychological, and social (socio-economical, socio-environmental, and cultural) factors all play a significant role in human development. We are all born with specific genetic traits inherited from our parents, such as eye color, height, and certain personality traits. Beyond our basic genotype, however, there is a deep interaction between our genes and our environment: our unique experiences in our environment influence

whether and how particular traits are expressed, and at the same time, our genes influence how we interact with our environment (Diamond, 2009; Lobo, 2008). There is a reciprocal interaction between nature and nurture as they both shape who we become, but the debate continues as to the relative contributions of each.

Heritability refers to the origin of differences among people; it is a concept in biology that describes how much of the variation of a trait in a population is due to genetic differences in that population. Individual development, even of highly heritable traits such as eye color, depends not only on heritability but on a range of environmental factors, such as the other genes present in the organism and the temperature and oxygen levels during development. Environmental inputs can affect the expression of genes, a relationship called gene-environment interaction. Genes and the environment work together, communicating back and forth to create traits.

RESEARCH METHODS

Developmental psychology employs many of the research methods used in other areas of psychology; however, infants and children cannot be tested in the same ways as adults. To study changes in individuals over time, developmental psychologists use systematic observation, including naturalistic or structured observation; self-reports, which could be clinical interviews or structured observation; clinical or case study methods; and ethnography or participant observation. Three research methods used include the experimental, correlational, and case study approach.

EXPERIMENTAL RESEARCH

The experimental method involves actual manipulation of treatments, circumstances, or events to which the participant or subject is exposed. This design points to cause-and-effect relationships and thus allows for strong inferences to be made about causal relationships between the manipulation of one or more independent variables and subsequent subject behavior. A limit to this method is that the artificial environment in which the experiment is conducted may not be applicable to the general population.

CORRELATIONAL RESEARCH

The correlational method explores the relationship between two or more events by gathering information about these variables without researcher intervention. The advantage of using a correlational design is that it estimates the strength of a relationship among variables in the natural environment. However, the limitation is that it can only indicate that a relationship exists between the variables; it cannot determine which one caused the other.

CASE STUDY

In a case study, developmental psychologists collect a great deal of information from one individual in order to better understand physical and psychological changes over his or her lifespan. Data can be collected through the use of interviews, structured questionnaires, observation, and test scores. This particular approach is an excellent way to better understand individuals who are exceptional in some way, but it is especially prone to researcher bias in interpretation, and it is difficult to generalize conclusions to the larger population.

RESEARCH DESIGNS

Regardless of whether studies employ the experimental, correlational, or case study methodology, they can use research designs or logical frameworks to make key comparisons within research studies. These include longitudinal, cross-sectional, sequential, and microgenetic designs.

LONGITUDINAL DESIGN

In a longitudinal study, a researcher observes many individuals born at or around the same time (a cohort) and carries out new observations as members of the cohort age. This method can be used to draw conclusions about which types of development are universal (or normative) and occur in most members of a cohort. Researchers may also observe ways that development varies between individuals and hypothesize the causes of such variation. Longitudinal studies often require large amounts of time and funding, making them unfeasible in some situations. Also, because members of a cohort all experience historical events unique to their generation, apparently normative developmental trends may only be universal to the cohort itself.

THE PRINCIPLES OF DEVELOPMENTAL PSYCHOLOGY

Life-span developmental psychology is the field of psychology which involves the examination of both constancy and change in human behaviour across the entire life span, that is, from conception to death (Baltes, 1987). Developmental psychologists are concerned with diverse issues ranging from the growth of motor skills in the infant, to the gains and losses observed in the intellectual functioning of the elderly.

The goal of study in developmental psychology is to further our knowledge about how development evolves over the entire life span, developing a knowledge of the general principles of development and the differences and similarities in development across individuals. The range of topics comprising the study of modern psychology is vast, and encompasses sub-areas as diverse as social psychology, comparative psychology, the study of learning, neuropsychology, abnormal psychology, and cognitive psychology.

However, the study of development is possible within each of these areas. Thus, in one sense, developmental psychology can be thought of as an approach that one takes to the broader study of psychology (Buss, 1995). This text focuses on a narrower portion of the life span, specifically, on the time development between conception and adolescence.

important in its own right but it also has the potential to significantly inform us about the nature of human development. By studying the earlier forms of a behaviour and the changes which behaviour undergoes, we can gain a better understanding of the 'end product', that is, adult behaviour. While this text does focus specifically on children's development, the wider principles of lifespan developmental psychology (which we discuss shortly) apply equally to this area as they do to the study of development across the life span.

When we speak of development, to what, in fact are we referring? One frequently used definition refers to development as patterns of change over time which begin at conception and continue throughout the life span. Development occurs in different domains, such as the biological (changes in our physical being), social (changes in our social relationships), emotional (changes in our emotional understanding and experiences), and cognitive (changes in our thought processes). Some developmental psychologists prefer to restrict the notion of development only to changes which lead to qualitative reorganizations in the structure of a behaviour, skill or ability (Crain, 2000).

For example, Heinz Werner (1957) argued that development refers only to changes which increase the organization of functioning within a domain. Werner believed that development consisted of two processes: integration and differentiation. Integration refers to the idea that development consists of the integration of more basic, previously acquired behaviours into new, higher level

structures. For example, according to Piaget (1952), the baby who learns to successfully reach for objects has learned to coordinate a variety of skills such as maintaining an upright posture, moving the arm, visually coordinating the position of the hand and the object, and grasping the object under an integrated structure called a scheme. New developments build on and incorporate what has come before. Differentiation refers to the idea that development also involves the progressive ability to make more distinctions among things, for example, learning to adjust one's grasp to pick up small objects (which requires the use of the fingers and fine motor control) versus larger objects (which only require closing the hand around the object and less fine motor control). Werner defined development as a combination of these two processes of integration and differentiation; he saw development as a process of increasing hierarchical integration and increasing differentiation. Of course, Werner's view of development is by no means universally accepted within developmental psychology. Many developmentalists argue that anything which evidences change over time is relevant to the study of development (Crain, 2000). Thus, this debate remains a tension within the study of human development.

PRINCIPLES OF LIFE-SPAN DEVELOPMENT

Paul Baltes (1987) has articulated a set of principles which guide the study of human development within a life-span framework. Baltes argues that these principles form a family of beliefs which specify a coherent view of the nature of development. It is the application of these beliefs as a coordinated whole which characterizes the life-span approach. In this book, although we focus on development in children, we will take a life-span approach to the study of development. The first of the principles which Baltes (1987) discussed is the belief that development is lifelong. This belief has two separate aspects. First, the potential for development extends across the entire life span: there is no assumption that the life course must reach a plateau or decline during adulthood and old age. Second, development may involve processes which are not present at birth but emerge throughout the life span. Development is also multidimensional and multidirectional. Multidimensionality refers to the fact that development cannot be described by a single criterion such as increases or decreases in a behaviour. The principle of multidirectionality maintains that there is no single, normal path that development must or should take. In other words, healthy developmental outcomes are achieved in a wide variety of ways.

Development is often comprised of multiple abilities which take different directions, showing different types of change or constancy. Another principle of development is the belief that development involves both gains and losses. According to Baltes, any developmental process involves aspects of growth and decline. For example, formal schooling increases a child's knowledge base and develops their cognitive abilities but also restricts their creativity as they learn to follow rules defined by others. These two aspects of growth and decline need not occur in equal strength, and, moreover, the balance between gains and losses can change with time.

Contextualism in developmental psychology As we have seen, Baltes (1987) stressed the importance of contextualism to the study of life-span development. In order to create a coherent framework for understanding contextual influences, Baltes proposed a three-factor model of contextual influences on development (Baltes, Reese, & Lipsitt, 1980). The first factor is normative age-graded influences. These are the biological and environmental influences that are similar for individuals in a particular age group. Examples of normative age-graded influences are events such as puberty or the entry into formal schooling.

A second type of influence is what Baltes referred to as normative history-graded influences. These

are biological and environmental influences associated with historical periods in time which influence people of a particular generation. For example, the effects of World War II on much of the world's population or the changes in the structure of government experienced by the people of the Soviet Union during the 1980s would constitute examples of normative history-graded influences. Nonnormative life events are unusual occurrences that have a major impact on an individual's life. The occurrence of these events is relatively unique to an individual and is not tied to a historical time period. Moreover, the influence of these events often does not follow a typical developmental course. Being struck with a major illness or losing a parent in childhood are examples of this kind of contextual influence. It is important for developmentalists to recognize that explanations of behavioural development are likely to be complex and require consideration of the wide variety of possible influences on a given individual's development.

THEMES AND ISSUES IN DEVELOPMENTAL PSYCHOLOGY

A number of major themes have emerged in the study of child development, themes which are recurrent across the various domains of study. For example, the debate over whether development is best characterized as driven by biological or environmental factors has guided study within areas as diverse as emotional, social and cognitive development. The same is true for each of the other major themes which we will examine. After you become familiar with each of the issues described here, you should think about these themes as you read Chapters 4 through 10. You should be able to identify where these themes occur when studying the areas of development discussed in the last seven chapters.

CONTINUITY AND DISCONTINUITY

An important question which continually confronts the researcher in the study of child development is how to best characterize the nature of developmental change. There are two contrasting positions on developmental change. According to those who hold to the first position, development is best viewed as a continuous process. That is, development is conceived of as a process of the gradual accumulation of a behaviour, skill, or knowledge. On this model, development proceeds in a smooth and orderly fashion, with each change building on previous abilities. In contrast, those who hold to the second view would suggest that developmental change is best characterized as discontinuous in nature. These theorists suggest that behaviours or skills often change qualitatively across time, and that new organizations of behaviours, skills, or knowledge emerge in a rather abrupt or discrete fashion.

The notion of a stage of development is central to discontinuous views of development. A stage of development can be thought of as a particular organization of the child's knowledge and behaviour that characterizes their development at a particular point in time. The movement to a new stage of development means that a qualitative reorganization of previous knowledge or behaviour has taken place. For example, Piaget (1952) believed that between 7 to 11 years of age, children's thinking could be described as concrete, in that it is closely tied to the nature of the objects with which they interact. In contrast, during adolescence, thinking becomes more abstract; it is less bound to particular objects and takes into account the possible or hypothetical. It should be clear that these two positions — development viewed as a continuous process or as a discontinuous process — describe development in quite different ways; ways that on the surface are seemingly difficult to reconcile with one another.

Siegler (1998) has argued that whether a particular aspect of development appears to be continuous or discontinuous in nature depends largely on how we choose to examine development. When we

examine the change in a given behaviour at large intervals (e.g., yearly) or in different age groups such as 4-year-olds and 8-year-olds, development will tend to look very discontinuous or stage-like. If we plotted the level of development of some skill over time, the developmental function might look like a staircase, with periods of little change followed by abrupt shifts in the level of performance. In contrast, if we were to examine the behaviour more closely, at smaller intervals, we might find that development took on a much more continuous character. That is, increases in the level of performance would be seen to occur gradually, with no abrupt shifts. We would also find that there is great variability in the methods or strategies that children use to solve problems. Siegler's (1998) own work on children's learning in the domain of mathematics shows that children often use a variety of strategies in their attempts to learn how to add together two numbers. Because learning to decide which strategies work best takes some time, the shifts between the use of different strategies is a gradual process. If we plotted the development of strategy use for addition problems, Siegler claims we would obtain a picture quite different from the staircase model just described. Instead, we would see what he calls 'overlapping waves' of development.

FACTORS IN DEVELOPMENT

Growth and Development Defined?

Although the terms growth and development are used synonymously, they have different meanings biologically. Growth refers to the incremental changes in physical characteristics such as height, weight, size, etc., while development refers to qualitative changes to growth in an orderly and meaningful fashion which results in maturity. Growth and development contribute to each other, are inseparable, and occur simultaneously. For example, most babies, by the time they grow up to be 8 months old, can weigh around 8 to 10 kilograms and can sit up.

10 Factors That Influence the Growth and Development of a Child Nature and nurture both contribute to the growth and development of children. Although what's endowed by nature is constant, nurture tends to make a big difference too. Here are a few factors affecting children's growth and development.

1. HEREDITY

Heredity is the transmission of physical characteristics from parents to children through their genes. It influences all aspects of physical appearance such as height, weight, body structure, the colour of the eye, the texture of the hair, and even intelligence and aptitudes. Diseases and conditions such as heart disease, diabetes, obesity, etc., can also be passed through genes, thereby affecting the growth and development of the child adversely. However, environmental factors and nurturing can bring the best out of the already present qualities in the genes.

2. ENVIRONMENT

The environment plays a critical role in the development of children and it represents the sum total of physical and psychological stimulation the child receives. Some of the environmental factors influencing early childhood development involve the physical surroundings and geographical conditions of the place the child lives in, as well as his social environment and relationships with family and peers. It is easy to understand that a well-nurtured child does better than a deprived one; the environment children are constantly immersed in contributes to this. A good school and a loving family build in children strong social and interpersonal skills, which will enable them to excel in other areas such as academics and extracurricular activities. This will, of course, be different for children who are raised in stressful environments.

3. SEX

The sex of the child is another major factor affecting the physical growth and development of a child. Boys and girls grow in different ways, especially nearing puberty. Boys tend to be taller and physically stronger than girls. However, girls tend to mature faster during adolescence, while boys mature over a longer period of time. The physical structure of their bodies also has differences which make boys more athletic and suited for activities that require physical rigour. Their temperaments also vary, making them show interest in different things.

4. EXERCISE AND HEALTH

The word exercise here does not mean physical exercise as a discipline or children deliberately engaging in physical activities knowing it would help them grow. Exercise here refers to the normal playtime and sports activities which help the body gain an increase in muscular strength and put on bone mass.

Proper exercise helps children grow well and reach milestones on time or sooner. Exercise also keeps them healthy and fights off diseases by strengthening the immune system, especially if they play outside. This is because outdoor play exposes them to microbes that help them build resistance and prevent allergies.

5. HORMONES

Hormones belong to the endocrine system and influence the various functions of our bodies. They are produced by different glands that are situated in specific parts of the body to secrete hormones that control body functions. Their timely functioning is critical for normal physical growth and development in children. Imbalances in the functioning of hormone-secreting glands can result in growth defects, obesity, behavioural problems and other diseases. During puberty, the gonads produce sex hormones which control the development of the sex organs and the appearance of secondary sexual characteristics in boys and girls.

6. NUTRITION

Nutrition is a critical factor in growth as everything the body needs to build and repair itself comes from the food we eat. Malnutrition can cause deficiency diseases that adversely affect the growth and development of children. On the other hand, overeating can lead to obesity and health problems in the long run, such as diabetes and heart disease. A balanced diet that is rich in vitamins, minerals, proteins, carbohydrates and fats is essential for the development of the brain and body.

7. FAMILIAL INFLUENCE

Families have the most profound impact in nurturing a child and determining the ways in which they develop psychologically and socially. Whether they are raised by their parents, grandparents or foster care, they need basic love, care and courtesy to develop as healthy functional individuals. The most positive growth is seen when families invest time, energy and love in the development of the child through activities, such as reading to them, playing with them and having deep meaningful conversations. Families that abuse or neglect children would affect their positive development. These children may end up as individuals who have poor social skills and difficulty bonding with other people as adults. Helicopter parenting also has negative effects as they render children dependent on the parents even as young adults and unable to deal with difficulties in life on their own.

8. GEOGRAPHICAL INFLUENCES

Where you live also has a great influence on how your children turn out to be. The schools they attend, the neighbourhood they live in, the opportunities offered by the community and their peer circles are some of the social factors affecting a child's development. Living in an enriching community that has parks, libraries and community centres for group activities and sports all play a role in developing the child's skills, talents, and behaviour. Uninteresting communities can push some children to not go outside often but play videogames at home instead. Even the weather of a place influences children in the form of bodily rhythms, allergies and other health conditions.

9. SOCIO-ECONOMIC STATUS

The socio-economic status of a family determines the quality of the opportunity a child gets. Studying in better schools that are more expensive definitely has benefits in the long run. Well-off families can also offer better learning resources for their children and they afford special aid if the kids need it. Children from poorer families may not have access to educational resources and good nutrition to reach their full potential. They may also have working parents who work too many hours and cannot invest enough quality time in their development.

10. LEARNING AND REINFORCEMENT

Learning involves much more than schooling. It is also concerned with building the child up mentally, intellectually, emotionally, and socially so they operate as healthy functional individuals in the society. This is where the development of the mind takes place and the child can gain some maturity. Reinforcement is a component of learning where an activity or exercise is repeated and refined to solidify the lessons learned. An example is playing a musical instrument; they get better at playing it as they practice playing the instrument. Therefore, any lesson that is taught has to be repeated until the right results are obtained.

STAGES OF DEVELOPMENT

What aspects of ourselves change and develop as we journey through life? We move through significant physical, cognitive, and psychosocial changes throughout our lives—do these changes happen in a systematic way, and to everyone? How much is due to genetics and how much is due to environmental influences and experiences (both within our personal control and beyond)? Is there just one course of development or are there many different courses of development? In this module, we'll examine these questions and learn about the major stages of development and what kind of developmental tasks and transitions we might expect along the way.

DEFINING HUMAN DEVELOPMENT IN STAGES

Human development refers to the physical, cognitive, and psychosocial development of humans throughout the lifespan. What types of development are involved in each of these three domains, or areas, of life? Physical development involves growth and changes in the body and brain, the senses, motor skills, and health and wellness. Cognitive development involves learning, attention, memory, language, thinking, reasoning, and creativity. Psychosocial development involves emotions, personality, and social relationships.

PHYSICAL DOMAIN

Many of us are familiar with the height and weight charts that pediatricians consult to estimate if babies, children, and teens are growing within normative ranges of physical development. We may also be aware of changes in children's fine and gross motor skills, as well as their increasing coordination, particularly in terms of playing sports. But we may not realize that physical development also involves brain development, which not only enables childhood motor coordination but also

greater coordination between emotions and planning in adulthood, as our brains are not done developing in infancy or childhood. Physical development also includes puberty, sexual health, fertility, menopause, changes in our senses, and primary versus secondary aging. Healthy habits with nutrition and exercise are also important at every age and stage across the lifespan.

COGNITIVE DOMAIN

If we watch and listen to infants and toddlers, we can't help but wonder how they learn so much so fast, particularly when it comes to language development. Then as we compare young children to those in middle childhood, there appear to be huge differences in their ability to think logically about the concrete world around them. Cognitive development includes mental processes, thinking, learning, and understanding, and it doesn't stop in childhood. Adolescents develop the ability to think logically about the abstract world (and may like to debate matters with adults as they exercise their new cognitive skills!). Moral reasoning develops further, as does practical intelligence—wisdom may develop with experience over time. Memory abilities and different forms of intelligence tend to change with age. Brain development and the brain's ability to change and compensate for losses is significant to cognitive functions across the lifespan, too.

PSYCHOSOCIAL DOMAIN

Development in this domain involves what's going on both psychologically and socially. Early on, the focus is on infants and caregivers, as temperament and attachment are significant. As the social world expands and the child grows psychologically, different types of play and interactions with other children and teachers become important. Psychosocial development involves emotions, personality, self-esteem, and relationships. Peers become more important for adolescents, who are exploring new roles and forming their own identities. Dating, romance, cohabitation, marriage, having children, and finding work or a career are all parts of the transition into adulthood. Psychosocial development continues across adulthood with similar (and some different) developmental issues of family, friends, parenting, romance, divorce, remarriage, blended families, caregiving for elders, becoming grandparents and great grandparents, retirement, new careers, coping with losses, and death and dying.

As you may have already noticed, physical, cognitive, and psychosocial development are often interrelated, as with the example of brain development. We will be examining human development in these three domains in detail throughout the modules in this course, as we learn about infancy/toddlerhood, early childhood, middle childhood, adolescence, young adulthood, middle adulthood, and late adulthood development, as well as death and dying.

KEY ISSUES IN HUMAN DEVELOPMENT

There are many different theoretical approaches regarding human development. As we evaluate them in this course, recall that human development focuses on how people change, and the approaches address the nature of change in different ways:

- Is the change smooth or uneven (continuous versus discontinuous)?
- Is this pattern of change the same for everyone, or are there different patterns of change (one course of development versus many courses)?
- How do genetics and environment interact to influence development (nature versus nurture)?

IS DEVELOPMENT CONTINUOUS OR DISCONTINUOUS?

Continuous development views development as a cumulative process, gradually improving on existing skills (Figure 2). With this type of development, there is a gradual change. Consider, for

example, a child's physical growth: adding inches to their height year by year. In contrast, theorists who view development as **discontinuous** believe that development takes place in unique stages and that it occurs at specific times or ages. With this type of development, the change is more sudden, such as an infant's ability to demonstrate awareness of object permanence (which is a cognitive skill that develops toward the end of infancy, according to Piaget's cognitive theory—more on that theory in the next module). Stage theories hold that the sequence of development is universal. For example, in cross-cultural studies of language development, children from around the world reach language milestones in a similar sequence (Gleitman & Newport, 1995). Infants in all cultures coo before they babble. They begin babbling at about the same age and utter their first word around 12 months old. Yet we live in diverse contexts that have a unique effect on each of us. For example, researchers once believed that motor development followed one course for all children regardless of culture. However, childcare practices vary by culture, and different practices have been found to accelerate or inhibit the achievement of developmental milestones such as sitting, crawling, and walking (Karasik, Adolph, Tamis-LeMonda, & Bornstein, 2010).

For instance, let's look at the Aché society in Paraguay. They spend a significant amount of time foraging in forests. While foraging, Aché mothers carry their young children, rarely putting them down in order to protect them from getting hurt in the forest. Consequently, their children walk much later: They walk around 23–25 months old, in comparison to infants in Western cultures who begin to walk around 12 months old. However, as Aché children become older, they are allowed more freedom to move about, and by about age 9, their motor skills surpass those of U.S. children of the same age: Aché children are able to climb trees up to 25 feet tall and use machetes to chop their way through the forest (Kaplan & Dove, 1987). As you can see, our development is influenced by multiple contexts, so the timing of basic motor functions may vary across cultures. However, the functions are present in all societies.

PERIODS OF HUMAN DEVELOPMENT

Think about the lifespan and make a list of what you would consider the basic periods of development. How many periods or stages are on your list? Perhaps you have three: childhood, adulthood, and old age. Or maybe four: infancy, childhood, adolescence, and adulthood. Developmentalists often break the lifespan into eight stages:

1. Prenatal Development
2. Infancy and Toddlerhood
3. Early Childhood
4. Middle Childhood
5. Adolescence
6. Early Adulthood
7. Middle Adulthood
8. Late Adulthood

In addition, the topic of "Death and Dying" is usually addressed after late adulthood since overall, the likelihood of dying increases in later life (though individual and group variations exist). Death and dying will be the topic of our last module, though it is not necessarily a stage of development that occurs at a particular age. The list of the periods of development reflects unique aspects of the various stages of childhood and adulthood that will be explored in this book, including physical, cognitive, and psychosocial changes. So while both an 8-month-old and an 8-year-old are considered children, they have very different motor abilities, cognitive skills, and social relationships. Their

nutritional needs are different, and their primary psychological concerns are also distinctive. The same is true of an 18-year-old and an 80-year-old, both considered adults. We will discover the distinctions between being 28 or 48 as well. But first, here is a brief overview of the stages.

PRENATAL DEVELOPMENT

Conception occurs and development begins. There are three stages of prenatal development: germinal, embryonic, and fetal periods. All of the major structures of the body are forming and the health of the mother is of primary concern. There are various approaches to labor, delivery, and childbirth, with potential complications of pregnancy and delivery, as well as risks and complications with newborns, but also advances in tests, technology, and medicine. The influences of nature (e.g., genetics) and nurture (e.g., nutrition and teratogens, which are environmental factors during pregnancy that can lead to birth defects) are evident. Evolutionary psychology, along with studies of twins and adoptions, help us understand the interplay of factors and the relative influences of nature and nurture on human development.

INFANCY AND TODDLERHOOD

The first year and a half to two years of life are ones of dramatic growth and change. A newborn, with many involuntary reflexes and a keen sense of hearing but poor vision, is transformed into a walking, talking toddler within a relatively short period of time. Caregivers similarly transform their roles from those who manage feeding and sleep schedules to constantly moving guides and safety inspectors for mobile, energetic children. Brain development happens at a remarkable rate, as does physical growth and language development. Infants have their own temperaments and approaches to play. Interactions with primary caregivers (and others) undergo changes influenced by possible separation anxiety and the development of attachment styles. Social and cultural issues center around breastfeeding or formula-feeding, sleeping in cribs or in the bed with parents, toilet training, and whether or not to get vaccinations.

EARLY CHILDHOOD

Early childhood is also referred to as the preschool years, consisting of the years that follow toddlerhood and precede formal schooling, roughly from around ages 2 to 5 or 6. As a preschooler, the child is busy learning language (with amazing growth in vocabulary), is gaining a sense of self and greater independence, and is beginning to learn the workings of the physical world. This knowledge does not come quickly, however, and preschoolers may initially have interesting conceptions of size, time, space and distance, such as demonstrating how long something will take by holding out their two index fingers several inches apart. A toddler's fierce determination to do something may give way to a four-year-old's sense of guilt for doing something that brings the disapproval of others.

MIDDLE CHILDHOOD

The ages of 6-11 comprise middle childhood and much of what children experience at this age is connected to their involvement in the early grades of school. Now the world becomes one of learning and testing new academic skills and assessing one's abilities and accomplishments by making comparisons between self and others. Schools participate in this process by comparing students and making these comparisons public through team sports, test scores, and other forms of recognition. The brain reaches its adult size around age seven, but it continues to develop. Growth rates slow down and children are able to refine their motor skills at this point in life. Children also begin to learn about social relationships beyond the family through interaction with friends and fellow students; same-sex friendships are particularly salient during this period.

The theory of psychosocial development created by Erik Erikson is one of the best-known personality theories. The theory differs from many others in that it addresses development across the entire lifespan, from birth through death. At each stage, the individual deals with a conflict that serves as a turning point in development. When the conflict is resolved successfully, the person is able to develop the psychosocial quality associated with that particular stage of development. Learn about each psychosocial stage, including the conflict confronted and the major events that occur during each point of development.

STAGE 1: TRUST VERSUS MISTRUST

Trust versus mistrust is the earliest psychosocial stage that occurs during the first year or so of a child's life. During this critical phase of development, an infant is utterly dependent upon his or her caregivers. When parents or caregivers respond to a child's needs in a consistent and caring manner, the child then learns to trust the world and the people around him.

STAGE 2: AUTONOMY VERSUS SHAME AND DOUBT

The second psychosocial stage involves the conflict between autonomy and shame or doubt. As the child enters the toddler years, gaining a greater sense of personal control becomes increasingly important. Tasks such as learning how to use the toilet, selecting foods and choosing toys are ways that children gain a greater sense of independence.

STAGE 3: INITIATIVE VERSUS GUILT

The third psychosocial stage is known as initiative versus guilt and occurs between the ages of about three and five. This stage is centered on developing a sense of self-initiative. Children who are allowed and encouraged to engage in self-directed play emerge with a sense of strong initiative, while those who are discouraged may begin to feel a sense of guilt over their self-initiated activities.

STAGE 4: INDUSTRY VERSUS INFERIORITY

During middle childhood between the ages of about six and eleven, children enter the psychosocial stage known as industry versus inferiority. As children engage in social interaction with friends and academic activities at school, they begin to develop a sense of pride and accomplishment in their work and abilities. Children who are praised and encouraged to develop a sense of competence. Those who are discouraged are left with a sense of inferiority.

STAGE 5: IDENTITY VERSUS CONFUSION

In the fifth psychosocial stage is centered on identity versus role confusion. At this point in development, the formation of a personal identity becomes critical. During adolescence, teens explore different behaviors, roles, and identities. Erikson believed that this stage was particularly crucial and that forging a strong identity serves as a basis for finding future direction in life. Those who find a sense of identity feel secure, independent and ready to face the future, while those who remain confused may feel lost, insecure and unsure of their place in the world.

SUCCESSFUL AGING

One of the major achievements of medical science over the last few centuries is an extension of life expectancy. Historically, almost all religions practices have valued long life. Some of the religions emphasize disengagement/detachment in the old age as frailty becomes inevitable. However, till recent times, researchers did not discuss much about how best to live long life. Over the years, there is an emphasis on not just having for long only but also having disease-free long life. Fortunately, the life expectancy has also increased in India. Compared to life expectancy of 32 years at the time

of independence, it was estimated to be 65 years for the year 2011. Those aged >60 years formed 5.5% of the total population in 1951, which increased to 8.5% in 2011 and it is projected that by 2050, elderly will form 19% of the total population, with higher growth for those aged ≥80 years. However, should we be happy with increase in life expectancy and proportion of elderly only or should we focus on aging healthily. Unfortunately, there is no focus on healthy aging in India. In this editorial, an attempt is made to understand the concept of successful aging and in the end an attempt is made to understand the relevance to India.

In the Western world, before 1980s, much of the discussion in relation to aging was on distinction between the pathological and nonpathological aging with focus on having or not having diseases or disabilities. The basic understanding was that those who were free from disease and disability, other age-related physical functions, and cognitive functions were normal, which was primarily determined by the genetic factors.

However, this concept was challenged, and one of the major concepts which have emerged over the last three decades or so is successful aging. In a landmark article, Rowe and Kahn introduced the term successful aging and distinguished usual aging from "successful aging." They considered successful aging to include three main components, i.e., having low probability of disease and associated disability, high cognitive and physical functioning, and active engagement with life.

They further emphasized that successful aging does not merely involve the absence of disease or maintenance of functional capabilities, but requires combination of both along with active engagement with life. Thus, although maintenance of functional capacities and low risk for disease are very important, their combination with active engagement is considered central for defining successful aging. On the basis of this definition, research started in this area, and many authors evaluated the model of Rowe and Kahn and it was soon realized that very few older people fulfilled all the three components of successful aging. Further, some of the researchers criticized the concept that the model of Rowe and Kahn and suggested that the model downplayed the importance of genetics and species-determined deterioration of late life, did not lay emphasis on spirituality and subjective well-being.

Further, it was suggested that from a life-span developmental perspective, successful aging model failed to address losses, gains, and balance in later life. Over the years, many researchers developed their own model for and described different components of successful aging. In fact, the concept was also referred differently, i.e. the various synonymous terms used include positive aging, active aging, aging well, healthy aging, optimum aging, productive aging, vital aging, and robust aging. In recent decades, the most popular term in the United States has been successful aging and that in Europe has been active aging.

There is no universally accepted definition of successful aging. In fact, in a review of quantitative studies on successful aging in 2006, it was reported that there were at least 29 different definitions of the concept and most of these definitions focused on physical health. The various components considered by these definitions include disability/physical functioning (26 definitions), cognitive functioning (13 definitions), life satisfaction/well-being (9 definitions), social/productive engagement (8 definitions), presence of illness (6 definitions), longevity (4 definitions), self-rated health (3 definitions), personality (2 definitions), environment/finances (2 definitions), and self-rated successful aging (2 definitions). Based on the definition, the prevalence of successful agers in different studies ranged from 0.4% to 95%.

In a systematic review of lay perspectives of successful ageing, three components, i.e., biomedical (physical functioning/disability, cognitive functioning/disability, affective status, presence/probability of disease, mental health, and longevity), psychosocial (personal resources, engagement, life satisfaction/well-being, support system, and independence/autonomy), and extrinsic factors (environment, finances-income, and financial security) were identified. The authors reported that from lay perspective psychosocial components, notably engagement (e.g., social engagement), and personal resources (e.g., attitude) are the important components of successful aging, more often than "physiological" components, such as longevity or physical functioning.

THEORIES OF DEVELOPMENT: PSYCHOANALYTICAL

When child development experts talk about the study of development, they have in mind some fundamental theories of development that were codified by brilliant clinicians and scientists well before we had the technology to correlate them to brain development. In this post, we'll pay homage to these theorists. After all, every clinician who works with kids routinely and almost reflexively thinks of these scholars. The irony is that the theories are so pervasive and useful, that often the beginnings of these theories are lost in the story. Understanding how these theories came into being can therefore help to direct therapists and parents when they're deciding how best to understand their children.

Roughly speaking, these theories can be categorized as emotional, cognitive and moral. Erik Erikson developed the most common theories of emotional development. Jean Piaget developed the most common theories of cognitive development. And, Lawrence Kohlberg developed the dominant theories of moral development. Let's look at Erikson first. Erikson saw the world as a series of age-matched developmental crises, and he conceptualized these crises as binary and competing values. He didn't think of the crises as bad things; rather, each crisis represented an opportunity to move forward.

Infancy, for example, is characterized by Trust (a positive value) versus Mistrust (a negative value). Adolescence is a battle between Identity Formation (good) versus Role Diffusion (bad). According to Erickson, if these binary crises are not successfully negotiated—if an infant, for instance, can't trust the adults of the world to keep him warm and fed and held—then that infant will grow up with a fundamental lack of trust, and at some point, will have to actively address this issue. These ideas actually stem directly from the psychoanalytic notions that Sigmund Freud put on the map, namely that past experience influences future feelings and behaviors. Erickson studied children and adults, and he characterized each stage of development as follows:

Hope: Trust vs. Mistrust (2 years) **Will:** Autonomy vs. Shame & Doubt (2-4 years) **Purpose:** Initiative vs. Guilt (Preschool, 4-5 years) **Competence:** Industry vs. Inferiority (5-12 years) **Fidelity:** Identity vs. Role Confusion (13-19 years) **Love:** Intimacy vs. Isolation (20-40 years) **Care:** Generativity vs. Stagnation (40-64 years) **Wisdom:** Ego Integrity vs. Despair (65-death) You can see from the bold print that Erickson associated certain personality characteristics with successful passage through these crises. He called these characteristics values. The infant who can trust, develops hope; the young adult who can be intimate, develops the capacity to love. In this sense, Erickson created a mechanism by which different individuals can be developmentally assessed. The adult who feels ashamed is automatically thrown back to the age where she first experienced shame; as shame occurs at around age 2 to 4, Erickson would argue that the ashamed adult will more likely act like a toddler. And, an adult behaving like a toddler gets into more trouble. This helps to

provide a roadmap for the clinician.

This way of looking at development has its critics. Many have argued that Erickson's theories are primarily Western, and as the world becomes more multi-cultural, one must be wary of the generalizations that Erickson's work might engender. Not all cultures, for example, view adolescence as a time for identity formation. Gil Noam, an internationally-known developmental psychologist at Harvard, has noted as well that Erickson seemed to skip an important stage between the values of **competence** and **fidelity**. Noam notes that young adolescents, or middle school kids, are less concerned with who they are as individuals, and more with what group defines them—hence, the emphasis on popularity in middle school. Noam calls this the "Psychology of Belonging," and he has shown through numerous studies that young teens can be helped most by being made to feel that they belong.

Jean Piaget is the next theorist we'll discuss. Piaget was more interested in how kids change the way they think about the world; that's why he is considered the father of cognitive development. Piaget watched how kids figure things out. He noticed that when kids are teeny, they do lots of touching and tasting. From this, he decided that very young kids learn about their new world by doing simple experiments. What does that cat feel like? How does the side of the table taste? After that, he felt that children moved onto a more binary view of the world. He noticed that school-aged kids rarely abstract; in today's world, for example, four fouls is an out every single time in first grade. He decided, therefore, that young school-aged kids are focused primarily on a black-and-white view of the world.

But then he noticed that as that first grader moves through elementary school, her views of the world change; at first, four fouls is an out every single time. By second grade, four fouls is an out because those are the rules that are used to keep the game fun. By third grade, four fouls is an out, but that rule doesn't have to be; in fact, by third grade, lots of energy is used in discussing the possible variations in the rules. By sixth grade, kids start to eschew the rules altogether. To heck with the rules, they say—We make the rules.

And just like that, Piaget noticed that with the onset of adolescence emerged the capacity to abstract. Think of the shift, in just six years, from "the rules are the rules because they're the rules," to "we make the rules." Piaget categorized the way kids make sense of the world like this: **Preoperational** (ages 2-7) – Lots of gray matter, much less white matter **Concrete Operational** (ages 7-11) – White matter starts to connect in linear patterns **Formal Operations** (ages 11+) – Gray matter decreases as white matter flowers. Of course, Piaget couldn't have made the notations you read above about the changes in gray and white matter; But, it turns out the Piaget's theories correlate exactly with the neurobiology that he didn't yet have the tools to understand when he was writing in the early part of the 20th century.

All of this helped to set the stage for Lawrence Kohlberg (he came after Erickson and Piaget, but actually worked directly with Erickson). Kohlberg decided that if kids move along their development both emotionally and cognitively, then they must also move forward morally.

PSYCHOANALYTIC THEORY

Stages of Psychoanalytic Theory:

I. SIGMUND FREUD'S PSYCHOSEXUAL STAGES:

Freud believed our most basic drive is the sex drive. If you believe that biologically speaking the goal of our lives is to pass on our genes, then you might agree with Freud that the sex drive is central to everything else. He outlined five stages in child and adolescent development, which he called psychosexual stages.

At each of these stages, sexual energy is invested in a different part of the body, and gratification of the urges associated with those areas of the body is particularly pleasurable. He labelled these stages the oral, anal, phallic, latency, and genital stages. He believed that the way in which gratification of urges is handled during each of these stages determines the nature of an adult's personality and character.

Disturbances in any of the stages can result in psychological disturbance in adulthood. We will describe these stages and Freud's ideas about the effects later in life if development during these stages does not go well. The oral stage lasts from birth to about 18 months of age. The zone of pleasure is the mouth. A baby for whom taking in food is not pleasurable might not survive. If you give a 6-month-old baby a toy, what is the first thing she is likely to do? Toy makers are aware that children are likely to put anything in their mouths and warn us against giving them toys with small parts that can cause choking.

Freud developed the idea that someone can get "stuck" or fixated in one of the first three psychosexual stages of early childhood. That person will then exhibit characteristics of that stage later in life. For example, an individual who is fixated in the oral stage may want to continue to try to satisfy his oral urges by overeating or smoking.

Many of us have some remnants of this stage as we chew on our fingers or pencils; however, a fixation is really only a concern when it interferes with adaptive functioning in some critical way. The anal stage lasts from 18 months to 3 years. At this age the pleasure center moves to the anus, and issues of toilet training become central. Although many of us squirm to think of the anus as a pleasure center, we have only to listen to the "poopy talk" of young children to see the hilarity it brings about. The task of the child at this age is to learn to control his bodily urges to conform to society's expectations.

A person who is fixated at this stage may become over controlled as an adult. Everything must be in its proper place to an extreme degree. Conversely, someone might become "anal explosive," creating "messes" wherever he goes. The phallic stage lasts from 3 to 6 years of age. At this stage Freud believed that the paths followed by boys and girls diverge in ways that have been extremely controversial. We will first look at the path for boys. A boy's pleasure becomes focused on the penis. Many parents must patiently explain to their little boy that he cannot keep his hand in his pants while out in company.

Later during this stage the boy develops what Freud called the Oedipus complex, named after the character from Greek mythology that unknowingly killed his own father and married his mother. The boy focuses all his affections on his mother and becomes angry at his father, who stands in the way of the child's sole possession of her. However, in the normal course of events, the boy becomes uncomfortable with this anger at his father. Rather than experiencing the anger, he projects the feeling onto his father and fears that his father is angry at him. In this stage when he is focused on his own penis, the retribution he imagines from his father is that he will cut off the boy's penis.

Consequently, the boy develops what Freud called castration anxiety. In order to avoid this fate, the boy gives up his dream of marrying his mother and decides to become like or identify with his

father. A man who does not resolve the Oedipus complex may become fixated in this stage.

He may find rivalry or competition with other men overwhelming, as he doubts his ability to measure up to others. He may also find it difficult to have intimate relations with women, as they remind him of forbidden impulses toward his mother.

For girls, the picture is much more complicated and controversial, even for therapists who practice psychoanalysis. In the phallic stage, Freud believed that girls come to believe that they once had a penis and that it was cut off, leaving them with penis envy. Girls go through a similar complex, called the Electra complex, in which they want to marry their fathers and do away with their mothers.

Freud believed that girls must learn to identify with their mothers, whom they see as damaged in the same way that they themselves are. The only way in which they will achieve a sense of wholeness when they produce a penis by having a baby boy. Freud believed that girls must accept their passive, receptive nature and those who do not adequately resolve the Electra complex might try to overcome their feelings of inferiority by being too assertive and masculine.

The critique of Freud's view of female development has been fierce, even from the early days of the development of psychoanalytic theory. Female psychoanalysts have argued that this explanation of female development has more to do with a little boy's view of girls than the girl's view of herself.

They also have argued that boys and men are just as jealous of women's ability to give birth as girls are of a boy's penis. Feminist Gloria Steinem satirized Freud's treatment of women by proposing a

version of psychoanalytic theory developed by a fictional "Phyllis Freud," based on womb and breast envy rather than penis envy.

The latency stage occurs between 6 and 12 years of age. Latent means inactive, and Freud believed that during this time the sex drive goes underground. Children move from their fantasies in the phallic period of marrying their parent to a new realization that they must take the long road toward learning to become a grown-up.

The sex drive provides energy for the learning that must take place but is not expressed overtly. Children transfer their interest from parents to peers. At this age children who had cross-sex friendships often relinquish them as boys and girls learn the meaning of "cooties" and each sex professes disgust for the other. This separation of the sexes begins to change at age 12, when young adolescents enter the genital stage. At this point, sexual energy is focused on the genital area, and true sexual interest occurs between peers.

II. ERIK ERIKSON'S PSYCHOSOCIAL STAGES:

Many of the people who initially studied and worked with Freud have gone on to change psychoanalytic theory in significant ways. Erik Homburger Erikson is one of the most influential. Erikson focused more on issues of the ego rather than the id. Ego means "I" or "self," and Erikson's major focus was on the development of identity.

He described a series of stages based on issues that arise during the process of psychosocial development. Erikson describes psychosocial stages because these issues are rooted in social

experiences that are typical of each stage of development rather than in sexual urges. At each age he believed that there is a central conflict to be resolved and the way in which we resolve that conflict lays the groundwork for the next stages of our development. For example, Erikson believed that infants have to establish trust in the world around them, while toddlers have to struggle with developing autonomy, or a level of independence from their parents.

The other important aspect of Erikson's theory is that he believed that development does not stop in adolescence. He went beyond Freud's stages to add three stages of adulthood. He was the first theorist to acknowledge that we continue to grow and develop throughout our lives.

MODERN APPLICATIONS OF PSYCHOANALYTIC THEORY:

Although psychoanalytic theory has been controversial, ideas that come from psychoanalytic theory are still very influential, particularly in relation to the study of the development of mental and emotional disorders, a field known as developmental psychopathology. Many psychotherapists continue to use therapy that is designed to uncover inner conflicts from earlier life experiences, especially early trauma, as the basis for current psychological symptoms. A number of modern theories and therapeutic approaches also have their roots in concepts taken from psychoanalytic theory.

If you take advanced courses in psychology, you are likely to learn more about some of these approaches. Evidence from other types of research that follow the scientific method has yielded mixed results. Some ideas have been supported by research, and others have not. Erikson's ideas about the effect of social experiences on the development of personality throughout the life span have remained an important influence in the field of child development. A number of his ideas have influenced contemporary child care practices and our understanding of how development occurs as a series of interrelated experiences.

For instance, we urge new parents to be sensitive and responsive to their infants as a way to establish a sense of trust, as Erikson described. We better understand the challenge of adolescence when we see it as a struggle to establish a coherent sense of individual identity. These concepts have also been used to help in the treatment of children with emotional disturbances by providing a framework for understanding the central issues to be dealt with at different ages.

BEHAVIORIST APPROACH

Behaviorism is a theory of learning which states all behaviors are learned through interaction with the environment through a process called conditioning. Thus, behavior is simply a response to environmental stimuli. Behaviorism is only concerned with observable stimulus-response behaviors, as they can be studied in a systematic and observable manner.

The behaviorist movement began in 1913 when John Watson wrote an article entitled 'Psychology as the behaviorist views it,' which set out a number of underlying assumptions regarding methodology and behavioral analysis:

ALL BEHAVIOR IS LEARNED FROM THE ENVIRONMENT:

Behaviorism emphasizes the role of environmental factors in influencing behavior, to the near exclusion of innate or inherited factors. This amounts essentially to a focus on learning. We learn new behavior through classical or operant conditioning (collectively known as 'learning theory'). Therefore, when born our mind is 'tabula rasa' (a blank slate).

PSYCHOLOGY SHOULD BE SEEN AS A SCIENCE:

Theories need to be supported by empirical data obtained through careful and controlled

observation and measurement of behavior. Watson (1913) stated that: 'Psychology as a behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is ... prediction and control.' (p. 158). The components of a theory should be as simple as possible. Behaviorists propose the use of operational definitions (defining variables in terms of observable, measurable events). Behaviorism is primarily concerned with observable behavior, as opposed to internal events like thinking and emotion: While behaviorists often accept the existence of cognitions and emotions, they prefer not to study them as only observable (i.e., external) behavior can be objectively and scientifically measured. Therefore, internal events, such as thinking should be explained through behavioral terms (or eliminated altogether).

There is little difference between the learning that takes place in humans and that in other animals: There's no fundamental (qualitative) distinction between human and animal behavior. Therefore, research can be carried out on animals as well as humans (i.e., comparative psychology). Consequently, rats and pigeons became the primary source of data for behaviorists, as their environments could be easily controlled.

BEHAVIOR IS THE RESULT OF STIMULUS-RESPONSE:

All behavior, no matter how complex, can be reduced to a simple stimulus-response association). Watson described the purpose of psychology as: 'To predict, given the stimulus, what reaction will take place; or, given the reaction, state what the situation or stimulus is that has caused the reaction.' (1930, p. 11).

TYPES OF BEHAVIORISM

Historically, the most significant distinction between versions of behaviorism is that between Watson's original 'methodological behaviorism,' and forms of behaviorism later inspired by his work, known collectively as neobehaviorism (e.g., radical behaviorism).

METHODOLOGICAL BEHAVIORISM

Watson's article 'Psychology as the behaviorist views it' is often referred to as the 'behaviorist manifesto,' in which Watson (1913, p. 158) outlines the principles of all behaviorists: 'Psychology as the behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is the prediction and control of behavior. Introspection forms no essential part of its methods, nor is the scientific value of its data dependent upon the readiness with which they lend themselves to interpretation in terms of consciousness. The behaviorist, in his efforts to get a unitary scheme of animal response, recognizes no dividing line between man and brute. The behavior of man, with all of its refinement and complexity, forms only a part of the behaviorist's total scheme of investigation'.

RADICAL BEHAVIORISM

Radical behaviorism was founded by B.F Skinner and agreed with the assumption of methodological behaviorism that the goal of psychology should be to predict and control behavior. Skinner, like Watson, also recognized the role of internal mental events, and while he agreed such private events could not be used to explain behavior, he proposed they should be explained in the analysis of behavior. Another important distinction between methodological and radical behaviorism concerns the extent to which environmental factors influence behavior. Watson's (1913) methodological behaviorism asserts the mind is *tabula rasa* (a blank slate) at birth. In contrast, radical behaviorism accepts the view that organisms are born with innate behaviors, and thus recognizes the role of genes and biological components in behavior.

THE HISTORY OF BEHAVIORISM

- Pavlov (1897) published the results of an experiment on conditioning after originally studying digestion in dogs.
- Watson (1913) launches the behavioral school of psychology, publishing an article, Psychology as the behaviorist views it.
- Watson and Rayner (1920) conditioned an orphan called Albert B (aka Little Albert) to fear a white rat.
- Thorndike (1905) formalized the Law of Effect.
- Skinner (1936) wrote The Behavior of Organisms and introduced the concepts of operant conditioning and shaping.
- Clark Hull's (1943) Principles of Behavior was published.
- B.F. Skinner (1948) published Walden Two, in which he described a utopian society founded upon behaviorist principles.
- Journal of the Experimental Analysis of Behavior begun in 1958.
- Chomsky (1959) published his criticism of Skinner's behaviorism, "Review of Verbal Behavior."
- Bandura (1963) publishes a book called the Social Learning Theory and Personality development which combines both cognitive and behavioral frameworks.
- B.F. Skinner (1971) published his book, Beyond Freedom and Dignity, where he argues that free will is an illusion.

COGNITIVE DEVELOPMENT

Children grow and develop rapidly in their first five years across the four main areas of development. These areas are motor (physical), language and communication, cognitive and social/emotional. Cognitive development means how children think, explore and figure things out. It is the development of knowledge, skills, problem solving and dispositions, which help children to think about and understand the world around them. Brain development is part of cognitive development. As a parent, it is important to foster your child's cognitive development as soon as he/she is born because doing so provides the foundation for your child's success in school and later in life. For example, research shows that children who can distinguish sounds at six months of age are better at acquiring the skills for learning to read at four and five years of age. To promote your child's cognitive development, it is important that you actively engage in quality interactions on a daily basis. Examples include:

- Talking with your baby and naming commonly used objects.
- Letting your baby explore toys and move about.
- Singing and reading to your baby.
- Exposing your toddler to books and puzzles.
- Expanding on your child's interests in specific learning activities. For example, your toddler might show an early interest in dinosaurs, so you can take him/her on a trip to the natural history museum to learn more about the time that these creatures roamed the earth.
- Answering your child's "why" questions.

Another way that you can foster your child's cognitive development is to provide him/her with choices and prompt him/her to make thoughtful decisions. You should also allow your child to explore different ways of solving problems. While you may want to provide some gentle guidance and encouragement, allow your child some time to figure out things, like a new puzzle. This may require some patience on your part, but it will ultimately help him/her to learn.

SENSORY MOTOR ACTIVITIES

The foundation of growth, development, and learning in a child starts with sensory and motor interaction with the world. The brain is built from the bottom up and this starts with movement and sensory exploration. Sensory stimulation and feedback drive the brain, but the motor system drives sensory stimulation—you can't have one without the other. This is at the core of everything we do at Brain Balance Achievement Centers. It is crucial to improve motor skills, sensory detection, and processing before any higher learning, behavioral or academic changes can truly happen.

MOTOR SKILLS

In almost every case, children who have been assessed with a developmental deficit in one or more areas are the kids who struggle with learning or behavioral issues. Invariably, these kids are the ones with inadequately developed sensory and motor systems. We often see they are uncoordinated, clumsy, and awkward with their gait. Motor activities involve a number of different skills, including:

- Muscle tone, strength, and coordination
- Rhythm and timing
- Bilateral coordination
- Gross and fine-motor skills
- Primitive and postural reflexes
- Eye-muscle balance and coordination
- Vestibular balance and posture

SENSORY SKILLS

Much like underdeveloped motor skills, the same applies when there are atypical sensory deficits — smell, touch, vision, hearing, and balance. No sensory function works in isolation. All the senses are dependent on other sensory functions, which are dependent on a baseline and acceptable level of development. Engaging our senses is a powerful way to engage our brain. At BB we engage the senses:

- Smell
- Touch
- Vestibular (inner ear)
- Proprioception (the ability to know where one's body is in space)
- Balance and spatial perception

At Brain Balance Achievement Centers, we assess all of these skills with standardized and accepted testing and we quantify them by grade, age, or functional level. Our program then works to integrate sensory input and strengthen motor skills through the frequency and duration of activities.

SENSORY AND MOTOR DEVELOPMENT, AGES 1 TO 12 MONTHS

Sensory and motor development is the gradual process by which a child gains use and coordination of the large muscles of the legs, trunk, and arms, and the smaller muscles of the hands. A baby begins to experience new awareness through sight, touch, taste, smell, and hearing. Babies' sensory and motor development generally follows a typical pattern:

- At 1 month of age, babies' neck muscles are not developed enough to support their heads for prolonged periods of time. Babies can lift their heads only briefly when lying on their stomachs. Limb movements are influenced by newborn reflexes, such as the startle reflex, which makes a

baby throw out his or her arms and spread the fingers in response to a loud noise or other sudden, unexpected stimulus. By 6 weeks of age, newborn reflexes begin to fade and the baby's strength and coordination improve.

- By age 3 months, your baby can control his or her head movements. Put your baby on his or her tummy during awake periods and closely supervise. Allowing your baby to exercise and move in this position helps develop head and neck muscles. Around 4 months of age, babies gain control and balance in their head, neck, and trunk. Most babies can balance their heads for short periods when in a stable position. Around this same age, your baby starts playing with his or her hands and grasps your finger on purpose, rather than as a reflex.
- Between 4 and 6 months of age, babies' balance and movement dramatically improve as they gain use and coordination of large muscles. During this time, babies purposefully roll over and may be able to sit with their hands balancing them in front (tripod position). Reaching toward an object with both hands, babies may grasp at toys with their palms.
- Babies gain more control of their muscles between 6 and 9 months of age as the nervous system connections continue to form. By the 7th month, babies can see almost as well as an adult. Babies develop leg and trunk coordination, sit alone steadily, and may crawl using both their hands and feet. Some babies even pull themselves up to a standing position, although the timing and sequence of these milestones vary widely.
- Between 9 months and 12 months of age, babies explore the world with all their senses. At the same time, they are developing more control over their hands and fingers and may be able to grab small objects with a forefinger and thumb. Most babies this age like to experience and explore objects through taste and texture, which prompts them to put almost anything they can into their mouths. The brain continues to grow, helping to refine control over the large muscles. By now, your baby will probably be able to crawl and stand. In these few months before babies begin to walk, they often spend hours "cruising" around the room holding on to furniture and other objects. Cruising develops muscles and coordination and gives your baby a chance to practice walking.
- Many toddlers start to walk around 9 to 15 months of age. Those first steps are possible because of changes that have taken place in the brain and the spinal cord.

LANGUAGE DEVELOPMENT

Language, be it spoken, signed, or written, has specific components: a lexicon and grammar. **Lexicon** refers to the words of a given language. Thus, lexicon is a language's vocabulary. **Grammar** refers to the set of rules that are used to convey meaning through the use of the lexicon (Fernández & Cairns, 2011). For instance, English grammar dictates that most verbs receive an "-ed" at the end to indicate past tense. Language development is the process by which children come to understand and communicate language during early childhood.

DESCRIPTION

From birth up to the age of five, children develop language at a very rapid pace. The stages of language development are universal among humans. However, the age and the pace at which a child reaches each milestone of language development vary greatly among children. Thus, language development in an individual child must be compared with norms rather than with other individual children. In general girls develop language at a faster rate than boys. More than any other aspect of development, language development reflects the growth and maturation of the brain. After the age of five it becomes much more difficult for most children to learn language.

Receptive language development (the ability to comprehend language) usually develops faster than expressive language (the ability to communicate). Two different styles of language development are

recognized. In referential language development, children first speak single words and then join words together, first into two-word sentences and then into three-word sentences. In expressive language development, children first speak in long unintelligible babbles that mimic the cadence and rhythm of adult speech. Most children use a combination these styles.

INFANCY

Language development begins before birth. Towards the end of pregnancy, a fetus begins to hear sounds and speech coming from outside the mother's body. Infants are acutely attuned to the human voice and prefer it to other sounds. In particular they prefer the higher pitch characteristic of female voices. They also are very attentive to the human face, especially when the face is talking. Although crying is a child's primary means of communication at birth, language immediately begins to develop via repetition and imitation.

BETWEEN BIRTH AND THREE MONTHS OF AGE, MOST INFANTS ACQUIRE THE FOLLOWING ABILITIES:

- seem to recognize their mother's voice
- quiet down or smile when spoken to
- turn toward familiar voices and sounds
- make sounds indicating pleasure
- cry differently to express different needs
- grunt, chuckle, whimper, and gurgle
- begin to coo (repeating the same sounds frequently) in response to voices
- make vowel-like sounds such as "ooh" and "ah"

BETWEEN THREE AND SIX MONTHS, MOST INFANTS CAN DO THE FOLLOWING:

- turn their head toward a speaker
 - watch a speaker's mouth movements
 - respond to changes in a tone of voice
 - make louder sounds including screeches
 - vocalize excitement, pleasure, and displeasure
 - cry differently out of **pain** or hunger
 - laugh, squeal, and sigh
 - sputter loudly and blow bubbles
 - shape their mouths to change sounds
 - vocalize different sounds for different needs
 - communicate desires with gestures
 - babble for attention
 - mimic sounds, inflections, and gestures
 - make many new sounds, including "p," "b," and "m," that may sound almost speech-like
- The sounds and babblings of this stage of language development are identical in babies throughout the world, even among those who are profoundly deaf. Thus all babies are born with the capacity to learn any language. Social interaction determines which language they eventually learn. Six to 12 months is a crucial age for receptive language development. Between six and nine months babies begin to do the following:

- search for sources of sound
- listen intently to speech and other sounds

- take an active interest in conversation even if it is not directed at them
- recognize "dada," "mama," "bye-bye"
- consistently respond to their names
- respond appropriately to friendly and angry tones
- express their moods by sound and body language
- **play** with sounds
- make long, more varied sounds
- babble random combinations of consonants and vowels
- babble in singsong with as many as 12 different sounds
- experiment with pitch, intonation, and volume
- use their tongues to change sounds
- repeat syllables
- imitate intonation and speech sounds

BETWEEN NINE AND 12 MONTHS BABIES MAY BEGIN TO DO THE FOLLOWING:

- listen when spoken to
- recognize words for common objects and names of **family** members
- respond to simple requests
- understand "no"
- understand gestures
- associate voices and names with people
- know their own names
- babble both short and long groups of sounds and two-to-three-syllable repeated sounds (The babble begins to have characteristic sounds of their native language.)
- use sounds other than crying to get attention
- use "mama" and "dada" for any person
- shout and scream
- repeat sounds
- use most consonant and vowel sounds
- practice inflections
- engage in much vocal play

TODDLERHOOD

During the second year of life language development proceeds at very different rates in different children. By the age of 12 months, most children use "mama/dada" appropriately. They add new words each month and temporarily lose words. Between 12 and 15 months children begin to do the following:

- recognize names
- understand and follow one-step directions
- laugh appropriately
- use four to six intelligible words, usually those starting with "b," "c," "d," and "g," although less than 20 percent of their language is comprehensible to outsiders
- use partial words
- gesture and speak "no"
- ask for help with gestures and sounds

AT 15 TO 18 MONTHS OF AGE CHILDREN USUALLY DO THE FOLLOWING:

- understand "up," "down," "hot," "off"
- use 10 to 20 intelligible words, mostly nouns
- use complete words
- put two short words together to form sentences
- chatter and imitate, use some echolalia (repetitions of words and phrases)
- have 20 to 25 percent of their speech understood by outsiders

At 18 to 24 months of age toddlers come to understand that there are words for everything and their language development gains momentum. About 50 of a child's first words are universal: names of foods, animals, family members, **toys** vehicles, and clothing. Usually children first learn general nouns, such as "flower" instead of "dandelion," and they may overgeneralize words, such as calling all toys "balls." Some children learn words for social situations, greetings, and expressions of love more readily than others. At this age children usually have 20 to 50 intelligible words and can do the following:

- follow two-step directions
- point to parts of the body
- attempt multi-syllable words
- speak three-word sentences
- ask two-word questions
- enjoy challenge words such as "helicopter"
- hum and sing
- express pain verbally
- have 50 to 70 percent of their speech understood by outsiders

After several months of slower development, children often have a "word spurt" (an explosion of new words). Between the ages of two and 18 years, it is estimated that children add nine new words per day. Between two and three years of age children acquire:

- a 400-word vocabulary including names
- a word for most everything
- the use of pronouns
- three to five-word sentences
- the ability to describe what they just saw or experienced
- the use of the past tense and plurals
- names for body parts, colors, toys, people, and objects
- the ability to repeat rhymes, songs, and stories
- the ability to answer "what" questions

Children constantly produce sentences that they have not heard before, creating rather than imitating. This **creativity** is based on the general principles and rules of language that they have mastered. By the time a child is three years of age, most of a child's speech can be understood. However, like adults, children vary greatly in how much they choose to talk. Preschool

THREE TO FOUR-YEAR-OLDS USUALLY CAN DO THE FOLLOWING:

- understand most of what they hear

- converse
- have 900 to 1,000-word vocabularies, with verbs starting to predominate
- usually talk without repeating syllables or words
- use pronouns correctly
- use three to six-word sentences
- ask questions
- relate experiences and activities
- tell stories (Occasional **stuttering** and stammering is normal in preschoolers.)

LANGUAGE SKILLS USUALLY BLOSSOM BETWEEN FOUR AND FIVE YEARS OF AGE. CHILDREN OF THIS AGE CAN DO THE FOLLOWING:

- verbalize extensively
- communicate easily with other children and adults
- articulate most English sounds correctly
- know 1,500 to 2,500 words
- use detailed six to eight-word sentences
- can repeat four-syllable words
- use at least four prepositions
- tell stories that stay on topic
- can answer questions about stories

SCHOOL AGE

At age five most children can do the following:

- follow three consecutive commands
- talk constantly
- ask innumerable questions
- use descriptive words and compound and complex sentences
- know all the vowels and consonants
- use generally correct grammar

Six-year-olds usually can correct their own grammar and mispronunciations. Most children double their vocabularies between six and eight years of age and begin reading at about age seven. A major leap in reading comprehension occurs at about nine. Ten-year-olds begin to understand figurative word meanings. Adolescents generally speak in an adult manner, gaining language maturity throughout high school.

COMMON PROBLEMS

Language delay is the most common **developmental delay** in children. There are many causes for language delay, both environmental and physical. About 60 percent of language delays in children under age three resolve spontaneously. Early intervention often helps other children to catch up to their age group.

Common circumstances that can result in language delay include:

- concentration on developing skills other than language
- siblings who are very close in age or older siblings who interpret for the younger child
- inadequate language stimulation and one-on-one attention

- bilingualism, in which a child's combined comprehension of two languages usually is equivalent to other children's comprehension of one language
- psychosocial deprivation

LANGUAGE DELAY CAN RESULT FROM A VARIETY OF PHYSICAL DISORDERS, INCLUDING THE FOLLOWING:

- mental retardation
- maturation delay (the slower-than-usual development of the speech centers of the brain), a common cause of late talking
- a hearing impairment
- a learning disability
- cerebral palsy
- autism (a developmental disorder in which, among other things, children do not use language or use it abnormally)
- congenital blindness, even in the absence of other neurological impairment
- Klinefelter syndrome, a disorder in which males are born with an extra X chromosome

BRAIN DAMAGE OR DISORDERS OF THE CENTRAL NERVOUS SYSTEM CAN CAUSE THE FOLLOWING:

- receptive aphasia or receptive language disorder, a deficit in spoken language comprehension or in the ability to respond to spoken language
- expressive aphasia, an inability to speak or write despite normal language comprehension
- childhood apraxia of speech, in which a sound is substituted for the desired syllable or word

PARENTAL CONCERNS

Language development is enriched by verbal interactions with other children and adults. Parents and care-givers can have a significant impact on early language development. Studies have shown that children of talkative parents have twice the vocabulary as those of quiet parents. A study from the National Institute of Child Health and Human Development (NICHD) found that children in high-quality childcare environments have larger vocabularies and more complex language skills than children in lower-quality situations. In addition language-based interactions appear to increase a child's capacity to learn. Recommendations for encouraging language development in infants include:

- talking to them as much as possible and giving them opportunities to respond, perhaps with a smile; short periods of silence help teach the give-and-take of conversation
- talking to infants in a singsong, high-pitched speech, called "parentese" or "motherese" (This is a universal method for enhancing language development.)
- using one- or two-syllable words and two to three-word sentences
- using proper words rather than baby words
- speaking slowly, drawing-out vowels, and exaggerating main syllables
- avoiding pronouns and articles
- using animated gestures along with words
- addressing the baby by name
- talking about on-going activities
- asking questions
- singing songs

- commenting on sounds in the environment
- encouraging the baby to make vowel-like and consonant-vowel sounds such as "ma," "da," and "ba"
- repeating recognizable syllables and repeating words that contain the syllable

When babies reach six to 12 months-of-age, parents should play word games with them, label objects with words, and allow the baby to listen and participate in conversations. Parents of toddlers should do the following:

- talk to the child in simple sentences and ask questions
 - expand on the toddler's single words
 - use gestures that reinforce words
 - put words to the child's gestures
 - name colors
 - count items
 - gently repeat correctly any words that the child has mispronounced, rather than criticizing the child
- Parents of two to three-year-olds should do the following:
- talk about what the child and parent are doing each day
 - encourage the child to use new words
 - repeat and expand on what the child says
 - ask the child yes-or-no questions and questions that require a simple choice

(TABLE BY GGS INFORMATION SERVICES.)

Language development	Activity
Age	Activity
Two months	Cries, coos, and grunts.
Four months	Begins babbling. Makes most vowel sounds and about half of consonant sounds.
Six months	Vocalizes with intonation. Responds to own name.
Eight months	Combines syllables when babbling, such "Ba-ba."
Eleven months	Says one word (or fragment of a word) with meaning.
Twelve months	Says two or three words with meaning. Practices inflection, such as raising pitch of voice at the end of a question.
Eighteen months	Has a vocabulary between five and 20 words, mostly nouns. Repeats word or phrase over and over. May start to join two words together.
Two years	Has a vocabulary of 150–300 words. Uses I, me, and you. Uses at least two prepositions (in, on, under). Combines words in short sentences. About two-thirds of what is spoken is understandable.
Three years	Has a vocabulary of 900–1000 words. Uses more

	verbs, some past tenses, and some plural nouns.
	Easily handles three- word sentences. Can give own name, sex, and age. About 90% of speech is understandable.
Four years	Can use at least four prepositions. Can usually repeat words of four syllables. Knows some colors and numbers. Has most vowels and diphthongs and consonants p, b, m, w, and n established. Talks a lot and repeats often.
Five years	Can count to ten. Speech is completely understandable, although articulation might not be perfect. Should have all vowels and consonants m, p, b, h, w, k, g, t, d, n, ng, y. Can repeat sentences as long as nine words. Speech is mostly grammatically correct.
Six years	Should have all vowels and consonants listed above, has added, f, v, sh, zh, th, l. Should be able to tell a connected story about a picture.
Seven years	Should have consonants -z, r, voiceless th, ch, wh, and soft g. Should be able to do simple reading and print many words.
Eight years	All speech sounds established. Carries on conversation at a more adult level. Can tell complicated stories of past events. Easily uses complex and compound sentences. Reads simple stories with ease and can write simple compositions.
SOURCE : Child Development Institute. 2004. http://www.childdevelopmentinfo.com .	

- encourage the child to ask questions
- read books about familiar things, with pictures, rhymes, repetitive lines, and few words
- read favorite books repeatedly, allowing the child to join in with familiar words
- encourage the child to pretend to read
- not interrupt children when they are speaking

PARENTS OF FOUR TO SIX-YEAR-OLDS SHOULD:

- not speak until the child is fully attentive
- pause after speaking to give the child a chance to respond
- acknowledge, encourage, and praise speech
- introduce new words
- talk about spatial relationships and opposites
- introduce limericks, songs, and poems
- talk about the television programs that they watch
- encourage the child to give directions
- give their full attention when the child initiates a conversation

Parents of six to 12-year-olds should talk to the children, not at them, encourage conversation by asking questions that require more than a yes-or-no answer, and listen attentively as the child recounts the day's activities. Additional recommendations for parents and care-givers, by the American Academy of Pediatrics and others, include:

- talking at eye level with a child and supplementing words with body language, gestures, and facial expressions to enhance language comprehension
- talking in ways that catch a child's attention
- using language to comfort a child
- using correct pronunciations
- using expressive language to discuss objects, actions, and emotions
- playing with sounds and words
- labeling objects and actions with words
- providing objects and experiences to talk about
- choosing activities that promote language
- listening carefully to children and responding in ways that let them know that they have been understood, as well as encouraging further communication
- using complete sentences and adding detail to expand on what a child has said
- knowing when to remain silent
- reading to a child by six months of age at the latest
- encouraging children to ask questions and seek new information
- encouraging children to listen to and ask questions of each other

TELEVISION VIEWING DOES NOT PROMOTE LANGUAGE DEVELOPMENT. WHEN TO CALL THE DOCTOR

Parents should call the pediatrician immediately if they suspect that their child may have a language delay or a hearing problem. Warning signs of language delay in toddlers include:

- avoiding eye contact
- neither understanding nor speaking words by 18 months of age
- difficulty learning nursery rhymes or simple songs
- not recognizing or labeling common objects
- inability to pay attention to a book or movie
- poor articulation, such that a parent cannot understand the child more than 50 percent of the time

KEY TERMS

Apraxia —Impairment of the ability to make purposeful movements, but not paralysis or loss of sensation.

Expressive aphasia —A developmental disorder in which a child has lower-than-normal proficiency in vocabulary, production of complex sentences, and word recall, although language comprehension is normal.

Expressive language —Communicating with language.

Expressive language development —A style of language development in which a child's babble mimics the cadence and rhythm of adult speech.

Receptive aphasia —A developmental disorder in which a child has difficulty comprehending spoken and written language.

Receptive language —The comprehension of language.

Referential language development —A style of language development in which a child first speaks single words and then joins words together into two- and three-word sentences.

EMOTIONAL DEVELOPMENT

Emotional development, emergence of the experience, expression, understanding, and regulation of emotions from birth and the growth and change in these capacities throughout childhood, adolescence, and adulthood. The development of emotions occurs in conjunction with neural, cognitive, and behavioral development and emerges within a particular social and cultural context.

INFANCY

The expression of emotions during infancy promotes the transition from complete dependency to autonomy. The expression of interest promotes exploration and cognitive development. Social (intentional) smiles and other expressions of joy promote social interaction and healthy attachment relationships with primary caregivers. The expression of sadness encourages empathy and helping behaviour, and the expression of anger signals protest and discomfort. Infants' unique tendency to experience and express particular emotions and the threshold for expressing those emotions is usually referred to as their temperament or characteristic emotionality.

Researchers generally agree that neonatal (nonintentional) smiles are present at birth and that social smiling and emotional expressions of interest appear as early as six weeks of age. By four to five months of age, infants selectively smile at familiar faces and at other infants, and their caregivers begin to share positive emotional exchanges with them. Researchers disagree in their explanations of the development and time of emergence of discrete negative emotional expressions. Consistently with the view that infants express negative emotions in early infancy, scientists have shown that infants perceive and respond differentially to the negative emotional expressions (e.g., sadness, anger) of others by the age of four months.

During the second six months of life, as infants gain rudimentary cognitive and memory capacities, they begin to express particular emotions based on context. Emotions begin to emerge dynamically as the infant begins to take a more direct role in emotional exchanges with caregivers. The emotional bond with the caregiver is increasingly important, as infants seek support for exploration and look for signals of danger.

TODDLERHOOD AND EARLY CHILDHOOD

During the toddler period, in conjunction with rapid maturation of the frontal lobes and the limbic circuit in the brain, recognition of the self emerges. As a result, the toddler strives to become more independent, and the expression of anger and defiance increases in that struggle for autonomy. The ability to differentiate the self from others also promotes basic empathetic behaviour and moral understanding. By the end of the second year of life, toddlers respond to negative signals from others, and they have specific emotional responses to their own negative actions. The emotions that emerge with a rudimentary conception of the self are often called self-conscious emotions and include shame, embarrassment, guilt, and pride. Some self-conscious emotions, such as pride and guilt, do not emerge until toddlers and young children have learned to conceptualize internalized standards of behaviour.

As children enter preschool, they begin to label their own emotions and rely on discourse about emotions within the family to facilitate their understanding of basic emotions. Young children first distinguish happiness from negative emotions and then begin to distinguish negative emotions such as sadness, anger, and fear from each other. They begin to recognize these emotions in facial expressions, and then, as they enter middle childhood, they begin to understand situational determinants of emotions. An understanding of emotional subjectivity also develops as children learn that what makes one child happy may not make another child feel the same way.

The emergence of emotional self-regulation is particularly important during early childhood and occurs in the context of family and peer relationships. Open expression of positive emotions and warm, supportive relationships between parents and children promote effective emotional self-regulation. On the other hand, frequent expression of negative emotions in the family and harsh, punitive disciplinary responses increase the experience of distressing and dysregulated emotions that may lead to psychopathology. Appropriate peer relationships characterized by shared play activities are also important for the development of emotional regulation during early childhood. Children gain emotional understanding and the capacity for empathetic and helping behaviour from well-regulated emotional exchanges with peers.

MIDDLE AND LATE CHILDHOOD

During middle and late childhood, stable self-concepts based on the child's typical emotional experiences emerge. With the increased capacity for self-reflection, children gain an understanding of their self-conscious emotions. As a result, the consistent experience of patterns of self-conscious emotions has an impact on the child's self-concept. For example, the tendency to experience shame rather than guilt in response to negative transgressions affects the child's emergent self-esteem and may encourage a tendency to respond with aggression or violence.

Also during middle and late childhood, children begin to understand that a single situation or event can lead to the experience of multiple, mixed emotions. For example, older children understand that a goodbye party for a sibling who will leave for college is likely to be both a happy and a sad event for the child and his sibling. This capacity likely emerges with the cognitive capacity to understand multiple aspects of a situation, called decentration. Children also learn emotional display rules as they progress through middle and late childhood. For example, a child learns to look happy even though she feels upset when a friend or family member gives her an undesirable gift. The use of display rules tends to increase as children begin to consider what consequences their actions may have for others. Display rules are used judiciously, and the likelihood of suppressing negative emotion depends on a number of factors, including the child's gender, the likely recipients of the expression, the specific context, and the child's cultural milieu.

ADOLESCENCE

With adolescence comes an additional struggle for autonomy and increased time spent with peers and less time spent with the family. Adolescents become less emotionally dependent on their parents, but this emotional autonomy often emerges after a period of conflict and increased experience of negative emotions. Young adolescents often experience more negative affect than younger children, but the negative affect often decreases during the high school years. However, girls often experience a longer period of elevated negative affect than boys. Adolescents tend to experience more extreme emotions, both negative and positive, than their parents even in response to the same event.

SMSC- SPIRITUAL, MORAL, SOCIAL AND CULTURAL ASPECTS OF LEARNING:

At its heart, SMSC is about relationships and attitudes. At Halton School we begin with the values projected by staff, pupils and governors, the interactions between people and the way they care for one another. This includes the quality of the physical environment, the range of opportunities provided by the school both within the curriculum and beyond it and the relationship developed by the school with the wider community.

Teachers seek to plan learning experiences that have relevance to the children, that will combine the

awe and wonder of the world with practical skills to aid them in their daily lives.

Pupils' **spiritual development** is shown by their:

- Beliefs, religious or otherwise, which inform **their perspective on life** and their **interest in and respect for different people's feeling and values**
- Sense of **enjoyment** and **fascination** in learning about **themselves, others** and the **world around them**, including the intangible
- Use of **imagination** and **creativity** in their learning
- Willingness to **reflect** on their **experiences**.

PUPILS' MORAL DEVELOPMENT IS SHOWN BY THEIR:

- Ability to **recognise** the difference between **right** and **wrong** and their readiness to **apply** this understanding **in their own lives**
- Understanding of the **consequences of their actions**
- **Interest in investigating**, and offering reasoned views about, **moral and ethical issues**

PUPILS' SOCIAL DEVELOPMENT IS SHOWN BY THEIR:

- **Use** of a range of **social skills** in **different contexts**, including **working** and **socialising** with pupils from **different backgrounds**
- **Willingness to participate** in a **variety of social settings**, **cooperating well with others** and being able to **resolve conflicts** effectively
- **Interest in**, and understanding of, the way **communities** and societies **function** at a variety of levels.

PUPILS' CULTURAL DEVELOPMENT IS SHOWN BY THEIR:

- Understanding and appreciation of the wide range of cultural influences that have shaped their own **heritage**
- **Willingness to participate** in, and **respond to** artistic, musical, sporting, mathematical, technological and scientific **opportunities**
- Interest in **exploring** and **respecting cultural diversity** and the extent to which they **understand, accept and respect diversity**, as shown by their **attitudes** towards **different religious, ethnic and socio-economic** groups in the **local, national and global communities**.

WHAT IS PSYCHOPATHOLOGY: CONCEPT, MENTAL STATUS EXAMINATION, CLASSIFICATION, CAUSES?

PSYCHOPATHOLOGY: CONCEPT, MENTAL STATUS EXAMINATION, CLASSIFICATION, CAUSES

How do we currently define psychopathology? In short, this discipline can be understood as an in-depth study of problems related to mental health. Just like pathology is the study of the nature of disease (including causes, development, and outcomes), psychopathology is the study of the same concepts within the realm of mental health (or illness). This study of mental illness can include a long list of elements: symptoms, behaviors, causes (genetics, biology, social, psychological), course, development, categorization, treatments, strategies, and more.

In this way, psychopathology is all about exploring problems related to mental health: how to understand them, how to classify them, and how to fix them. Because of this, the topic of psychopathology extends from research to treatment and covers every step in between. The better we can understand why a mental disorder develops, the easier it will be to find effective treatments.

SIGNS OF PSYCHOPATHOLOGY

Signs of psychopathology vary depending on the nature of the condition. Some of the signs that a person might be experiencing some form of psychopathology include:

- Changes in eating habits
- Changes in mood
- Excessive worry, anxiety, or fear
- Feelings of distress
- Inability to concentrate
- Irritability or anger
- Low energy or feelings of fatigue
- Sleep disruptions
- Thoughts of self-harm or suicide
- Trouble coping with daily life
- Withdrawal from activities and friends

DIAGNOSTIC SYSTEMS

Professionals engaged in research and treatment of psychopathology must use systems to arrive at conclusions regarding the best course of action for treatment. These systems are used to classify what are considered mental health disorders.

Currently, the most widely used systems for classifying mental illness in the United States are the following.²

DIAGNOSTIC AND STATISTICAL MANUAL OF MENTAL DISORDERS (DSM)

The Diagnostic and Statistical Manual of Mental Disorders (DSM) is created by the American Psychiatric Association (APA) as an assessment system for mental illness. The DSM-5 published in 2013 is the current edition and includes identifiable criteria that mental health professionals use to arrive at a specific diagnosis.³ The criteria and list of disorders sometimes change as new research emerges. Some examples of disorders listed in the DSM-5 include major depressive disorder, bipolar disorder, schizophrenia, paranoid personality disorder, and social anxiety disorder.

INTERNATIONAL CLASSIFICATION OF DISEASES (ICD)

The ICD is a system similar to the DSM. Now in its eleventh version, the ICD was developed over a century ago and was taken over by the World Health Organization (WHO) when it was founded in 1948. So, how does the ICD-11 differ from the DSM-5? First, the ICD-11 is produced by a global agency (the World Health Organization), while the DSM-5 is produced by a national professional association (the American Psychiatric Association). The ICD-11 is approved by the World Health Assembly composed of health ministers from 193 WHO member countries.

Second, the goal of the ICD-11 is to reduce the burden of disease globally. It includes medical as well as mental health diagnoses. Third, the ICD-11 is freely available on the Internet. In contrast, the DSM must be purchased, and the American Psychiatric Association derives revenue from sales of the book and related products. Beyond these standard systems for classifying mental disorders, there also exists a burgeoning area of research and theory that moves away from the checklist

format of making diagnoses. Since it's possible to have symptoms of a mental illness but not meet the criteria for an official diagnosis, studies of descriptive psychopathology hold promise for a better system of understanding.

The RDoC is a research framework initiative by the National Institute of Mental Health (NIMH) based on translational research from areas such as neuroscience, genomics, and experimental psychology. In this way, the RDoC is involved in describing the signs and symptoms of psychopathology rather than grouping them into disorders as has been historically done with the DSM and ICD. The RDoC is primarily aimed at planning and funding research.

WORKS IN PSYCHOPATHOLOGY?

Just as the scope of psychopathology is broad-ranging from research to treatment, so too is the list of types of professionals who tend to be involved in the field. At the research level, you will find research psychologists, psychiatrists, neuroscientists, and others trying to make sense of the different manifestations of mental disorders seen in clinical practice. At the clinical level, you will find many types of professionals attempting to apply the diagnostic systems that are in place to provide effective treatments to individuals living with psychopathology. These can include the following and more:

- Clinical psychologists
- Counselors
- Criminologists
- Marriage and family therapists
- Nurse practitioners
- Psychiatric nurses
- Psychiatrists
- Social workers
- Sociologists

IDENTIFYING PSYCHOPATHOLOGY

How do psychologists and psychiatrists decide what extends beyond normal behavior to enter the territory of "psychopathology?" Psychiatric disorders can be conceptualized as referring to problems in four areas: deviance, distress, dysfunction, and danger.⁴ For example, if you were experiencing symptoms of depression and went to see a psychiatrist, you would be assessed according to a list of symptoms (most likely those in the DSM-5):

- **Deviance** refers to thoughts, emotions, or behaviors that deviate from what is common or at odds with what is deemed acceptable in the society. In the case of depression, you might report thoughts of guilt or worthlessness that are not common among other people.
- **Distress** refers to negative feelings either felt within a person or that result in discomfort in others around that person. In the case of depression, you might report extreme feelings of distress over sadness or guilt.
- **Dysfunction** refers to the inability to achieve daily functions like going to work. In the case of depression, you might report that you can't get out of bed in the morning or that daily tasks take you much longer than they should.
- **Danger** refers to behavior that might put you or someone else at some type of detrimental risk. In the case of depression, this could include reporting that you are having thoughts of suicide or harming yourself.

In this way, you can see that the distinction between normal versus psychopathological behavior comes down to how issues are affecting you or the people around you. Often it is not until things come to a crisis point that a diagnosis is made when someone comes in contact with a medical or mental health professional.⁵

CAUSES

There is not a single cause for psychopathology. There are a number of factors that can increase the risk of mental illness, including:

- Biological factors, including genes and brain chemistry
- Chronic medical conditions
- Family members with mental illness
- Feelings of isolation
- Lack of social support
- Substance or alcohol use
- Traumatic or stressful experiences

It is also important to realize that mental health can change over time. The Centers for Disease Control and Prevention (CDC) suggests that 50% of all people will be diagnosed with a mental illness at some point in their life.⁶

TYPES

Some of the different types of psychopathology include, but are not limited to:

- Anxiety disorders
- Bipolar disorders
- Depressive disorders
- Disruptive, impulse-control, and conduct disorders
- Dissociative disorders
- Eating disorders
- Neurocognitive disorders
- Neurodevelopmental disorders
- Obsessive-compulsive disorders
- Personality disorders
- Schizophrenia spectrum and other psychotic disorders
- Sleep disorders
- Somatic symptom disorders
- Trauma- and stressor-related disorders
- Substance-related disorders

HISTORY OF THE STUDY OF MENTAL ILLNESS

We've come a long way since the earliest beginnings of trying to make sense of mental illness. Although individuals with mental health issues still face stigma and a lack of understanding, things were very different in the past. Hippocrates, the 4th century BC Greek physician, rejected the notion of evil spirits and argued instead that mental illness was a disease of the brain relating to imbalances of bodily humors, or chemicals in the body fluids. Around the same time, the philosopher Plato argued that mental distress involved issues of virtue, morality, and the soul.

If you lived in the 16th century with a mental health problem, chances are you would not have been treated very well. At that time, mental illness was often viewed from a religious or superstitious point of view. Accordingly, it was assumed that people demonstrating strange behavior must have been overtaken by evil spirits or demons. The cure? You might have been tortured to bring you back to sanity. If that didn't work? Execution. Later, in the 19th century, interest surged in the role of childhood and trauma in the development of mental illness. Following on the heels of this era, Sigmund Freud introduced talk therapy to deal with these unresolved childhood issues. As of the present day, our understanding of mental illness has broadened, and so, thankfully, have the available treatments.

PSYCHOPATHOLOGY IS A TERM WHICH REFERS TO EITHER THE STUDY OF MENTAL ILLNESS OR MENTAL DISTRESS OR THE MANIFESTATION OF BEHAVIOURS AND EXPERIENCES WHICH MAY BE INDICATIVE OF MENTAL ILLNESS OR PSYCHOLOGICAL IMPAIRMENT.

MENTAL STATE EXAMINATION

Mental State Examination (MSE) is compared with physical examination as a reliable method of objective data investigation. There is a growing concern with psychiatric clinics, nosology, and the reliability of diagnostic interview methods as a source of valid diagnostic strategy. Efforts to achieve an international diagnosis protocol have been unsuccessful or polemical. This paper focuses on psychopathology, MSE, and mental function development within Brazilian psychiatry over the last few decades.

Methods: Searches, interviews, and narrative reviews were done to look for systematic ways in which to conduct MSE, mental functions, symptom clusters, orientations about data observation and records. Brazilian psychopathology textbooks were examined, if they provided access to consolidated knowledge on psychopathology examination.

Results: Sixteen textbooks were selected from a 49 year span. Descriptive psychopathology with phenomenological orientation was the primary trend in the MSE. Concepts derived from different traditions, most lacking common terminology, suggested some divergence among authors. Recommendations for patient observation and how to collect objective data was clear, but MSE standardization efforts were missing. A detailed description of mental function abnormalities was the main MSE record strategy, without consensus about ways to summarize and record this data. In an examination summary, mental strata was divided into "mental functions," and MSE subsets were frequent. All authors considered the following mental functions: consciousness, perception, thought, memory, attention, orientation, and volition.

Discussion: Psychiatric competence demands MSE proficiency. Official documents are not clear about performance and recording standards. MSE data was usually recorded through descriptive psychopathology. A shift from detailed descriptive findings, to an array of observed pathological elements, described through a mental function checklist was observed over time. Clinical practice and research guidelines should consider the development of reliable MSE practices; however, it has been neglected by modern psychiatry/neuroscience through the excessive emphasis on interview protocols. Better MSE practices, and the improvement of bedside skill in psychiatry are necessary and depend on the recovery of psychopathological debates and semiological reasoning, which will allow the return of phenomenology-oriented "observational" techniques.

In modern clinical medicine, a diagnosis is obtained through the crossover of symptoms, obtained

by anamnesis or by a clinical interview, and signs of symptoms, obtained through a physical examination and laboratory or image tests (). The former is supposed to spark multiple hypotheses which the clinician then further investigates by looking at patient's signs and symptoms. Semiology has been described in many textbooks as Porto () or Bates (), and was over time formalized as the paramount method of clinical examination in internal medicine. Such standard foundational programs were made possible through Claude Bernard's experimental medicine (), confirmed by Alvan Feinstein one century later, whereby stating that recent clinical epidemiology belongs to the same epistemological strata (). The same method was implemented in most medical specialties, including psychiatry (). With regard to general medical practice, physical examination (PE), lab, and image procedures provide the standard method to gather objective information, which is then used to refine the previously elaborated hypothesis through the anamnesis/interview method. The very idea of a PE and semiology was strengthened by the transformations of modern medicine, and was consolidated with the Flexnerian reformation of medical schools ,).

Psychiatry has tried to take part in this agenda and match such standards (). Clinical interviews as a standard procedure for anamnesis in psychiatry, has been rigorously investigated. An extensive bibliography, concerning how to improve an examiners agreement about symptoms, and a rising consensus about the need for a minimal structure for better clinician reliability, is now evident(). Mental health practice often uses Mental State Examination (MSE) as an equivalent to PE from routine clinical examination and as a reliable method for objective data gathering , -), since PE and MSE are logically correlated. However, clinical interview/anamnesis is previous to, and also guides PE procedures and laboratory searches, but it is the core of the mental/psychic examination process and used predominately in most cases. However, the interview is a narrative, history taking method, and not an objective sign gatherer tool.

The interview should be a narrative, recollection method, not an objective investigative tool. PE is consistently mentioned throughout almost all propaedeutical textbooks in medicine, with minimal, if not aesthetical, variations. MSE however has not achieved any international protocol or structured general tool, not even a minimal array of standard techniques and clinical report methods. Although MSEs widespread use as a PE correlative might not be suitable and may also be equivocated ,), it still universally used to gather data, objective information and evidence in mental health practice. MSE was simultaneously developed in different regions of the world, influenced by philosophically-oriented ideas on psychopathology (). Many psychopathology textbooks have also been written in different languages, according to different traditions, which have resulted in vast variations in technique and nomenclature). Nevertheless, mental semiology has been overlooked in most historiographical efforts, despite the importance of nosological history).

In the last 30 years, new trends in the history of psychiatry in Brazil developed, but none has considered mental examination. Estellita-Lins attempted to emphasize the phenomenology of living space (*espace vécu*) in Jaspers Psychopathology Textbook and its vital role concerning signs, "evidence" and examination (). Cheniaux () reviewed some of the Brazilian, and even foreign textbooks about "descriptive psychopathology," searching for conceptual regularity or terminological "uniformity" among authors, but MSE was not addressed. Viotti Daker worked on the main Brazilian textbook by Nobre de Melo, examining its psychopathological models (). Again, the MSE was not mentioned, but Melo's emphasis on fully assessing the person, before evaluating the particular functions subdivision, is noteworthy.

There is an increasing concern related to clinics and nosology in psychiatry. This concern might be

traced back to Nancy Andreassen's claim concerning the loss of psychopathological knowledge by younger psychiatrists, and to Parnas' Danish group that contested the validity of the schizophrenia nosologic construct in DSM/ICD, further extended to the unreliability of diagnostic interview methods with structured diagnostic questionnaires (). We should also mention Jacob's questioning of MSE training in India (), Aragona's interrogation about the collaboration of neuroscience in psychiatric diagnosis, among many others). As Rodrigues and Banzato have stated, if a sound agreement concerning the "validity" of a concept in psychiatry had already been achieved, there would not be such confusion around it).

We foresee epistemological issues concerning psychiatry and mental health care, that have not yet been resolved, as the importance of examination skills and training in the evidence-based era. These themes are not simply classificatory issues but are fundamental psychopathological efforts demanding a discussion concerning the diagnosis process in mental health and psychiatry. This study deals with modern psychiatry from a historical perspective but addresses some clinical problems such as MSE, examination reporting, patient records and psychopathology teaching/transmission. A narrow comprehension of what evidence means may have been overlooked such as bedside skills and in particular phenomenological examining tradition (-). Maybe ongoing "taxonomic issues" and "classification wars" in psychiatry () are fair and useful, but we should also pinpoint some relevant matters that concern the examination, clinical reasoning and the diagnostic process itself). Aiming to elucidate the origins, development, and methods of how MSE has been consolidated in Brazil, a review was carried out on the national literature.

METHODS

MSE still lacks proper categorization in MESH and DeCS, and the best results of descriptors or key word searches were related to standard clinical interviews, therefore unsuitable for systematic MSE research purposes. Textbooks are known to be the introductory means to access expert knowledge in the medical field as defined by Ludwig Fleck . It was then decided to consider textbooks on psychopathology as a primary reference, following a timeline based on its reference and contents. A backward reference search was carried out at the start of 2017, using the Universidade Federal do Rio de Janeiro Library System, to look for psychopathology textbooks written or edited by Brazilian authors (UFRJ, Rede Minerva).¹ The same search strategy was extended to main bookstore digital systems, and sites specialized in old or out of print editions, and finally to Google and Google Scholar. The main search string used was "psicopatologia" or "psiquiatria."

RESULTS

An initial list of 35 textbooks was selected. Among them were textbooks translated into Portuguese, not edited or written by Brazilian authors, and which were therefore excluded. Other books without any relevant chapters on MSE were also excluded. Twelve textbooks were finally chosen for the present study. The original list of books found and selected are presented in , . Whenever possible, the first and last edition of each book was consulted, and discussions about systematic ways to conduct MSE, the ordering of MSE topics (distinct functions), orientations about data gathering and registration, definitions about "mental functions" and its levels, symptom clusters, groupings and set organization, were studied. Referenced articles and books citations were also checked. In older textbooks, terms and notions that are semantically related to MSE have changed over time. Therefore, any mention of a mental examination that clearly described careful mental observation techniques or descriptions was considered as similar or equivalent to MSE.

TABLE 1

Table 1. Textbook set with editions, publication years, and the 12 titles (in bold) chosen for investigation of MSE.

TABLE 2

Table 2. MSE in the investigated textbooks, number of items, how it is named, and their items or assessed functions. A comprehensive review was carried out on Brazilian authors, researchers and literature, focusing on different MSE traditions, describing its various approaches and MSE segmentation around psychic functions. The list of discrete elements assembled into MSE was studied in detail. A structured method to register significant psychopathological abnormalities/anomalies through examinations did show up in the search results. It was identified as “súmulapsicopatológica” (psychopathological summary) in some textbooks.

The works examined spanned over the last 49 years. The books were written mostly by psychiatrists with clinical expertise, working as University Professors or lecturers. Most publications were designed to teach psychopathology to medical doctors being trained as a resident/internist in psychiatry. No MSE standard was identified, even though every author confirmed its relevance and consistency. Most authors provided orientations on how to proceed with a careful patient observation during an interview, aimed at obtaining objective data. The most referred method, to organize and register MSE, consistently cited by some authors, was descriptive psychopathology with a phenomenological orientation. Textbooks agreed and actively encouraged a very detailed description of observed mental functions as the best way to record MSE. Additionally, there was no agreement on how to summarize its components (–, –).

Throughout the time span studied, MSE was not the standard term used to refer to psychic examination and was first adopted in 2000 in the Brazilian psychopathology and semiology textbook by Paulo Dalgalarrodo (), after which it was consistently used. It remains unclear if the term was chosen because of evidence-based efforts on examination, or if it represents a particular tradition. Regardless, Luiz Salvador de Miranda Sá Jr mentioned “mental examination,” an expression semantically related (), and Elias Paim called it “psychic examination” around 1976, as did Leme Lopes in about 1980 (). The only author that did not use MSE after 2000 was Claudio Lyra Bastos, who still mentioned “Psychic Examination” ().

All authors used subdivisions to analyze and describe MSE, but each provided a specific set. Even though there was a clear consensus that consciousness could only be artificially fragmented for didactic purposes, no agreement, convergence or discussion about the nature or number of necessary items could be identified. The theoretical basis underlying the operating subdivisions is therefore lacking. It remains unclear how these mental strata turned into a divided set of “mental functions.” shows the items that form MSE, according to each author. A concise examination summary through “súmula psicopatológica” was mentioned by only four authors (). It was not possible to track the origins of this notion, since the authors did not mention or contextualize it. Some hypothesis is developed through discussion.

It is noteworthy that among the initial textbook list, some belonged to a field aimed at researching psychotherapy and psychoanalysis— therefore promoting a broader signification of psychopathology. Although these books were not included, and considering that psychoanalytic psychopathology is different from descriptive psychopathology, it probably suggests that psychoanalysis has had

some influence in Brazilian psychiatric practices, perhaps in a slightly different way than what occurred in the United States (, ,). The term “interview” has widespread use when referring to the diagnostic and therapeutic encounter with patients, including psychoanalytical sessions, which may add further confusion when searching for Psychiatric methods of MSE using indexed expressions, and which justifies the frequency of these textbooks in the initial search sample. A better evaluation of such influence would be desirable, but it is out of the scope of this paper.

DISCUSSION

Mental Health as a Brazilian tradition started in the nineteenth-century, after the creation of the hospice, by a Portuguese emperor (). It was not before the beginning of 1900, however, that academic psychiatry began to thrive, particularly after studies published by Juliano Moreira, Ulisses Pernambucano, followed by studies on forensic psychiatry published by Nina Rodrigues and Franco da Rocha psychiatry. The first psychopathology textbook edited by a Brazilian author was published by Isaías Paim at the very end of the 1960s as far as we were able to trace. Paim's textbook stresses that psychopathology is not a psychiatric “tool,” but an entirely different “science,” that could be applied by psychiatrists to comprehend and investigate mental illness. Influenced by German and French authors, Paim thoroughly recommended detailed observations and descriptions of subjective reports and behaviors as the best way to register and carry out psychic examination. This coupling of observation and description was continually reinforced by most authors analyzed. The vast majority of textbooks considered MSE with clear subdivisions, except Paim's) *Psychiatry Treatise*. The number of partitions ranged from 6 up to 18 items. The first time they are referred to as “Mental Functions” in our textbook sample was in Dalagalarrondo's “*Psicopatologia e Semiologia*.” Despite considerable variations in mental function descriptions and items adopted, all authors have explicitly considered the following mental functions: consciousness, perception, thought (not frequently comprising its 3-fold structure—Flow, Process, and content/Beliefs), memory, attention, orientation, and volition. Paim did not list mental functions in his treatise but had openly used it in his 1969 psychopathology textbook. These conceptual developments in Brazilian psychopathology call for further studies. We considered them as hints at the importance of mental function fragmentation and structure in psychopathology.

It was not possible to identify how subdivisions were adopted or created according to Brazilian textbooks. The lack of theoretical background may be responsible for the significant variation observed. Dividing or stratifying MSE seems to be the best method to analyze and to conveniently engage in description efforts, to evaluate psychic life. A discussion concerning ways to split MSE for adequate observation and educational purposes is out of the scope of the present review, but highly desirable. Since there are no globally standardized guidelines on psychopathology training (), bedside examination skills must be regarded seriously, as an asset worth further exploring. This chronologically considered textbook series, suggests that the first Brazilian authors that wrote about psychopathology—Nobre de Melo, () and Isaías Paim, ()—did not aim to or were not used to describe MSE as mental function subdivisions, but were eager to build long and meticulous reports of observed behavior, through a personal interaction with patients. Contemporary Brazilian authors however usually mention clear descriptions of mental function subdivisions, setting standards on how to study MSE and how to describe it. It was not possible to identify a “standard” MSE organization, although a written description of all that is observed is consistent in both older and recent textbooks.

We could not identify any efforts aimed toward comparative clinical psychopathology. The origins of the clinical resume called “*súmula psicopatológica*” could not be identified. It may

have a forensic and juridical background, as its etymology suggests. Besides lawsuit writing rights, there were many other compulsory examination practices that the Brazilian and then the eugenics Constitution (1937) recommended. Psychiatrists were accountable for defining a person's state of mental health in many common judiciary cases such as criminal subjects, couples before marriage, institutionalized children, among others. For instance, forensic demands synthesis during a long diagnostic process and extensive judicial records. Some leading psychiatrists, such as Franco da Rocha were very fond of this reporting procedure after clinical examination. A historiographic article, reviewing old patient files, depicts an explicit use of "súmula" by psychiatrists when writing down their patient's observations around 1929. It is then possible to affirm that the use of "súmula" as the name given to the set of observed signs and symptoms in psychiatric interview was already widespread in Brazilian psychiatry by the early twenties.

Within the textbook set investigated, the first register of the word "súmula"—as a concise list of mental function subdivisions, containing psychopathological disturbances, observed through MSE—appears in Dalgarrondo's textbook. The term "súmula psicopatológica" was also mentioned in Cheniaux psychopathology treatise. Cheniaux's communication, however, admitted that this precise notion had been in colloquial use since the early 90s, and declared that he was first introduced to it by prof Dr. Miguel Chalub, who also introduced him to categorized lists of mental functions with descriptive purposes².

Chalub, in turn, declared that he learned this exact expression from Professor José Leme Lopes, the chairman of UFRJ Psychiatric Institute in the seventies. However, Leme Lopes' "Diagnoses in Psychiatry," published in 1980 does not contain any mention of it (). Neither Chalub nor Cheniaux needed to trace its roots but acknowledged its common use in bedside practices. Both authors hypothesized that it was borrowed from international psychopathological tradition, and that it become mainstream through everyday use in many institutional facilities in Brazil. The same inference about the expression "mental function" might therefore be adopted.

Efforts to standardize medical examinations have been at the core of scientific experimental medicine. These attempts have branched alongside psychopathology developments. The systematization of diagnostic psychiatric interview has been considered a significant step toward the improvement of clinician reliability. However, doubts about the best way to use it clinically, still remains. Countries, like Denmark, have already regulated the use of at least one standard interview in clinical practice, for any diagnosis in psychiatry and others such as Australia use diagnostic tools in a mental health triage. These are anamnesis/interview standardized methods however, not MSE.

ICD and DSM contain examining tools (Schedules for Clinical Assessment in Neuropsychiatry—SCAN, Structured Clinical Interview for DSM-5 Disorders—SCID-5, Mini International Neuropsychiatric Interview—MINI). OPCRIT is supposedly useful to organize MSE, although it seems vastly different from what is usually accepted in descriptive psychopathology, since it provides neither mental function subdivisions nor any coordinated step care to enhance MSE observation and description). Nevertheless, the entire MSE procedure demands more than a structured interview, since it is not analogous to anamnesis, but correlated to the PE procedure. We suppose that MSE is not entirely congruent or wholly embedded in semi-structured interview protocols. Attempting to turn personal experiences into objective data is probably a source of unreliability between examiners, as previously described. As far as we know, there is no standard method or procedure for MSE.

Parnas argues that DSM-V and ICD-10 were constructed to avoid subjectivity, but its developers have

not accomplished such intent . He emphasizes that it is easy to find objective, observable signs inside many diagnostic criteria, such as “blunt affect” in schizophrenia or “fast speech” in mania. Such categories should have been avoided in a categorial diagnostic system based on a standard interview, that was developed to eliminate examiner opinion as a source of unreliability. In a standard interview, all diagnostic emphasis relies on a “yes” and “no” type series of questions, directed at the patient, who decides if a symptom is or is not present. If MSE categories were to be used in a categorial diagnostic system, it should provide a template MSE method to be followed by the examiner during practice. A list of valid abnormal psychopathological categories for classificatory issues should also be provided.

In Brazil, at least one recent official report, demands a careful description of MSE subdivisions into patient record files . The official document on psychiatric training in Brazil states that all candidates must be proficient on MSE skills (apply and record). Despite that, a standard MSE is not explicitly provided, and it is not clear how it should be done or registered . The Brazilian Association of Psychiatry (ABP), the professional body responsible for education, training, setting and raising standards in Brazilian Psychiatry, did not mention or provide any statements concerning MSE, until now (4th of May 2018).³

Since 2014, doctors that have experience in psychiatry or that have attended a psychiatry internship and desire to obtain a certificate in psychiatry must be submitted to a practical clinical examination test, in which they are observed while interviewing and examining a patient.³ It is not evident in the documentation how the MSE, or even the clinical interview, would be assessed and what they are expected to perform during a practical examination test . The only clue provided is from Dalgalarondo's textbook inclusion of bibliographic references, which suggests that a detailed descriptive MSE and “súmula psicopatológica” is expected from candidates.

CONCLUSION

Our research suggests that descriptive psychopathology seems to be the usual MSE method used to observe and record data, not much different from the European schools or other parts of the world . Seven mental functions were consistently identified in the selected textbooks (consciousness, perception, thought, memory, attention, orientation, and volition), however no standard MSE and mental functions set was found. It was possible to identify a shift from the semiological discussion in Brazil during the last 50 years, from a detailed descriptive routine observed during the patient interaction to an array of observed pathological elements described through a mental function checklist. The “súmula psicopatológica” appears to be one pattern of examination, which could be improved or updated. Ethnopsychiatry or transcultural psychiatry research is needed regarding MSE, to achieve a regional attunement with patients and to comprehend the MSE practice in general.

MSE altogether, with anamnesis or a clinical interview, provides the basis for psychiatric clinics and research. Good clinical exercise and research guidelines in psychiatry must include the development of reliable MSE practice; however, it seems to have been neglected by modern psychiatry and neuroscience. Stressing interview protocols might flatten examination skills and impoverish MSE abilities. Development of better MSE practices and the improvement of bedside skills in psychiatry rely on reviving the psychopathological debate and semiologic reasoning of a vibrant tradition, and allowing for the return to a phenomenology-oriented “observational” technique.

Since we are now dealing with knowledge that has almost become lost, the recovery of the history of psychiatry and of national/regional practices plays a paramount role in bringing previous

experiences to the foreground, that could assist in the pursuit of this everlasting objective. In other words, the history of psychiatry plays a critical and hermeneutical role, and particular national attempts and enterprises in psychopathology should be re-evaluated. Practice standardization is now an international goal, but should not lead to one-way, top-down unification from high-tech oriented research centers, as global mental health policies have already advised. A call for diverse, multiple and manifold cultural experiences in MSE is necessary for the future development and improvement in Psychiatric practice and research.

LIMITATIONS

This is a comprehensive review about Psychopathology Textbooks in Brazil and, although rigorous work has been done, it is possible that some critical publication is lacking due to methodological bias. Furthermore, because we dealt with vintage books, which have not yet been cataloged by electronic repositories, it is possible that old Brazilian Textbooks with some contradictory information were not found. Mainstream psychiatry has neglected psychiatric semiology, Mental State Examination, Mental Functions and its role in psychopathology standards and clinical practice, so it is possible that other authors have already answered the questions presented here, which was not picked up by our search strategy. This is a very complicated issue that needs to be addressed by a multi-professional team of linguists, anthropologist, science and medicine historians, and psychiatry practitioners. Further work may clarify and better elucidate these questions and issues.

CLASSIFICATION OF PSYCHOPATHOLOGY: CONCEPTUAL AND HISTORICAL BACKGROUND

While not all psychiatric disorders have such dramatic “avalanche-like” transitions, they are fairly common in clinical psychiatry and challenge the authors’ conclusions that there is little viable evidence that psychiatric disorders need to be understood from a categorical perspective. Let me turn to a quite different issue. I was concerned by the manner in which the authors characterize the DSM process: “group discussions and associated political processes”, manifesting “sociopolitical dynamics”, issuing ex cathedra decisions with the final diagnoses resulting from “presumed authority and fiat”. This tone will not aid interdisciplinary discourse. The authors imply that they are the objective scientists while those who worked on DSM are, by comparison, bogged down in political discourse and constrained by old-fashioned historical dictates. While this is not the place to discuss this in detail, any organized effort in science to develop classifications involves “sociopolitical dynamics”. Readers who think otherwise might consult a history of the decision of the International Astronomical Union to remove Pluto from the official list of planets.

I want to conclude by talking about standards of diagnostic validation. At the risk of over-simplification, the Hierarchical Taxonomy of Psychopathology (HiTOP) program emphasizes psychometric methods in its typological proposals. Such methods have been key in the history of psychology, for example in the development of personality typologies and measures of various cognitive skills. So, it is sensible that they should be applied in the area of psychopathology. However, this approach differs considerably from the medical tradition emphasized by DSM. Put simply, the medical tradition wants diagnoses that tell us a lot about the patient — the course, the likely etiologic process, the best treatment, etc.. We organize our literature around our diagnoses, from cohort studies to randomized controlled trials.

The specific articulation of this viewpoint in psychiatry was first given by Robins and Guze with their list of validators, substantially expanded since then. Since DSM-III, the role of the evaluation of validators in diagnostic change has, albeit somewhat unevenly, gradually increased. The main approach

has been the use of literature reviews trying to summarize available information on validators. These questions were the specific focus of the Scientific Review Committee that evaluated every proposed diagnostic change in DSM-5. The procedures developed for change in DSM-5 by the American Psychiatric Association's Steering Committee are empirically rigorous and data driven. It is not surprising that the scientific disciplines of psychiatry and clinical psychology have developed different approaches to the creation and evaluation of diagnostic entities/dimensions. Optimal communication between these two disciplines, however, requires an understanding of the similarities and differences in these approaches, the relative strengths and limitations of each approach, and the acceptance by both sides that each is likely to be able to contribute meaningfully to the difficult challenge of designing an optimal psychiatric classification.

THE INTERNATIONAL CLASSIFICATION OF DISEASES

A second classification system, the International Classification of Diseases (ICD), is also widely recognized. Published by the World Health Organization (WHO), the ICD was developed in Europe shortly after World War II and, like the DSM, has been revised several times. The categories of psychological disorders in both the DSM and ICD are similar, as are the criteria for specific disorders; however, some differences exist. Although the ICD is used for clinical purposes, this tool is also used to examine the general health of populations and to monitor the prevalence of diseases and other health problems internationally (WHO, 2013).

The ICD is in its 10th edition (ICD-10); however, efforts are now underway to develop a new edition (ICD-11) that, in conjunction with the changes in DSM-5, will help harmonize the two classification systems as much as possible (APA, 2013). A study that compared the use of the two classification systems found that worldwide the ICD is more frequently used for clinical diagnosis, whereas the DSM is more valued for research (Mezzich, 2002). Most research findings concerning the etiology and treatment of psychological disorders are based on criteria set forth in the DSM (Oltmanns & Castonguay, 2013). The DSM also includes more explicit disorder criteria, along with an extensive and helpful explanatory text (Regier et al., 2012). The DSM is the classification system of choice among U.S. mental health professionals, and this chapter is based on the DSM paradigm.

THE COMPASSIONATE VIEW OF PSYCHOLOGICAL DISORDERS

As these disorders are outlined, please bear two things in mind. First, remember that psychological disorders represent extremes of inner experience and behavior. If, while reading about these disorders, you feel that these descriptions begin to personally characterize you, do not worry—this moment of enlightenment probably means nothing more than you are normal. Each of us experiences episodes of sadness, anxiety, and preoccupation with certain thoughts—times when we do not quite feel ourselves. These episodes should not be considered problematic unless the accompanying thoughts and behaviors become extreme and have a disruptive effect on one's life. Second, understand that people with psychological disorders are far more than just embodiments of their disorders.

We do not use terms such as schizophrenics, depressives, or phobics because they are labels that objectify people who suffer from these conditions, thus promoting biased and disparaging assumptions about them. It is important to remember that a psychological disorder is not what a person is; it is something that a person has—through no fault of his or her own. As is the case with cancer or diabetes, those with psychological disorders suffer debilitating, often painful conditions that are not of their own choosing. These individuals deserve to be viewed and treated with compassion, understanding, and dignity.

WHAT IS PSYCHOTHERAPIES: PSYCHOANALYSIS, PERSON-CENTERED, GESTALT, EXISTENTIAL, ACCEPTANCE COMMITMENT THERAPY, BEHAVIOR THERAPY, REBT, CBT, MBCT, Play therapy, Positive psychotherapy, Transactional Analysis, Dialectic behavior therapy, Art therapy, Performing Art Therapy, Family therapy?

PSYCHOTHERAPIES: PSYCHOANALYSIS, PERSON-CENTERED, GESTALT, EXISTENTIAL
Psychotherapy is a general term for treating mental health problems by talking with a psychiatrist, psychologist or other mental health provider. During psychotherapy, you learn about your condition and your moods, feelings, thoughts and behaviors. Psychotherapy helps you learn how to take control of your life and respond to challenging situations with healthy coping skills. There are many types of psychotherapy, each with its own approach. The type of psychotherapy that's right for you depends on your individual situation. Psychotherapy is also known as talk therapy, counseling, psychosocial therapy or, simply, therapy.

Why it's done Psychotherapy can be helpful in treating most mental health problems, including:

- **Anxiety disorders**, such as obsessive-compulsive disorder (OCD), phobias, panic disorder or post-traumatic stress disorder (PTSD)
- **Mood disorders**, such as depression or bipolar disorder
- **Addictions**, such as alcoholism, drug dependence or compulsive gambling
- **Eating disorders**, such as anorexia or bulimia
- **Personality disorders**, such as borderline personality disorder or dependent personality disorder
- **Schizophrenia** or other disorders that cause detachment from reality (psychotic disorders)

Not everyone who benefits from psychotherapy is diagnosed with a mental illness. Psychotherapy can help with a number of life's stresses and conflicts that can affect anyone. For example, it may help you:

- **Resolve conflicts** with your partner or someone else in your life
- **Relieve anxiety or stress** due to work or other situations
- **Cope with major life changes**, such as divorce, the death of a loved one or the loss of a job
- **Learn to manage unhealthy reactions**, such as road rage or passive-aggressive behavior
- **Come to terms with an ongoing or serious physical health problem**, such as diabetes, cancer or long-term (chronic) pain
- **Recover from physical or sexual abuse** or witnessing violence
- **Cope with sexual problems**, whether they're due to a physical or psychological cause
- **Sleep better**, if you have trouble getting to sleep or staying asleep (insomnia)

In some cases, psychotherapy can be as effective as medications, such as antidepressants. However, depending on your specific situation, psychotherapy alone may not be enough to ease the symptoms of a mental health condition. You may also need medications or other treatments.

RISKS

Generally, there's little risk in having psychotherapy. But because it can explore painful feelings and experiences, you may feel emotionally uncomfortable at times. However, any risks are minimized by working with a skilled therapist who can match the type and intensity of therapy with your needs. The coping skills that you learn can help you manage and conquer negative feelings and fears.

How you prepare

HERE'S HOW TO GET STARTED:

- **Find a therapist.** Get a referral from a doctor, health insurance plan, friend or other trusted source. Many employers offer counseling services or referrals through employee assistance programs (EAPs). Or you can find a therapist on your own, for instance, by looking for a professional association on the Internet.
- **Understand the costs.** If you have health insurance, find out what coverage it offers for psychotherapy. Some health plans cover only a certain number of psychotherapy sessions a year. Also, talk to your therapist about fees and payment options.
- **Review your concerns.** Before your first appointment, think about what issues you'd like to work on. While you also can sort this out with your therapist, having some sense in advance may provide a good starting point.

CHECK QUALIFICATIONS

Before seeing a psychotherapist, check his or her background, education, certification, and licensing. Psychotherapist is a general term rather than a job title or indication of education, training or licensure. Trained psychotherapists can have a number of different job titles, depending on their education and role. Most have a master's or doctoral degree with specific training in psychological counseling. Medical doctors who specialize in mental health (psychiatrists) can prescribe medications as well as provide psychotherapy.

Examples of psychotherapists include psychiatrists, psychologists, licensed professional counselors, licensed social workers, licensed marriage and family therapists, psychiatric nurses, or other licensed professionals with mental health training. Make sure that the therapist you choose meets state certification and licensing requirements for his or her particular discipline. The key is to find a skilled therapist who can match the type and intensity of therapy with your needs.

What you can expect

YOUR FIRST THERAPY SESSION

At the first psychotherapy session, the therapist typically gathers information about you and your needs. You may be asked to fill out forms about your current and past physical and emotional health. It might take a few sessions for your therapist to fully understand your situation and concerns and to determine the best approach or course of action. The first session is also an opportunity for you to interview your therapist to see if his or her approach and personality are going to work for you. Make sure you understand:

- What type of therapy will be used
- The goals of your treatment
- The length of each session
- How many therapy sessions you may need

Don't hesitate to ask questions anytime during your appointment. If you don't feel comfortable with the first psychotherapist you see, try someone else. Having a good fit with your therapist is critical for psychotherapy to be effective.

STARTING PSYCHOTHERAPY

You'll likely meet in your therapist's office or a clinic once a week or every other week for a session

that lasts about 45 to 60 minutes. Psychotherapy, usually in a group session with a focus on safety and stabilization, also can take place in a hospital if you've been admitted for treatment.

TYPES OF PSYCHOTHERAPY

There are a number of effective types of psychotherapy. Some work better than others in treating certain disorders and conditions. In many cases, therapists use a combination of techniques. Your therapist will consider your particular situation and preferences to determine which approach may be best for you. Although many types of therapies exist, some psychotherapy techniques proven to be effective include:

- **Cognitive behavioral therapy (CBT)**, which helps you identify unhealthy, negative beliefs and behaviors and replace them with healthy, positive ones
- **Dialectical behavior therapy**, a type of CBT that teaches behavioral skills to help you handle stress, manage your emotions and improve your relationships with others
- **Acceptance and commitment therapy**, which helps you become aware of and accept your thoughts and feelings and commit to making changes, increasing your ability to cope with and adjust to situations
- **Psychodynamic and psychoanalysis therapies**, which focus on increasing your awareness of unconscious thoughts and behaviors, developing new insights into your motivations, and resolving conflicts
- **Interpersonal psychotherapy**, which focuses on addressing problems with your current relationships with other people to improve your interpersonal skills — how you relate to others, such as family, friends and colleagues
- **Supportive psychotherapy**, which reinforces your ability to cope with stress and difficult situations. Psychotherapy is offered in different formats, including individual, couple, family or group therapy sessions, and it can be effective for all age groups.

DURING PSYCHOTHERAPY

For most types of psychotherapy, your therapist encourages you to talk about your thoughts and feelings and what's troubling you. Don't worry if you find it hard to open up about your feelings. Your therapist can help you gain more confidence and comfort as time goes on. Because psychotherapy sometimes involves intense emotional discussions, you may find yourself crying, upset or even having an angry outburst during a session. Some people may feel physically exhausted after a session. Your therapist is there to help you cope with such feelings and emotions. Your therapist may ask you to do "homework" — activities or practices that build on what you learn during your regular therapy sessions. Over time, discussing your concerns can help improve your mood, change the way you think and feel about yourself, and improve your ability to cope with problems.

CONFIDENTIALITY

Except in rare and specific circumstances, conversations with your therapist are confidential. However, a therapist may break confidentiality if there is an immediate threat to safety (yours or someone else's) or when required by state or federal law to report concerns to authorities. Your therapist can answer questions about confidentiality.

LENGTH OF PSYCHOTHERAPY

The number of psychotherapy sessions you need — as well as how frequently you need to see your therapist — depends on such factors as:

- Your particular mental illness or situation
- Severity of your symptoms
- How long you've had symptoms or have been dealing with your situation
- How quickly you make progress
- How much stress you're experiencing
- How much your mental health concerns interfere with day-to-day life
- How much support you receive from family members and others
- Cost and insurance limitations

It may take only weeks to help you cope with a short-term situation. Or, treatment may last a year or longer if you have a long-term mental illness or other long-term concerns.

Results Psychotherapy may not cure your condition or make an unpleasant situation go away. But it can give you the power to cope in a healthy way and to feel better about yourself and your life.

GETTING THE MOST OUT OF PSYCHOTHERAPY

Take steps to get the most out of your therapy and help make it a success.

- **Make sure you feel comfortable with your therapist.** If you don't, look for another therapist with whom you feel more at ease.
- **Approach therapy as a partnership.** Therapy is most effective when you're an active participant and share in decision-making. Make sure you and your therapist agree about the major issues and how to tackle them. Together, you can set goals and measure progress over time.
- **Be open and honest.** Success depends on willingness to share your thoughts, feelings and experiences, and to consider new insights, ideas and ways of doing things. If you're reluctant to talk about certain issues because of painful emotions, embarrassment or fears about your therapist's reaction, let your therapist know.
- **Stick to your treatment plan.** If you feel down or lack motivation, it may be tempting to skip psychotherapy sessions. Doing so can disrupt your progress. Try to attend all sessions and to give some thought to what you want to discuss.
- **Don't expect instant results.** Working on emotional issues can be painful and may require hard work. You may need several sessions before you begin to see improvement.
- **Do your homework between sessions.** If your therapist asks you to document your thoughts in a journal or do other activities outside of your therapy sessions, follow through. These homework assignments can help you apply what you've learned in the therapy sessions to your life.
- **If psychotherapy isn't helping, talk to your therapist.** If you don't feel that you're benefiting from therapy after several sessions, talk to your therapist about it. You and your therapist may decide to make some changes or try a different approach that may be more effective.

PSYCHOANALYTIC PSYCHOTHERAPY

Psychoanalytic or Psychodynamic Psychotherapy is a form of clinical practice which is based on psychoanalytic theory and principles. It's a treatment modality that in many ways is quite similar to psychoanalysis, although often considered less intense. Psychoanalytic psychotherapy utilizes psychoanalytic theories as the frame for formulation and understanding of the therapy process. These multiple theories apply to the psychotherapy situation, with a focus on increasing self understanding and deepening insight into emotional issues and conflicts which underlie the presenting difficulties. Typically therapists make use of exploration of unconscious thoughts and feelings, understanding

aspects of the relationship between therapist and patient, which may relate to underlying emotional conflicts, interpretation of defensive processes which obstruct emotional awareness, and consideration of issues related to sense of self and self esteem.

Most often therapy sessions occur between one and four times weekly. The focus is on exploration of the patient's inner experience, emphasizing this as it occurs in current daily life, as it carries over from significant and influential events and relationships of the past, and as it is manifest in the context of the therapeutic relationship. The efficacy of psychoanalytic psychotherapy, often referred to as psychodynamic psychotherapy, has been well documented. Current research indicates this as a powerfully curative treatment. P

WHO IS A PSYCHOANALYTIC PSYCHOTHERAPIST?

Clinicians who practice psychoanalytic or psychodynamic psychotherapy all share a common orientation about how to assess and treat emotional problems. Most psychodynamic therapists have extensive training. The formats and contexts of this training are wide ranging — from graduate or medical school instruction and case supervision to **rigorous and formal** advanced psychotherapy training programs or psychoanalytic training. The vast majority of psychoanalytic psychotherapists elect to pursue ongoing additional training beyond their graduate or medical school instruction in order to deepen and extend their skills. Psychoanalytic psychotherapists can be found in a variety of professional disciplines, including social work, psychology, psychiatry, and psychiatric nursing.

WHO CAN BENEFIT FROM PSYCHOANALYTIC PSYCHOTHERAPY?

While there is no simple answer to this question, it is important to emphasize that psychodynamic psychotherapy can be an effective treatment or component of a combined treatment for a very wide range of emotional and psychological difficulties. This includes, in one form or another all ages, and many diagnostic categories. The range of indications is significantly wider than that for psychoanalysis. In order to address this question for any individual, a careful evaluation with a well qualified therapist is an important first step.

PERSON-CENTERED THERAPY (ROGERIAN THERAPY)

Person-centered therapy was developed by Carl Rogers in the 1940s. This type of therapy diverged from the traditional model of the therapist as expert and moved instead toward a nondirective, empathic approach that empowers and motivates the client in the therapeutic process. The therapy is based on Rogers's belief that every human being strives for and has the capacity to fulfill his or her own potential. Person-centered therapy, also known as Rogerian therapy, has had a tremendous impact on the field of psychotherapy and many other disciplines.

ROGERIAN THEORY IN PSYCHOTHERAPY

Rather than viewing people as inherently flawed, with problematic behaviors and thoughts that require treatment, person-centered therapy identifies that each person has the capacity and desire for personal growth and change. Rogers termed this natural human inclination "actualizing tendency," or self-actualization. He likened it to the way that other living organisms strive toward balance, order, and greater complexity. According to Rogers, "Individuals have within themselves vast resources for self-understanding and for altering their self-concepts, basic attitudes, and self-directed behavior; these resources can be tapped if a definable climate of facilitative psychological attitudes can be provided."

The person-centered therapist learns to recognize and trust human potential, providing clients with

empathy and unconditional positive regard to help facilitate change. The therapist avoids directing the course of therapy by following the client's lead whenever possible. Instead, the therapist offers support, guidance, and structure so that the client can discover personalized solutions within themselves.

Person-centered therapy was at the forefront of the humanistic psychology movement, and it has influenced many therapeutic techniques and the mental health field, in general. Rogerian techniques have also influenced numerous other disciplines, from medicine to education.

SIX FACTORS NECESSARY FOR GROWTH IN ROGERIAN THEORY

Rogers identified six key factors that stimulate growth within an individual. He suggested that when these conditions are met, the person will gravitate toward a constructive fulfillment of potential. According to Rogerian theory, the six factors necessary for growth are:

- 1. Therapist-Client Psychological Contact:** This first condition simply states that a relationship between therapist and client must exist in order for the client to achieve positive personal change. The following five factors are characteristics of the therapist-client relationship, and they may vary by degree.
- 2. Client Incongruence or Vulnerability:** A discrepancy between the client's self-image and actual experience leaves him or her vulnerable to fears and anxieties. The client is often unaware of the incongruence.
- 3. Therapist Congruence or Genuineness:** The therapist should be self-aware, genuine, and congruent. This does not imply that the therapist be a picture of perfection, but that he or she be true to him- or herself within the therapeutic relationship.
- 4. Therapist Unconditional Positive Regard (UPR):** The clients' experiences, positive or negative, should be accepted by the therapist without any conditions or judgment. In this way, the client can share experiences without fear of being judged.
- 5. Therapist Empathy:** The therapist demonstrates empathic understanding of the clients' experiences and recognizes emotional experiences without getting emotionally involved.
- 6. Client Perception:** To some degree, the client perceives the therapist's unconditional positive regard and empathic understanding. This is communicated through the words and behaviors of the therapist.

GESTALT THERAPY

Gestalt therapy is a humanistic, holistic, person-centered form of psychotherapy that is focused on an individual's present life and challenges rather than delving into past experiences. This approach stresses the importance of understanding the context of a person's life and taking responsibility rather than placing blame. It can be a little intimidating to consider starting therapy, especially if you imagine yourself sitting in the therapy room talking about the past. Although revisiting the past is an important part of identifying what needs to be healed, Gestalt therapy is an approach that focuses more on the "here and now" experience of the client.

Gestalt, by definition, refers to the form or shape of something and suggests that the whole is greater than the sum of its parts. There is an emphasis on perception in this particular theory of counseling. Gestalt therapy gives attention to how we place meaning and make sense of our world and our experiences. Within Gestalt therapy, the client has space to safely explore their experiences without fear of judgment. In fact, the clients are encouraged to not simply talk about their emotions or experiences, but to bring them into the room so they can be processed in real-time with the therapist. Gestalt therapy suggests that, inherently, people strive for self-regulation and growth. However, we

sometimes develop techniques to emotionally survive unfortunate and painful experiences. Some of these techniques feel helpful in the short-term because they can help minimize our pain or distress. However, over the long-term, they leave us in more emotionally shaky places, unable to express ourselves. We may find it hard to interact with others, and difficult to learn how to effectively regulate ourselves and be whole, responsible beings.

STRENGTHS AND WEAKNESSES

Gestalt therapy has both some pluses and minuses. Research suggests that it can be effective for treating a variety of conditions including anxiety and personality disorders and is at least as effective as other psychotherapy approaches. Existential Psychotherapy

Existential psychotherapy is a style of therapy that places emphasis on the human condition as a whole. Existential psychotherapy uses a positive approach that applauds human capacities and aspirations while simultaneously acknowledging human limitations. Existential psychotherapy shares many similarities with humanistic psychology, experiential psychotherapy, depth psychotherapy, and relational psychotherapy.

TIMELINE OF EXISTENTIAL THERAPY

Existential therapy developed out of the philosophies of Friedrich Nietzsche and Soren Kierkegaard. As one of the first existential philosophers, Kierkegaard theorized that human discontent could only be overcome through internal wisdom. Later, Nietzsche further developed the theory of existentialism using concepts such as the will to power and personal responsibility. In the early 1900s, philosophers such as Martin Heidegger and Jean-Paul Sartre began to explore the role of investigation and interpretation in the healing process. Over the next several decades, other contemporaries started to acknowledge the importance of experiencing in relation to understanding as a method to achieving psychological wellness and balance.

Otto Rank was among the first existential therapists to actively pursue the discipline, and by the middle of the 20th century, psychologists Paul Tillich and Rollo May brought existential therapy into the mainstream through their writings and teachings, as did Irvin Yalom after them. The popular approach began to influence other theories, including logotherapy, which developed by Viktor Frankl, and humanistic psychology. At the same time, British philosophers expanded existentialism further with the foundation of The Philadelphia Association, an organization dedicated to helping people manage their mental health issues with experiential therapies. Other institutions that embody the theory of existentialism include the Society for Existential Analysis, founded in 1988, and the International Community of Existential Counselors, created in 2006.

EXISTENTIAL PSYCHOTHERAPY 'GIVENS'

Existential psychotherapy is based upon the fundamental belief that all people experience intrapsychic conflict due to their interaction with certain conditions inherent in human existence, which are known as givens. The theories recognize at least four primary existential givens:

- Freedom and associated responsibility
- Death
- Isolation
- Meaninglessness

A confrontation with any of the aforementioned conditions, or givens, fills an individual with a type of dread commonly referred to as existential anxiety. This anxiety is thought to reduce a person's

physical, psychological, social, and spiritual awareness, which may lead to significant long-term consequences. For example, the fact that each one of us and each one of our loved ones must die at some unknown time may be a source of deep anxiety to us, and this may tempt us to ignore the reality and necessity of death in human existence. By reducing our awareness of death, however, we may fail to make decisions that can actually safeguard or even enrich our lives. At the other end of the spectrum, people who are overly conscious of the fact that death is inevitable may be driven to a state of neurosis or psychosis. The key, according to existential psychotherapy, is to strike a balance between being aware of death without being overwhelmed by it. People who maintain a healthy balance in this way are motivated to make decisions that can positively impact their lives, as well as the lives of their loved ones. Though these people may not know how their decisions will actually turn out, they do appreciate the need to take action while they can. In essence, the reality of death encourages us to make the most of opportunities and to treasure the things we have.

Like death, the threat of isolation, the perceived meaninglessness of life, and the weighty responsibility of making life-altering decisions may each be a source of acute existential anxiety. According to the theories of existential therapy, the manner in which a person processes these internal conflicts, and the decisions they make as a result, will ultimately determine that person's present and future circumstances.

ACCEPTING FEARS AND OVERCOMING THEM

Existential psychotherapy encourages people to not only address the emotional issues they face through full engagement but to also take responsibility for the decisions that contributed to the development of those issues. People who participate in this form of therapy are guided to accept their fears and given the skills necessary to overcome these fears through action. By gaining control of the direction of their life, the person in therapy is able to work to design the course of their choosing. Through this work, people often come to feel both a sense of liberation and the ability to let go of the despair associated with insignificance and meaninglessness. Thus, existential psychotherapy involves teaching people in therapy to grow and embrace their own lives and exist in them with wonder and curiosity. Developing the ability to view life with wonder can help people be able to view the life experience as a journey rather than a trial and can also help eradicate the fear associated with death.

EXISTENTIAL THERAPISTS' PROCESS

Therapists who practice existential psychotherapy do not focus on a person's past. Instead, they work with the person in therapy to discover and explore the choices that lie before them. Through retrospection, the person in therapy and therapist work together to understand the implications of past choices and the beliefs that led those to take place, only as a means to shift to the goal of creating a keener insight into the self. In existential therapy, the emphasis is not to dwell on the past, but to use the past as a tool to promote freedom and newfound assertiveness. By coming to the realization that they are neither unique nor destined for a specific purpose, the person in therapy is able to release the obligatory chains that may have been preventing them from existing in fullness from moment to moment. When that happens, they then achieve the ability to become truly free.

HOW CAN EXISTENTIAL PSYCHOTHERAPY HELP?

People in therapy who are willing to explore the reasons for their intrapsychic conflicts and the decisions that led to their current circumstances can benefit greatly from existential psychotherapy. There are many behavioral and mental health issues that may be successfully treated with this therapeutic approach, including depression, anxiety, substance dependency, and posttraumatic stress

resulting from exposure to military combat, rape, childhood sexual abuse, interpersonal violence, or other life-threatening experiences. Individuals who respond to treatment tend to find meaning and purpose in their lives and often experience heightened self-awareness, self-understanding, self-respect, and self-motivation. The realization that they are primarily responsible for their own recovery often increases the likelihood that people in treatment will see beyond the limits of a therapy session and view recovery as a therapeutic process.

COMMON CONCERNS AND LIMITATIONS

Existential psychotherapy, much like other types of therapy, may be misunderstood by people who do not have a thorough grasp of the fundamental principles or scope of the associated theories. It can help to develop awareness of the principles, theories, and givens before and while participating in treatment. Common misperceptions of existential psychotherapy include the following beliefs:

- **One distinctive, united existential theory, free of internal tension, covers all the basic assumptions of existential psychology.** In fact, there are at least five categories of the approach, and most scholars view this as a strength of the approach, as it leads to consistent examination of the basic assumptions of the approach and allows for greater adaptability.
- **There is no difference between existential psychology and existential philosophy.** Though there are points of agreement between existential philosophy and existential psychology, there are also points of difference, and the variation in perspectives of the leading pioneers and scholars of the two fields help contribute to the development of each approach.
- **Existential psychology takes an antireligious or anti-spiritual approach, for example, denying the existence of God.** Though existential psychology is not innately religious and does discourage people from following one person or religion without question, it is also not anti-religious, and many of the leading scholars and pioneers were Christian theologians.
- **Existential and humanistic theories are the same thing.** Though there is agreement between the two theories, they are not identical. However, disagreements between these two schools of thought tend to be more degrees of emphasis and less complete divergences.
- **Existential psychotherapy takes a negative, dark, or pessimistic view of life.** Because writings on existential psychology can be read as pessimistic, due to their view that suffering can be embraced as part of the human existence.

This is not an encouragement of suffering, though, only recognition of the fact that it is an inescapable part of being human. What existential therapy does do is encourage people to embrace the reality of suffering in order to work through and learn from it. **The approach is fundamentally an intellectual one and, as such, is only beneficial to people of high intellect, who are not experiencing chronic behavioral or mental health conditions.** People of any intelligence level are capable of the awareness of their own humanity and able to make meaning of their emotions and anxieties. It is not necessary for a person to be a philosopher or scholar to benefit from the principles of existential therapy, and many people who are actively struggling with mental health issues can also be helped by the approach.

Because existential psychotherapy targets the underlying factors of perceived behavioral and mental health concerns, an existential approach may not directly address the primary issue a person in treatment is experiencing. Because of this, existential therapy, which is quite adaptable, is often used along with other approaches to treatment. Combining approaches can help maximize the effectiveness of both and promote greater recovery. Additionally, the in-depth, penetrative approach used in existential psychotherapy may not appeal to people who do not wish to explore their

intrapyschic processes, or who are solely interested in finding a quick fix for their mental health challenges.

ACCEPTANCE AND COMMITMENT THERAPY (ACT)

Acceptance and Commitment Therapy (ACT) encourages people to embrace their thoughts and feelings rather than fighting or feeling guilty for them. It may seem confusing at first, but ACT paired with **mindfulness-based therapy** offers clinically effective treatment. After all: Running away from any problem only increases the distance from the solution. The easiest way to escape from the problem is to solve it. Medical conditions such as anxiety, depression, OCD, addictions, and substance abuse can all benefit from ACT and Mindfulness-Based Cognitive Therapy (MBCT). ACT develops psychological flexibility and is a form of behavioral therapy that combines mindfulness skills with the practice of self-acceptance. When aiming to be more accepting of your thoughts and feelings, commitment plays a key role. In the case of ACT, you commit to facing the problem head-on rather than avoiding your stresses. Imagine committing to actions that help you facilitate your experience and embrace any challenge.

As you will see later in this piece, ACT is effective for a wide range of psychological disorders, and it is also effective as a life-affirming and inspirational perspective of self-determination. “a unique empirically based psychological intervention that uses acceptance and mindfulness strategies, together with commitment and behavior change strategies, to increase psychological flexibility.” The ACBS views ACT as a therapy based on the concept that suffering is a natural and inevitable condition for humans. We have an instinct to control our experiences, but this instinct does not always serve us.

The founder of ACT has also offered a definition of ACT in terms familiar to the psychology field: “a psychological intervention based on modern behavioral psychology, including **Relational Frame Theory**, that applies mindfulness and acceptance processes, and commitment and behavior change processes, to the creation of psychological flexibility” (Hayes, “The Six Core Processes of ACT”). To put it in less clinical terms, Dr. Russell Harris (2011) has defined ACT as “a mindfulness-based behavioral therapy that challenges the ground rules of most Western psychology.” Its unique goal is to help patients create a rich and meaningful life and develop mindfulness skills alongside the existence of pain and suffering.

CORE PROCESSES

Six core processes of ACT guide patients through therapy and provide a framework for developing psychological flexibility (Harris, 2011). These six core processes of ACT include the following:

- Acceptance;
- Cognitive Defusion;
- Being Present;
- Self as Context;
- Values;
- Committed Action.

Acceptance is an alternative to our instinct to avoid thinking about negative—or potentially negative—experiences. It is the active choice to allow unpleasant experiences to exist, without trying to deny or change them. Acceptance is not a goal of ACT, but a method of encouraging action that will

lead to positive results. Cognitive Defusion refers to the techniques intended to change how an individual reacts to their thoughts and feelings. Acceptance and Commitment Therapy does not intend to limit our exposure to negative experiences, but rather to face them and come out the other side with a decreased fixation on these experiences.

Being Present can be understood as the practice of being aware of the present moment, without judgment the experience. In other words, it involves experiencing what is happening without trying to predict or change the experience. Self as Context is the idea that an individual is not simply the sum of their experiences, thoughts, or emotions. The "self as context" process offers the alternative concept that there is a self outside of the current experience. We are not only what happens to us. We are the ones experiencing what happens to us. **Values** in this context are the qualities we choose to work towards in any given moment. We all hold values, consciously or unconsciously, that direct our steps. In ACT, we use tools that help us live our lives in accordance with the values that we hold dear.

Finally, ACT aims to help patients commit to actions that will assist in their long-term goals and live a life consistent with their values. Positive behavior changes cannot occur without awareness of how a given behavior affects us. ACT is not all that different from other behavioral-based therapies; it just emphasizes acceptance instead of avoidance, and in that way, differs from many other forms of therapy. This departure from most mainstream treatment can be traced back to the background of ACT's founder, Stephen C. Hayes.

THE ROLE OF ACT IN PSYCHOLOGY AND MINDFULNESS

Acceptance and Commitment Therapy is built on the Relational Frame Theory, a theory based on the idea the human ability to relate is the foundation of language and cognition. Relating involves noting the dimensions along which relation exists. For example, we may associate an apple with an orange, but our ability of relating allows us to understand that although they have a similar shape (round) and function (to be eaten), they have different colors and textures. Humans, unlike most other animals, have an uncanny ability to relate even neutral events, as well as seemingly unrelated words and ideas.

While this is an advantageous ability, it also facilitates negative thoughts and judgment about ourselves. If we can relate the word “cookie” to the experience of eating a cookie, then we can also relate the word “worthless” to feeling that we are worthless. Our ability to form relational networks (e.g., I relate the words “orange”, “apple”, and “pear” to the concept of “fruit”) can be a destructive ability when anxiety and depression impact us. For example, we might relate “worthless” to an ability to perform my job and, by extension, relate the word “worthless” to my life. ACT is built on **Relational Frame Theory**. We often form relational networks that are not complimentary or life-giving, but we can also change those relations when we apply mindfulness to accept our feelings and change how we react and relate to them, instead of trying to avoid them.

1. TRIGGERS, BEHAVIORS, AND PAYOFFS

This worksheet is a fillable matrix on page 6 with one column for writing down triggers (situations, thoughts, or feeling that immediately precede a certain behavior), behaviors (what you actually do), and payoffs (the immediate outcomes of the behavior that encourage the behavior to continue). This worksheet can help you or your clients identify self-defeating behaviors with the motivation behind them, which can be a first step to recognizing and modifying problematic behavior.

2. BULL’S EYE: CLARIFYING YOUR VALUES

Another worksheet presents the Values Bull’s Eye, or a set of concentric circles that are separated into four quadrants: work/education, leisure, personal growth/health, and relationships. The exercise involves placing an “X” on the circle that most closely represents how you feel in the present moment. The closer to the middle the X is, the more you feel you are behaving like the person you want to be. The further out the X is, the less you feel like the person you want to be.

3. THE ‘TRIFLEX’ PSYCHOLOGICAL FLEXIBILITY ASSESSMENT TOOL

The final pages in the PDF from ACT Mindfully help you estimate your psychological flexibility based on three factors:

1. Ability to open up
2. Ability to be present
3. Ability to do what matters

Here you will find a visual representation of psychological flexibility, an explanation of each of these three factors, and a method of estimating your abilities in these areas at this moment.

4. “THE HAPPINESS TRAP” WORKSHEET THE COST OF AVOIDANCE WORKSHEET

This worksheet presents four sentences for you to complete:

1. The thoughts I’d most like to get rid of are:
2. The feelings I’d most like to get rid of are:
3. The sensations I’d most like to get rid of are:
4. The memories I’d most like to get rid of are:

Next, you are asked to write a list of everything you have done to try to avoid or get rid of these thoughts, feelings, sensations, and memories. Distracting yourself from these, avoiding activities, or using substances to self-medicate are a few examples of avoidance techniques. Then you are asked to consider these questions for each item:

1. Did this action get rid of my painful thoughts and feelings in the long term?
2. Did it bring me closer to a rich, full, and meaningful life?
3. If the answer to question 2 is “no,” then what did this action cost me in terms of time, energy, money, health, relationships, and vitality?

This worksheet can help you become aware of your own avoidance strategies, and whether they are producing the results you want.

INFORMAL MINDFULNESS EXERCISES

This page introduces two simple mindfulness exercises for any typical day:

1. **Mindfulness in Your Morning Routine:** This exercise encourages you to notice the sensations while getting ready in the morning, such as the taste of your toothpaste, the smell of your face wash, or the feel of hot water on your body in the shower.
2. **Mindfulness of Domestic Chores:** This exercise is one you can practice by simply being aware of the sensations you experience as you sweep the floors, do a load of laundry, or make dinner. Since you “always” have to do the dishes, why not take the time to do it mindfully? It’s good for your brain. This worksheet allows space for you to imagine some informal mindfulness exercises to add to your day, such as while waiting in traffic or while walking from your car to your door. Maybe it’s as little as “no-phone” time while you grocery shop or wait in line.

VALUES ASSESSMENT RATING FORM

The Values Assessment Rating Form provides a matrix with 10 life domains (e.g., couples/intimate relationships, parenting, employment, etc.) and 4 columns to fill out:

- Valued direction (a brief summary of your goal for each domain)
- Importance of this value in your life
- Success in living this value
- Rank in order of importance you place on working on this domain right now

The Values Assessment Rating Form can help you identify where you are falling short of your goals and where you are meeting your goals, as well as aiding the prioritization of meeting these goals going forward.

GOAL SETTING WORKSHEET

This worksheet guides the reader through the values that underlie their goals and how to make sure these goals are SMART goals. SMART is an acronym for goals that are Specific, Meaningful, Adaptive, Realistic, and Time-bound. This activity will help you understand how to set goals that you can meet, rather than lofty ideas that are not backed by concrete actions.

WHAT TO DO IN A CRISIS

This informational page offers a practical and useful response for when you face a crisis.

This response is called STOP:

- Slow your breathing: enter into a quick and simple mindfulness practice.
- Take note: noticing what you are experiencing in the present moment.
- Open up: allow yourself to feel without judgment or avoidance.
- Pursue your values: decide what the best course of action is based on your most important values.

Here is a list of things to consider during this exercise:

1. Consider if you need assistance or support, and who could provide you with the assistance or support you need.
2. Think about whether you have experienced anything similar before, and how you responded to it then.
3. Consider ways to improve the situation, even in the smallest way, whether it's in the next few minutes or the next few days.
4. Be willing to practice acceptance if you cannot improve your situation, and commit to spending your time and energy in a constructive way.
5. Ask yourself what the best way is to deal with this situation or, as the metaphor goes, how to play the game with the cards you have been dealt.
6. Remember to practice self-compassion; if you need inspiration, imagine a friend or loved one was going through your experience right now, and tell yourself whatever you imagine telling them.

5. PSYCHOLOGICAL INFLEXIBILITY

For therapists and other mental health professionals from The Happiness Trap aligns with ACT principles as well. It provides questions for you to assess your clients for their psychological inflexibility. Psychological inflexibility is the extent to which anyone has trouble practicing the six core processes. The questions map to the opposite of the six core processes as follows:

- The dominance of the conceptualized past or future; limited self-knowledge (vs. acceptance)
- Fusion (vs. defusion)
- Experiential avoidance (vs. being present)
- Attachment to the conceptualized self (vs. self as context)
- Lack of values clarity/contact (vs. values)
- Unworkable action (vs. committed action)

This set of questions can be a great tool to help your clients ascertain where to focus their energy. This is a critical step to embracing their experiences and act according to their deepest values.

BEHAVIORAL THERAPY IS USED IN PSYCHOLOGY

In behavioral therapy, the goal is to reinforce desirable behaviors and eliminate unwanted or maladaptive ones. Behavioral therapy is rooted in the principles of behaviorism, a school of thought focused on the idea that we learn from our environment. The techniques used in this type of treatment are based on the theories of classical conditioning and operant conditioning. One important thing to note about the various behavioral therapies is that unlike some other types of therapy that are rooted in insight (such as psychoanalytic and humanistic therapies), behavioral therapy is action-based. Behavioral therapists are focused on using the same learning strategies that led to the formation of unwanted behaviors.

Because of this, behavioral therapy tends to be highly focused. The behavior itself is the problem and the goal is to teach clients new behaviors to minimize or eliminate the issue. Old learning led to the development of a problem, and so the idea is that new learning can fix it. There are three major areas that also draw on the strategies of behavioral therapy:

- **Cognitive-behavioral therapy** relies on behavioral techniques but adds a cognitive element, focusing on the problematic thoughts that lie behind behaviors.

- **Applied behavior analysis** uses operant conditioning to shape and modify problematic behaviors.
- **Social learning theory** centers on how people learn through observation. Observing others being rewarded or punished for their actions can lead to learning and behavior change.

Edward Thorndike was one of the first to refer to the idea of modifying behavior. Other early pioneers of behavior therapy included psychologists Joseph Wolpe and Hans Eysenck. Behaviorist B.F. Skinner's work had a major influence on the development of behavior therapy and his work introduced many of the concepts and techniques that are still in use today.

Later on, psychologists such as Aaron Beck and Albert Ellis began adding a cognitive element to behavioral strategies to form a treatment approach known as cognitive-behavioral therapy (CBT).

THE FOUNDATION OF BEHAVIORAL THERAPY

In order to understand how behavioral therapy works, let's start by exploring the two basic principles that contribute to behavioral therapy: Classical and operant conditioning.

- **Classical conditioning** involves forming associations between stimuli. Previously neutral stimuli are paired with a stimulus that naturally and automatically evokes a response. After repeated pairings, an association is formed and the previously neutral stimulus will come to evoke the response on its own.
- **Operant conditioning** focuses on how reinforcement and punishment can be utilized to either increase or decrease the frequency of a behavior. Behaviors followed by desirable consequences are more likely to occur again in the future, while those followed by negative consequences become less likely to occur.

BEHAVIOR THERAPY BASED ON CLASSICAL CONDITIONING

Classical conditioning is one way to alter behavior, and a number of techniques exist that can produce such change. Originally known as behavior modification, this type of therapy is often referred to today as applied behavior analysis. There are several different techniques and strategies used in this approach to therapy.

FLOODING

This process involves exposing people to fear-invoking objects or situations intensely and rapidly. It is often used to treat phobias. During the process, the individual is prevented from escaping or avoiding the situation. For example, flooding might be used to help a person who is suffering from an intense fear of dogs. At first, the client might be exposed to a small, friendly dog for an extended period of time during which they cannot leave. After repeated exposures to the dog during which nothing bad happens, the fear response begins to fade.

SYSTEMATIC DESENSITIZATION

In this technique, a client makes a list of fears and then learns to relax while concentrating on these fears. The use of this process began with psychologist John B. Watson and his famous Little Albert experiment in which he conditioned a young child to fear a white rat. Later, Mary Cover Jones replicated Watson's results and utilized counterconditioning techniques to desensitize and eliminate the fear response. Systematic desensitization is often used to treat phobias and other anxiety disorders. The process follows three basic steps.

1. First, the therapist teaches the client relaxation techniques.
2. Next, the individual creates a ranked list of fear-invoking situations.
3. Starting with the least fear-inducing item and working their way up to the most fear-inducing item,

the client confronts these fears under the guidance of the therapist while maintaining a relaxed state.

For example, an individual with a fear of the dark might start by looking at an image of a dark room, before moving on to thinking about being in a dark room, and then actually confronting his fear by sitting in a dark room. By pairing the old fear-producing stimulus with the newly learned relaxation behavior, the phobic response can be reduced or even eliminated.

AVERSION THERAPY

This process involves pairing an undesirable behavior with an aversive stimulus in the hope that the unwanted behavior will eventually be reduced. For example, someone suffering from alcoholism might take disulfiram, a drug which causes severe symptoms (such as headaches, nausea, anxiety, and vomiting) when combined with alcohol.

HOW AVERSION THERAPY WORKS TO FIX UNWANTED BEHAVIORS

Behavior Therapy Based on Operant Conditioning Many behavior techniques rely on the principles of operant conditioning, which means that they use reinforcement, punishment, shaping, modeling and related techniques to alter behavior. These methods have the benefit of being highly focused, which means that they can produce fast and effective results.

TOKEN ECONOMIES

This type of behavioral strategy relies on reinforcement to modify behavior. Clients are allowed to earn tokens that can be exchanged for special privileges or desired items. Parents and teachers often use token economies to reinforce good behavior. Kids earn tokens for engaging in preferred behaviors and may lose tokens for displaying undesirable behaviors. These tokens can then be traded for rewards such as candy, toys, or extra time playing with a favorite toy.

CONTINGENCY MANAGEMENT

This approach uses a formal written contract between a client and a therapist (or parent or teacher) that outlines behavior-change goals, reinforcements, rewards, and penalties. Contingency contracts can be very effective in producing behavior changes since the rules are spelled out clearly, preventing both parties from backing down on their promises.

MODELING

This technique involves learning through observation and modeling the behavior of others. The process is based on Albert Bandura's social learning theory, which emphasizes the social components of the learning process. Rather than relying simply on reinforcement or punishment, modeling allows individuals to learn new skills or acceptable behaviors by watching someone else perform those desired skills. In some cases, the therapist might model the desired behavior. In other instances, watching peers engage in sought-after behaviors can also be helpful.

EXTINCTION

Another way to produce behavior change is to stop reinforcing a behavior in order to eliminate the response. Time-outs are a perfect example of the extinction process. During a time-out, a person is removed from a situation that provides reinforcement. For example, a child who starts yelling or striking other children would be removed from the group and required to sit quietly in a place where there are no opportunities for attention and reinforcement. By taking away the attention that the child found rewarding, the unwanted behavior is eventually extinguished.

RATIONAL EMOTIVE BEHAVIOR THERAPY (REBT)

Rational emotive behavior therapy, also known as REBT, is a type of cognitive-behavioral therapy developed by psychologist Albert Ellis. REBT is focused on helping clients change irrational beliefs. History of Rational Emotive Behavior Therapy As a young man, Ellis found himself longing for companionship yet experienced a severe fear of talking to women. In order to tackle his fear, Ellis decided to perform an experiment. For a month, he visited a nearby park and forced himself to talk to 100 different women. Over time, Ellis found that his fear of speaking to women had diminished considerably. This experience served as a basis for developing his approach to therapy, combining behavioral strategies with assessing underlying thoughts and emotions. Ellis had trained as a clinical psychologist. As he treated patients, he became increasingly dissatisfied with the results offered by the traditional psychoanalytic approach to therapy. While his patients were able to become aware of their underlying problems, their behavior did not necessarily change. Simply becoming conscious of the problem was not enough, he concluded.

By the 1950s, Ellis had started experimenting with other types of psychotherapy. He was heavily influenced by philosophers and psychologists including Karen Horney and Alfred Adler, as well as the work of behavioral therapists. Ellis's goal was to develop what he viewed as an action-oriented approach to psychotherapy designed to produce results by helping clients manage emotions, cognitions, and behaviors. "People are not disturbed by things but rather by their view of things," Ellis said. The fundamental assertion of rational emotive behavior therapy (REBT) is that the way people feel is largely influenced by how they think.¹

When people hold irrational beliefs about themselves or the world, problems can result. The goal of REBT is to help people alter illogical beliefs and negative thinking patterns in order to overcome psychological problems and mental distress.²

Rational emotive behavior therapy was one of the very first types of cognitive therapies. Ellis first began developing REBT during the early 1950s and initially called his approach "rational therapy."¹ In 1959, the technique was renamed "rational emotive therapy," and then became "rational emotive behavior therapy" in 1992. Ellis continued to work on REBT until his death in 2007.

THE ABC MODEL

Ellis suggested that people mistakenly blame external events for unhappiness. He argued, however, that it is our interpretation of these events that truly lies at the heart of our psychological distress. To explain this process, Ellis developed what he referred to as the ABC Model.

- **A – Activating Event:** Something happens in the environment around you.
- **B – Beliefs:** You hold a belief about the event or situation.
- **C – Consequence:** You have an emotional response to your belief.¹

The events and situations that people encounter throughout life are only one piece of the puzzle. In order to understand the impact of such events, it is also essential to look at the beliefs people hold about these experiences as well as the emotions that arise as a result of those beliefs.

THE BASIC STEPS OF REBT

In order to better understand how REBT works, it is important to take a closer look at the therapeutic process itself. Identify Irrational Thought Patterns and Beliefs The very first step in the process is to identify the underlying, irrational thoughts, feelings, and beliefs that lead to psychological distress. In many cases, these irrational beliefs are reflected as absolutes, as in "I must," "I should," or "I cannot." According to Ellis, some of the most common irrational beliefs include:

- Feeling excessively upset over other people's mistakes or misconduct
- Believing that you must be 100% competent and successful in everything to be valued and worthwhile
- Believing that you will be happier if you avoid life's difficulties or challenges
- Feeling that you have no control over your own happiness, that your contentment and joy are dependent upon external forces¹

Holding such unyielding beliefs makes it almost impossible to respond to activating situations in a psychologically healthy way. Possessing such rigid expectations of ourselves and others only leads to disappointment, recrimination, regret, and anxiety.

CHALLENGE IRRATIONAL BELIEFS

Once these underlying feelings have been identified, the next step is to challenge the mistaken beliefs. In order to do this, the therapist disputes these beliefs using very direct and even confrontational methods. Ellis suggested that rather than simply being warm and supportive, therapists need to be blunt, honest, and logical in order to push people toward changing their thoughts and behaviors.

GAIN INSIGHT AND CHANGE BEHAVIOR

As you might imagine, REBT can be a daunting process for the client. Facing irrational thought patterns can be difficult, especially because accepting these beliefs as unhealthy is far from easy. Once the client has identified the problematic beliefs, the process of actually changing these thoughts can be even more challenging. While it is perfectly normal to feel upset when making a mistake, the goal of REBT is to help people respond rationally to such situations. When faced with this type of situation in the future, the emotionally healthy response would be to realize that it is not realistic to expect success in every endeavor. You made a mistake, but that's okay. Everyone makes mistakes. All you can do is learn from the situation and move on.

While REBT uses cognitive strategies, it focuses on emotions and behaviors as well.² In addition to identifying and disputing irrational beliefs, therapists and clients also work together to target the emotional responses that accompany problematic thoughts. Clients are encouraged to change unwanted behaviors using strategies such as meditation, journaling, and guided imagery.

COGNITIVE BEHAVIORAL THERAPY (CBT)

Cognitive behavioral therapy (CBT) is a type of psychotherapeutic treatment that helps people learn how to identify and change destructive or disturbing thought patterns that have a negative influence on behavior and emotions.¹

Cognitive behavioral therapy focuses on changing the automatic negative thoughts that can contribute to and worsen emotional difficulties, depression, and anxiety. These spontaneous negative thoughts have a detrimental influence on mood. Through CBT, these thoughts are identified, challenged, and replaced with more objective, realistic thoughts.

CBT is about more than identifying thought patterns; it is focused on using a wide range of strategies to help people overcome these thoughts. Such strategies may include journaling, role-playing, relaxation techniques, and mental distractions.

TYPES OF COGNITIVE BEHAVIORAL THERAPY

CBT encompasses a range of techniques and approaches that address thoughts, emotions, and behaviors. These can range from structured psychotherapies to self-help materials. There are a number of specific types of therapeutic approaches that involve CBT:

- **Cognitive therapy** centers on identifying and changing inaccurate or distorted thinking patterns, emotional responses, and behaviors.³
- **Dialectical behavior therapy (DBT)** addresses thoughts and behaviors while incorporating strategies such as emotional regulation and mindfulness.
- **Multimodal therapy** suggests that psychological issues must be treated by addressing seven different but interconnected modalities, which are behavior, affect, sensation, imagery, cognition, interpersonal factors, and drug/biological considerations.⁴
- **Rational emotive behavior therapy (REBT)** involves identifying irrational beliefs, actively challenging these beliefs, and finally learning to recognize and change these thought patterns.

While each type of cognitive behavioral therapy takes a different approach, all work to address the underlying thought patterns that contribute to psychological distress.

USES

Cognitive-behavior therapy can be effectively used as a short-term treatment centered on helping people with a very specific problem and teaching them to focus on present thoughts and beliefs.¹ CBT is used to treat a wide range of conditions including:

- Addictions
- Anger issues
- Anxiety²
- Bipolar disorder
- Depression
- Eating disorders
- Panic attacks
- Personality disorders
- Phobias⁵
- Problems with stress

Cognitive behavioral therapy is highly goal-oriented and focused, with the therapist taking a very active role. People work with their therapist toward mutually established goals. The process is explained in detail and people are often given homework to complete between sessions.

IMPACT

The underlying concept behind CBT is that thoughts and feelings play a fundamental role in behavior.¹ For example, a person who spends a lot of time thinking about plane crashes, runway accidents, and other air disasters may avoid air travel as a result. The goal of cognitive behavior therapy is to teach people that while they cannot control every aspect of the world around them, they can take control of how they interpret and deal with things in their environment. Cognitive behavior therapy has become increasingly popular in recent years with both mental health consumers and treatment professionals. Some reasons for this include:

- By becoming aware of the negative and often unrealistic thoughts that dampen their feelings and moods, people are able to start engaging in healthier thinking patterns.¹
- CBT can be an effective short-term treatment option.

- It can help people with certain types of emotional distress that don't require psychotropic medication.
 - It is empirically supported and has been shown to effectively help patients overcome a wide variety of maladaptive behaviors.¹
 - It is often more affordable than some other types of therapy.
- One of the greatest benefits of cognitive behavioral therapy is that it helps clients develop coping skills that can be useful both now and in the future.¹

CBT STRATEGIES

People often experience thoughts or feelings that reinforce or compound faulty beliefs. Such beliefs can result in problematic behaviors that can affect numerous life areas, including family, romantic relationships, work, and academics.

IDENTIFY NEGATIVE THOUGHTS

It is important to learn how thoughts, feelings, and situations can contribute to maladaptive behaviors.⁶ The process can be difficult, especially for people who struggle with introspection, but it can ultimately lead to self-discovery and insights that are an essential part of the treatment process.

PRACTICE NEW SKILLS

It is important to start practicing new skills that can then be put in to use in real-world situations. For example, a person with a substance use disorder might start practicing new coping skills and rehearsing ways to avoid or deal with social situations that could potentially trigger a relapse.

SET GOALS

Goal setting can be an important step in recovery from mental illness and helping you make changes to improve your health and life. During CBT, a therapist can help with goal-setting skills by teaching you how to identify your goal, distinguish between short- and long- term goals, set SMART (specific, measurable, attainable, relevant, time-based) goals, and focus on the process as much as the end outcome.

PROBLEM SOLVE

Learning problem solving skills can help you identify and solve problems that arise from life stressors, both big and small, and reduce the negative impact of psychological and physical illness. Problem solving in CBT often involves five steps: identifying a problem, generating a list of possible solutions, evaluating the strengths and weaknesses of each possible solution, choosing a solution to implement, and implementing the solution.⁷

SELF MONITOR

Also known as diary work, self-monitoring is an important part of CBT that involves tracking behaviors, symptoms, or experiences over time and sharing them with your therapist. Self-monitoring can help provide your therapist with the information needed to provide the best treatment. For example, for eating disorders, self- monitoring may involve keeping track of eating habits as well as any thoughts or feelings that went along with consuming that meal or snack.⁸

PROGRESS GRADUALLY

In most cases, CBT is a gradual process that helps a person take incremental steps towards a behavior change. For example, someone with social anxiety might start by simply imagining anxiety-provoking social situations. Next, they might start practicing conversations with friends, family, and acquaintances. By progressively working toward a larger goal, the process seems less daunting and

the goals easier to achieve.

HOW BEHAVIORAL THERAPY IS USED IN PSYCHOLOGY POTENTIAL PITFALLS

There are several challenges that people may run into during the course of cognitive behavioral therapy. Change Can Be Difficult Initially, some patients suggest that while they recognize that certain thoughts are not rational or healthy, simply becoming aware of these thoughts does not make it easy to alter them.

CBT IS VERY STRUCTURED

Cognitive behavioral therapy doesn't tend to focus on underlying unconscious resistances to change as much as other approaches such as psychoanalytic psychotherapy.⁹ It is often best-suited for clients who are more comfortable with a structured and focused approach in which the therapist often takes an instructional role.

PEOPLE MUST BE WILLING TO CHANGE

For cognitive behavioral therapy to be effective, the individual must be ready and willing to spend time and effort analyzing their thoughts and feelings. Such self-analysis and homework can be difficult, but it is a great way to learn more about how internal states impact outward behavior.

WHAT TO EXPECT DURING YOUR FIRST THERAPY SESSION HISTORY

CBT emerged during the 1960s and originated in the work of psychiatrist Aaron Beck, who noted that certain types of thinking contributed to emotional problems. Beck labeled these "automatic negative thoughts" and developed the process of cognitive therapy. Where earlier behavior therapies had focused almost exclusively on associations, reinforcements, and punishments to modify behavior, the cognitive approach addressed how thoughts and feelings affect behaviors. Since then, CBT has emerged as an effective first-line treatment for a wide range of disorders and conditions.

MINDFULNESS-BASED COGNITIVE THERAPY (MBCT) MINDFULNESS-BASED COGNITIVE THERAPY (MBCT)

combines cognitive behavioral techniques with mindfulness strategies in order to help individuals better understand and manage their thoughts and emotions in order to achieve relief from feelings of distress. Though originally developed to address recurrent depression, MBCT may be beneficial to people seeking treatment for a wide range of mental health concerns.

DEVELOPMENT OF MBCT

MBCT, which was developed by Zindel Segal, Mark Williams, and John Teasdale, is primarily derived from the earlier work of Teasdale, Jon Kabat-Zinn, and Phillip Barnard. The approach, which is still relatively new—the first clinical trial was published in 2000—incorporates principles from Kabat-Zinn's mindfulness-based stress reduction modality, an 8-week program designed to help people cope with the mental and physical effects of health concerns, and Bernard and Teasdale's ICS (interactive cognitive subsystems) model. ICS is based on the premise that the human mind possesses different modes for receiving and processing data, the two primary modes of which are the "being" mode and the "doing" mode. The model also suggests mental health may be dependent on a person's ability to detach from one mode and move between other modes, based on what is present in the environment. The MBCT program emphasizes the "being" mode, as this mode is believed to promote lasting emotional change, specifically for individuals experiencing recurrent depressive episodes.

HOW DOES MBCT WORK?

In this therapy approach, people can learn how to use cognitive methods and mindfulness meditation to interrupt the automatic processes often triggering depression. Low mood, negative thoughts, and certain body sensations such as weariness and sluggishness often occur together during an episode of depression. Even after the episode passes, connections may still exist between the different symptoms, and it is possible for a small negative stimulus to trigger a large downward spiral: Researchers have found when people with a history of depression experience a low mood, they may also experience negative memories and thoughts from the past, which may, in turn, lead to worry about the future and physical sensations such as fatigue.

MBCT helps participants learn how to recognize their sense of being and see themselves as separate from their thoughts and moods. This disconnect can allow people to become liberated from thought patterns in which the same negative messages may be replayed over and over. After developing an awareness of the separation between thoughts, emotions, and the self, people in treatment may find that while the self and the emotions may exist simultaneously, they do not have to exist within the same dimension. This insight can contribute to healing by helping individuals learn to interject positive thoughts into negative moods in order to disarm those negative moods. In general, MBCT attempts to give participants the necessary tools to combat depressive symptoms as they arise. People who learn these skills may then be able to revert to these methods in times of distress or when faced with potentially overwhelming situations.

TECHNIQUES USED IN MBCT

This therapy is delivered as a weekly group treatment program over the course of eight weeks. Each weekly session lasts for two hours, but completing a 45-minute homework assignment six days a week is also required. For homework, participants listen to audio recordings and practice mindfulness meditation. People in treatment are also introduced to a technique called the three-minute breathing space. This technique encourages participants to incorporate formal practice into their day-to-day life.

Though there is currently no consensus as to how mindfulness should be defined, the basic concept refers to the practice of developing, in a non-judgmental manner, a deeper awareness of what is happening within one's mind and body from moment to moment. Certain meditation techniques—breathing meditations, sitting meditations, body scan meditations, walking meditations, and yoga—may help to improve a person's mindfulness. In MBCT, individuals in treatment are also taught cognitive concepts such as the association between thoughts and feelings, and they also often have the opportunity to develop a deeper understanding of depression.

ISSUES TREATED WITH MBCT

Mindfulness is believed to promote good health, and many studies have associated mindfulness with decreases in depression and anxiety. Thus, many mental health professionals have incorporated mindfulness-promoting activities into therapy sessions, and these activities have been shown to help reduce symptoms of depression, decrease stress, and improve emotional control, regardless of the specific issues being addressed. MBCT in particular may be used as a primary treatment modality or in conjunction with other forms of therapy. Individuals experiencing certain medical concerns may also obtain benefit from MBCT: In a 2013 study of 33 women with fibromyalgia,

researchers found that those who were treated with MBCT demonstrated a significantly reduced impact of fibromyalgia, a significant decrease in depressive symptoms, and a slight decrease in the intensity of bodily pain when compared to those who did not receive MBCT. Researchers have also shown individuals with cancer, diabetes, chronic pain, and epilepsy who incorporate MBCT into treatment plans may see improvement in well-being. Over the past 15 years, the results of numerous randomized controlled trials have demonstrated that MBCT can be a powerful intervention for people who have experienced clinical depression three or more times. Evidence indicates MBCT may reduce the rate of relapse for individuals with recurrent depression by 50%. MBCT has also been applied to mood and anxiety concerns other than depression, with reported success. A 2014 review of the usefulness of MBCT as a treatment modality for several health conditions found the approach may be effective when addressing issues such as depressive relapse, current depression, residual depression, bipolar, anxiety, food and eating issues, and psychosis, among others.

TRAINING AND CERTIFICATION

Certification in MBCT is provided by a number of approved institutions around the world, including the UCSD Mindfulness- Based Professional Training Institute (United States), the Oxford Mindfulness Centre (England), the University of Geneva (Switzerland), The Centre for Mindfulness Studies (Canada), and Bangor University (Wales). Therapists who are interested in gaining certification as a teacher of MBCT are required to fulfill two training phases: teacher qualification and teacher certification.

The teacher qualification phase provides applicants with the necessary foundation for teaching MBCT. It consists of six steps:

- Satisfy the prerequisites for a five-day MBCT teacher training retreat
- Attend and participate in the retreat or acquire equivalent training
- Successfully complete either the MindfulNoggin Online MBCT course or the Participant Observer in Live MBCT course
- Apply for teacher-in-training status after successful completion of the program
- Receive a minimum of 20 hours of mentorship while teaching at least two MBCT courses, where each course lasts for eight weeks
- Submit application for teacher qualification

Once teacher qualification status has been achieved, applicants may present themselves as a “qualified teacher of MBCT” and begin phase two of the training process if they wish to pursue certification. Teacher certification involves the following five steps:

- Obtain teacher qualification
- Teach at least three additional eight-week MBCT courses after receiving teacher qualification
- Attend and complete the Advanced Teacher Training Intensive (ATTI)
- Receive a minimum of 10 hours of mentorship while teaching an MBCT course
- Submit application for teacher certification

LIMITATIONS AND CONCERNS

The effectiveness of mindfulness based cognitive therapy is supported by considerable empirical evidence and has, according to research, generally produced positive results for people in treatment. However, because it is a relatively new treatment modality, the long-term benefits of this approach may not yet be fully determinable. A growing body of empirical evidence supports the approach, but

further research may provide greater support for its effectiveness when treating bipolar, eating issues, psychosis, and other conditions. Several critics have highlighted methodological shortcomings in some MBCT studies such as small sample size, a lack of control groups, and a lack of randomization, all of which have potential to affect the results obtained. More rigorous studies are needed to evaluate whether MBCT is more effective than other, more widely practiced forms of therapy, such as cognitive behavioral therapy.

PLAY THERAPY

Play therapy is a form of therapy primarily geared toward children. In this form of therapy, a therapist encourages a child to explore life events that may have an effect on current circumstances, in a manner and pace of the child's choosing, primarily through play but also through language.

Play therapy, can help individuals communicate, explore repressed thoughts and emotions, address unresolved trauma, and experience personal growth and is widely viewed as an important, effective, and developmentally appropriate mental health treatment.

HISTORY AND DEVELOPMENT OF PLAY THERAPY

Though some of the earliest theories and methods mentioned below are no longer practiced and may not be acceptable based on current research and ethical standards, they did play a part in advancing play therapy to the extent that it is now regarded as an established therapeutic approach. Some key individuals in the development of this therapy and their contributions to the field include:

- **Hermine Hug-Hellmuth**, who is widely regarded as the world's first psychoanalyst to specialize in treating children and the first person to use play as a form of therapy. In 1921, she introduced a formal play therapy process by providing the children in her care with the necessary materials to express themselves and advocated the use of play to analyze children.
- **Melanie Klein**, who used play as an analytic tool as well as a means to attract the children she worked with to therapy. Klein believed play provided insight into a child's unconscious.
- **David Levy**, who developed a therapeutic approach called "release therapy" in 1938. This was a structured approach that encouraged a traumatized child to engage in free play. The therapist then gradually introduced materials related to the traumatic event, allowing the child to re-experience the stressful event and release any unresolved emotions or actions.
- **Joseph Soloman**, who used an approach called "active play" to assist children who displayed impulsivity and a tendency to act out. The approach was based on Soloman's belief that expressing emotions such as fear and anger in play would result in more socially acceptable behavior.
- **Anna Freud**, who presented theoretical arguments for the use of play as a means to build a positive relationship between the child and therapist, thus allowing the therapist better access to a child's inner thoughts and emotions.
- **Carl Rogers**, who developed person-centered therapy during the 1940s and 1950s. This type of therapy emphasizes the importance of genuineness, trust, and acceptance in the therapeutic relationship.
- **Virginia Axline**, who developed nondirective play therapy by modifying Rogers' approach into a play therapy technique that was more appropriate for children.
- **Roger Phillips**, who posited the idea to combine cognitive therapy and play therapy in the early 1980s. Cognitive behavioral play therapy has been used to treat children as young as two years old.

THE NEUROSCIENCE BEHIND THE IMPORTANCE OF PLAY

Though play is often regarded simply as a way for individuals, particularly children, to relax, scientific

research has proven that play is a crucial factor in healthy child development. Studies show that newborn babies possess billions of brain cells; however, these young cells lack the complex neural interconnectivity that is characteristic of a mature, fully-functional human brain. Neuroscience has revealed that the majority of the brain's growth takes place within the first five years of a child's life, and the act of play contributes significantly toward the development of interconnections between neurons. These neural links play a major role in key areas of the child's life, such as learning, social development, emotional development, and memory.

Play is considered to be especially important for the healthy development of children who have experienced stressful events or past trauma. While the effects of trauma tend to reside in the nonverbal areas of the brain—the hippocampus, amygdala, thalamus, and brain stem—a person's capacity to communicate and process adverse issues resides in the brain's frontal lobes. As a result, children affected by trauma may find it difficult to let other people know that they need help. The physical and role-playing activities associated with play therapy have proven instrumental in helping to move traumatic memories and sensations from the nonverbal brain areas to the frontal lobes.

HOW DOES PLAY THERAPY WORK?

When children are experiencing adverse personal issues they will often act out or engage in inappropriate behavior. Parents may be eager to help but may find it difficult or impossible to offer effective aid if a child is unable or unwilling to discuss the problem. Play therapy is thought to be one of the most beneficial means of helping children who are experiencing emotional or behavioral challenges. Though the approach may benefit people of all ages, it is specially designed to treat children under 12. A typical session may last for 30-45 minutes and may be conducted with one child only or in groups.

During treatment, the therapist creates a comfortable, safe environment in which the child is allowed to play with as few limits as possible. This counseling space is often referred to as a playroom, and it comes equipped with a selection of specifically chosen toys that are meant to encourage the child to express his or her feelings and develop healthier behaviors. The child's interactions with these toys essentially serve as the child's symbolic words. This allows the therapist to learn about specific thoughts and emotions that a child may find difficult or impossible to express verbally. Toys used in therapy may include a sandbox with associated miniature figurines, art materials, Legos or other construction toys, costumes or other clothing, stuffed animals, dolls, a dollhouse with miniature furniture, puppets, indoor sports equipment, and other indoor games. The therapist may also incorporate the use of tools and techniques such as clay, therapeutic storytelling, music, dance and movement, drama/role play, and creative visualization.

At first children in therapy are generally allowed to play as they wish. As treatment progresses, the therapist may begin to introduce specific items or play activities which are related to the issues the child is facing. Play therapy may benefit the child in a variety of ways such as encouraging creativity, promoting healing from traumatic events, facilitating the expression of emotions, encouraging the development of positive decision-making skills, introducing new ways of thinking and behaving, learning problem-solving skills, developing better social skills, and facilitating the communication of personal problems or concerns.

Play therapy may be nondirective or directive. Nondirective play therapy is grounded in the idea that if allowed optimal therapeutic conditions and the freedom to play, children in therapy will be able to resolve issues on their own. This approach is viewed as non-intrusive since there is minimal

instruction from the therapist regarding how a child should engage in play. Directed play therapy involves much greater input from the therapist and is based on the belief that faster therapeutic results may be obtained than in nondirective play therapy sessions.

PLAY THERAPY FOR ADULTS

Play therapy can also be used to treat issues faced by teenagers and adults. By adulthood, most people have lost their ability to playfully explore themselves. Play therapists are trained to help adolescents, adults, and even the elderly relearn the values of play. Playful exploration has been proven to enhance both cognitive and physical behaviors, and there is a significant amount of research from the fields of neurophysiology and molecular biology that supports play therapy as a valid therapeutic technique for those past childhood. A growing number of organizations and experts are dedicated to play research and advocacy, believing that play is important for people of all ages.

Play has been shown to optimize learning, enhance relationships, and improve health and well-being. Adults and children engaged in a therapeutic alliance that focuses on play have an opportunity to choose from a variety of modalities such as movement (body play), sand play, dream play, nature play, social play, pretend (fantasy) play, creative play, storytelling, and vocal play. Play therapy may be used to address a variety of health challenges experienced by adults, especially if incorporated with other treatment modalities. One of the most significant benefits is that play can provide a comfortable and safe environment that may prompt an adult to approach more serious issues. Play therapy can be used to treat (in children or adults):

- Dementia
- Grief and loss
- Posttraumatic stress
- Obsessions and compulsions
- Attention deficit hyperactivity
- Mood issues
- Anxiety
- Depression
- Developmental issues
- Arrested emotional development

GUIDELINES FOR EFFECTIVE PLAY THERAPY

Play therapy has proven to be an effective therapeutic approach for people from all age groups, though minors respond particularly well to this type of treatment. Therapists may employ several general guidelines and practices in treatment in order to foster the greatest benefits for people in their care.

When working with a child, a therapist may provide adjunctive therapy for adults who play key roles in the child's life. Throughout therapy, the therapist will typically place emphasis on the promotion of mental health and psychosocial development, explaining treatment plans to the person receiving treatment and a child's legal guardians, if necessary. Therapists may also coordinate treatment with doctors or other health care professionals to ensure that a child's welfare remains the treatment priority. If inappropriately touched by a child in treatment, the therapist may find it best to explain that it is important that each person's body is respected, document the event, then discuss the situation with the child's legal guardians at the earliest opportunity. A therapist may also find it necessary to make arrangements to prevent the child, or any person they are treating, from feeling abandoned, should there be a break in treatment.

TRAINING FOR PLAY THERAPISTS

Mental health professionals who seek specialized training and experience in play therapy may earn their credentials from the Association for Play Therapy (APT). The APT is a nationally recognized professional institution which aims to further the play therapy modality and advance the expertise and knowledge of mental health professionals involved in the clinical practice, instruction, and supervision of play therapy. The APT offers two standard credentials: the Registered Play Therapist™ (RPT) and the Registered Play Therapist-Supervisor™ (RPT-S).

APPLICANTS DESIRING TO BECOME A REGISTERED PLAY THERAPIST™ MUST:

- Possess an active individual state license which allows him or her to independently provide clinical mental health services.
- Have earned a master's degree or higher in a mental health field, with special emphasis on areas such as child development, psychotherapy, theories of personality, ethics, or child and adolescent psychopathology.
- Have two years of general clinical experience (as required for state licensure) and 2000 hours of general mental health clinical experience.
- Complete 150 hours of play therapy instruction from APT-approved providers or tertiary level academic institutions.

To become a Registered Play Therapist-Supervisor™, an applicant must also have 500 hours of experience in play therapy, conducted under supervision, plus an additional 50 hours of field-specific supervision. The Registered Play Therapist™ (RPT) credential lasts for one year, and it must be renewed annually to maintain active status. To qualify for renewal, the applicant must have a current and active state license to offer clinical mental health services and follow a continuing education cycle by receiving 18 hours of instruction specific to play therapy from a tertiary level academic institution or an APT-approved provider every 36 months.

POSITIVE PSYCHOTHERAPY (PPT)

Positive Psychotherapy (PPT) is a relatively new therapeutic approach, influenced by both the humanistic and psychodynamic approaches towards diagnosis and treatment. Its core focus is on moving away from what's 'wrong' or the negative aspects of an individual, and instead move towards what's good and positive. Seligman, Rashid, and Parks (2006) offer the following definition for PPT concerning depression: Positive psychotherapy (PPT) contrasts with **standard interventions** for depression by increasing positive emotion, engagement, and meaning rather than directly targeting depressive symptoms.

PPT often uses a range of interdisciplinary approaches of **psychotherapy**, including the use of multicultural stories, ideas, and metaphors to help individuals create a new view of their mental health in positive ways. Therapists using PPT often invite the individual to place themselves in the stories used, so they become active in their healing process in an empowered way, and in so doing, become the 'therapist' of their own recovery. While the emphasis is on positivity and positive outcomes, the overall theory of PPT also asserts that three core principles need to be addressed to allow this to happen:

1. The Principle of Hope: This principle encourages the individual to focus on the overall positivity of humanity, and negative experiences are to be seen as having a higher purpose with a positive reframing. Any disruptions to a sense of well-being are encouraged to be explored and reframed as signals that there is an imbalance that requires addressing.
 2. The Principle of Balance: This principle examines how we experience discontent and the coping methods we might use to address this. According to PPT, negative symptoms arise when these coping methods aren't working, and our areas of life are out of balance, with discontent impacting how we think and feel.
1. Pesechskian (1979) ascertained there are four key areas where we will experience imbalance: body/sense, achievement/activities, contact/environment, and fantasy/future. These are the areas PPT focuses on when exploring and addressing the principle of balance.
 2. The Principle of Consultation: This principle sets out the five stages of therapy that must be worked through to address any issues that arise in the above two principles, to achieve a positive outcome:
 1. Observation – where the individual provides an account of the issues, challenges, or situations that are upsetting them and those that are making them happy.
 2. Inventory — where the therapist and individual work together to explore and highlight the correlation between negative feelings/symptoms and the individual's true capabilities.
 3. Situational Support — where the individual is asked to focus on their positive traits and those of the people around them who significantly offer them support.
 4. Verbalization — where the individual is encouraged to verbally discuss and talk openly about any negative feelings, challenges, or symptoms.
 5. Development of Goals — where the individual is invited to turn their focus to the future, setting positive goals, and envisioning the positive feelings they want to cultivate, as well as connecting these with their unique strengths.

Another core component of PPT is the emphasis it places on core capabilities. According to PPT theory, everyone — regardless of gender, age, class, ethnicity, or preconceived ideas of their mental health — has two core capabilities:

1. The Capability of Perception: Our ability to draw connections between the different areas of life with more significant reasons behind the meaning of not only our own existence but the existence of everything around us.
2. The Capability of Love: Our ability to develop emotionally and develop interpersonal relationships. Pesechskian (1979) concluded that these two core capabilities are what lay behind our further abilities. PPT seeks to explore an individual's two core capabilities to understand better and, where appropriate, address imbalances to create additional positive outcomes.

Due to its openness around utilizing multicultural stories and ideas, one criticism of PPT is that it does not work as well in westernized society. This is because there is often a focus on individualism and independence, and by not allowing enough exploration of negative or traumatic experiences can be seen to lead to trivializing these experiences. Overall, PPT has been received very positively in the positive psychology community, with some wonderful outcomes and results.

NOSSRAT PESECHKIAN'S WORK AND A BRIEF HISTORY OF POSITIVE PSYCHOTHERAPY

Although Seligman is often attributed as being one of the co-founders of PPT, similar therapies

focusing on happiness or **quality of life** over emphasis on negatively experienced symptoms pre-date Seligman's work. Most notably is Nossrat Peseschkian, an Iranian-born psychotherapist, psychiatrist, and neurologist, who set up practice in Germany in the 1960s.

Influenced by humanist psychology, meetings with multiple influential psychologists, and spiritual practitioners, as well as his own experiences working with clients across more than twenty cultures, Peseschkian wanted to create an integrative therapy model that focused on positive experiences alongside being culturally sensitive. In the 1970s, Peseschkian began to deliver lectures around his therapy model and published four books based on PPT during this time. In the early 1970s, Peseschkian referred to his model as 'Differentiation Analysis.'

In 1977 he published his first book, 'Positive Psychotherapy,' and in so doing renamed his approach. During this time, PPT gained further acknowledgment with structured training and the founding of the Psychotherapeutic Group of Wiesbaden, The German Association for Positive Psychotherapy, and the Journal of Positive Psychotherapy in 1979. Through the 1980s and 1990s, PPT grew in its structure, uses, and acknowledgment as a prevalent theory outside of Germany, with Peseschkian traveling to more than 60 countries to deliver talks and lectures, and opening more than 30 centers. He also continued to publish books, and the 'Wiesbaden Inventory for Positive Psychotherapy and Family Therapy' was also published in 1988.

In 1994 the International Center for Positive Psychotherapy opened its doors, later becoming the World Association for Positive Psychotherapy in 2008. The first effectiveness study of PPT was conducted between 1995 and 1997, concluding that PPT demonstrated a strong therapeutic influence for a range of mental health diagnoses. Peseschkian wasn't the only one to recognize the benefits of focusing on the positive in therapy. During this time, several other psychologists also explored similar concepts.

Fordyce (1977) developed a 'Happiness' intervention and worked with students to help them utilize a series of 14 tactics aimed at assisting them in developing a better sense of well-being and happiness. These tactics came with detailed instructions and included things such as socializing, engaging in meaningful work, deepening close relationships with loved ones, and managing expectations. Fordyce found that those students who used the tactics and instructions reported being happier and showed fewer depressive symptoms over a control group.

Fava (1999) and Fava and Ruini (2003) developed their Well-Being Therapy (WBT), which places a focus on building personal mastery across different areas of life, including environmental, personal growth, life purpose, self-acceptance and positive relationships with others. Alongside Peseschkian's approach, Seligman has been responsible for developing the PPT model alongside more contemporary notions of positive psychology. Where Peseschkian's model is more integrative, cross-disciplinary, and focuses on multi-cultural concepts, more modern PPT practice is primarily based on Seligman's notion of happiness and well-being overall (Seligman, 2002). It's important to acknowledge that while similar, there are some slight differences between the two approaches.

FIVE BENEFITS OF POSITIVE PSYCHOTHERAPY

The primary goal of PPT is to help individuals better understand the skills and capabilities they have, and ones they might need to develop, to achieve a greater sense of inner balance. This is achieved by exploring innate resources — physical, emotional, spiritual, and cognitive — the individual already has and may need help tapping into in positive ways. There are many **benefits of positive psychotherapy** and in approaching our mental health in this way. Below I've explored the top five in

more detail:

1. EMPOWERS THE INDIVIDUAL

As PPT places a strong emphasis on helping the individual to examine their strengths, skills, and capabilities in a positively reframed manner, it increases their sense of empowerment and control over the different areas of their life, as well as their capacity to handle challenges and negative experiences (Rashid, 2014). The therapist's role in the client-therapist relationship is to encourage the individual to uncover things on their own terms. It places the good with the bad, helping individuals find the balance they need to accept all parts of themselves. This integration of skills, weaknesses, virtues, vulnerabilities, and strengths helps to build a more balanced perspective rather than reducing individuals to merely their symptoms or what challenges them.

2. POSITIVE REFRAMING OF NEGATIVE SYMPTOMS AND A FOCUS ON BALANCE

A great benefit of PPT is how it brings the negative in line with the positive. Although it might sound like the model only focuses on positive and dismisses the negative, it focuses more on bringing the two into alignment and balance. This approach helps individuals to better understand their strengths and skills, where they might have gaps and how these can perpetuate negative feelings or imbalances if not addressed appropriately.

3. ACKNOWLEDGES AND SUPPORTS CULTURAL TRANSITIONS AND DIFFERENCES

Because PPT encourages empowerment on the individual, it can help them to feel more in control across different areas of their life, even when it might feel that external circumstances are taking over. This has proven especially beneficial for individuals experiencing conflict in multicultural environments or relationships. Bontcheva and Huysse-Gaytandjieva (2013) explored migration and the challenges faced by those who had moved to new countries and cultures. They found that those who applied positive psychotherapy techniques were better able to overcome these challenges, with two-thirds of participants reporting depressive symptoms were entirely resolved.

4. BETTER MANAGEMENT OF EXPECTATIONS AND THERAPY OUTCOMES

Another important benefit of PPT is how it acknowledges the importance of the client-therapist relationship, and how the self-directed techniques used are instrumental in helping individuals get the most out of the therapy (Rashid and Seligman, 2018). With a greater sense of awareness for personal capabilities, strengths, and skills, the individual can understand their mental health journey better, and how they can act to improve this. As a result, therapy expectations are better managed, and individuals see the outcome of PPT as being about more than merely eliminating negative symptoms or feelings.

5. PROVEN TO HELP A RANGE OF MENTAL HEALTH CONDITIONS

With its focus on strengths and cultivation of the positive elements of life, PPT has shown to be highly beneficial across a range of mental health conditions including psychosis (Schrank et al., 2016), suicidal ideation (Johnson et al., 2010), depression (Seligman, Rashid, and Parks, 2006, Carver, Scheier and Segerstrom, 2010) and borderline personality disorder (Uliaszek, 2016).

HOW DOES POSITIVE PSYCHOTHERAPY RELATE TO POSITIVE PSYCHOLOGY?

While the two approaches sound very similar, there are some cross-overs in how each tackles individual experiences within therapy. Positive psychology is popularly attributed as being the brain-child of Martin Seligman, developed in 1998, where positive psychotherapy is more commonly attributed to Nossrat Pesechkian, first developed in 1968. Both approaches draw influences from humanistic and psychodynamic models of psychology.

WHAT ARE THE SIMILARITIES AND DIFFERENCES BETWEEN THE TWO?

Both approaches place emphasis on personal development and the importance of tapping into innate resources and strengths to overcome challenges and negatively experience emotions. Both also work on the assumption that we are all inherently good, and need to work hard to uncover when external influences prevent us from becoming the best versions of ourselves. There are also some slightly nuanced, but very essential differences:

Positive Psychotherapy	Positive Psychology
Believes all negative experiences can be challenged and reframed in a positive way, as they are essentially opportunities for further growth.	Acknowledges negative experiences and emotions but doesn't necessarily incorporate them in the same way.
Focuses more on multi-cultural experiences and the challenges that individuals can face across different cultures — both similar and different.	Has a more Westernised approach to therapy and an individual's experiences.
Influenced equally by humanistic and psychodynamic approaches and seeks to integrate the best of both.	Less focused on humanistic models and therapies and less integrative of other psychological approaches.

Seligman has spoken extensively about both approaches, and how the two are related in specific ways, identifying that positive psychotherapy helps individuals to move past the process of suffering to uncover deeper insights about their wellbeing (Seligman and Wyatt, 2008). While acknowledging negative or traumatic experiences is a core component of many therapeutic approaches, Seligman has acknowledged that positive psychotherapy does place a more positive focus when going through this process.

3 POSITIVE PSYCHOTHERAPY INTERVENTIONS

As touched on briefly, positive psychotherapy has proven beneficial in a range of clinical settings addressing various mental health concerns. The interventions utilized in PPT are varied, and will often rely on what the individual expresses in the therapy sessions for the therapist to select the ones most appropriate. A very distinct component of the interventions used in PPT is how it incorporates imagination and intuition as part of the therapeutic process. Storytelling is another key way PPT encourages individuals to engage with their therapy journey, and this idea of building the self into the stories helps individuals to better articulate their journeys, experiences, challenges, and desires. Through this process, PPT therapists can begin to introduce adjustments or dive deeper into sensitive topics without seeming to ‘attack’ the individual.

Therapists can also help those they work with to reframe their experiences and symptoms in positive ways, and then proactively work on rebuilding them positively within their lives (creating better balance). Once individuals can accept all aspects of themselves and begin to see negative experiences in a positive light, they generally no longer repeat those negative experiences. The specific interventions used in this process have a focus on empowering the individual and providing them with the tools and resources to face up to negative or traumatic experiences, cultivate resilience, and develop better emotional functioning.

These include:

1. PRACTICING GRATITUDE

Gratitude is a strong cognitive state, generally associated with the idea that you have achieved a personal benefit that wasn't initially intentionally sought after (Emmons and McCullough, 2003). Feeling gratitude can have a strong re-energizing impact on our emotional well-being and has been shown to lead to greater feelings of happiness and healing. In therapy, practicing gratitude can begin with making the time to acknowledge all the small everyday things that occur and for which we can feel grateful. Gratitude journals, **worksheets**, and resources are widely available, and it's a popular intervention in PPT to help show individuals everything they have in their lives to feel grateful for — something many of us often forgets to acknowledge.

2. PRACTICING FORGIVENESS

Many therapists agree that forgiveness — for the self, others, and general experiences — is

a vital part of healing and promoting a greater sense of well-being. Worthington (2003) proposed two core types of forgiveness within clinical/therapy settings:

1. Decisional Forgiveness: Where the individual states a behavioral intent to forgive.
2. Emotional Forgiveness: Where the individual has true emotional acceptance of the situation, experience, or personal feelings that requires forgiveness.

We can utilize decisional forgiveness but still feel emotionally upset, which can lead to further unforgiveness and negative symptoms related to our mental health (Worthington and Scherer, 2007). PPT utilizes the practice of forgiveness as a key intervention, particularly focusing on emotional forgiveness so that individuals feel a complete sense of healing when moving past negative symptoms.

3. PRACTICING EMPATHY

The PPT approach teaches that all humans are inherently good, and innately want to live meaningful lives and have enriching relationships. Empathy is a core component of this, but it has been shown to routinely fail as an innate ability in several challenging or conflicting scenarios (Zaki & Cikara, 2015).

Most empathy-related interventions build on the notion that we are all capable of empathy, and these interventions support individuals to focus instead on developing their ability to tap into empathy and target it in specific ways. One approach utilized by PPT is using the storytelling method to ask individuals to put themselves in another’s shoes and describe how they might feel, react or respond to challenging situations, as well as how they might react to positive situations.

THE POSITIVE PSYCHOTHERAPY MODEL (INC. TABLE WITH BRIEF SESSION DESCRIPTIONS)

Similar to other therapy models, the PPT model focuses on a series of sessions aimed at uncovering ideas, desires, vulnerabilities and strengths, and working through them to reach positive reframing and overall balance between the positive and the negative.

The below outline of sessions is a brief overview of the PPT model. Some versions of this relate more to the approach developed by Pesechian, and as with all therapy models, there can be slight nuances depending on the therapist and where they practice.

Session and Topic	Description
Orientation to PPT; Current Positive Resources	Psychological distress is discussed as a lack of positive resources, such as positive emotions, relationships, meaning, and accomplishment. To explore this, the therapist might use an exercise that encourages the individual to write a one-page, real-life story that called for the best in them and has a positive ending.
Individual Character Strengths	In this session, individual character strengths are explored, and the concept of engagement and flow is introduced. To begin exploring individual character strengths, the individual may be asked to identify what they believe are their signature strengths both in the session and through an online self-report. They may also ask two other close persons to rate their signature strengths.
Signature Strengths & Positive	Following on from the last session, signature strengths are discussed in more detail.

Emotions	As an exercise, the therapist may ask the individual to compile a signature strengths profile, which could include setting SMART (specific, measurable, achievable, realistic, and timely) goals.
Good vs. Bad Experiences, Symptoms or Memories	The concept of how negative experiences and symptoms can be perpetuated is discussed in alignment with positive experiences.
	The therapist might use an exercise that asks the individual to explore a memory or experience that elicited feelings of anger, bitterness, or resentment and how these feelings further perpetuated the negative experience.
Forgiveness	Forgiveness is explored as a resource to reframe negative symptoms and feelings into more positive emotions. The therapist might use a letter-writing exercise that asks the participant to remember a negative experience and to write out a letter of forgiveness towards the perceived transgressor/s of the scenario — themselves included.
Gratitude	Alongside forgiveness, gratitude is explored as a resource for generating better balance, and to view individual circumstances more positively. The role of positive and negative memories, feelings, and symptoms are discussed with an emphasis on gratitude for all the lessons both of these states have allowed for. The therapist might use gratitude journaling as an exercise to help build
	more focus and awareness of all the things for which the individual is grateful.
Mid-Therapy Check	At this point, the therapist may follow up on any at-home tasks related to the forgiveness and gratitude sessions, and to revisit any of the previous sessions that may feel unresolved. This is also the opportunity for the individual to discuss their perceived gains or hurdles they might be experiencing so far as an outcome of these sessions. As an exercise, the therapist may seek to explore different ways the individual can overcome any of the hurdles, utilizing their signature strengths uncovered previously.
Satisficing vs. Maximizing	The therapist may now introduce the two concepts of satisficing (mainly, being 'good enough') and maximizing. The individual may be asked to explore the different ways in life they have not felt 'good enough' and to tell the story of one experience where they did feel good enough, and one where they did not. Again, these can be explored regarding
	the individual's signature strengths.
Hope and Optimism	The additional concepts of optimism and hope are explored. As an exercise, the therapist may ask the individual to think about a time when they may have felt they lost out on something, only to discover it opened up new opportunities.
Positive Communication	Various interventions that involved developing positive communication, such as Active-constructive, are explored and referenced in

	association to the individual's signature strengths.
Signature Strengths of Others	The importance of recognizing, acknowledging, and associating with the signature strengths of the key people the individual has close relationships with is explored. As an exercise, the therapist may ask the individual to draw up a 'Family Strengths Tree' where the individual asks their significant relationships to complete an online self-report strengths test and identify their signature
	strengths. These can then be discussed in the session.
Savoring	The concept of savoring is explored, as well as some of the techniques and strategies that can be used to prevent adaptation, along with techniques and strategies to safeguard against adaptation.
Gift of Time and Positive Legacy	The benefits of kindness, sharing, and helping others are explored and discussed in alignment with therapeutic outcomes. As an exercise, the therapist might ask the individual to make plans for how they might give the gift of their time utilizing their signature strengths.
The Full Life	In the final session, 'The Full Life' is discussed in terms of what the individual feels they have that leads to this. Therapeutic gains are discussed, focusing on positive emotions, engagement, and meaning. How to keep this momentum going is

also discussed, and ways of doing this are devised with the individual taking the lead and considering their signature strengths to achieve this. As mentioned, the above is a brief overview of the sessions that can be included in the PPT model. If you'd like to find out more about the model and detailed descriptions of the sessions, as well as interventions and **positive psychotherapy exercises** that can be used within them, you can find more information through the **Positive Psychology Toolkit**.

POSITIVE PSYCHOTHERAPY RESOURCES

As a psychological approach, PPT has grown considerably in popularity over the past decade or so. There is now a wide range of resources, tools, books, and other media to help you either as a therapist or an individual better understand this model and utilize it in productive ways.

TRANSACTIONAL ANALYSIS

We've all experienced communication breakdowns. You know the feeling. One minute you're having a normal conversation with someone, and the next you're fighting or one of you has shut down. In both cases, there's a breakdown. The conversation has failed to achieve its goal, whether it's being heard, solving a problem, feeling connected, making a decision, etc.

THIS HAPPENS ALL THE TIME. IT TAKES SECONDS FOR A CONVERSATION TO SHIFT FROM A POSITIVE, CONNECTION-DRIVEN INTERACTION INTO A NEGATIVE ONE.

And negative interactions take a toll on our relationships. Studies show that we need 5 positive interactions to make up for every negative interaction we have with someone close to us.

ACCORDING TO TRANSACTIONAL ANALYSIS, COMMUNICATION BREAKDOWNS HAPPEN BECAUSE WE'RE NOT FULLY PRESENT IN OUR CONVERSATIONS.

Instead of reacting to the here and now, we're communicating from different 'ego states'. And when these ego states are crossed, conflict happens. This article will teach you how to use Transactional Analysis to have better, more constructive conversations (and interactions, in general) with the people closest to you. Part 1 will introduce Transactional Analysis, the different ego states, and common transactions. Part 2 will focus on the 'games we play' and how to change them.

TRANSACTIONAL ANALYSIS

Transactional Analysis (TA) is a psychological theory, developed by Eric Berne in the 1960s, that helps explain why we think, act and feel the way we do. TA claims that we can better understand ourselves by **analyzing our transactions** with the people closest to us. Transaction = conversation/interaction between two people. TA is most effective for understanding: 1) transactions with **people you're close** to, not colleagues or acquaintances and 2) transactions about **sensitive, important topics** such as sex, money, jealousy...pretty much anything that's triggering, i.e. causes a deep-rooted emotional reaction in you or the other person.

TA IS BASED ON 3 PRINCIPLES:

- We all have **three 'ego states'** (Parent, Adult, and Child)
- We all have **transactions** (with other people, or internally with ourselves)
- We all (unconsciously) **activate our ego states** in our transactions, which can lead to conflict, negative emotions, pain, etc.

Basically, transactional analysis is about identifying which ego states are present in your transactions so that you can become more conscious of your thoughts and behaviors, and ultimately have better, more constructive transactions with the people closest to you.

EGO STATES: PARENT, ADULT & CHILD

We all have all three ego states: Parent, Adult, and Child. These ego states are made up of consistent feelings and behaviors. *Ego states aren't always negative, see below. These ego states are being activated all the time, whether we're aware of it or not: **Parent (rooted in the past)** — Contains the attitudes, feelings, and behavior incorporated from our parents (or any primary caregiver). It involves responding as one of our parents would have: saying what they would have said, feeling what they would have felt, behaving how they would have behaved. nurturing parent: caring, loving, helping

- controlling parent: criticizing, reprimanding, censoring, punishing, etc.
Adult (rooted in the present) — Our ability to think and act based on what's happening in the here and now. Think of transactions you have with colleagues or acquaintances. These are usually pretty straightforward, without a lot of emotional triggers.
- A good way to know if your Adult ego state is activated is to examine whether your questions/comments are fueled by compassion and curiosity, or the desire to blame, criticize or prove a point.
Child (rooted in the past) — Contains the thoughts, feelings, and behaviors that we experienced as a child.
- natural child: curious, creative, open, loving
- adaptive child: guilty, afraid, depressed, anxious, envious, prideful, trying to please everyone...you get the picture.

IMPORTANT: The adaptive child is one of the most troublesome parts of our personality. It developed as we learned to change(adapt) our feelings and behavior in response to the world around us.

UNDERSTANDING EGO STATES

According to TA, our 3 ego states 'show up' whether we want them to or not, so it's important to be aware of what they 'look' like. The good news is that this is pretty easy to do. Simply think back and answer the following questions:

- **Child:** When you were a kid what do you remember feeling? What was a theme in your interaction with your parents? Were you always fighting for their attention? Did you feel unconditional love? Did you feel that you needed to prove yourself?
This is what Tony Robbins is getting at when he asks: "Think of the person whose love you craved most: what did you have to be for that person to accept and love you? What did you have to think or do to gain their approval?"
- **Parent:** When you were a kid how do you remember your parents behaving? Were they critical? Distrustful of others? Overly cautious? Reckless? What were their beliefs about the world, money, people, etc.?

Now pay attention to which elements of your Child and Parent ego states you've integrated into your own thoughts, beliefs, and behaviors. Every person's Parent and Child ego states are different. For example, when my Child ego state is activated I shut down and can't talk to anybody. Other people's Child may get defensive or lash out. It all depends on the patterns you picked up as a child. Now, think about the people closest to you. What does your partner's Child ego state look like? What about their Parent?

UNDERSTANDING TRANSACTIONS: COMPLEMENTARY, CROSSED & ULTERIOR

According to TA, there are three kinds of transactions: Complementary, Crossed & Ulterior. Part 1 will only focus on Complementary and Crossed transactions. Part 2 will focus on Ulterior transactions.

It's important to realize that there are three parts to each transaction:

1. **What you say** (your activated ego state)
2. **THE RESPONSE (AND EGO STATE) YOU EXPECT TO 'RECEIVE'**
3. **The response you actually receive** Complementary

Complementary transactions = effective and successful communication.

Complementary transactions are when two people's ego states are sympathetic or complementary to one another. This means that what you say and the response you expect to receive, and actually receive, are aligned. A complementary interaction is when Person 1 (Parent) speaks to Person 2 (Child), and Person 2 (Child) responds to Person 1 (Parent). It's easier to understand with pictures, see below.

EXAMPLE 1: ADULT – ADULT

Money is a trigger topic (at least in my experience) because it's uncomfortable, stressful and emotional to talk about. A complementary transaction around money would look like this: In this transaction, all is good:

- **Person 1** is curious about something, and asks a question from the Adult ego state, hoping they'll receive an answer from Person 2's Adult ego state.
- **Person 2** responds from his/her Adult ego state.
- **Result:** All good, two Adults are working together to understand a problem, make decisions, etc.

*I'm assuming that Person 1's question is fueled by curiosity, thus coming from the Adult ego state. However, it could be that Person 1's question is actually fueled by a desire to blame or prove a point. In this case, Person 1's 'Parent' ego state is probably being activated, not the Adult. Either way, the point of transactional analysis is to pay attention to your conversations with the people closest to you. To bring awareness to what roles (ego states) you're both activating and why.

EXAMPLE #2: PARENT - CHILD

Another complementary transaction is Parent -> Child. For example, this can occur when one person is sick and wants to be taken care of by the other person (P).

- **Person 1** feels like shit. Their Child ego state is activated because they want to be taken care of. They expect Person 2 to respond as a Parent.
- **Person 2** understands Person 1's request and is happy to oblige. Person 2's Parent ego state is activated and they happily take care of Person 1.
- **Result:** All is good. There's a balance of 'giving & receiving' and both parties feel loved.

HOW DO YOU KNOW YOU'RE HAVING A COMPLEMENTARY TRANSACTION?

1. **You feel ok** (i.e. you're not overwhelmed with emotions)
2. **YOU FEEL SEEN AND UNDERSTOOD**
3. **The conversation can go on forever** (no emotional outbursts, hurt feelings, slamming doors, or conversation stoppers — i.e. "I'm done with this conversation right now"). This means you can actually reason about things, make decisions, create a plan, etc.

CROSSED TRANSACTIONS

Crossed transactions happen when Person 1 says something from one ego state, and receives a different response than he/she is expecting. For example: Back to the money topic. In this transaction, all is NOT good:

- **Person 1** is curious about something, and asks a question from the Adult ego state, hoping they'll receive an answer from Person 2's Adult ego state.
- **Person 2** is triggered. Their Child ego state is activated (they feel criticized or patronized) and they're pissed.
- **Result:** Probably a fight, or an abrupt end to the conversation. Of course it's ok if this happens once in a while, however habitual communication breakdown is harmful to a relationship. Another example is:
- **Person 1** feels like shit. Their Child ego state is activated because they want to be taken care of. They expect Person 2 to respond as a Parent.
- **Person 2** hears Person 1, but doesn't see what the big deal is. His/her Adult ego state is activated and they tell Person 1 to rest.
- **Result:** Person 1 probably feels hurt because his/her needs weren't being met. *Again, crossed transactions happen all the time. TA is about bringing awareness to these transactions so we can

reduce their negative effect.

ACCORDING TO TA, ALL COMMUNICATION BREAKDOWNS OCCUR BECAUSE OF A CROSSED TRANSACTION.

When you're in the middle of a crossed transaction, the only way to get it back to a constructive place is for one, or both of you, to shift ego states. Usually, it's best to shift (or try very very hard to shift) to the Adult ego state. However, it can vary. You need to be attuned to what's actually happening in a conversation and the needs of each person (hard to do, but possible with practice).

DIALECTIC BEHAVIOR THERAPY

Dialectical behavior therapy (DBT) treatment is a type of psychotherapy — or talk therapy — that utilizes a cognitive-behavioral approach. DBT emphasizes the psychosocial aspects of treatment. The theory behind the approach is that some people are prone to react in a more intense and out-of-the-ordinary manner toward certain emotional situations, primarily those found in romantic, family and friend relationships. DBT theory suggests that some people's arousal levels in such situations can increase far more quickly than the average person's, attain a higher level of emotional stimulation, and take a significant amount of time to return to baseline arousal levels.

People who are sometimes diagnosed with borderline personality disorder experience extreme swings in their emotions, see the world in black-and-white shades, and seem to always be jumping from one crisis to another. Because few people understand such reactions — most of all their own family and a childhood that emphasized invalidation — they don't have any methods for coping with these sudden, intense surges of emotion. DBT is a method for teaching skills that will help in this task.

COMPONENTS OF DBT

- **Support-oriented:** It helps a person identify their strengths and builds on them so that the person can feel better about him/herself and their life.
- **Cognitive-based:** DBT helps identify thoughts, beliefs, and assumptions that make life harder: "I have to be perfect at everything." "If I get angry, I'm a terrible person" & helps people to learn different ways of thinking that will make life more bearable: "I don't need to be perfect at things for people to care about me", "Everyone gets angry, it's a normal emotion.
- **Collaborative:** It requires constant attention to relationships between clients and staff. In DBT people are encouraged to work out problems in their relationships with their therapist and the therapists to do the same with them. DBT asks people to complete homework assignments, to role-play new ways of interacting with others, and to practice skills such as soothing yourself when upset. These skills, a crucial part of DBT, are taught in weekly lectures, reviewed in weekly homework groups, and referred to in nearly every group. The individual therapist helps the person to learn, apply and master the DBT skills.

GENERALLY, DIALECTICAL BEHAVIOR THERAPY (DBT) MAY BE SEEN AS HAVING TWO MAIN COMPONENTS:

1. **Individual weekly psychotherapy sessions** that emphasize problem-solving behavior for the past week's issues and troubles that arose in the person's life. Self-injurious and suicidal behaviors take first priority, followed by behaviors that may interfere with the therapy process. Quality of life issues and working toward improving life in general may also be discussed. Individual sessions in DBT also focus on decreasing and dealing with post-traumatic stress responses (from previous

trauma in the person's life) and helping enhance their own self-respect and self-image. Both between and during sessions, the therapist actively teaches and reinforces adaptive behaviors, especially as they occur within the therapeutic relationship[...]. The emphasis is on teaching patients how to manage emotional trauma rather than reducing or taking them out of crises [...]. Telephone contact with the individual therapist between sessions is part of DBT procedures. (Linehan, 2014) During individual therapy sessions, the therapist and client work toward learning and improving many basic social skills.

- 2. Weekly group therapy sessions**, generally 2 1/2 hours a session which is led by a trained DBT therapist. In these weekly group therapy sessions, people learn skills from one of four different modules: interpersonal effectiveness, distress tolerance/reality acceptance skills, emotion regulation, and mindfulness skills are taught.

THE 4 MODULES OF DIALECTICAL BEHAVIOR THERAPY

1. Mindfulness

The essential part of all skills taught in skills group are the core mindfulness skills. Observe, Describe, and Participate are the core mindfulness "what" skills. They answer the question, "What do I do to practice core mindfulness skills?" Non-judgmentally, One-mindfully, and Effectively are the "how" skills and answer the question, "How do I practice core mindfulness skills?"

2. INTERPERSONAL EFFECTIVENESS

The interpersonal response patterns –how you interact with the people around you and in your personal relationships — that are taught in DBT skills training share similarities to those taught in some assertiveness and interpersonal problem-solving classes. These skills include effective strategies for asking for what one needs, how to assertively say 'no,' and learning to cope with inevitable interpersonal conflict. People with borderline personality disorder frequently possess good interpersonal skills. They experience problems, however, in the application of these skills in specific contexts — especially emotionally vulnerable or volatile situations. An individual may be able to describe effective behavioral sequences when discussing another person encountering a problematic situation, but may be completely incapable of generating or carrying out a similar set of behaviors when analyzing their own personal situation. This module focuses on situations where the objective is to change something (e.g., requesting someone to do something) or to resist changes someone else is trying to make (e.g., saying no). The skills taught are intended to maximize the chances that a person's goals in a specific situation will be met, while at the same time not damaging either the relationship or the person's self-respect.

3. DISTRESS TOLERANCE

Most approaches to mental health treatment focus on changing distressing events and circumstances. They have paid little attention to accepting, finding meaning for, and tolerating distress. This task has generally been tackled by religious and spiritual communities and leaders. Dialectical behavior therapy emphasizes learning to bear pain skillfully. Distress tolerance skills constitute a natural development from mindfulness skills. They have to do with the ability to accept, in a non-evaluative and nonjudgmental fashion, both oneself and the current situation. Although the stance advocated here is a nonjudgmental one, this does not mean that it is one of approval: acceptance of reality is not approval of reality. Distress tolerance behaviors are concerned with tolerating and surviving crises and with accepting life as it is in the moment. Four sets of crisis survival strategies are taught: distracting, self-soothing, improving the moment, and thinking of

pros and cons. Acceptance skills include radical acceptance, turning the mind toward acceptance, and willingness versus willfulness.

4. EMOTION REGULATION

People with borderline personality disorder or who may be suicidal are typically emotionally intense and labile — frequently angry, intensely frustrated, depressed, and anxious. This suggests that people grappling with these concerns might benefit from help in learning to regulate their emotions.

Dialectical behavior therapy skills for emotion regulation include:

- Learning to properly identify and label emotions
- Identifying obstacles to changing emotions
- Reducing vulnerability to “emotion mind”
- Increasing positive emotional events
- Increasing mindfulness to current emotions
- Taking opposite action
- Applying distress tolerance techniques

ART THERAPY, PERFORMING ART THERAPY

Art therapy is an integrative mental health and human services profession that enriches the lives of individuals, families, and communities through active art-making, creative process, applied psychological theory, and human experience within a psychotherapeutic relationship. Art therapy, facilitated by a professional art therapist, effectively supports personal and relational treatment goals as well as community concerns. Art therapy is used to improve cognitive and sensorimotor functions, foster self-esteem and self-awareness, cultivate emotional resilience, promote insight, enhance social skills, reduce and resolve conflicts and distress, and advance societal and ecological change.

Art Therapy is an integrative mental health and human services profession that enriches the lives of individuals, families, and communities through active art-making, creative process, applied psychological theory, and human experience within a psychotherapeutic relationship. Art Therapy, facilitated by a professional art therapist, effectively supports personal and relational treatment goals as well as community concerns.

Art Therapy is used to improve cognitive and sensory-motor functions, foster self-esteem and self-awareness, cultivate emotional resilience, promote insight, enhance social skills, reduce and resolve conflicts and distress, and advance societal and ecological change. Art therapists are master-level clinicians who work with people of all ages across a broad spectrum of practice. Guided by ethical standards and scope of practice, their education and supervised training prepares them for culturally proficient work with diverse populations in a variety of settings. Honoring individuals' values and beliefs, art therapists work with people who are challenged with medical and mental health problems, as well as individuals seeking emotional, creative, and spiritual growth. Through integrative methods, art therapy engages the mind, body, and spirit in ways that are distinct from verbal articulation alone. Kinesthetic, sensory, perceptual, and symbolic opportunities invite alternative modes of receptive and expressive communication, which can circumvent the limitations of language. Visual and symbolic expression gives voice to experience, and empowers individual, communal, and societal transformation.

Performing Art Therapy in Geriatric Care – Presentation Transcript

1. Performing Art Therapy in Geriatric Care Dr. D. Dutta Roy Psychology Research Unit Indian Statistical Institute, Kolkata – 700108 Web :<http://www.isical.ac.in/~ddroy> E-mail: ddroy @ isical ac.in Venue: Paripurnata, 12.11.09 Audience: Senior People.

2. What is performing art therapy ?

- Performing art generally includes dance, music, songs, drama in organized fashion. Besides, painting, sculpturing, Yoga, farming etc. are the performing arts.
- Performing art therapy is the therapeutic process in which performing art therapist tends to explore one's needs, values, crisis in the life cycle;
- improvise performing art in such a fashion so that client can understand own needs and can develop coping strategy to overcome the crisis.
- In performing art, client is not merely receptive but productive and creative. Therefore, the objective of therapist will be to stimulate the client to understand self and socially accepted coping strategies. It develops adaptability within individual.

3. Role of Performing Art therapist

- Performing art therapist acts as the tool for
- Diagnosis
- Restoring (condition at control)
- Preventing and
- Promoting physical, mental, social and spiritual health.
- It is the process of achieving three layers of consciousness.

4. What happens during PAT ?

- During performing art, individual travels around different layers of consciousness – the outer, inner and inner core layers.
- During traveling, individual understands own crisis in life cycle, underlying reasons and sets own coping strategy.
- It helps individual to find meaning in life, to realize own self and develop high efficacy in cognitive, emotional, psycho motor co-ordination and over all health efficacy.
- It increases desires for life expectancy.
- It controls ageing process.

5. CONSCIOUSNESS PARADIGM Outer Layer: -Missing -Anomalies Inner Layer -Vividness -Orderliness -Complexity

- Inner Core Layer
- Harmony with Environment
- Aesthetics
- Cleanliness

6. A Journey

- Rabindrasangeet is a journey from outer layer to inner core through inner layer of consciousness.
- “Chokher aloy dekhechilem chokherbahire” (outer layer)
- “Antare aaj dekhbo, jakhan alok nahi re” (inner layer) & “Dharay jakhan dao na dhara hriday takhan tomay bhara, ekhon tomar apan aloy tomay chahi re” (innercore layer)

7. Playing in the outer layer

- “ Ami keboli swapan karechi bapan batase-
- Tai akashkusum karinu chayan hatashe
- Chayar matan milay dharani, kul nahi pay ashar tarani,
- Manaspratima bhasia beray akashe”
- “ Emni karei jay jadi din jak na, Mon ureche uruk na re mele diyeganer pakhna”

8. Mixing with inner core/Saraswat layer

- “ Amar poran jaha chay tumi tai, tumi tai Go toma chharaar e jogote mor keho nai, keho nai Go.
- Tumi sukh jodi nahi pao, jao sukher sondhane jao amitomare peyechhi hridhoymajhe, ar kichhu nahi chai go.
- Ami tomar birohe rohibo bileen, tomate koribo baasdirgho dibos dhirgho rojoni, dirgho boroshmaas.”

9. The Second stage

- The journey is not very smooth. Lot of ideas are broken,built and rebuilt.
- “ Tomay niye khelechilem khelar gharete khelar putul bhenge geche pralayy jhaarete Thak tabe sei kebol khela, hok -na ekhon praner mela- tarer bina bhanglo, hriday-binay gahi re. ”

10. Case Study 1: Where all fail, Rabindrasangeet acts

11. Response control of OCD

- A woman of 52 years old came to me with complaint of OCD to dirt. Patient reported her inability to control washing compulsion. For last 30 years, she regularly went to toilet for washing and cleaning hands. She always closed her hands tightly so that her hands would be completely cleaned. Before visit to me, she was treated by many psychiatrists and one psychologist. No notable changes are noticed except long time sleep.

12. Patient’s behaviour

- Very inhibitive;
- Hand clasping tightly;
- Strong resistance to open clasping;
- Non-cooperative to participate;
- Not able to administer any available psychological tests.

13. Analysis of patient

- Patient is searching for dirt in the outer layer.
- In the inner layer, dirt is perceived as threatening;
- Patient wants to move away from inner to inner corelayer. For the same, she spends most of the

time in worshipping the God and keeping cleanliness.

- She is not happy with soaping hands as this can not help her to reach at the innercore layer of consciousness.
- This results approach – avoidance conflict.
- (Approaching to the soap in order to avoid dirt, again few soaping is not sufficient, so more soaping is required).

14. Analysis of family

- Repeated soaping consumes more water;
- Family assumes that it is unreasonable but patient assumes it as reasonable ;
- Family member is not aware of consciousness dynamics playing inside the patient.

15. Therapeutic analysis

- Target: Preventing clasping hands;
- Consciousness model:
- Outer layer : Dirt perception;
- Inner layer : Dirt as threat;
- Innercore : Feeling of cleanliness;
- Currently, patient is moving around outer and inner layers only.
- Therapeutic target: Providing her Feeling of cleanliness.
- Rabindrasangeet is non-dirt area;
- Explore the song suitable for feeling of non-dirt area;

16. Session-1

- In the first session , patient was highly inhibitive to reveal herself. Due to difficulty in rapport establishment. I started singing — “Ananda loka, mangala loka” (moving to spiritual land).
- Suddenly, she started singing with me in very low voice;
- I paid my attention to her and started moving the hands keeping with the rhythm and waves of the song loudly. She participated into my hand movement and sang the song loudly.

17. Session-2

- In the 2nd session after 6 days, the client sang with me same song by standing. She moved her hands above head when she sang “Grahataraka chandra tapanabyakula drutabege” (the planets, satellites are moving speedily). It is noted that her hands now completely opened.

18. Session-3

- In the 3rd sitting, patient reported that she alone practiced two songs
- “Ektuku chona lage...” (feeling light touch), and
- “Eto din je bosechinu” (waiting for long days) at home. Finally, she sang with me both songs along with Ananda loka, danced and she never closed her hands.
- Termination : Patient herself is able to prevent stopping hand clasping.

19. Searching Principle : Growth of inquisitiveness Feeling of scattered impulses,needs etc. Searching cues Does it give meaningful pattern ? N Y

20. Geriatric assessment

21. Geriatric Disorders

- Organic Disorders : Dementia, Delirium
- Psychological Disorders :
- Neurotic (Anxiety disorder, Phobic disorder, Conversion reaction, Dissociative Reaction, Obsessive Compulsive disorder, Depression, Hypochondriasis)
- Psychotic (Schizophrenia, Manic-Depressive Disorder,Paranoia)
- Substance abuse
- Sexual disorder

22. History

- Modern geriatrics in the United Kingdom really began with the "Mother" of Geriatrics, Dr. Marjorie Warren . Warren emphasized that rehabilitation was essential to the care of older people. She developed the concept that merely keeping older people fed until they died was not enough- they needed diagnosis, treatment, care and support . She found that patients, some of whom had previously been bedridden, were able to gain some degree of independence with the correct assessment and treatment.
- Another "hero" of British Geriatrics is Bernard Isaacs , who described the "giants" of geriatrics: incontinence, immobility, impaired intellect and instability. Isaacs asserted that if you look closely enough, all common problems with older people relate back to one of these giants

23. Geriatric Psychology for the Care givers

- To understand different principles leading to formation of different symptoms of geriatric disorders.
- Biological Paradigms : Brain mapping, Loss or injury
- Psychological Paradigms : Psychodynamic, Learning,Cognitive
- To understand principles of Psychology in order to improve quality of life of the elderlylyly people.
- Counseling, Psychotherapy, Individual and communitycare.

24. BIOLOGICAL PARADIGM

- BRAIN MAPPING
- LOSS OF BRAIN FUNCTIONS

25. Brain Mapping

- Frontal Lobe
- How we know what we are doing within our environment (Consciousness). How we initiate activity in response to our environment. Judgments we make about what occurs in our daily activities. Controls our emotional response. Controls our expressive language. Assigns meaning to the words we choose. Involves word associations. Memory for habits and motor activities.
- Parietal Lobe

- Location for visual attention. Location for touch perception. Goal directed voluntary movements. Manipulation of objects. Integration of different senses that allows for understanding a single concept.
- Occipital Lobe
- Vision
- Temporal Lobe
- Hearing ability Memory acquisition Some visual perceptions Categorization of objects.
- Brain Stem
- Breathing Heart Rate Swallowing Reflexes to seeing and hearing (Startle Response). Controls sweating, blood pressure, digestion, temperature (Autonomic Nervous System). Affects level of alertness. Ability to sleep. Sense of balance (Vestibular Function).
- Cerebellum
- Coordination of voluntary movement Balance and equilibrium Some memory for reflex motor acts.

26. Loss of Brain Functions

- Frontal Lobe
- Loss of simple movement of various body parts (Paralysis). Inability to plan a sequence of complex movements needed to complete multi-stepped tasks, such as making coffee (Sequencing). Loss of spontaneity in interacting with others. Loss of flexibility in thinking. Persistence of a single thought (Perseveration). Inability to focus on task (Attending). Mood changes (Emotionally Labile). Changes in social behavior. Changes in personality. Difficulty with problem solving. Inability to express language (Broca's Aphasia).
- Parietal Lobe
- Inability to attend to more than one object at a time. Inability to name an object (Anomia). Inability to locate the words for writing (Agraphia). Problems with reading (Alexia). Difficulty with drawing objects. Difficulty in distinguishing left from right. Difficulty with doing mathematics (Dyscalculia). Lack of awareness of certain body parts and/or surrounding space (Apraxia) that leads to difficulties in self-care. Inability to focus visual attention. Difficulties with eye and hand coordination.
- Occipital Lobe
- Inability to attend to more than one object at a time. Inability to name an object (Anomia). Inability to locate the words for writing (Agraphia). Problems with reading (Alexia). Difficulty with drawing objects. Difficulty in distinguishing left from right. Difficulty with doing mathematics (Dyscalculia). Lack of awareness of certain body parts and/or surrounding space (Apraxia) that leads to difficulties in self-care. Inability to focus visual attention. Difficulties with eye and hand coordination.
- Temporal Lobe
- Difficulty in recognizing faces (Prosopagnosia). Difficulty in understanding spoken words (Wernicke's Aphasia). Disturbance with selective attention to what we see and hear. Difficulty with identification of, and verbalization about objects. Short-term memory loss. Interference with long-term memory Increased or decreased interest in sexual behavior. Inability to categorize objects (Categorization). Right lobe damage can cause persistent talking. Increased aggressive behavior.

27. Comprehensive geriatric assessment

- Identification : Age, sex, brought in by whom, chief complaint

- Source of History (include reliability rating) : Patient, caregiver, family, friends Medical records, Previsit questionnaire
- History of Present Problems/Condition
- Medications — old medication lists, herbal/alternative medications , Allergies/Adverse Drug Reactions : Name specific medications and characterize specific allergic/adverse drug reaction for each medication
- Habits : tobacco, recreational drugs
- Social History : Education, Marital Status/Children, Household members, Activities/Exercise, Travel, Occupational History/Toxin Exposures, Diet, Caffeine, Sexual Activity, Caregiver roles
- Past Medical History : (ask about previous medical records, old lab/imaging/study reports)
- Family History : Heart disease, cancer, diabetes, TB,HTN, mental health, Alzheimer's disease
- Care Resources : past and present Home Health, Case Management, etc.
- Personal History : Environment, Reverse developmental milestones
- Review of Systems :
 - General : fevers, chills, malaise, fatiguability, nightsweats, weight changes
 - Neurologic : syncope, seizures, weakness, paralysis, abnormal sensation/coordination, tremors, memory loss
 - Psychiatric : depression, mood changes, difficulty concentrating, nervousness, tension, suicidal ideation, irritability, sleep disturbances
 - Sensory Functions : visual changes, hearing changes, neuropathy, balance/coordination
 - Motor Functions : gait, falls, ataxia
 - Diet : preferences, restrictions (religious, allergic, disease), vitamins/supplements, caffeine, food/liquid intake diary , "look in fridge test" , who prepares/obtains food
 - Skin : rash/eruption, itching, pigmentation, excessive sweating, nail/hair abnormalities
 - Head : Headaches, dizziness, syncope, severe head injuries, loss of consciousness
 - Eye : visual changes, blurring, diplopia, photophobia, pain, eye medication use, eye trauma, FH of eye disease
 - Ears : hearing loss, pain, discharge, tinnitus, vertigo
 - Nose : sense of smell, obstruction, epistaxis, postnasal drip, sinus pain, rhinorrhea
 - Oral : hoarseness, sore throat, gum bleeding/soreness, tooth abscess/extraction, ulcers, taste changes Comprehensive geriatric assessment²⁹.
 - Cardiac/Peripheral Vascular : Chest pain, palpitations,dyspnea, orthopnea, edema, claudication, HTN, previous MI, exercise tolerance, previous cardiac studies
 - Pulmonary : pleuritic pain, dyspnea, cyanosis, wheezing, cough/sputum, hemoptysis, TB exposure, previous CXR's
 - Gastrointestinal : appetite, digestion, dysphagia, heartburn, nausea, vomiting, hematemesis, diarrhea, constipation, stool changes, flatulence, hemorrhoids,hepatitis, jaundice, dark urine, history of ulcers/gallstones/polyps/tumors, previous X-rays
 - Renal/Urinary :dysuria, flank/suprapubic pain, urgency,frequency, nocturia, hematuria, polyuria, hesitancy, dribbling, force of stream changes, STD's
 - Hematologic : anemia (dizziness/fatigue/dyspnea), easy bruising/bleeding, blood cell abnormalities, transfusions
 - Lymphatic : lymph node enlargement/tenderness
 - Endocrine/Metabolic : thyroid enlargement/pain, heat/cold intolerance, unexplained weight change, diabetes,polydipsia, polyuria, facial/body hair changes, increased hat/glove size, striae
 - Musculoskeletal : joint stiffness, pain, limited ROM, swelling, redness, heat, bone deformity
 - Sexual : libido, intercourse frequency, sexual difficulties, impotence
 - Gynecologic : itching, last Pap smear, menopause age

- Breasts : pain, tenderness, discharge, lumps,mammograms, self-breast exams Comprehensive geriatric assessment

30. Geropsychiatric Mental Status Exam

- Most of this exam is observed through the interview conversation with patient
- General Appearance/Behavior: Grooming and hygiene,unusual movements, attitude, psychomotor activity, eye contact
- Affect: (external range of expression) flat, blunted, labile, full/wide range
- Mood: (internal emotional tone) dysphoric, euphoric, angry, euthymic, anxious
- Thought Processes: Language (quality/quantity of speech), tone, associations, speech fluency
Note presence of: pressured speech, poverty of speech, blocking, flight of ideas, loosening of associations,tangentiality, Circumstantiality, echolalia, neologisms,clanging, perseveration, ideas of reference
- Thought Content: note hallucinations, delusions, illusions,derealization, depersonalization, suicidal or homicidal ideation
- Cognitive: (mostly covered by psychometric tests)level ofconsciousness, orientation
- Insight: the patient's understanding of his or her problemsand implications of these problems
- Judgment: based on history of patient's decision making abilities

31. Geriatric care by the caregiver

- I) Social Information II) Caregiver Information III) Patient'sHealth IV) Head Injury V) Activities of Daily Living VI) History of Falls VII) Vision VIII) Hearing IX) Dentition X) Bowel/Bladder XI) Sexuality XII) Nutrition XIII) Communication XIV) Usual daily activities (with exercise) XV) Sleeping XVI) Finances XVII) Home Safety Checklist XVIII) Current Medications XIX) Care resources/agencies

32. Geriatric care by Psychologist

33. Counselling VS Psychotherapy

- Counselling
- A brief treatment focusing on patient's current problems.
- Helping people who have the capacity to cope in most circumstances, who are experiencing temporary difficulties or in a psychosocial transition.
- Psychotherapy
- Psychotherapy is more concerned with the resolution of longstanding personal issues and may be either brief or long term.
- When issues are more symptomatic of something deeper.

34. Why Psychotherapy ?

- It helps aged to deal with those issues and the emotional problems surrounding them and to understand their behavior on others. In addition to improving interpersonal relations psychotherapy increases self esteem and self confidence, decreases feelings of helplessness and anger and improves the quality of life. Psychotherapy of the aged has the general aim of assisting the old person to have minimal complaints to help him or her make and keep fresh of both sexes, and to have sexual relationship where there is still interest and capacity. Psychotherapy helps relieve tension of biological and cultural origins andhelps old persons work and play within the limits of

their functional status and as determined by their past training activities and self concept in society.

35. Psychodynamic Paradigm

- Pathology of elderly people is due to conflict between structures of mind – Id, Ego and Super Ego.
- Study the pathology in terms of energy processing from Unconscious to conscious through Pre-conscious.
- Psychosexual stages
- Oral, Anal, Phallic, Genital and Latency
- Study it in terms of Ego-defense mechanisms — Regression, Repression, projection, rationalization, displacement, reaction formation etc.

36. Neo-Freudian

- ADLER
- Study abnormal behavior in terms of
- one's failure in striving for perfection,
- Organ Inferiority, Psychological inferiority.
- Defenses
- Compensation
- Superiority Complex
- ERIKSON
- Abnormality is due to one's failure in handling crisis of earlier stage.
- Stage One Oral-Sensory: from birth to one, trust vs. mistrust, feeding;
- Stage Two Muscular-Anal: 1-3 years, autonomy vs. doubt, toilet training;
- Stage Three Locomotor: 3-6 years, initiative vs. inadequacy, independence;
- Stage Four Latency: 6-12 years, industry vs. inferiority, school;
- Stage Five Adolescence: 12-18 years, identity vs. confusion, peer relationships;
- Stage Six Young Adulthood: 18-40 years, intimacy vs. isolation, love relationships;
- Stage Seven Middle Adulthood: 40-65 years, generativity vs. stagnation, parenting;
- Stage Eight Maturity: 65 years until death, integrity vs. despair, acceptance of one's life.

37. Psychodynamic Counseling

- Psychodynamic therapists make genetic links between early childhood experiences and deal patient's current character structure and symptomatology. The patient's emotional response to the therapist (transference) and the therapist's emotional response to the patients (counter transference) are also sources of learning. Key patterns of feeling and behaving from early childhood are repeated or 'transferred' on to the people in the patient's adult life including the therapist.

38. Geriatric care by Performing art therapist

39. Performing art acts as tool for diagnosis and therapy

40. Dance, song and drama make your body fit

41. Social dancing

- Social dancing increases feeling of generativity and reduces stagnation in life;

- It reduces feeling of loneliness;
- It provides social support and care;
- It encourages life expectancy
- It contributes to the longevity of the dancers, giving them something to enjoy and focus upon – to live for.
- it alleviates social isolation and quite literally helps take away the aches and pains associated with older age."

EXPRESSIVE ARTS THERAPY

Expressive arts therapy is a multimodal approach to therapy similar to its cousins drama therapy and music therapy. Expressive arts therapy may incorporate writing, drama, dance, movement, painting, and/or music. People utilizing expressive arts therapy are encouraged by a qualified therapist to explore their responses, reactions, and insights through pictures, sounds, explorations, and encounters with art processes. A person is not required to have artistic ability to use or benefit from expressive arts therapy.

HISTORY OF EXPRESSIVE ARTS THERAPY

Relatively new in its formation, expressive arts therapy began circa 1970 at the Leslie College Graduate School in Cambridge, Massachusetts. Paolo Knill, a leader in the field, founded the International Network of Expressive Arts Therapy Training Centers and, in 1984, began the ISIS European Training Institutes. Expressive arts therapy was formed as a distinct practice alongside the modalities at the root of its creation. It utilizes all expressive modalities such as art, music, drama, and dance therapies. Although expressive arts therapists are not experts in all of these areas (many have multiple proficiencies), they typically possess the sensitivity and ability to grasp the intermodal technique.

EXPRESSIVE ARTS THERAPY PROCESS

Use of the expressive arts multiplies the avenues by which a person in therapy may seek meaning, clarity, and healing. It deepens and transcends traditional talk therapy by acknowledging that each person's process is unique. While one individual may like talk therapy, another person may prefer to use journaling, movement, art, or a combination of different experiences during therapy. The accessibility of expressive arts therapy is due to the focus being not on artistic outcomes but rather on the process of creating. A person who utilizes expressive arts therapy is not required to have any artistic ability. Rather, it is through the use of the individual's senses that the imagination can process, flourish, and support healing. As such, the process is often referred to as "low skill, high sensitivity."

Each creative arts modality is unique, and the use of each is carefully considered by each expressive arts therapist. For example, journaling might be an appropriate expressive outlet for someone new to therapy. On the other side of the spectrum, a person who has already established a strong therapeutic relationship with his or her therapist may appreciate the use of movement or drama. Careful use of each modality is determined by the strength, timing, pacing, and readiness of the person in therapy. Different modalities may be used at any point throughout the therapeutic process as needed. Homework may also be issued for the person in therapy to complete between sessions.

CONDITIONS TREATED WITH EXPRESSIVE ARTS THERAPY

Expressive arts therapy may be used as a part of the treatment strategy for a wide variety of behavioral, emotional, and mental health conditions. These include:

- Attention-deficit hyperactivity
- Developmental disabilities
- Eating disorders
- Traumatic brain injury
- High levels of stress
- Anxiety
- Depression
- Posttraumatic stress
- Chronic medical illnesses
- Social challenges

EXPRESSIVE ARTS THERAPY TECHNIQUES

Many definitions of expressive arts therapy mention its use of distinct features such as music, movement, play, psychodrama, sculpture, painting, and drawing. If necessary, though, therapists may choose to combine several techniques in order to provide the most effective treatment for the individual in therapy. Popular therapeutic approaches may involve the use of various drawing and art techniques, including:

- Finger painting
- The squiggle drawing game (sometimes used in other therapeutic approaches, especially with children)
- Mask making
- The blob and wet paper technique
- The kinetic family drawing technique

To illustrate, finger painting may be used as a form of projective play wherein the therapist takes note of the types of lines drawn, the colors used, as well as the work rate and rhythm of the person in treatment. In a typical session the therapist will describe the process, but will not suggest a specific topic or the colors to be used. Instead, the therapist may provide broad instructions such as “paint something important to you” or “paint a picture of a dream you had.” The therapist then observes the content being produced and the behavior of the person in therapy. Once the picture is finished, the therapist will ask the affected individual to tell a story about the painting. Finger painting has proven effective in the treatment of children with behavioral issues or other related mental health issues. Through consistent use of this technique, therapists may be able to learn about a child’s personality traits, motor skills, and inner world.

EXPRESSIVE ARTS THERAPY RESEARCH

The therapeutic impact of expressive arts therapy is focused on four major areas:

- Expression
- Imagination
- Active participation
- Mind-body connection.

Studies indicate that music may help individuals experiencing a wide range of social, developmental, and behavioral issues grow in self-awareness and self-confidence and learn new skills and concepts. Expressive arts therapy has also successfully helped children experiencing hyperactivity or social anxiety to control impulsive and aggressive behaviors. Though evidence from empirically valid studies is limited, expressive arts therapy has been used to help individuals with disordered eating

habits to explore issues regarding body image, self-esteem, social isolation, and depression.

People with medical illnesses may also benefit from expressive arts therapy. Past research has studied how creating artistic photographs may help people cope with the distress of hospitalization. Another study concluded elderly men and women who are part of an active choir report better health, less doctor visits, fewer falls, and less medication use than peers who are not part of an organized arts program. Finally, another body of research on children with cystic fibrosis who took part in a creative arts support program found the children learned how to better express themselves, reduce stress, and find meaning in their current health situation.

HOW ART THERAPY DIFFERS FROM EXPRESSIVE ARTS THERAPY

Modalities such as art therapy, music therapy, poetry therapy, dance/movement therapy, and expressive arts therapy are all examples of creative arts therapy. While the majority of these disciplines are based in a single art modality, however, expressive arts therapy integrates therapeutic tools and techniques from many different art forms. The combination of a variety of arts-based therapeutic modalities creates a new approach which is distinct from its individual components. Certified expressive arts therapists rely on their creativity and training in order to decide which modality should be utilized at a particular time. Expressive arts therapists may even employ techniques from a range of other modalities in a single therapy session. The focus of expressive arts therapy is on the therapeutic effect of the creative experience, and it highlights the human capacity to transform thoughts, emotions, and experiences into tangible shapes and forms. The approach is described as “integrative” when different art techniques are intentionally used in combination with traditional medicines to promote improved health.

TRAINING FOR EXPRESSIVE ARTS THERAPISTS

Training to be an expressive arts therapist requires at least a master’s degree in counseling with a concentration in expressive arts therapy from an accredited university. Additionally, some institutions offer certificate programs or studies in expressive arts for those who wish to use the expressive arts in related fields such as coaching, consulting, and education. Bachelor’s and PhD options are available, while certification and training continues to grow internationally. For a list of current available resources, please visit the International Expressive Arts Therapy Association (IEATA), which highlights graduate training programs, certificates, and professional development programs in expressive arts therapy. Those wishing to access this type of therapy are encouraged to find a therapist certified in expressive arts therapy.

LIMITATIONS OF EXPRESSIVE ARTS THERAPY

One of the major criticisms of expressive arts therapy is the fact that the primary reason for healing is not clearly discernible. It is not clear whether healing occurs from the creative process or if it is due to positive interactions with the therapist. As currently published studies tend to focus on immeasurable qualitative benefits, a lack of empirical evidence in support of the effectiveness of the approach is a concern.

FAMILY THERAPY

We all start this life with a family, whether that family is composed of blood relatives, adopted parents, a close-knit neighborhood, or a foster family. This family that we acquire when we are born influences every aspect of our lives, from our first moments to our last. Our family affects who we are and who we become, for better and for worse. We learn our vocabulary, our habits, our customs and rituals, and how to view and observe the world around us. We also learn how to love and how to

interact with others from these first important relationships. If we are born into a healthy family with healthy relationships, we are likely to learn how to maintain healthy relationships. If we are born into a dysfunctional family that struggles to connect, we may also struggle to connect with others. While it is certainly unlucky to be born into the second kind of family, it's not an unchangeable situation. Nearly all families deal with some sort of dysfunction at one time or another, yet most families retain or regain a sense of wholeness and happiness.

Family therapy offers families a way to do this—a way to develop or maintain a healthy, functional family. Family therapy is a type of psychological counseling (psychotherapy) that can help family members improve communication and resolve conflicts. Family therapy is usually provided by a psychologist, clinical social worker or licensed therapist. These therapists have graduate or postgraduate degrees and may be credentialed by the American Association for Marriage and Family Therapy (AAMFT). Family therapy is often short term. It may include all family members or just those able or willing to participate. Your specific treatment plan will depend on your family's situation. Family therapy sessions can teach you skills to deepen family connections and get through stressful times, even after you're done going to therapy sessions.

Family therapy can help you improve troubled relationships with your partner, children or other family members. You may address specific issues such as marital or financial problems, conflict between parents and children, or the impact of substance abuse or a mental illness on the entire family. Your family may pursue family therapy along with other types of mental health treatment, especially if one of you has a mental illness or addiction that also requires additional therapy or rehabilitation treatment. For example:

- Family therapy can help family members cope if a relative has a serious mental illness such as schizophrenia — but the person who has schizophrenia should continue with his or her individualized treatment plan, which may include medications, one-on-one therapy or other treatment.
 - In the case of addiction, the family can attend family therapy while the person who has an addiction participates in residential treatment. Sometimes the family may participate in family therapy even if the person with an addiction hasn't sought out his or her own treatment.
- Family therapy can be useful in any family situation that causes stress, grief, anger or conflict. It can help you and your family members understand one another better and learn coping skills to bring you closer together.

HOW YOU PREPARE

You can ask your primary care doctor for a referral to a therapist. Family members or friends may give recommendations based on their experiences. You also can ask your employee assistance program, clergy, or state or local mental health agencies for suggestions for therapists.

Before scheduling sessions with a therapist, consider whether the therapist would be a good fit for your family. Here are some factors to consider and questions to ask:

- **Education and experience.** What is your educational and training background? Are you licensed by the state? Are you accredited by the AAMFT or other professional organizations? Do you have specialty training in family psychotherapy? What is your experience with my family's type of problem?
- **Location and availability.** Where is your office? What are your office hours? Are you available in case of emergency?
- **Length and number of sessions.** How long is each session? How often are sessions scheduled?

How many sessions should I expect to have?

- **Fees and insurance.** How much do you charge for each session? Are your services covered by my health insurance plan? Will I need to pay the full fee upfront? What is your policy on canceled sessions?

WHAT YOU CAN EXPECT

Family therapy typically brings several family members together for therapy sessions. However, a family member may also see a family therapist individually. Sessions typically take about 50 minutes to an hour. Family therapy is often short term — generally about 12 sessions. However, how often you meet and the number of sessions you'll need will depend on your family's particular situation and the therapist's recommendation.

DURING FAMILY THERAPY, YOU CAN:

- Examine your family's ability to solve problems and express thoughts and emotions in a productive manner
- Explore family roles, rules and behavior patterns to identify issues that contribute to conflict — and ways to work through these issues
- Identify your family's strengths, such as caring for one another, and weaknesses, such as difficulty confiding in one another

EXAMPLE: DEPRESSION

Say that your adult son has depression. Your family doesn't understand his depression or how best to offer support. Although you're worried about your son's well-being, conversations with your son or other family members erupt into arguments and you feel frustrated and angry. Communication diminishes, decisions go unmade, family members avoid each other and the rift grows wider. In such a situation, family therapy can help you:

- Pinpoint your specific challenges and how your family is handling them
- Learn new ways to interact and overcome unhealthy patterns of relating to each other
- Set individual and family goals and work on ways to achieve them

RESULTS

Family therapy doesn't automatically solve family conflicts or make an unpleasant situation go away. But it can help you and your family members understand one another better, and it can provide skills to cope with challenging situations in a more effective way. It may also help the family achieve a sense of togetherness.

WHAT IS APPLICATIONS OF THEORIES OF MOTIVATION AND LEARNING IN SCHOOL FACTORS IN EDUCATIONAL ACHIEVEMENT TEACHER EFFECTIVENESS GUIDANCE IN SCHOOLS: NEEDS, ORGANIZATIONAL SET UP AND techniques Counselling: Process, skills, and techniques?

APPLICATIONS OF THEORIES OF MOTIVATION AND LEARNING IN SCHOOL

In a couple of previous posts I briefly touched on theories of motivation and on how they can be tapped into to raise student achievement. In particular I concerned myself with a relatively unknown and yet powerful catalyst of motivation, self-efficacy, or expectancy of success, which, if nurtured regularly and adequately in the classroom can majorly impact learning. In this post I will very

concisely outline the main principles underpinning other influential motivational theories and how I deploy them in my every day teaching in an attempt to enhance my students' motivation. Here is a **very minimalistic** overview of 8 of the 20 theories of motivation I brainstormed before writing this article. Please note that their tenets and implications for the classroom have been overly simplified; hence, if you are keen to apply them to your specific teaching context, you may want to find out more about them.

1. COGNITIVE DISSONANCE

Cognitive dissonance occurs when there is an unresolved conflict in our mind between two beliefs, thoughts or perceptions we hold about a given subject. The level of tension resulting from such conflict will be a function of:

- How strong the conflict is between the two dissonant thoughts;
- How important the issue they relate to are to a specific individual or group;
- How difficult it is to rationalize (justify through logical or pseudo-logical reasoning) the dissonance.

Cognitive dissonance is a very powerful motivator which, as I shall discuss in a future post, is often used in transformational change programs both in the business and educational world. The reason why it is so powerful is because, when used effectively, Cognitive dissonance creates a sense of discomfort in an individual which in order to be resolved results in one of two outcomes:

- The individual changes behavior (possibly replacing the existing behavior with the newly modelled one);
- The individual does not adopt the new behavior and justifies his/her behaviour by changing the conflicting cognition created by the new information, instead.

Implications for the classroom: Whenever you want to change a student's attitude, first identify the beliefs at the heart of that attitude; when you have a fairly clear picture induce cognitive dissonance by producing powerful information and arguments which counter those beliefs. The degree of cognitive dissonance should be as high as possible for the attitudinal change we purport to bring about to be effective. For example, when dealing with a misbehaving child, to simply tell them off for what they did will be way less effective than raising their awareness of the ways their conduct affected others negatively and explaining why is morally/ethically wrong. Or, to impose a new methodology to one's team of teachers by saying it is more effective than the one currently in use by merely providing statistics from a few research studies which point to its greater effectiveness will not be as powerful as explaining to them **why the old approach is failing the target students and the new can more effectively address the identified shortcomings**. Another example in the realm of language learning: many foreign language students in England hold negative views about the country (ies) where the target language is spoken. If one wants to change such attitudes one may want to first find out what beliefs are at the root of those attitudes (e.g. are they xenophobic stereotypes?); then in a lesson or series of lesson (at the beginning of the year, maybe?) provide objective and solid reasons to prove that those beliefs are indeed false using supporting evidence which will resonate with the students' sub-culture, thereby creating cognitive dissonance. Research suggests that over-using statistics may be detrimental and that engaging the target students in a discussion on the issues-in-hand after the new information has been provided, will enhance the chances of attitudinal change to occur. This process may induce the learners to restructure their cognition.

2. DRIVE REDUCTION THEORY

This theory is centred on the notion that we all have needs that we attempt to satisfy in order to

reduce the tension or arousal they cause. **The internal stimuli these needs produce are our main drives in life.** There are Primary drives which refer to basic needs (food, sleep, procreation, etc.) and Secondary drives which refer to social identity and personal fulfillment. As we act on our needs we are conditioned and acquire habits and subconscious responses. So, for example: when a child needs to feel good about himself, he may recite a poem, sing a song, perform a dance or other 'feats' to his parents knowing he is going to get some recognition. Whenever he needs recognition in other contexts, this individual will possibly use the same tactics in order to get the same response from any other figure of authority — including teachers. When the driven action does not satisfy his needs or the enacting of drives is frustrated, negative emotions (e.g. anxiety) arise. To go back to the previous example: if the boy is looking for a chance to show off to an authority figure his 'skills' but he is not given the opportunity to do so, he will feel frustrated, angry and/or unappreciated — a very common scenario in school, often dismissed as the child being 'naughty' or 'unruly'. Implications for the classroom: find out what drives your students, especially the difficult ones. Instead of approaching the problem by 'punishing' them, have a one-on-one chat with them and try to discover what is that they find fulfilling and see if you can find opportunities in your lessons for them to enact their drives. For instance, if you have a student passionate about drama who does not seem to enjoy language learning, ask them to contribute their acting skills by miming vocabulary or sentences in lessons or setting up a mini-production in the target language.

3. ATTRIBUTION THEORY

When we make a mistake or 'fail' at something we tend to go through a two-step process. We first experience an automatic response involving **internal attribution** (i.e. the error is our fault); then a conscious, slower reaction which seeks to find an alternative **external attribution** (e.g. the error is due to an external factor). This is because we all have a vested interest in 'looking good' in our own eyes — a sort of survival mechanism. This type of response, however, is unlikely to lead to self-improvement, as it results in an individual not addressing the real cause of their error/bad performance in the future. Roesch and Amirham (1997) found that more experienced and successful athletes made more self-serving attributions which lead to identifying and addressing the internal causes of their performance errors. Implications for the classroom: when dealing with students who complain about not progressing because the subject, skill or task is too hard for them, show them — where applicable — that the reasons why they are not improving is not intrinsic in the nature of that subject, skill or task, but has more to do with other factors under his/her control (e.g. the study habits, such as lack of systematic revision). This will create cognitive dissonance and may have an impact on their attitude, **especially if they are shown strategies that may help them improve in the problematic area(s) of their learning.** The afore mentioned research by Roesch and Amirham (1997) and their findings could be drawn upon and discussed with your students to reinforce the point; I often do, citing the example of famous athletes the students admire and pointing out how they learn from their mistakes by watching videos of themselves playing a match over and over again or asking peers/experts for feedback in order to identify and address their shortcomings.

4. ENDOWED PROGRESS EFFECT

When people feel they have made some progress towards a goal, they will feel more committed towards its achievement. Conversely, people who are making little or no progress are more likely to give up early in the process. In my work with very low achieving 'difficult' students when I operated in challenging inner-city-area schools, sitting with them at the beginning of a task and guiding them through open questioning often 'did the trick' where threatening them with sanctions had

failed miserably. Implications for the classroom: Whatever the task you engage your students in, ensure that they all experience success in the initial stages. This may call for two approaches which are not mutually exclusive: (1) design any instructional sequence in a 'stepped' fashion, with 'easy' tasks that become gradually more difficult; (2) provide lots of scaffolding (support) at the initial stages of teaching.

5. COGNITIVE EVALUATION THEORY

When looking at a task, we assess it in terms of how well it meets our need to feel competent and in control. We will be intrinsically motivated by tasks we believe fall in our current level of competency and 'put off' by those which we deem we will do poorly at. This issue is often more about self-perception of one's levels of competency than objective truth. Implications for the classroom: we need to ensure that before engaging students in challenging tasks that they may perceive as being beyond their levels of competence we prepare them adequately, cognitively and emotionally. For instance, in language learning, before carrying out a difficult listening comprehension task, students should be exposed several times to any unfamiliar vocabulary or other language item contained in the to-be-heard recording so as to facilitate the task. Moreover, modelling strategies that may facilitate the tasks and giving them the opportunity to experience some success in similar tasks through those very strategies may increase their sense of self-efficacy; this will give them greater expectancy of success and a feeling of empowerment which will feed into their sense of competency and control. Another important implications relate to the way we design the curriculum and assessment. For effective progression from a lower level to a higher one to be possible, students must be given plenty of opportunities to consolidate the material processed at the lower level before moving on. This does not often happen in courses which rely heavily on textbooks. For instance, in most of the institutions I have worked in over 25 years of teaching, I was asked to teach a unit of work every six-seven weeks, a totally unrealistic pace when contact time is limited to one or two hours a week. The result: the weaker children are usually left behind.

6. SELF-DETERMINATION THEORY; INTRINSIC AND EXTRINSIC MOTIVATION.

Individuals differ from one another in terms of PLOC (personal locus of causality). Some will feel that their behavior is self-determined; they are the initiators and sustainers of their actions and their PLOC will be internal. Others will see external forces as determinants of their lives; coercing them into actions. These people's PLOC will be external. The internal locus is connected with **intrinsic motivation**, whilst the external locus is connected with **extrinsic** motivation. Extrinsic motivation is when one is motivated by external factors, such as rewards, social recognition or fear of punishment. This kind of motivation focuses people on rewards rather than action. Intrinsic motivation, on the other hand, refers to the desire to do things because we enjoy doing them, hence it is a stronger motivator than Extrinsic motivation. Three needs lead to intrinsic motivation:

- Being successful at what we do (i.e. I enjoy French because I am good at it);
- Being connected with others (i.e. I love my French class because I have bonded well with the rest of the class)
- Having autonomy (see below)

An important factor leading to Intrinsic Motivation creation is providing learners with the opportunity to develop **effectance**. Effectance refers to one of the 3 points made above (being successful at what we do) and is given rise to when the learner accomplishes success at something that they perceive challenging and falling in what Deci (1997) terms 'Optimal zone of development'

— i.e.: a task that it is perceived as difficult enough to be challenging but within the stretch of the learner's ability. Effectance does not arise when we simply give students 'easy' work; that is why the 'easy wins' strategy often fails with students with poor intrinsic motivation; students are not stupid, they know you are dumbing down the work to make them feel good and the ensuing praise will not affect their self-regard as learners of your subject.

Self-determination theory assumes that there are individuals for whom a feeling of being in control of their life and responsible for their actions is very important for their personal fulfillment and, consequently, for their motivation. Implications of Self-Determination theory for the classroom: it may be useful to identify which students in your classes have an internal or external PLOC. In my experience this is not difficult. Once identified the internal PLOC of the target individuals, it is very important to cater for their self-determination needs and grant them a degree of autonomy in and ownership over their learning. E.g.: when staging a reading session in the classroom; carrying out a project; asking students to practise vocabulary online, let them choose how to go about it (whilst setting some guidelines for the sake of consistency). People with high internal PLOC thrive in self-directed learning tasks and contexts; teachers must endeavour to exploit to the fullest this personality trait's greater potential for autonomy in L2 learning. People with a high external PLOC will need more praise, direction from and a sense of accountability to teachers and caretakers. Implications of Intrinsic and Extrinsic motivation theory: Pretty obvious. The main ones: (1) make lessons as enjoyable as possible and make them experience EFFECTANCE regularly in your lessons, as this may help boost their intrinsic motivation; (2) Plan every single one of your lessons with the following questions in mind: 'How can I make sure that every student goes out of my lessons feeling they have progressed?'; (3) foster connectedness in the class by creating a team spirit and a sense that the whole class is working towards the same goal and that every student feels comfortable working with everyone else (e.g. make sure that people do not work with the same partners all the time when staging group work); give plenty of opportunities for positive peer feedback (e.g. get students' to celebrate other students' achievements). (4) Show them the benefits of learning the TL for their future job prospect, personal growth, etc. and of every activity you stage in lessons in terms of learning benefits; use praise as a means to validate their efforts but ensure that you do not over-praise or it will lose its motivational power (most students can sense when you are just trying to bribe them with compliments; this may engender complacency and even loss of motivation in the long-run).

There is a myth circulating amongst some educators these days (including some of my colleagues) that Extrinsic motivation should not be tapped into as a strategy to encourage students to improve. However, there is no sufficient credible evidence that Extrinsic Motivation is detrimental to learning to do away with it; on the contrary, research shows consistently that extrinsic motivation, when not overused and deployed in synergy with some of the other strategies discussed in this post, can eventually bring about Intrinsic motivation. Example: a student that does not enjoy French may, through experiencing a sense of effectance and obtaining consistent (thoroughly deserved and proportionate) praise and rewards become more appreciative of the subject, especially if she is experiencing steady growth in her mastery of the language and feels connected and supported by his peers. It is self-evident that using Extrinsic motivation will work with certain individuals rather than others; hence, as already mentioned, identifying the orientation of their Personal Locus Of Causality (PLOC) is fundamental, prior to carrying out any intervention.

7. VALENCE- INSTRUMENTALITY- EXPECTANCY (VIE) THEORY

In this paradigm, motivation refers to three factors

- Valence: what we think we will get out of a given action/behaviour (what's in it for me?)
- Instrumentality: the belief that if I perform a specific course of action I will succeed (clear path?)
- Expectancy: the belief that I will be definitely able to succeed (self-efficacy)

IMPLICATIONS FOR THE CLASSROOM:

- (1) make clear to students why a specific outcome is desirable (e.g. getting an A/A* at GCSE speaking exams). Make sure you list as many benefits as possible, especially those that most relevant to their personal preferences, interests and life goals;
- (2) provide them with a clear path to get there. This may involve showing them a set of strategies they can use (e.g. autonomously seeking opportunities for practice with native speakers in school) or a **clear** course of action they can undertake which is within their grasp (e.g. talk to your teacher about how to improve your essay writing; identify with their help the two or three main issues; work out with them some strategies to address those issues; monitor with their help through regular feedback and meetings with them that they are working and if they are not why; etc.). A clear path gives a struggling student a sense of empowerment, especially if they feel that they are being provided with effective tips and support to overcome the obstacles in the way;
- (3) support their self-belief that that outcome can be achieved (e.g. by mentioning to them examples of students from previous cohorts of similar ability who did it) and by reminding them of similar/comparable challenges they successfully undertook in the past.

8. GOAL-RELATED THEORY

In order to direct ourselves in our personal, educational and professional life we set ourselves goals. These can be:

- Clear (so we know what to do and what not to do)
- Challenging (so we get some stimulation)
- Achievable (so we do not fail)

If we set goals ourselves, rather than having them imposed on us, we are more likely to work harder in order to achieve them. Moreover, Locke and Kristoff (1996) identified specific and challenging goals as those which are more likely to lead to higher achievement. Implications for the classroom: instead of setting goals for your students in a top-down fashion, involve them actively in the process of learning. Moreover, help the students narrow down the goals set as much as possible and gauge them as accurately as possible to their existing level of competence. E.g.: instead of simply telling a student to check his next essay more accurately next time around and give them a lengthy error checklist, sit down with them and ask them to choose three challenging error categories that they would like to focus on and to aim to attain 80, 90 or even 100% accuracy in those categories in their essay due the following week. Make sure that the knowledge required by the learners to prevent or fix the target errors is learnable and that the students are provided with learning strategies which will assist them in achieving the set goals. I did this in my PhD study with excellent results.

I picked the above theories as they are the ones that I have been using more successfully over 25 years as a classroom teacher and subject leader. It goes without saying that in order to apply them effectively one has to ensure first and foremost that they know and listen to the learners they are dealing with. Cognitive and emotional empathy are a must for the success of any of the above motivational strategies. These strategies work best in synergy rather than in isolation. In a future

post, for instance, I will endeavour to show how attitudinal change may be brought about by using a combination of the above principles to achieve the desired outcomes.

FACTORS THAT MAY AFFECT STUDENTS' ACADEMIC ACHIEVEMENT

Here are some of the factors that may affect a student's academic achievement:

- The support and availability of the parents, their financial situation and standard of living. In Québec, as in other places in the world where the topic is studied, it has been observed that students in socioeconomically disadvantaged areas get lower marks.
- The geographical location of the educational institution.
For example, English as a second language is not learned in the same conditions throughout Québec.
- The percentage of students in a school whose mother tongue is not the language of instruction
- The diversity of student profiles in the same class
- The grouping together, in certain schools, of students with severe learning difficulties, or with problems associated with psychosocial integration in special education classes
- The various practices pertaining to the student admission requirements. Some educational institutions admit students indiscriminately, whereas others select them on the basis of previous academic achievement or their results on aptitude tests.

TEACHER EFFECTIVENESS

To make dramatic improvements in all students' preparation for college and careers, states need thoughtful, intentional human capital strategies that get the right teachers in the right places in the right subjects. The need is especially acute in states that have or plan to adopt college- and career-ready academic standards and graduation requirements: they will need highly effective teachers – particularly in upper-level mathematics and science courses – capable of teaching rigorous content to all students. State policymakers are well aware that the quality of teaching is the most critical school-based factor contributing to student learning, especially for low-income and minority students.¹

The Race to the Top criteria accordingly encourage states to adopt policies to measure the effectiveness of individual teachers and leaders use those measures to inform a range of human capital systems and decisions, ensure an equitable distribution of effective teachers and leaders, and provide high-quality support for educators and principals (see Table 1). If enacted, all of these policies could help a state advance its college and career readiness agenda, since that agenda will require higher and higher levels of teaching quality in order to succeed. But meeting these criteria presents special challenges in the college and career readiness context, especially when it comes to identifying, developing and deploying effective teachers at the high school level. The challenge is particularly great in high school mathematics and science, where research suggests that subject matter expertise is vital for effective teaching.²

The following two sections focus on those special challenges. The first explores what states need to consider in meeting the Race to the Top's teacher effectiveness criteria at the high school level if they are committed to a college- and career-ready agenda. The second asks how states can go beyond RTTT to provide effective instruction in rigorous content to all students, regardless of where they go to school. While the Race to the Top criteria also encourage states to focus on improving leadership, the focus here is on high school teachers because of the specific issues teacher effectiveness poses for the college- and career-ready agenda.

MEETING THE RACE TO THE TOP CHALLENGE:

Effective High School Teachers Measuring Effectiveness. A central tenet of the Race to the Top criteria is that states need viable approaches to measure the effectiveness of teachers, provide an effectiveness rating to each individual teacher, and use those ratings to inform professional development, compensation, promotion, tenure, and dismissal. A state's measure must include multiple inputs, but must include "student growth." Even without Race to the Top criteria, experts and education leaders have increasingly come to see current teacher evaluation methods as inadequate, largely because they fail to differentiate between teachers with varying levels of effectiveness.³ Utilizing data about student growth as part of teacher performance measurement presents technical and political challenges even at the elementary and middle school levels, where states increasingly have assessment and data systems that enable year-to-year tracking of individual student progress.⁴ At the high school level, the challenges are more daunting because, by and large, state assessment systems do not enable this kind of longitudinal tracking of individual student progress from one year to the next. Many states assess high school student mastery through a single cumulative assessment or through a series of end-of-course exams where there is not a clear progression of content from course to course (such as end-of-course exams in Biology and Chemistry). While these assessments may provide valuable information about student achievement, the structure and sequence of states' high school assessment systems may prohibit or make it more challenging to obtain meaningful growth measures.⁵ As states consider how to meet this RTTT criterion at the high school level, they have several options, each of which presents significant but not insurmountable challenges to states. These options include:

Building student-level growth measurement into revised high school assessment systems. Many states will be revising their high school assessment systems as they advance the college- and career-ready agenda and/or compete in the Race to the Top. As they do so, states can design their new systems to measure high school students' progress toward college- and career standards from year to year.

The challenge will be to create a system of assessments with the right sequence and relationship. States pursuing this option would need to design assessments aligned to college- and career-ready end-of-high-school standards, and then design a sequence of assessments taken earlier in high school that share sufficiently related content with the end-of-high-school tests (e.g. end-of-course assessments in Algebra I and Algebra II or English II and English III). School systems would need to report growth results using a metric that allows for meaningful and straightforward interpretations of student progress over time, which could include approaches using common scales, value tables, or growth percentiles.⁶ It is also important to note that this option does limit the proportion of teachers within a high school for whom measures of effectiveness could be calculated, since it may not be possible for states to develop an appropriate sequence of related assessments for teachers of all content areas. • Introducing pre-tests or interim assessments aligned to college- and career-ready standards. States with end-of-course or end-of-grade assessments could design beginning-of-the-year pre-tests to assess students' incoming knowledge, and then generate individual growth scores by comparing pre- and post-test results.

This might seem like an additional burden, but in fact pre-assessment of individual students is likely essential for excellent teaching. States should also consider using interim assessments aligned to college- and career-ready standards and assessments as a method for evaluating individual students' growth towards standards throughout the year.⁷ Such approaches may allow states to

develop measures of teacher effectiveness for content areas in which year-to-year growth measures are not feasible.

MAPPING

. To get the right teachers into the right places in the right subjects, states need a clear picture of the gaps they need to fill. The Race to the Top's premium on improving the distribution of teaching quality to high-poverty schools and hard-to-staff subjects heightens this imperative. The only way to gain this picture is by carefully mapping the quality of teachers currently employed in the state's high schools versus what is needed to meet ambitious college and career readiness goals. Ideally, this mapping would be based on measures of teaching effectiveness rather than on the paper qualifications of teachers, which research suggests are weakly correlated or not correlated with student outcomes.⁹

Since states typically lack real effectiveness measures at the high school level, however, they will have to rely in the short term on the best available proxies which, in secondary schools, are measures of content knowledge such as teachers' scores on content assessments and teachers' college and graduate school course-taking in the content area(s) they are teaching.

A "map" implies a static picture at a point in time, but states should strive to obtain a dynamic view of the teacher quality distribution. It is important to understand the flows of effective teachers in and out of schools, districts, and the state itself: What kinds of schools are gaining or losing effective teachers over time? Mapping teacher effectiveness would require most states to enhance significantly their data systems. A necessary element is a system of teacher identifiers that enables the state to follow teachers as they move from school to school and reliably link them to the results of the students they are teaching.¹⁰

Instituting such a system would also likely require a state to change the reporting it asks districts and schools to do regarding their teacher workforce, to ensure that full data about each teacher's background and current status are part of the system. In some states, leading districts may already have outpaced the state in developing teacher data systems. In such cases, states have an opportunity to partner with those districts to extend their cutting-edge approaches

GUIDANCE IN SCHOOLS: NEEDS, ORGANIZATIONAL SET UP AND TECHNIQUES

The guidance refers to advice or information provided by a person of experience, to solve a problem or improve something. The guidance refers to the process of helping individuals to discover and develop their potential. The need of guidance is something that cannot be ignored by anyone. Furthermore, guidance helps in the development of educational, vocational, and psychological skills in an individual. Most noteworthy, guidance would help an individual to achieve an optimal level of happiness and peace in life. Moreover, an individual who receives proper guidance would surely contribute significantly to society. The concept of guidance is quite democratic in nature. This is because; a properly guided individual would be able to shape his destiny. Guidance ensures that each individual's choices must serve the interests of the society as well as the interest of the individual.

PRINCIPLES OF GUIDANCE

The principles of guidance certainly form the basis of the need of guidance. Furthermore, principles of guidance are important principles without which guidance cannot take place. Below are the principles of guidance: Principle of all-round development- Guidance must take into account the all-round development of the person. Furthermore, guidance must ensure this desirable adjustment in any specific area of the individual's personality. Principle of human uniqueness- Certainly no two individuals are alike. Furthermore, individuals differ in mental, social, physical, and emotional development. Moreover, guidance must recognise these important differences and guide individuals according to their specific need.

Principle of holistic development- This principle states that guidance must take place in the context of total personality development. Moreover, a child grows as a whole. Also, if one aspect of personality is in focus, then the other areas of development must be kept in mind. Most noteworthy, these other areas of development indirectly influence the personality. Principle of cooperation- This

principle states that there cannot be any force on any individual regarding guidance. Moreover, the cooperation and consent of the individual is a pre-requisite for providing guidance.

Principle of continuity- The principle says that the guidance must take place as a continuous process to an individual. Also, this guidance must take place in different stages of the individual's life. Principle of extension- In this principle, there should not be a limitation of guidance to a few individuals. Most noteworthy, the extension of guidance must be to all individuals of all ages. Principle of adjustment- It is certainly true that guidance influences every aspect of an individual's life. However, guidance is chiefly concerned with a person's mental or physical health. Furthermore, this adjustment takes place at school, home, society, and vocation.

NEED OF GUIDANCE

Guidance certainly has an enormous need in every individual's life. Below are some factors which highlight the need for guidance: Different stages of development- The division of an individual's life can take place into various stages. These stages are infant, childhood, pre-adolescent, adolescence and manhood. So, an individual needs guidance in every stage of life. Maximum guidance is required during the adolescence stage. Differences among persons- Psychology inform us that no individuals are alike. Furthermore, no two individuals get similar opportunities in life. Therefore, every individual requires guidance, in order to find out the most suitable profession for him.

Career Maturity- Guidance is certainly essential for the development of a positive work attitude. Furthermore, guidance would help build suitable habits and values towards one's work or profession. This is because; guidance increases the awareness of one's world of work. Also, an individual is able to plan and prepare for his work or profession efficiently due to guidance. Educational growth- Guidance certainly helps in the development of educational skills and abilities. Above all, these skills would facilitate learning and achievement.

WHY SHOULD YOU DEVELOP A STRUCTURE FOR YOUR ORGANIZATION?

- **Structure gives members clear guidelines for how to proceed.** A clearly-established structure gives the group a means to maintain order and resolve disagreements.
- **Structure binds members together.** It gives meaning and identity to the people who join the group, as well as to the group itself.
- **Structure in any organization is inevitable** -- an organization, by definition, implies a structure. Your group is going to have some structure whether it chooses to or not. It might as well be the structure which best matches up with what kind of organization you have, what kind of people are in it, and what you see yourself doing.

WHEN SHOULD YOU DEVELOP A STRUCTURE FOR YOUR ORGANIZATION?

It is important to deal with structure early in the organization's development. Structural development can occur in proportion to other work the organization is doing, so that it does not crowd out that work. And it can occur in parallel with, at the same time as, your organization's growing accomplishments, so they take place in tandem, side by side. This means that you should think about structure from the beginning of your organization's life. As your group grows and changes, so should your thinking on the group's structure.

ELEMENTS OF STRUCTURE

While the need for structure is clear, the best structure for a particular coalition is harder to

determine. The best structure for any organization will depend upon who its members are, what the setting is, and how far the organization has come in its development. Regardless of what type of structure your organization decides upon, three elements will always be there. They are inherent in the very idea of an organizational structure. They are:

- Some kind of governance
- Rules by which the organization operates
- A distribution of work

GOVERNANCE

The first element of structure is governance - some person or group has to make the decisions within the organization.

RULES BY WHICH THE ORGANIZATION OPERATES

Another important part of structure is having rules by which the organization operates. Many of these rules may be explicitly stated, while others may be implicit and unstated, though not necessarily any less powerful.

DISTRIBUTION OF WORK

Inherent in any organizational structure also is a distribution of work. The distribution can be formal or informal, temporary or enduring, but every organization will have some type of division of labor. There are four tasks that are key to any group:

- Envisioning desired changes. The group needs someone who looks at the world in a slightly different way and believes he or she can make others look at things from the same point of view.
- Transforming the community. The group needs people who will go out and do the work that has been envisioned.
- Planning for integration. Someone needs to take the vision and figure out how to accomplish it by breaking it up into strategies and goals.
- Supporting the efforts of those working to promote change. The group needs support from the community to raise money for the organization, champion the initiative in the state legislature, and ensure that they continue working toward their vision.

COMMON ROLES

Every group is different, and so each will have slightly different terms for the roles individuals play in their organization, but below are some common terms, along with definitions and their typical functions.

- An initial steering committee is the group of people who get things started. Often, this group will create plans for funding, and organizational and board development. It may also generate by-laws, and then dissolve. If they continue to meet after approximately the first six months, we might say they have metamorphosed into a coordinating council.
- A coordinating council (also referred to as a coordinating committee, executive committee, and executive council), modifies broad, organization-wide objectives and strategies in response to input from individuals or committees.
- Often, one person will take the place of the coordinating council, or may serve as its head. Such a person may be known as the Executive Director, Project Coordinator, Program

Director, or President. He or she sometimes has a paid position, and may coordinate, manage, inspire, supervise, and support the work of other members of the organization.

- Task forces are made up of members who work together around broad objectives. Task forces integrate the ideas set forward with the community work being done. For example, from the director of a coalition to reduce violence in a medium-sized city: "Currently, we have three operational task forces. Members of each have an ongoing dialogue with members of the coordinating council, and also with their action committees. The oldest was formed with the goal of eliminating domestic violence about fifteen years ago, when a local woman was killed by her husband. Then, after several outbreaks of violence in the schools a few years back, our group offered to help, and a second task force sprung up around reducing youth violence. We've just started a third, with the goal of increasing gun safety. 'Cause, you know, the strategies you use to stop a ninth grader from bringing a gun to school just aren't the same as the ones you use to stop a 40-year-old man on unemployment from beating his wife."

- Action committees bring about specific changes in programs, policies, and practices in the sectors in which they work.

For example, the task force on domestic violence mentioned above has the following action committees:

- A government and law enforcement committee. Members include police officers, lawyers, a judge, and a state representative. Currently, they are trying to pass laws with stronger penalties for those convicted of domestic violence, especially repeat offenders. They are also training officers to be better able to spot an abusive relationship, and better able to inform a victim of his or her options.
- A social services committee. Members (who include representatives from most of the service agencies in town) work to assure that staff members know where to send someone for the resources he or she needs. They are also trying to increase the number of trained volunteer counselors who work at the battered women's shelter.
- A media committee. Members include local journalists, writers, and graphic designers. They keep the project and the issue in the public's minds as much as possible with editorials, articles and news clips of events, as well as advertisements and public service announcements.
- Support committees are groups that help ensure that action committees or other individuals will have the resources and opportunities necessary to realize their vision. Financial and media committees are examples of committees formed to help support or facilitate your work.
- Community trustees, also known as the board of trustees or as the board of directors, provide overall support, advice, and resources to members of the action groups. They are often either people who are directly affected by the issue or have stature in the community. That way, they are able to make contacts, network with other community leaders, and generally remove or weaken barriers to meeting organizational objectives.
- Grantmakers are another part of the picture. Grantmakers exist on an international, national, state, and local level and may be private companies and foundations, or local, county, state, or federal government organizations (for example, block grants given by the city would fall into this category).
- Support organizations (not to be confused with the support committees listed above) are groups that can give your organization the technical assistance it needs.
- Partner organizations are other groups working on some of the same issues as your organization. Although this list is pretty extensive, your organization may only use two or three of the above

mentioned roles, especially at the beginning. It's not uncommon for a group to start with a steering committee, ask others to serve as board members, and then recruit volunteers who will serve as members of action committees. In this broad spectrum of possibilities, consider: Where does your organization fit in? Where do you want to be?

EXAMPLES OF STRUCTURE

So how can all of these pieces be put together? Again, the form a community group takes should be based on what it does, and not the other way around. The structures given are simply meant to serve as examples that have been found to be effective for some community-based organizations; they can and should be adapted and modified for your own group's purposes.

A RELATIVELY COMPLEX STRUCTURE

EXAMPLE - THE STE. GENEVIEVE'S CHILDREN'S COALITION

The Ste. Genevieve's Children's Coalition is a relatively large community-based group. They have a coordinating council, a mediacommittee, and three task forces, dealing with adolescent pregnancy, immunization, and child hunger. Each of the task forces has action committees as well. For example, the adolescent pregnancy reduction task force has a schools committee that focuses on keeping teen parents in school and modifying the humansexuality curriculum. A health organizations committee focuses on increasing access and use of the youth clinic. The media committee works to keep children's issues in the news, and includes professionals from the local television stations, radio stations, newspaper, and a marketing professional. The coordinating council is composed of the executive director, her assistant, the mediacommittee chair, and the chairs of each of the three task forces. A board of directors has been invaluable in helping keep the coalition financially viable.

COUNSELLING: PROCESS, SKILLS, AND TECHNIQUES

(ACA), professional counseling is the process of building relationships with individuals that empower them to accomplish mental health and wellness, education, and career goals. It is a collaborative relationship between the counselor and their client.

Professional counseling can take the form of:

- Individual counseling is the most common type of counseling that focuses on the growth and mental health of an individual.
- Couples or marriage counseling focuses on assisting couples in overcoming conflict and working towards a stronger relationship.
- Family counseling involves the different familial dynamics and how they affect the family structure.
- Group counseling is the use of group interaction to facilitate growth.

When you become a counselor, you are likely to engage in many of these types of counseling throughout your therapeutic work. The Process of Counseling following components.

Opening: The opening process is perhaps, one of the most important parts of the interaction with your client. It is your chance to get to know your client and for them to get to know you. It is also where you will set the tone for the rest of the therapeutic relationship.

Exploring Client Understanding: The exploration process is where you will begin to understand your client. You will explore their past and evaluate their current concerns. Here, you will together establish goals and set expectations.

Understanding: Important in developing a strong relationship with your client, you can demonstrate understanding by using verbal and nonverbal cues, as well as reflections and paraphrases.

Intervention: The intervention process is about choosing the appropriate counseling techniques that will encourage growth within your client.

Exploring Problems: Exploration is the process of learning more about your client and why they have come to counseling. Exploration is necessary in truly understanding a client's thoughts and feelings in relation to their pressing problem.

Empower to Create Own Solutions: Empowering your client is not about providing them with all the answers. It is about empowering them, with your counseling skills, to find their own solutions. Counseling Skills As a student, your master's degree in counseling is about developing and expanding upon the counseling skills that will best help your clients. These are some of the most important counseling techniques you are likely to use in your counseling sessions.

Listening/Observing: Listening is one of the most valuable counseling skills in the therapeutic relationship. It can be used in three ways:

- **Attending:** Attending is the ability to be physically present for the client. It means giving them your undivided attention and making appropriate eye contact, mirroring body language, and nodding. These attending behaviors show your client that you care. In fact
- **Active listening:** Active listening occurs when you are listening with all of your senses. According to the , active listening involves listening with your body, heart, ears, eyes, and mouth.
- **Verbal listening:** This is a form of showing you are listening through the words that you use.. This can be as simple as 'yes', or 'go on'. It can also be in the form of paraphrasing or repeating a word of emotion that the client has just said.

Asking Questions: Questions are helpful in the therapeutic environment because they allow you to learn more about your client. The type of questions that you ask will set the tone of the session and the entire counseling process. Questions occur in two forms.

- **Closed:** A closed question is the practice of asking a question that can be answered as a 'yes' or 'no'. Closed questions should generally be avoided in the counseling relationship, as they do not encourage deeper exploration.
- **Open:** An open question is necessary to gather information. An open question is one that cannot be answered with a simple 'yes' or 'no' and it requires reflection or exploration on the client's end. Every open question should be intentional and therapeutic.
- **Feelings reflections:** Reflections allow clients to hear the feelings they have just expressed. Sometimes you have to look for the descriptive feeling in a client's statement. It can also be helpful to look at a client's nonverbal feeling cues.
- **Restating/Rephrasing:** Restating and rephrasing can build a stronger client therapist relationship. Rephrasing a client's statement allows you to better understand what a client has just said and to gain further clarity, if you have gotten it wrong.
- **Affirmation:** Affirmation is a form of encouragement that is used to affirm behaviors or life choices. Affirmation is important for empowering clients [External link](#) . A few common affirmations include affirming progress that a client has made toward a goal or encouraging a client to

do what is important to them.

Empathy: Empathy is the ability to put yourself in someone else's shoes. It is much more than sympathy in that you are able to show your understanding of your clients' feelings surrounding an experience.

Genuineness: Being genuine is creating congruence between yourself and your words. Every therapist is different and will provide a different therapeutic process. It is important to remain genuine in all counseling techniques and verbal and nonverbal cues.

Unconditional Positive Regard: Demonstrating unconditional positive regard. External link is the idea of accepting your client for who they are. It is a means of expressing warmth and respect.

Counselor Self-Disclosure: This is a tricky counseling skill to maneuver. A general rule to follow is to only share personal information that is beneficial to the therapeutic process. It might also be used to help the counselor relate better with their client.

COUNSELING THEORIES

Counseling theories. External link are used as a guideline for understanding human nature and to determine which counseling skills you will use in your counseling sessions.

- **Psychoanalytic Theory:** This theory was originally developed by Sigmund Freud. It supports the idea that unconscious forces drive human actions. A psychoanalytic therapy session includes skills such as dream analysis, free association, resistance analysis, and transference analysis. Much of the personality is thought to have developed in childhood and similarities are identified and explored in the therapeutic relationship.
- **Person-Centered Therapy:** This theory is a form of psychotherapy originally developed by Carl Rogers. Sometimes also known as Rogerian therapy, it operates on the assumption that every human being has the ability to fulfill their full potential. A client-centered approach in the therapeutic relationship involves self-actualization, empathy, and unconditional positive regard. When practicing person-centered therapy, the client-therapist relationship is very important because the positive interactions are a form of therapy themselves. The relationship should be supportive and the therapist acts more as a guide, as the client is the expert of their own life.
- **Cognitive Behavioral Therapy (CBT):** CBT is a shorter term approach. External link to the therapeutic process. This hands-on approach lends its practice to the theory that human problems stem from faulty patterns of thinking. The counseling process primarily involves the challenge of automatic thinking and often negative thought patterns. It encourages the client to find logic in their way of thinking. The counselor plays an important role in challenging these thoughts.
- **The Family Systems Model:** Family Systems view all human troubles and conflicts as a familial unit. The theory, originally developed by Murray Bowen, is focused on the idea that family is the primary source of emotions and personality. A family system can be present in many forms, including structural, strategic, and intergenerational. Common techniques used in the therapeutic process include the creation of a genogram, family projection activities, emotional triangles, and the differentiation of self. This counseling theory is often used in marriage and family counseling sessions. Counseling is about creating strong relationships with your clients that will empower

them to obtain mental health and to fulfill their goals. Through the use of intentional counseling techniques and an understanding of human nature developed through counseling theories, you can guide your client in reaching optimal mental health.

EFFECTIVE COUNSELLING SKILLS

Counsellors use counselling skills to help them better understand and listen to clients. Through **active listening**, rapport is built, trust forms and the speaker feels heard and understood by the counsellor or listener. Core Counselling Skills Core listening skills are basic counselling skills, or practiced techniques, that help the counsellor to empathetically listen to the speaker.

Skills include:

- active listening
- being aware of nonverbal communication
- building rapport

The core counselling skills are described below.

1. Attending

Attending in counselling means being in the company of someone else and **giving that person your full attention**, to what they are saying or doing, valuing them as worthy individuals.

2. Silence

Silence in counselling gives the client control of the content, pace and objectives. This includes the counsellor listening to silences as well as words, sitting with them and recognising that the silences may facilitate the counselling process.

3. Reflecting and Paraphrasing

Reflecting in counselling is part of the 'art of listening'. It is making sure that the client knows their story is being listened to. This is achieved by the helper/counsellor by both **repeating and feeding a shorter version of their story back to the client**. This known as '**paraphrasing**'.

4. Clarifying and the Use of Questions

Questions in counselling are classed as a basic skill. The counsellor uses open questions to clarify his or her understanding of what the client is feeling. **Leading questions are to be avoided** as they can impair the counselling relationship.

5. Focusing

Focusing in counselling involves making decisions about what issues the client wants to deal with. The client may have mentioned a range of issues and problems and focusing allows the counsellor and client together to clear away some of the less important surrounding material and **concentrate on the central issues** of concern.

6. Building Rapport

Building rapport with clients in counselling is important, whatever model of counselling the counsellor is working with.

Rapport means **a sense of having a connection with the person**.

7. Summarising

Summaries in counselling are longer paraphrases. They **condense or crystallise the essence of what the client is saying and feeling**. The summary 'sums up' the main themes that are emerging.

8. Immediacy

Using immediacy means that the therapist reveals how they themselves are feeling in response to the client.

According to Feltham and Dryden (1993: 88), immediacy is 'the key skill of focusing attention on the here and now relationship of counsellor and client with helpful timing, in order to challenge defensiveness and/or heighten awareness'. Counseling Skills and Techniques Types of Counseling and Techniques Counselors must possess in-depth knowledge and skills if they are to help clients effectively. On the job, these professionals use a specific set of counseling skills to treat one or more unique populations. These counseling techniques may vary depending on which group of people a counselor serves (e.g., Counseling techniques appropriate for school counselors may not work for grief counselors.). In a master's program, counselors-in-training hone skills through practica and supervised work experience.

HOW DO DIFFERENT MENTAL HEALTH PROFESSIONS' SKILLS STACK UP?

All mental health professionals possess similar skills. In graduate-level counseling programs, all counselors-in-training first master a standard skill set. Only after specializing in a particular counseling subfield (e.g., addiction counseling, school counseling, etc.) do they begin to explore new skills that can help their future clients.

COUNSELOR VS THERAPIST SKILLS

On the job, counselors and therapists share many similar duties. Also, professionals in both careers typically possess master's degrees. However, therapists (e.g., marriage and family therapists) have a more honed skill set when it comes to interpreting clinical research. Also, unlike counselors, therapists play a more significant role in helping clients develop solutions to problems.

COUNSELOR VS PSYCHOLOGIST SKILLS

Although some psychologists possess a master's degree, many earn a doctorate, especially if they plan to teach psychology at the college level. On the job, they review the latest research to find new ways to treat clients, a task few counselors undertake. Psychologists also possess honed research and analytical skills, a boon if they plan to contribute original research to the psychology field.

COUNSELOR VS PSYCHIATRIST SKILLS

Psychiatrists possess the most advanced skill set of all mental health professionals. They first earn a medical degree before completing a residency in psychiatry. In addition to applying the interpersonal skills that psychologists and counselors possess, they use their pharmacological knowledge to prescribe medication when necessary. .

COUNSELOR VS SOCIAL WORKER SKILLS

Although social workers and counselors help clients in similar ways, social workers must have the collaborative and interpersonal skills necessary to research and provide community resources. For

example, a school social worker who believes that a child lives in an unsafe environment must coordinate with law enforcement and child protective services, among other relevant government agencies.

5 SKILLS EVERY COUNSELOR SHOULD POSSESS

- 1. Communication Skills:** An excellent counselor can convey information in a concise way that ensures that a client understands the counselor's concerns, advice, etc. This way, a client can leave a session without feeling confused and assured that the counselor answered all of his or her questions.
- 2. Listening and Attending:** Counselors need more than excellent listening and comprehension skills. During a session with a client, counselors must also project that they have a vested and genuine interest in the client's well being. They do this by making eye contact and using appropriate body language - counseling skills and techniques that also apply to the psychiatry and therapy fields.
- 3. Focusing and Paraphrasing:** When a client first meets with a counselor, he or she may not know their problems' root cause(s). The counselor must identify the client's issues and help the client decide which are causing the most harm. This way, the counselor and client can focus on those issues and develop solutions.
- 4. Validating and Challenging:** As counselors provide mental health services, they must make clients feel validated - that it is normal to feel upset, nervous, angry, etc. However, counselors must also challenge clients to adopt actions or mindsets that go against these feelings, ones that clients may not want to give up. Effective challenging requires excellent interpersonal and diplomatic skills.
- 5. Multicultural Competencies:** Counselors, especially guidance and school counselors, must possess multicultural competencies. In other words, a counselor should understand how a client's racial, cultural, and socioeconomic background affects them. Counselors can use this knowledge to better empathize with clients, gain their trust, and develop effective solutions.

MENTAL HEALTH COUNSELING TECHNIQUES

To make counseling effective, counselors must not only master counseling skills and techniques but also understand the different theories that guide mental health professionals. Comprehensive online master's in mental health counseling programs typically emphasize the following four theories - their history, impact, and continued relevance.

1. BEHAVIORAL THEORY

Behavioral theory explains people's behavior by examining life experiences. Psychologist B.F. Skinner was an advocate for behavioral theory, as he showed through animal testing that conditioning could affect behavior significantly. In a modern context, a behaviorist might argue that someone possesses violent tendencies because that person suffered physical abuse as a child.

2. COGNITIVE THEORY

Instead of focusing on actions, cognitive theory examines how people's thoughts influence their behavior. In a clinical setting, psychologists and psychiatrists use talk therapy to help clients identify and remedy negative thoughts. For example, a client who can verbalize his or her flying anxiety can begin to develop new, positive thought patterns that reduce stress.

3. HUMANISTIC THEORY

After the Second World War, many mental health professionals turned away from traditional behavioral and cognitive theories. Humanistic theory assumes that people are good and desire agency over their own lives. Counselors who use humanistic theory focus on clients' subjective feelings and use those feelings as a way to treat underlying problems.

4. INTEGRATIVE THEORY

As the name suggests, integrative theory synthesizes behavioral, cognitive, and humanistic theories, among others. Professionals who use integrative theory analyze clients' mental health needs from different viewpoints and also consider how age and life experience can guide treatment. Finally, integrative theory focuses less on finding a mental health 'cure.' Rather, professionals help clients improve as much as they can.

SCHOOL COUNSELING TECHNIQUES

School counselors possess a variety of techniques/skills that allow them to help students, collaborate with faculty, and implement new district- and school-level policies. In online master's in school counseling programs, students begin developing these skills before honing them in school settings (e.g., a practicum). However, many professionals do not master these skills until after they have acquired significant on-the-job experience.

1. PROBLEM-SOLVING AND CONFLICT RESOLUTION

Without much life experience to pull from, primary and secondary school students lack developed problem-solving and conflict resolution skills (e.g., dealing with a bully, student-teacher conflict, etc.). As a result, counselors must help students identify and remedy problem behavior. When more than one student is involved, counselors use small-group counseling techniques.

2. GROUP COUNSELING THEORIES

Group counseling has many advantages in the school setting. One, it brings together students who may share a similar problem or were part of a conflict. Group counseling can also promote empathy among students. Finally, group counseling allows a counselor to help many students at once, freeing up more time for other responsibilities and tasks.

3. SPECIAL NEEDS COUNSELING

Students with special needs (e.g., ADD, ADHD, Autism-spectrum disorder, etc.) require highly trained counselors who can promote their academic success while working within the context of the disability. Counselors-in-training must examine the latest research and work with students with disabilities. On the job, counselors collaborate with parents, administrators, and faculty to ensure that students with disabilities receive the best education possible.

IMPACT OF EFFECTIVE COUNSELING TECHNIQUES

Effective counseling can make a significant, positive impact on clients' lives. Some positive outcomes might include:

- Better decision making
- Coping skills
- Improved outlook on life
- Ability to plan for the future (e.g., college and careerpreparedness)
- Improve socialization with peers, teachers, and family
- Engagement with extracurricular activities

Human Development and Interventions MCQs

1. In Operant conditioning procedure, the role of reinforcement is:
 - (a) Strikingly significant
 - (b) Very insignificant
 - (c) Negligible
 - (d) Not necessary
 - (e) None of the aboveAnswer: A

2. According to Skinnerian Operant conditioning theory, a negative reinforcement is:
 - (a) Nothing but punishment
 - (b) A biofeedback
 - (c) A withdrawing or removal of a positive reinforcer
 - (d) An instinctive drift
 - (e) None of the aboveAnswer: C

3. Behaviour therapists believe that the respondent or classical conditioning is effective in dealing with the non-voluntary automatic behaviour, whereas the operant one is successful predominantly with motor and cognitive behaviours, Thus, unadaptive habits such as nail biting, trichotillomania, enuresis encopresis, thumb sucking etc. are satisfactorily dealt within the :
 - (a) Classical Method
 - (b) Operant Method
 - (c) Trial and Error Method
 - (d) Insightful learning procedure
 - (e) None of the aboveAnswer: B

4. Current positive reinforcement requires the individual to imagine performing a particular task or behaviour followed by a:
 - (a) Negative consequence
 - (b) Zero consequence
 - (c) Positive Consequence
 - (d) Neutral consequence
 - (e) None of the aboveAnswer: C

5. Aversion is one of the conditioning procedures used in:
 - (a) Non-directive therapy
 - (b) Psychoanalytic therapy
 - (c) Behaviour therapy
 - (d) Chemotherapy

(e) None of the above
Answer: C

6. A very useful principle of learning is that a new response is strengthened by:

(a) Punishment

(b) Reinforcement

(c) Biofeedback

(d) Discriminative Stimulus

(e) None of the above
Answer: B

7. In continuous reinforcement schedule (CRF), every appropriate response:

(a) Is reinforced

(b) Is not reinforced

(c) Is sometimes reinforced

(d) Is an instinctive drift

(e) None of the above
Answer: A

8. The continuous reinforcement schedule is generally used:

(a) In the last part of training

(b) In early stages of training

(c) In the middle period of training

(d) In both last and first part of training

(e) None of the above
Answer: B

9. In real life, reinforcement of every response (CRF) is:

(a) Of the nature of an exception rather than the rule

(b) Impossible

(c) Necessary

(d) Not necessary

(e) None of the above
Answer: A

10. Which schedule of reinforcement is a ratio schedule stating a ratio of responses to reinforcements?

(a) Variable Ratio Schedule

(b) Fixed Interval Schedule

(c) Variable Interval Schedule

(d) Fixed Ratio Schedule

(e) None of the above
Answer: D

11. Respondents are elicited and operants are not elicited but they are:

(a) Emitted spontaneously

- (b)** Emitted voluntarily
 - (c)** Permanent responses
 - (d)** Temporary responses
 - (e)** None of the above Answer: A
- 12.** In which schedule of reinforcement, appropriate movements are reinforced after varying number of responses?
- (a)** Fixed Ratio Schedule
 - (b)** Fixed Interval Schedule
 - (c)** Variable ratio Schedule
 - (d)** Variable Interval Schedule
 - (e)** None of the above Answer: C
- 13.** Which schedule of reinforcement does not specify any fixed number, rather states the requirement in terms of an average?
- (a)** Variable Ratio Schedule
 - (b)** Fixed Ratio Schedule
 - (c)** Fixed Interval Schedule
 - (d)** Variable Interval Schedule
 - (e)** None of the above Answer: A
- 14.** As a rule, variable ratio schedule (VR) arrangements sustain:
- (a)** Low rates of responding
 - (b)** High rates of responding
 - (c)** Zero responding
 - (d)** 90% of responding
 - (e)** None of the above Answer: B
- 15.** Under conditions of variable ratio schedule, the only sensible way to obtain more reinforcements is through emitting:
- (a)** 50% responses
 - (b)** 90% responses
 - (c)** Less number of responses
 - (d)** Greater number of responses
 - (e)** None of the above Answer: D
- 16.** In which schedule of reinforcement, the experimenter (E) reinforces the first correct response after a given length of time?
- (a)** Fixed Ratio Schedule
 - (b)** Fixed Interval Schedule

- (c) Variable Ratio Schedule
 - (d) Variable Interval Schedule
 - (e) None of the above Answer: B
- 17.** In our daily life, watching for the pot of milk to boil may be somewhat similar to the behaviour pattern observed in:
- (a) Fixed Interval Schedule
 - (b) Fixed Ratio Schedule
 - (c) Variable Ratio Schedule
 - (d) Variable Interval Schedule
 - (e) None of the above Answer: A
- 18.** In which schedule of reinforcement, the delay intervals vary as per a previously decided plan?
- (a) Fixed Ratio Schedule
 - (b) Variable Ratio Schedule
 - (c) Fixed Interval Schedule
 - (d) Variable Interval Schedule
 - (e) None of the above Answer: D
- 19.** In our daily life, any kind of looking for things which occur without any reference to our behaviour may illustrate the application of:
- (a) Variable Interval Schedule
 - (b) Fixed Ratio
 - (c) Variable Ratio Schedule
 - (d) Fixed interval Schedule
 - (e) None of the above Answer: A
- 20.** In case of continuous reinforcement, we get the least resistance to extinction and the:
- (a) Highest response rate during training
 - (b) 50% response rate during training
 - (c) Smallest response rate during training
 - (d) 90% response rate during training
 - (e) None of the above Answer: C
- 21.** The expression "Contingencies of reinforcement" occurs frequently in:
- (a) Operant Conditioning Literature
 - (b) Classical Conditioning Literature
 - (c) Trial and Error Learning Literature
 - (d) Latent Learning Literature
 - (e) None of the above Answer: C

- 22.** Who elucidates the contiguity theory of reinforcement in the most pronounced and consistent manner?
- (a) C. Hull
 - (b) Guthrie
 - (c) Tolman
 - (d) Mc Dougall
 - (e) J. B. Watson
- Answer: B
- 23.** In comparison with drive- reduction or need- reduction interpretation, stimulus intensity reduction theory has an added advantage in that:
- (a) It offers a unified account of primary and learned drives as also of primary and conditioned reinforcement
 - (b) It has some mathematical derivations which are conducive for learning theorists
 - (c) All learning theories can be explained through this
 - (d) None of the above
- Answer: A
- 24.** Who preferred to call Classical Conditioning by the name of "Sign Learning"?
- (a) I. P. Pavlov
 - (b) Mowrer
 - (c) Miller
 - (d) Guthrie
 - (e) J. B. Watson
- Answer: B
- 25.** Which type of learning tells us what to do with the world and applies to what is commonly called habit formation?
- (a) Insightful Learning
 - (b) Latent Learning
 - (c) Trial and Error Learning
 - (d) Instrumental Learning
 - (e) Classical Conditioning
- Answer: D
- 26.** Who propounded the expectancy theory of learning?
- (a) Guthrie
 - (b) C. Hull
 - (c) Tolman
 - (d) Thorndike
 - (e) I. P. Pavlov
- Answer: C
- 27.** Who said that any act is a movement but not vice versa?
- (a) J.B. Watson
 - (b) W. Kohler
 - (c) Guthrie

- (d) E. L. Thorndike
- (e) C. Hull

28. Guthrie believed that conditioning should take place:

- (a) After two trials
 - (b) After three trials
 - (c) After a single trial
 - (d) After ten trials
 - (e) None of the above
- Answer: C

29. According to Guthrie, forgetting is not a matter of decay of old impressions and associations but:

- (a) A result of inhibition of old connections by new ones
 - (b) A result of disinhibitions of old connections
 - (c) A result of generalizations of stimuli
 - (d) A result of discrimination
 - (e) None of the above
- Answer: A

30. The great learning theorist, Clark Hull was influenced by the moderate wing of:

- (a) Gestalt Psychology
 - (b) Behaviouristic Orientation
 - (c) Psychoanalytic Literature
 - (d) Logical Positivism and by conventionalism
 - (e) None of the above
- Answer: D

31. Who defined "Need" as a state of the organism in which a deviation of the organism from the optimum of biological conditions necessary for survival takes place?

- (a) Mc Dougall
 - (b) Clark H. Hull
 - (c) E.L Thorndike
 - (d) I.P. Pavlov
 - (e) None of the above
- Answer: B

32. According to Hullian theory, under the pressure of needs and drives, the organism undertakes:

- (a) Adaptive actions
- (b) Learning by foresight
- (c) Learning by hindsight
- (d) Transfer of training

(e) None of the above Answer: A

33. Hull believes that no conditioning will take place unless there is:

(a) Food

(b) Need Reduction

(c) Puzzle Box

(d) Secondary Reinforcement

(e) None of the above Answer: B

34. Who defined stimulus (S) in terms of physical energy such as mechanical pressure, sound, light etc.?

(a) E. L. Thorndike

(b) W. Kohler

(c) B. F. Skinner

(d) Clark Hull

(e) E. C. Tolman Answer: D

35. "Where a reaction (R) takes place in temporal contiguity with an afferent receptor impulse (S) resulting from the impact upon a receptor of a stimulus energy (S) and the conjunction is followed closely by the diminution in a need and the associated diminution in the drive, D, and in the drive receptor discharge, S_D , there will result in increment, A ($S \rightarrow R$), in the tendency for that stimulus on subsequent occasions to evoke that reaction".

Who has given the above definition of "reinforcement"?

(a) Clark L. Hull

(b) E. L. Thorndike

(c) I.P. Pavlov

(d) W. Kohler

(e) None of the above Answer: A

36. Most of Hull's explanations are stated in two languages, one of the empirical description and the other in:

(a) Psycho physiological terms

(b) Neurophysiological terms

(c) Physiological terms

(d) Physical terms

(e) None of the above Answer: B

37. The molar approach deals with the organism as a whole, the molecular approach:

(a) Deals with parts

(b) Deals with stimuli

(c) Deals with responses

- (d) Has nothing to do with theorganism
(e) Deals with the detailed, fine and exact elements of action of the nervous system Answer: E
- 38.** The hypothetico-deductive system in geometry was developed by:
(a) I.P. Pavlov
(b) B. L. Thorndike
(c) C. Hull
(d) Pieri
(e) E. C. Tolman Answer: D
- 39.** Whenever behaviour is correlated to specific eliciting stimuli, it is:
(a) Respondent Behaviour
(b) Operant Behaviour
(c) Stimulant Behaviour
(d) Fixed Behaviour
(e) Static Behaviour Answer: A
- 40.** Whenever behaviour is not correlated to any specific eliciting stimuli, it is:
(a) Respondent Behaviour
(b) Operant Behaviour
(c) Static Behaviour
(d) Modified Behaviour
(e) None of the above Answer: B
- 41.** According to Tolman, docile or teachable behaviour is:
(a) Molar
(b) Molecular
(c) Respondent
(d) Operant
(e) None of the above Answer: A
- 42.** According to Skinnerian theory, the "S" type of conditioning applies to:
(a) Modified Behaviour
(b) Stimulant Behaviour
(c) Operant Behaviour
(d) Respondent Behaviour
(e) None of the above Answer: D

- 43.** The sign-gestalt expectation represents a combination of:
- (a) Intelligence and Perception
 - (b) Perception and Learning
 - (c) Intelligence and Learning
 - (d) Perception and Motivation
 - (e) None of the above
- Answer: D
- 44.** Who stated that appetites and aversions are “states of agitation”?
- (a) E. L. Thorndike
 - (b) E. C. Tolman
 - (c) W. Kohler
 - (d) Clark Hull
 - (e) None of the above
- Answer: B
- 45.** Who said that the ultimate goal of aversion is the state of physiological quiescence to be reached when the disturbing stimulus ceases to act upon the organism?
- (a) E. L. Thorndike
 - (b) W. Kohler
 - (c) E. C. Tolman
 - (d) Clark Hull
 - (e) None of the above
- Answer: C
- 46.** According to E. C. Tolman, there are two aversions: fright and pugnacity. Fright is avoidance of injury and pugnacity is avoidance of:
- (a) Interference
 - (b) Affiliation
 - (c) Motivation
 - (d) Perception
 - (e) None of the above
- Answer: A
- 47.** “Equivalence Belief’ is a connection between” a positively cathected type of disturbance-object and a type of what may be called:
- (a) An interfering object
 - (b) A sub disturbance object
 - (c) A motivating object
 - (d) A goal-oriented object
 - (e) None of the above
- Answer: B
- 48.** Who revealed that “Field expectancy” takes place when one organism is repeatedly and

successfully presented with a certain environmental set-up?

- (a) E. C. Tolman
 - (b) C. L. Hull
 - (c) E. L. Thorndike
 - (d) I.P. Pavlov
 - (e) Guthrie
- Answer: A

49. Dollard and Miller related Thorndike's spread of effect to the:

- (a) Gradient of reinforcement
 - (b) Biological constraints
 - (c) Principle of preparedness
 - (d) None of the above
- Answer: A

50. Miller and Dollard are more concerned with:

- (a) Biological factor in learning
 - (b) Social factor in learning
 - (c) Physiological and Social factors in learning
 - (d) Personal factors in learning
 - (e) None of the above
- Answer: B

51. Mowrer's Sign learning comes close to Guthrie's contiguity and his 'solution learning' corresponds to:

- (a) Pavlov's Classical Conditioning
 - (b) Kohler's Insightful learning
 - (c) Skinner's instrumental learning
 - (d) Thorndike's trial and error learning
 - (e) None of the above
- Answer: C

52. Mowrer's two-factor theory takes into consideration the fact that:

- (a) Some conditioning do not require reward and some do
 - (b) Every conditioning requires reinforcement
 - (c) The organism learns to make a response to a specific stimulus
 - (d) Learning is purposive and goal-oriented
 - (e) None of the above
- Answer: A

53. When learning in one situation influences learning in another situation, there is evidence of:

- (a) Avoidance learning
- (b) Learned helplessness
- (c) Premise of Equipotentiality
- (d) Transfer of Training

(e) None of the above Answer: D

54. If learning in situation 'A' may favourably influence learning in situation 'B', then we have:

(a) Positive Transfer

(b) Negative Transfer

(c) Zero Transfer

(d) Bilateral Transfer

(e) Neutral Transfer Answer: A

55. If learning in situation 'A' has a detrimental effect on learning in situation 'B', then we have:

(a) Positive Transfer

(b) Zero Transfer

(c) Neutral Transfer

(d) Negative transfer

(e) None of the above Answer: D

56. Mediation occurs when one member of an associated pair is linked to the other by means of:

(a) A reinforcement

(b) An intervening element

(c) Generalization

(d) Secondary reinforcement

(e) None of the above Answer: B

57. Zero transfer is otherwise known as:

(a) Neutral Transfer

(b) Positive Transfer

(c) Negative Transfer

(d) Bilateral Transfer

(e) None of the above Answer: A

58. Negative Transfer of Training is otherwise known as:

(a) Neutral Transfer

(b) Habit interference

(c) Zero Transfer

(d) Bilateral Transfer

(e) None of the above Answer: B

59. "If you do not like milk, you may not like all milk products like cheesebutter, ghee and curd". This is due to:

(a) Generalization Gradient

- (b)** Avoidance Learning
 - (c)** Biological Constraints
 - (d)** Transfer of Training
 - (e)** None of the above Answer: D
- 60.** Who told, "Although Classical Conditioning is a laboratory procedure, it is easy to find real world examples."?
- (a)** B.J. Underwood (1983)
 - (b)** G. H. Bower (1976)
 - (c)** C. B. Osgood (1957)
 - (d)** Kimble and Germazy (1980)
 - (e)** Mc Geoch (1942) Answer: D
- 61.** According to Hull, a systematic behaviour or learning theory can be possible by happy amalgamation of the technique of conditioning and the:
- (a)** Law of Effect
 - (b)** Law of Exercise
 - (c)** Law of Frequency
 - (d)** Law of Recency
 - (e)** None of the above Answer: A
- 62.** The methods of verbal learning are important because:
- (a)** The use of standard methods for learning makes comparisons of results possible
 - (b)** Rewards are not necessary here
 - (c)** They minimise the effect of punishment
 - (d)** Punishment has no effect on learning
 - (e)** None of the above Answer: A
- 63.** Positive transfer of training is possible with:
- (a)** Dissimilar tasks
 - (b)** Motor tasks
 - (c)** Similar tasks
 - (d)** Verbal tasks
 - (e)** None of the above Answer: C
- 64.** A 'Skinner Box' is used for:
- (a)** Motor learning
 - (b)** Verbal learning
 - (c)** Sensory learning
 - (d)** Problem Solving

(e) Incidental learning
Answer: D

65. Punishment is effective only when it weakens:

- (a)** Undesirable response
- (b)** Desirable response
- (c)** Positive response
- (d)** Negative response
- (e)** None of the above
Answer: A

66. Which one of the following psychologists is not associated with the theories of learning?

- (a)** Sullivan
- (b)** C. Hull
- (c)** Tolman
- (d)** Thorndike
- (e)** Guthrie
Answer: A

67. In which method, the entire list is once exposed to 'S' and then he is asked to anticipate each item in the list before it is exposed on the memory drum?

- (a)** Recall
- (b)** Recognition
- (c)** Relearning and Saving
- (d)** Anticipation Method
- (e)** None of the above
Answer: D

68. The new items which are added to the original list in recognition method are known as:

- (a)** Stimulants
- (b)** Respondents
- (c)** Gradients
- (d)** Distractors
- (e)** None of the above
Answer: A

69. Learning to make new responses to identical or similar stimuli results in a:

- (a)** Negative Transfer
- (b)** Positive Transfer
- (c)** Zero transfer
- (d)** Neutral transfer
- (e)** None of the above
Answer: A

70. Both positive and negative transfers are largely the result of:

- (a)** Similarity of responses in the first and the second task

- (b)** Dissimilarity of responses in the first and the second task
 - (c)** Co-ordination of responses in the first and the second task
 - (d)** Both similarity and dissimilarity of responses in the first and the second task
 - (e)** None of the above
- Answer: B

71. The greater the similarity between the stimuli of the first task and the second task:

- (a)** The less the extent of transfer
 - (b)** The greater the extent of transfer
 - (c)** The minimum the extent of transfer
 - (d)** No transfer occurs
 - (e)** None of the above
- Answer: D

72. A high positive transfer results when stimuli are similar and responses are:

- (a)** Identical
 - (b)** Not Identical
 - (c)** Haphazard
 - (d)** Equipotential
 - (e)** None of the above
- Answer: A

73. It is possible to maximize a positive transfer from a classroom situation to real life situation by making formal education more realistic or closely connected with:

- (a)** Real-life problems
 - (b)** Imaginary problems
 - (c)** Temporary problems
 - (d)** Easy Problems
 - (e)** None of the above
- Answer: A

74. In programmed learning, the importance is placed on:

- (a)** Trial and error learning
 - (b)** Latent learning
 - (c)** Classical conditioning
 - (d)** Operant conditioning
 - (e)** None of the above
- Answer: D

75. Who is regarded as the father of the 'Programmed Learning'?

- (a)** B. F. Skinner
 - (b)** I. P. Pavlov
 - (c)** C.L. Hull
 - (d)** J.B. Watson
- Answer: A

- 76.** Who has first devised a machine for teaching in 1920?
- (a) M. R. F. Maier
 - (b) A. Luchins
 - (c) S. L. Pressey
 - (d) H. F. Harlow
 - (e) D. O. Hebb
- Answer: C
- 77.** In the system of programmed learning, the learner becomes:
- (a) An active agent in acquiring the acquisition
 - (b) A passive agent in acquiring the acquisition
 - (c) A neutral agent in acquiring the acquisition
 - (d) Instrumental in acquiring the acquisition
 - (e) None of the above
- Answer: A
- 78.** Programmed learning:
- (a) Is not helpful for teaching
 - (b) Is not helpful in the socialization of the child
 - (c) Is not helpful in classroom situation
 - (d) Is not helpful for teachers
 - (e) None of the above
- Answer: B
- 79.** Lewin's field theory gives more importance to behaviour and motivation and less to:
- (a) Incentive
 - (b) Drive
 - (c) Experience
 - (d) Intelligence
 - (e) None of the above
- Answer: C
- 80.** Kurt Lewin regards the environment of the individual as his:
- (a) life-space
 - (b) Instinctive drift
 - (c) Autoshaping
 - (d) Foresight
 - (e) None of the above
- Answer: A
- 81.** Guthrie's theory of learning is known as the learning by:
- (a) Interpretation
 - (b) Representation

- (c) Substitution
 - (d) Response
 - (e) None of the above Answer: D
- 82.** For Skinner, the basic issue is how reinforcement sustains and controls responding rather than:
- (a) Which stimulus evokes a response
 - (b) Which response is helpful
 - (c) Which stimulus can be generalized
 - (d) Which stimulus can be discriminated
 - (e) None of the above Answer: A
- 83.** Who said that the event that is drive reducing is satisfying?
- (a) E. C. Tolman
 - (b) R. S. Woodworth
 - (c) E. L. Thorndike
 - (d) Clark H. Hull
 - (e) None of the above Answer: D
- 84.** Materials like food for hungry animals or water for thirsty animals are called:
- (a) Secondary reinforcers
 - (b) Primary Reinforcers
 - (c) Intermittent reinforcers
 - (d) Fixed reinforcers
 - (e) None of the above Answer: B
- 85.** When a thing acquires some characteristics of a reinforcer because of its consistent association with the primary reinforcement, we call it a/an:
- (a) Secondary Reinforcer
 - (b) Primary Reinforcer
 - (c) Fixed Reinforcer
 - (d) Intermittent Reinforcer
 - (e) None of the above Answer: A
- 86.** In one experiment, the chimpanzees were taught to insert poker chips in a vending machine in order to obtain grapes. When this was done, they were made to pull, with all their strength, an iron bar attached to a similar machine to obtain poker chips. The chimpanzees learned it too, because they were allowed to cash those chips for grapes afterwards. Here the token chips had only a/an:
- (a) Primary Reinforcing Value
 - (b) Extra Reinforcing Value
 - (c) Special Reinforcing Value

- (d) Secondary Reinforcing Value
 - (e) None of the above
- Answer: A

87. Partial Reinforcement is often called:

- (a) Intermittent Reinforcement
 - (b) Schedules of Reinforcement
 - (c) Span of Reinforcement
 - (d) Reinforcement Schedule
 - (e) None of the above
- Answer: A

88. Reinforcing a given response only for sometime on trials is known as:

- (a) Partial Reinforcement
 - (b) Continuous Reinforcement
 - (c) Reinforcement Schedule
 - (d) No Reinforcement
 - (e) None of the above
- Answer: A

89. Most human habits are reinforced in a:

- (a) Variable fashion
 - (b) Constant fashion
 - (c) Partial Manner
 - (d) Particular Time span
 - (e) None of the above
- Answer: A

90. Most human habits are resistant to extinction because these are reinforced:

- (a) In a constant fashion
 - (b) All the times
 - (c) Every now and then
 - (d) In a variable fashion
 - (e) Very often
- Answer: D

91. Which type of learning experiments show how the behaviour of animals can be controlled or shaped in a desired direction by making a careful use of reinforcement?

- (a) Classical conditioning
 - (b) Operant conditioning
 - (c) Latent Learning
 - (d) Sign Learning
 - (e) None of the above
- Answer: B

92. In Operant Conditioning, the strength of an operant response is usually measured in terms of

the frequency of lever pressing:

- (a) Per unit of time
 - (b) In every five minutes
 - (c) As a whole
 - (d) In a day
 - (e) None of the above
- Answer: A

93. The method we use in memorising poetry is called:

- (a) Paired-associate learning
 - (b) Distributed learning
 - (c) Serial memorisation
 - (d) Massed learning
 - (e) Syntactic Memorisation
- Answer: C

94. Shifting from right-hand driving (in U.S.A.) to a left-hand driving (in India) is an illustration of:

- (a) Negative transfer of training
 - (b) Positive transfer of training
 - (c) Neutral transfer of training
 - (d) Both neutral and positive transfer of training
 - (e) None of the above
- Answer: A

95. The replacement of one conditioned response by the establishment of an incompatible response to the same conditioned stimulus is known as:

- (a) Backward Conditioning
 - (b) Counter Conditioning
 - (c) Forward Conditioning
 - (d) High order conditioning
 - (e) None of the above
- Answer: B

96. Experimental literature revealed that experiments on latent learning were done by:

- (a) Tolman and Honzik (1930)
 - (b) Gibson and Harlow
 - (c) Pavlov and Watson
 - (d) Kohler and Wertheimer
- Answer: A

97. Working with monkeys, Harlow (1949) propounded that the general transfer effect from one situation to another may be accounted for by the concept of:

- (a) "Learning how to learn" or "Learning Sets"
- (b) Sign learning
- (c) Latent learning

(d) Gradient of learning

(e) Plateau
Answer: A

98. Proactive Inhibition refers to the learning of 'A' having a detrimental effect on the learning of 'B'. So it is a:

(a) Neutral transfer of effect

(b) Zero transfer of effect

(c) Positive transfer of effect

(d) Negative transfer of effect

(e) None of the above
Answer: D

99. Who has defined "perceptual learning" as "an increase in the ability to extract information from the environment as a result of experience or practice with the stimulation coming from it."?

(a) I. P. Pavlov

(b) Wertheimer

(c) B. F. Skinner

(d) Eleanor Gibson (1969)

(e) J.B. Watson
Answer: D

100. To distinguish the calls of birds:

(a) Sign learning is necessary

(b) Perceptual learning is needed

(c) Operant conditioning would be conducive

(d) Insight is needed

(e) CR will be helpful
Answer: B

101. Delusions are characteristically seen in:

A. Schizophrenia

B. Delirium

C. Dementia

D. Depression
Answer: A

102. The presence of delusions, hallucinations, and disturbed cognitive function indicates:

A. Organic brain syndrome

B. Paranoid psychosis

C. Dissociative hysteria

D. Obsessive-compulsive disorder
Malingering-external motivation + Factitious disorder intentionally produced physical/psychological symptoms just to assume the sick role. Answer: A

103. The difference between neurosis and psychosis is:

- A. Severity
 - B. Insight
 - C. Clinical features
 - D. Duration of onset
- Features of psychosis include Gross impairment in reality testing
Answer: B

104. Cognition is:

- A. Perception
 - B. Thought
 - C. Behaviour
 - D. Feeling
- Cognition – thinking
Conation – action
Affect – feeling
Answer: B

105. Delusion is a disorder of:

- A. Perception
 - B. Thinking
 - C. Intelligence
 - D. Judgment
- Hallucination, illusion – are disorders of perception
Answer: B

106. Hallucination is a disorder of:

- A. Perception
 - B. Thinking
 - C. Intelligence
 - D. Memory
- Answer: A

107. Primary delusions are characterised by disorders of:

- A. Thought
 - B. Obsession
 - C. Hallucination
 - D. Loosening of association
- Answer: A

108. All the following are true about hallucinations, except:

- A. It represents a state of inner subjective space
 - B. It is dependent of the observer
 - C. It is as vivid as sensory perception
 - D. It occurs in the absence of perceptual stimulus
- Answer: B

109. The main excitatory neurotransmitter in the CNS is: (AI-2003, Pg-W9-SOP)

- A. Cysteate
 - B. Acetylcholine
 - C. Aspartate
 - D. Glutamate
- Inhibitory neurotransmitter is GABA
Answer: D

110. 25-years house wife come to the psychiatry outpatients department complaining that her nose was longer than usual. She felt that her husband did not like her because of the deformity and had developed relationship with the neighboring girl. Further she complained that people made fun of her. It was not possible to convince her that there was no deformity. Her symptoms include:

- A. Delusion
 - B. Depersonalization
 - C. Depression
 - D. Hallucination
- Delusion is a disorder of thinking, which is a firm, fixed, unshakable, and held with strong conviction, irrespective of sociocultural and educational background. The content of it being bizarre but not always. Answer: A

111. Neologism is:

- A. Minting of words
 - B. Totally
 - C. Has some meaning
 - D. Modification of word
- Neologisms: Newly formed words or phrases whose derivation cannot be understood. Paronyms – word approximations where normal words are used in an unconventional or distorted way, but the derivation can be understood. Answer: B

112. Delusion is a false belief which is:

- A. Reasonable
 - B. Comprehensible
 - C. Both of the above
 - D. None of the above
- Delusion is a false unshakable belief which is not amenable to reasoning and is not in keeping with the patient's sociocultural and educational background. Answer: B

113. Auditory hallucinations are seen in all of the following except:

- A. Hysteria
 - B. Mania
 - C. Amphetamine toxicity
 - D. Schizophrenia
- Answer: A

114. Tactile hallucinations are associated with:

- A. Schizophrenia
 - B. Cocaine psychosis
 - C. Temporal lobe epilepsy
 - D. All of the above
- Answer: D

115. Pseudo-hallucinations are not said symptoms of:

- A. Hysteria

- B. Schizophrenia
 - C. Pseudo-neurotic schizophrenia
 - D. Malingering
- Answer: A

116. Delusion is seen in all, except:

- A. Mania
 - B. Depression
 - C. Anxiety neurosis
 - D. Schizophrenia
- Answer: C

117. Delusion is a disorder of:

- A. Perception
 - B. Thought
 - C. Personality
 - D. Affect
- Answer: B

118. Delusion is:

- A. A feeling of loss of sensation
 - B. Not able to get proper answer
 - C. A false belief
 - D. An uncomfortable sensation
- Delusions are false unshakable beliefs which are not in keeping with patient's sociocultural and educational background. Answer: C

119. Thought disorder is seen in:

- A. Obsessive-compulsive disorder
 - B. Anxiety neurosis
 - C. Schizophrenia
 - D. Psychopathic personality
- Autistic thinking, loosening of association are forms of thought disorder seen in schizophrenia. Answer: C

120. A false belief unexplained by reality, which is shared by a number of people is:

- A. Delusion
 - B. Obsession
 - C. Superstition
 - D. Illusion
- Answer: C

121. One of the following is a disorder of thought:

- A. Illusion
- B. Hallucination
- C. Delirium

D. Delusion Illusion and hallucination are disorders of perception Delusion is a disorder of content of thought Delirium is an organic condition where there is an acute confusional state. Answer: D

122. Deja vu Phenomenon is:

- A.** Feeling palpable music
- B.** Feeling nauseating smell
- C.** Fear of impending doom
- D.** Familiarity to unfamiliar surroundings Illusion of familiarity in unfamiliar situations is Deja vu. Deja Pense – related to thoughts Deja entendu – related to auditory perception. Answer: D

123. Depersonalisation is a disorder of:

- A.** Mood
- B.** Thought
- C.** Perceptions
- D.** Cosmetic Other disorders of perceptions are Hallucinations and Illusions. Answer: C

124. The most common cause of mood congruent delusion is:

- A.** Obsessive-compulsive neurosis
- B.** Schizophrenia
- C.** Dementia
- D.** Mania Mood-congruence refers to occurrence of psychiatry symptoms in keeping with mood state. Answer: D

125. Visual hallucinations are seen in:

- A.** Alcoholism
- B.** Mania
- C.** Depression
- D.** Phobia Seen in Delirium tremens. Answer: A

126. Tactile hallucination is a feature of:

- A.** Anxiety neurosis
- B.** Cocaine poisoning
- C.** Morphine withdrawal
- D.** Schizophrenia Delirium and anxiety neurosis can also occur with cocaine. Answer: B

127. “Phantom limb” is an example of:

- A.** Delusion
- B.** Illusion
- C.** Phi phenomenon
- D.** Hallucination

E. Fantasy Answer: D

128. 'Mirage' is an example of:

- A. Illusion
- B. Delusion
- C. Hallucination
- D. Extrasensory perception
- E. Fantasy Answer: A

129. Delusion is not seen in:

- A. Anxiety
- B. Mania
- C. Depression
- D. Schizophrenia Answer: A

130. Cognition means:

- A. Behaviour
- B. Thought
- C. Perception
- D. Feeling There are three psychiatric domains. Cognition (thought) Affect (Feeling) Conation (action) Equilibrium normally exists between the domains. Answer: B

131. Delusions of influence are characteristic of:

- A. Obsessive state
- B. Schizophrenia
- C. Depression
- D. Dramatization Delusion of control/influence is seen commonly in schizophrenia. Answer: B

132. Delusions and hallucinations are known as:

- A. Psychotic symptoms
- B. Neurotic symptoms
- C. Behavioral symptoms
- D. Psychosomatic symptoms Term psychosis is defined as Gross impairment of reality testing Loss of weight Pressure of characteristic symptoms like delusions and hallucination. Answer: A

133. The commonest disorder of perception is:

- A. Delusion
- B. Hallucination
- C. Passivity

- D.** Compulsion Hallucination and passivity are disorders of perception Compulsion delusions are disorders of thought. Answer: B
- 134.** Therapeutic community concept was propagated by:
- A.** Freud
 - B.** Adler
 - C.** Maxwell Jones
 - D.** Watson. J Answer: C
- 135.** Psychoanalysis was found by:
- A.** Freud
 - B.** Jung
 - C.** Adler
 - D.** Eysenck Answer: A
- 136.** A false sensory perception in the absence of external stimulus is:
- A.** Hallucination
 - B.** Illusion
 - C.** Delusion
 - D.** Depersonalization Answer: A
- 137.** Loss of insight occurs in:
- A.** Anxiety neurosis
 - B.** Schizophrenia
 - C.** Psychosomatic disorder
 - D.** MDP Loss of weight is a feature of psychosis. It is seen both in schizophrenia and manic phase of MDP but prominent in schizophrenia. Answer: B
- 138.** Grimacing is a feature of:
- A.** Catatonic schizophrenia
 - B.** Hebephrenic schizophrenia
 - C.** Paranoid schizophrenia
 - D.** Juvenile schizophrenia Answer: A
- 139.** Flashbacks are seen with:
- A.** LSD
 - B.** Amphetamine
 - C.** Cocaine

- D.** Opiates Flashback is a spontaneous recurrence of Drug use experience in drug free state. Answer: A
- 140.** Loss of insight occurs in:
- A.** Hysteria
 - B.** Schizophrenia
 - C.** Obsessive-compulsive neurosis
 - D.** Somatoform disorders Loss of insight occurs in psychosis except schizophrenia all the other three disorders belongs to neuroses. Answer: B
- 141.** Confabulation is a defect of:
- A.** Memory
 - B.** Intelligence
 - C.** Affection
 - D.** Concentration Answer: A
- 142.** 'La belle indifference' is seen in:
- A.** Dissociative disorder
 - B.** Phobia
 - C.** Obsessive-compulsive disorder
 - D.** Depersonalization disorder Lack of concern towards symptoms in patients with dissociative disorder. Answer: A
- 143.** Ganser's syndrome is associated with:
- A.** Repeated lying
 - B.** Approximate answers
 - C.** Confabulation
 - D.** Malingering Ganser's syndrome is a dissociative disorder. It is also called hysterical pseudo dementia. Answer: B
- 144.** Nihilistic delusion is seen in:
- A.** Depression
 - B.** Schizophrenia
 - C.** Mania
 - D.** OCN Nihilistic delusion is mood – congruent type of delusion seen in depression. Answer: A
- 145.** Neologism is characteristic of:
- A.** Mania
 - B.** Schizophrenia
 - C.** Depression

D. OCN Answer: B

146. An 18-year-old hears voices discussing him in the third person. He has

A. TLE

B. Depression

C. Mania

D. Schizophrenia Answer: D

147. To become unfamiliar of familiar situation is called:

A. Deja vu

B. Jamais vu

C. Deja pence

D. Deja entendu Explanation:— Deja vu—illusion of visual recognition in which a new situation is incorrectly regarded as a repetition of a previous memory. Jamais vu—False feeling of unfamiliarity with a real situation that a person has experienced. Deja pence—Illusion that a new thought is recognised as a thought previously felt or expressed. - C. Passivity
- D. Depression Answer: A

153. Early in psychiatric interview, it is important for the physician to:

- A. Let patients talk about what is bothering them
- B. Obtain information about the patient's mood
- C. Record the family history
- D. Inform the patient of the fee
- E. Obtain details of any past psychiatric illness Answer: C

154. Epistemology is the branch of philosophy which deals with the theories of

- A. Reality
- B. Existence
- C. Knowledge
- D. Values Answer: Knowledge

155. "Things as they are and as they are likely to be encountered in life rather than words" was the slogan of the

- A. Pragmatists
- B. Realists
- C. Idealists
- D. Existentialists Answer: Realists

156. Who advocated the creation of a classless society ?

- A. Plato
- B. Auguste Comte
- C. M.K. Gandhi
- D. Karl Marx Answer: Karl Marx

157. The right to free and compulsory education for children between age group of 6 to 14 has been inserted in Indian Constitution as

- A. Article 46
- B. Article 16
- C. Article 45A
- D. Article 21A Answer: Article 21A

158. Who advocated the logical analysis of language for getting the true meaning ?

- A. A.J. Ayer
- B. Bertrand Russel
- C. Morris L. Biggie
- D. G.E. Moore Answer: A.J. Ayer

159. Sociology of Education is

- A. A branch of Anthropology
- B. A study of the Society
- C. An analysis of Sociological processes involved in the institutions of Education.
- D. A science which studies primitive societies. Answer: An analysis of Sociological processes involved in the institutions of Education.

160. Schools are basically social institutions as

- A. They preserve and instil the values of our culture in future generations.
- B. They suggest ways and means for social progress.
- C. They suggest solutions to social problems.
- D. They are established by the society. Answer: They preserve and instil the values of our culture in future generations.

161. Which is not a criterion used consistently for placing people in a particular social class ?

- A. Race
- B. Religion
- C. Knowledge
- D. Wealth Answer: Knowledge

162. Use of Science and Technology in replacing existing social practices is termed as

- A. Socialization
- B. Westernization
- C. Sanskritization
- D. Modernization Answer: Modernization

163. Which of the following chains represents the change processes underlying educational system of Free India ?

- A. Psychological change – Social change – Political change – Educational change.
- B. Political change – Social change – Psychological change – Educational change.
- C. Social change – Psychological change – Political change – Educational change.

- D.** Educational change – Social change – Psychological change. Answer: Political change – Social change – Psychological change – Educational change.
- 164.** Use of Science and Technology in replacing existing social practices is termed as
- A.** Socialization
 - B.** Westernization
 - C.** Sanskritization
 - D.** Modernization Answer: Modernization
- 165.** Equality of opportunities in education implies that each student
- A.** passes examination with first division.
 - B.** gets equal number of books and stationery.
 - C.** gets facilities according to his abilities and interests.
 - D.** gets facilities according to his potential and level in the society. Answer: gets facilities according to his abilities and interests.
- 166.** Which of the following is not a principle of development ?
- A.** Principle of continuity.
 - B.** Principle of individual difference.
 - C.** Principle of proceeding from specific to general response.
 - D.** Principle of integration. Answer: Principle of proceeding from specific to general response.
- 167.** Development of language in children, according to B.F. Skinner, is the result of
- A.** Training in grammar
 - B.** Imitation and reinforcement
 - C.** Innate abilities
 - D.** Maturation Answer: Imitation and reinforcement
- 168.** Behaviour pattern that increases in frequency when followed by a reward is known as
- A.** Shaping
 - B.** Classical Conditioning
 - C.** Generalization
 - D.** Operant Conditioning Answer: Operant Conditioning
- 169.** Find out the odd one :
- A.** Originality
 - B.** Punctuality
 - C.** Flexibility
 - D.** Fluency Answer: Punctuality
- 170.** Who propounded Self Theory of Personality ?
- A.** Kretschmer

- B. Allport
- C. Eysenck
- D. Roger Answer: Roger

171. Archimedes found the solution of his problem when he was in his bath tub. This will come under which step of process of creativity ?

- A. Preparation
- B. Incubation
- C. Illumination
- D. Verification Answer: Illumination

172. The pioneer of functionalism is

- A. Wilhelm Wundt
- B. William James
- C. J.B. Watson
- D. Kurt Lewin Answer: William James

173. Nihar fails in the examination and attributes his failure to the framing of the faulty question paper. Which defence mechanism does he use ?

- A. Projection
- B. Compensation
- C. Identification
- D. Rationalisation Answer: Rationalisation

174. Which of the following is not a characteristic of Naturalistic Inquiry ?

- A. Multiple Realities
- B. Generalisation
- C. Human Relations
- D. Value Based Research Answer: Generalisation

175. Which of the following variances is not controlled or manipulated in a research design ?

- A. Variance of independent variable.
- B. Variance of dependent variable.
- C. Variance of extraneous variables.
- D. Error variance Answer: Variance of dependent variable.

176. Which of the following is not a criterion for the statement of a good research problem ?

- A. Expression of relationship between/among variables.
- B. Clarity and unambiguousness.

- C. Possibility of empirical testing.
- D. Possibility of use of statistical analysis. Answer: Possibility of use of statistical analysis.

177. Which of the following variables is continuous ?

- A. Attitude towards school
- B. Family size in a locality
- C. Marital status of College students
- D. Religious affiliation of workers. Answer: Attitude towards school

178. Which of the following is a measure of location ?

- A. Mode
- B. Mean
- C. Percentile
- D. Standard Deviation Answer: Percentile

179. An investigator wants to study the vocational aspirations of visually challenged children in a wide geographical area. He should select his sample by using

- A. Simple Random sampling
- B. Stratified sampling
- C. Purposive sampling
- D. Convenient sampling Answer: Purposive sampling

180. The distribution of a large number of means based on samples of the sample size selected from the same population is known as

- A. normal distribution
- B. sampling distribution
- C. standard distribution
- D. rectangular distribution Answer: sampling distribution

181. Two variables X and Y are correlated. This means that the two variables

- A. cause variation in each other
- B. measure the same trait
- C. vary together
- D. vary independently Answer: vary together

182. When the questions are presented to the respondents in a face-to-face situation and the interviewer fills out the query rather than the subjects it is known as

- A. An inventory
- B. A questionnaire
- C. A schedule
- D. A test Answer: A schedule

- 183.** Who said this "Education is man-making. It is that by which character is formed, strength of mind is increased, intellect is expanded and by which man can stand on his own feet" ?
- A.** Vivekananda
 - B.** Tagore
 - C.** Dayanand Saraswati
 - D.** None of these Answer :Vivekananda
- 184.** Purpose of creation of the universe and its relation to man and god is discussed in
- A.** Metaphysics
 - B.** Ethics
 - C.** Epistemology
 - D.** None of these Answer: Metaphysics
- 185.** Which of the following agency regulates education ?
- A.** Church
 - B.** State
 - C.** School
 - D.** Library Answer: State
- 186.** "The greatness of a nation is to be measured not by its material power and wealth but by the intercultural relationship of its people." Who said this ?
- A.** Dr. Radhakrishnan
 - B.** Tagore
 - C.** Vivekananda
 - D.** Gandhi Answer:Dr. Radhakrishnan
- 187.** Which of the following does not specify Max Weber's concept of social stratification
- A.** Educational Status
 - B.** Income and Wealth
 - C.** Political Power
 - D.** 4 Social Prestige Answer: Educational Status
- 188.** If rules of multiplication helps in learning correlation or regression, then it is an example of
- A.** Sequential transfer
 - B.** Horizontal transfer
 - C.** Negative transfer
 - D.** Vertical transfer Answer:Vertical transfer
- 189.** According to Freud, Super Ego is properly developed during
- A.** latency period
 - B.** anal period

- C. phallic period
- D. none of these Answer: latency period

190. When response is based on uncommon area of the blot, it is denoted by

- A. S
- B. Dd
- C. DW
- D. DdW Answer: Dd

191. Individual psychology of personality was given by

- A. A. Adler
- B. Jung
- C. Eysenck
- D. None of these Answer: A. Adler

192. Which is the highest level of concept formation ?

- A. Formal level
- B. Sensory level
- C. Concrete level
- D. None of these Answer: Formal level

193. Which of the following is the apex body in the area of Teacher Education in India ?

- A. UGC
- B. MHRD
- C. NCTE
- D. NCERT Answer: NCTE

194. Who have signed MOU for accreditation of Teacher Education Institutions in India ?

- A. NAAC and UGC
- B. NCTE and NAAC
- C. UGC and NCTE
- D. None of the above Answer: NCTE and NAAC

195. As per NCTE norms, what should be the pattern of teaching staff for a unit of 100 students B.Ed. level ?

- A. 1 1 + 7
- B. 2 1 + 9
- C. 3 1 + 10
- D. 4 1 + 5 Answer: 1 + 7

196. There are three phases of teaching given by P. Jackson, which of the following is incorrect one

?

- A. Pre-active phase
- B. Underactive phase
- C. Interactive phase
- D. Post-active phase Answer: Underactive phase

197. Which of the following is the least important aspect of the teachers' role in the guidance of learning ?

- A. The development of insight into what constitutes an adequate performance.
- B. The development of insight to overcome the pitfalls and obstacles.
- C. The provision of encouragement and moral support.
- D. The provision of continuous diagnostic and remedial help. Answer: The development of insight to overcome the pitfalls and obstacles.

198. Which of the following qualities of a teacher will be liked most by you ?

- A. Idealistic philosophy
- B. Compassion
- C. The Discipline Run
- D. Entertaining Answer: Compassion

199. The most important challenge for a teacher is

- A. to maintain discipline in the classroom.
- B. to make students do their homework.
- C. to prepare the question-bank.
- D. to make teaching process enjoyable. Answer: to make teaching process enjoyable.

200. Techno-Pedagogic competency is

- A. a science of using technology in teaching.
- B. a technique of combining principles of technology and principles of teaching.
- C. a set of skills of interweaving technology into teaching and learning both scientifically and aesthetically.
- D. a competence to develop techno-pedagogic systems in education. Answer: a set of skills of interweaving technology into teaching and learning both scientifically and aesthetically.

201. Psycho-analytic approach of counselling was first introduced by

- A. Adler
- B. Jung
- C. Freud
- D. None of these Answer: Freud

202. Which of the following does not belong to the category of non-probability sample ?

- A. Quota sample
- B. Multi-stage sample

- C. Purposive sample
 D. Incidental sample Answer: Multi-stage sample
- 203.** The research proposals sent to research institutes for financial assistance must have
 A. The whole plan and procedure
 B. Budget requirements and time schedule
 C. 3 Definite objectives of research
 D. None of the above Answer: Budget requirements and time schedule
- 204.** Which of the following is not an approach of analysis of qualitative data ?
 A. Logical Analysis
 B. Criterion Analysis
 C. Content Analysis
 D. Inductive Analysis Answer: Criterion Analysis
- 205.** Internal criticism is done
 A. to verify the accuracy of the source.
 B. to verify the authenticity of the source.
 C. Both of these
 D. None of these Answer: to verify the accuracy of the source.
- 206.** Which of the following is described as Magna-Carta of Indian Education ?
 A. Sargent Commission
 B. Wood's Despatch
 C. Macaulay Minutes
 D. Hunter Commission Answer: Macaulay Minutes
- 207.** "Rising knowledge to wisdom is real education" was said by
 A. Rigveda
 B. Chhandogya Upanishad
 C. Samaveda
 D. Bhagvadh Geeta Answer: Chhandogya Upanishad
- 208.** The Oriental School of Thought is related to
 A. knowledge of science
 B. classical literature
 C. conservation of fashion
 D. learning of natives Answer: classical literature
- 209.** 'Project is a whole-hearted purposeful activity proceeding in a social environment', it was defined by
 A. John Dewey
 B. Ballard

- C. Kilpatrick
- D. Adamson Answer:Kilpatrick

210. Who said that the school be made as miniature society ?

- A. Skinner
- B. Thorndike
- C. Herbert
- D. Dewey Answer:Dewey

211. 'Socialization' is a process by which the individual is adapted to his

- A. classroom environment
- B. social environment
- C. political environment
- D. cultural environment Answer: social environment

212. The movement from one social class to another is known as

- A. social status
- B. social control
- C. social change
- D. social mobility Answer: social mobility

213. 'Cultural Lag' is the term used by

- A. Ogburn
- B. Pyne
- C. Weber
- D. Marx Answer: Ogburn

214. District Primary Education Programme (DPEP) was started in

- A. 990
- B. 1994
- C. 1998
- D. 1996 Answer:1994

215. Supervision is a continuous activity whereas Inspection is a

- A. general activity in a common place
- B. special activity in a given moment
- C. complex activity in a situation
- D. specific activity in a specific time Answer: specific activity in a specific time

216. Who propounded the 'self' theory of personality ?

- A. Allport
- B. Kretschmar

- C. Eysenck
- D. Roger Answer: Roger

217. University Education Commission constituted in 1948 was appointed by

- A. Ministry of Human Resource Development
- B. Ministry of Education
- C. NCERT
- D. ICSSR Answer: ICSSR

218. Education falls under the

- A. Concurrent List
- B. Fundamental Rights
- C. Constitution of India
- D. State List Answer: Concurrent List

219. Curriculum means

- A. all the experiences which students get in school.
- B. subject that are transferred by the faculty.
- C. syllabus prescribed for the course.
- D. class experiences, sports and games. Answer: all the experiences which students get in school.

220. Programmed learning is based on the principles of

- A. Conditioned Learning Theory
- B. Cognitive Learning Theory
- C. Gestalt Learning Theory
- D. Operant-conditioning Answer: Operant-conditioning

221. According to Piaget, at what stage does abstract thinking begin to develop ?

- A. Sensory motor
- B. Pre-operational
- C. Concrete operational
- D. Formal operational Answer: Formal operational

222. Which of the following is the incorrect pair ?

- A. Sign Theory of – Tolman Learning
- B. Field Theory of – Lewin Learning
- C. Social Learning – Bruner Theory
- D. Trial and error – Thorndike Theory Answer: Social Learning – Bruner Theory

223. Which is the most effective reinforcement schedule according to operant conditioning theory of learning for stable learning ?

- A. Continuous reinforcement
- B. Fixed ratio reinforcement
- C. Variable ratio reinforcement

D. Fixed interval reinforcement Answer: Variable ratio reinforcement

224. Xerophthalmia is a result of insufficient amount of

- A. Vitamin C
- B. Vitamin B
- C. Vitamin D
- D. Vitamin A Answer: Vitamin A

225. A child who has unusual difficulty in oral instruction may have the following impairment

- A. Intellectual disability
- B. Cerebral Palsy
- C. Hearing impairment
- D. Visual impairment Answer: Hearing impairment

226. The child who reads numbers wrongly has the following learning disability

- A. Dyscrasia
- B. Dyslexia
- C. Dyspepsia
- D. Dyscalculia Answer: Dyslexia

227. The child having the difficulty in picking up objects is suspected to have

- A. Lower level of intellectual function
- B. Sight impairment
- C. Speech impairment
- D. Locomotor impairment Answer: Locomotor impairment

228. Delinquency is committed by the children of the age group

- A. 8 – 18 years
- B. 6 – 14 years
- C. 7 – 15 years
- D. 9 – 19 years Answer: 8 – 18 years

229. Which of the following philosophies are most tilted to individualism ?

- A. Jainism
- B. Samkhya
- C. Buddhism
- D. None of these Answer: Jainism

230. Research means

- A. Searching again and again
- B. Finding solution to any problem

- C. Scientific approach to new truth
- D. Conducting experiment Answer: Scientific approach to new truth

231. Which of the following is the first step in the research process ?

- A. Searching sources of information.
- B. Survey of related literature.
- C. Identification of a broad area of research.
- D. Searching for solution to problem. Answer: Searching for solution to problem.

232. If a researcher conduct a research on finding out which administrative style contributes more to institutional effectiveness, this will be an example of

- A. Ex post facto research
- B. Action research
- C. Applied research
- D. Fundamental research Answer: Action research

233. A researcher is generally expected to

- A. study the existing literature in a field.
- B. generate new principles and theories.
- C. synthesize the ideas given by others.
- D. evaluate the findings of a study. Answer: generate new principles and theories

234. The Government of India conducts Census after every 10 years. The method of research used in this process is

- A. Case Study
- B. Developmental
- C. Survey
- D. Experimental Answer: Survey

235. Two variables X and Y are significantly correlated. This means that

- A. X causes variation in Y.
- B. Y causes variation in X.
- C. X and Y vary together.
- D. No such conclusion may be drawn. Answer: X and Y vary together.

236. Which of the following types of studies results in findings which could not be generalized to other situations ?

- A. Descriptive
- B. Historical
- C. Experimental
- D. Causal Comparative Answer: Historical

- 237.** The Rosarch Inkblot test consists of
- A. Five black and five coloured cards
 - B. Ten black and ten white cards
 - C. Five black and white & five multi-coloured cards
 - D. Ten multi-coloured cards Answer: Five black and white & five multi-coloured cards
- 238.** Which of the following terms is irrelevant to a qualitative study ?
- A. Comparison
 - B. Prediction
 - C. Correlation
 - D. Exploration Answer: Exploration
- 239.** Which of the following is a characteristic feature only of experimental studies ?
- A. Control of extraneous variables.
 - B. Study of cause and effect relationship.
 - C. Observing variation in the dependent variable.
 - D. Manipulation of treatment variable. Answer: Manipulation of treatment variable.
- 240.** When a researcher checks the genuineness and authenticity of the source material, it is known as
- A. External validity
 - B. External criticism
 - C. Concurrent validity
 - D. Internal consistency Answer: External criticism
- 241.** An investigator studied the census data for a given area and prepared a write-up based on them. Such a write-up is called
- A. Research Paper
 - B. Article
 - C. Thesis
 - D. Research Report Answer: Article
- 242.** A school counselor is planning a guidance lesson for seventh- and eighth-grade students. Which of the following instructional approaches would likely be most responsive to the developmental needs of students in this age range?
- A. small-group activities that involve active participation
 - B. open-ended activities that encourage free exploration
 - C. counselor-directed activities that are highly structured
 - D. individual activities that encourage friendly competition Answer : A.
- 243.** Lev Vygotsky's theory of human cognition and learning emphasizes which of the following concepts?
- A. the role of trial and error in learning

- B. learning as a conditioned response to external stimuli
- C. the role of social interaction in learning
- D. learning as a process that unfolds in a sequence of stages Answer : C

244. A school counseling department has been asked by the principal to implement a suicide prevention initiative at the school. Which of the following strategies would be most effective for the counselors to use in collaborating with teachers on this effort?

- A. encouraging teachers to make referrals to help identify the students most at risk of suicide
- B. meeting with teachers to plan how best to integrate the initiative into the existing school program
- C. training teachers to deliver a suicide prevention unit through classroom guidance lessons
- D. arranging for teachers to be responsible for publicizing the initiative throughout the school community Answer : B

245. A school counselor wishes to evaluate the impact and effectiveness of a developmental guidance unit on discrimination and harassment. Which of the following strategies would be the best to use for such an evaluation?

- A. surveying the opinions of faculty and staff on whether such behaviors have decreased
- B. interviewing parents/guardians about types of behaviors being demonstrated by their children at home
- C. using a spreadsheet to track incident reports related to such behavior at school
- D. soliciting feedback from students who are participating in behavior-related counseling groups

246. A school counselor wants to facilitate ongoing evaluation and feedback with regard to the counseling program's individual planning component. The most effective strategy for this purpose would be to:

- A. interview students with whom the counselor has conducted individual planning to discuss how the experience helped them and how it might be improved.
- B. maintain a chart of each student seen for individual planning, the amount of time spent with each student, and the primary issues and topics addressed.
- C. conduct periodic comparisons between the academic records of students who have been seen for individual planning and those of students who have not.
- D. ask the teachers of students who have received individual planning services to inform the counselor of any changes they notice in their students afterward. Answer : A.

247. After collecting referral data from teachers, an elementary school counselor concludes that it will be necessary to implement several small counseling groups focused on social skills. When selecting the members for each group, the counselor could best promote group effectiveness by:

- A. assembling groups of students whose members share similar backgrounds and values.
- B. creating groups whose members are already friends.
- C. establishing groups in which at least one member is a positive role model for other students.
- D. forming groups that have fewer than five members. Answer : C.

248. In response to a large caseload, a school counselor decides to implement small-group

counseling as an efficient way to meet students' needs. Which of the following steps would be best for the counselor to take first when implementing such counseling?

- A. obtaining informed consent from parents/guardians
 - B. conducting a needs assessment to identify potential topics and participants
 - C. developing goals and an action plan for the group
 - D. publicizing the decision to administrators, teachers, parents/guardians, and students
- Answer : B.

249. When meeting with the school counselor, a student reveals that she often feels faint and has been losing a significant amount of hair. During the session, the counselor observes that the student makes several negative comments about herself and her appearance and that she is wearing clothes that are noticeably too large. The student's disclosures and behaviors are most likely indicative of which of the following problems?

- A. drug or alcohol abuse
 - B. a mood disorder
 - C. physical abuse
 - D. an eating disorder
- Answer : D

250. A teacher at an elementary school dies suddenly during the school year and the school counselor is notified. The counselor's initial action in this situation should be to:

- A. offer to help plan a memorial service for the teacher.
 - B. assemble the school's crisis response team.
 - C. schedule individual and group counseling for students.
 - D. announce the school's cancellation for the rest of the week.
- Answer : B

251. A school counselor meets with a student who has shown signs of depression, including social withdrawal and loss of interest in previously enjoyed activities. At one point during the meeting, the student discloses having recurring thoughts about suicide. Which of the following would be the counselor's best response in this situation?

- A. pointing out to the student that suicide is an irreversible act
 - B. arranging to conduct a series of individual counseling sessions, beginning the following day
 - C. informing the student that the counselor must contact the student's family immediately
 - D. asking the student questions to evaluate the degree of risk
- Answer : D

252. A school counselor is planning a career development lesson focused on helping preteens expand their self-understanding. Which of the following types of assessments would likely be most effective to use in conjunction with this lesson?

- A. interest inventories
 - B. achievement tests
 - C. behavioral observations
 - D. intelligence tests
- Answer : A

253. A student with a physical disability is meeting with the school counselor to discuss postsecondary planning. The student is pessimistic about having a rewarding career and says that employers don't hire people with disabilities for anything but "boring jobs." Which of the following would be the counselor's best response?

- A. providing the student with examples of famous people with disabilities who have achieved success in various careers
 - B. reminding the student that individuals with disabilities have employment rights that are guaranteed by federal and state law
 - C. seeking out successfully employed individuals with similar disabilities who are willing to serve as mentors to the student
 - D. pointing out that many individuals who start out in entry-level jobs achieve career success through persistence and hard work
- Answer : C

254. Data on course enrollment at a high school indicate that students from a particular demographic group have been significantly underrepresented in college preparatory courses over the past four years. The school counselor's best initial response would be to:

- A. develop in-service training for teachers on how to guide targeted students to enroll in advanced-level courses.
 - B. schedule a parent night focused on how students' course selections can affect their prospects for postsecondary success.
 - C. develop informational handouts for entering ninth graders that stress the idea that every student is capable of succeeding in college.
 - D. schedule a meeting with the school principal to assess the scope of the problem and begin developing an action plan.
- Answer : D

255. A school counselor is reviewing a database of dropout rates for the school. The counselor sees that the school's ninth-grade dropout rate last year fell by 8 percent from the previous year. To obtain more precise information on school effectiveness, the counselor should take which of the following steps next?

- A. inspect different graphic representations of the data
 - B. disaggregate the data by various student subgroups
 - C. review similar data for other middle schools in the region
 - D. extend the current trend to project next year's dropout rate
- Answer : B

256. During a meeting with a school counselor, a student confides that she is pregnant and asks for information on obtaining an abortion. The counselor has a strong moral objection to abortion and is hesitant to provide the requested information. Under these circumstances, the counselor has an ethical responsibility to:

- A. refer the student to another counselor at the school.
 - B. explain that many people believe abortion to be wrong.
 - C. suggest that the student consider alternative options.
 - D. probe the student's level of commitment to her decision.
- Answer : A

257. Guidance refers to _____.

- (A) An advice provided by superior to resolve problem
 - (B) A professional advice provided by Counselor in overcoming from personal or Psychological problems
 - (C) Both A & B
 - (D) None of the above.
- Answer : A

- 258.** Counseling refers to_____.
- (A) A Professional advice byCounselor
 - (B) An Advice by Elder
 - (C) Both A & B
 - (D) All of the above..Answer : A
- 259.** Which of the following is notthe type of counseling?
- (A) Marriage and Family Counseling
 - (B) Mental Health Counseling
 - (C) Substance Abuse Counseling
 - (D) Above All are types ofCounselling
 - (E) None of the Above..Answer : D
- 260.** What does a school Counselordo?
- (A) helping students in theiracademic goals
 - (B) helping students in social andpersonal development
 - (C) helping students in their careerdevelopment
 - (D) All of the Above
 - (E) None of the above..Answer : D
- 261.** Guidance is a process of_____.
- (A) to give advice to the child
 - (B) teaching English to the Child
 - (C) Both A & B
 - (D) None of the Above..Answer : A
- 262.** In Probing or Questioning fromthe Counselor enables what?
- (A) to help students to moveforward in helping process
 - (B) investigate other parts of his orher story
 - (C) Counselor can be with studentsphysically or psychologically
 - (D) None of the Above..Answer : A
- 263.** The main aim of educationalguidance is__.
- (A) Pupil Development
 - (B) To Solve the Problems
 - (C) Improvement of Curriculum
 - (D) None of the Above..Answer : A
- 264.** A school Counselor worksin_____
- (A) Primary , Middle and HighSchools

- (B) In Colleges
- (C) In Universities
- (D) None of the Above. Answer : A

265. Main objective of educational guidance is to bring what change in the pupil_.

- (A) Psychological Development of the child
- (B) responsibility of self direction
- (C) Both A & B
- (D) None of the Above. Answer : B

266. Name the person who is credited with Guidance Movement ?

- (A) Einstein
- (B) George Washington
- (C) Frank Parsons
- (D) All of the Above. Answer : C

267. What are the characteristics of Continuous and Comprehensive Evaluation?

- (a) It increases the workload on students by taking multiple tests.
- (b) It replaces marks with grades.
- (c) It evaluates every aspect of the student.
- (d) It helps in reducing examination phobia.

Select the correct answer from the codes given below:

- (1) (a), (b), (c) and (d)
- (2) (b) and (d)
- (3) (a), (b) and (c)
- (4) (b), (c) and (d). Answer: 4

268. Which of the following attributes denote great strengths of a teacher?

- (a) Full-time active involvement in the institutional management
- (b) Setting examples
- (c) Willingness to put assumptions to the test
- (d) Acknowledging mistakes

Select the correct answer from the codes given below:

- (1) (a), (b) and (d)
- (2) (b), (c) and (d)
- (3) (a), (c) and (d)
- (4) (a), (b), (c) and (d). Answer: 2

269. Which one of the following statements is correct in the context of multiple-choice type questions?

- (a) They are more objective than true-false type questions.

- (b) They are less objective than essay type questions.
- (c) They are more subjective than short-answer type questions.
- (d) They are more subjective than true-false type questions. Answer: 1

270. What are required for good teaching?

- (a) Diagnosis
- (b) Remedy
- (c) Direction
- (d) Feedback

Select the correct answer from the codes given below:

- (1) (a), (b), (c) and (d)
- (2) (a) and (b)
- (3) (b), (c) and (d)
- (4) (c) and (d) Answer: 1

271. The main objectives of student evaluation of teachers are:

- (a) To gather information about student weaknesses.
 - (b) To make teachers take teaching seriously.
 - (c) To help teachers adopt innovative methods of teaching.
 - (d) To identify the areas of further improvement in teacher traits. Identify the correct answer from the codes given below:
- (1) (a) and (b) only
 - (2) (b), (c) and (d) only
 - (3) (a), (b) and (c) only
 - (4) (a) only Answer: 2

272. Identify the important element a teacher has to take cognizance of while addressing students in a classroom.

- (a) Avoidance of proximity
- (b) Voice modulation
- (c) Repetitive pause
- (d) Fixed posture Answer: 2

273. As a teacher, select the best option to ensure your effective presence in the classroom.

- (a) Use of peer command
- (b) Making aggressive statements
- (c) Adoption of well-established posture
- (d) Being authoritarian Answer: 3

274. Which set of learner characteristics may be considered helpful in designing effective teaching-learning systems? Select the correct alternative from the codes given below:

- (i) Prior experience of learners in respect of the subject.
- (ii) Interpersonal relationships of learner's family friends.
- (iii) Ability of the learners in respect of the subject.
- (iv) Student's language background.
- (v) Interest of students in following the prescribed dress code.
- (vi) Motivational-orientation of the students.

Codes:

- (a) (i), (ii), (iii) and (iv)
- (b) (i), (iii), (iv) and (vi)
- (c) (ii), (iii), (iv) and (v)
- (d) (iii), (iv), (v) and (vi) Answer: 2

275. The use of teaching aids is justified on the grounds of:

- (a) attracting students' attention in the class room.
- (b) minimising indiscipline problems in the classroom.
- (c) optimising learning outcomes of students.
- (d) effective engagement of students in learning tasks. Answer: 3

276. Select the alternative which consists of positive factors contributing to effectiveness of teaching: List of factors:

- (a) Teacher's knowledge of the subject.
- (b) Teacher's socio-economic background.
- (c) Communication skill of the teacher.
- (d) Teacher's ability to please the students.
- (e) Teacher's personal contact with students.
- (f) Teacher's competence in managing and monitoring the classroom transactions. Codes:

(1) (b), (c) and (d)

(2) (c), (d) and (f)

(3) (b), (d) and (e)

(4) (a), (c) and (f) Answer: 4

277. Which of the following set of statements represents acceptable propositions in respect of teaching-learning relationships? Choose the correct code to indicate your answer.

- (i) When students fail in a test, it is the teacher who fails.
- (ii) Every teaching must aim at ensuring learning.
- (iii) There can be teaching without learning taking place.
- (iv) There can be no learning without teaching.
- (v) A teacher teaches but learns also.
- (vi) Real learning implies rote learning.

Codes:

- (a) (ii), (iii), (iv) and (v)
- (b) (i), (ii), (iii) and (v)
- (c) (iii), (iv), (v) and (vi)
- (d) (i), (ii), (v) and (vi) Answer: 2

278. Effectiveness of teaching has to be judged in terms of

- (a) Course coverage
- (b) Students' interest
- (c) Learning outcomes of students
- (d) Use of teaching aids in the classroom Answer: 3

279. In which teaching method learner's participation is made optimal and proactive?

- (a) Discussion method
- (b) Buzz session method
- (c) Brainstorming session method
- (d) Project method Answer: 4

280. One of the most powerful factors affecting teaching effectiveness is related to the

- (a) Social system of the country
- (b) Economic status of the society
- (c) Prevailing political system
- (d) Educational system Answer: 4

281. Assertion (A): Formative evaluation tends to accelerate the pace of learning. Reason (R): As against summative evaluation, formative evaluation is highly reliable.

Choose the correct answer from the following code:

- (a) Both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) Both (A) and (R) are true, but (R) is not the correct explanation of (A).
- (c) (A) is true, but (R) is false.
- (d) (A) is false, but (R) is true. Answer: 3

282. Which of the following set of statements best represents the nature and objective of teaching and learning?

- (a) Teaching is like selling and learning is like buying.
- (b) Teaching is a social act while learning is a personal act.
- (c) Teaching implies learning whereas learning does not imply teaching.
- (d) Teaching is a kind of delivery of knowledge while learning is like receiving it.
- (e) Teaching is an interaction and is triadic in nature whereas learning is an active engagement in a subject domain.

Code:

- (1) (a), (d) and (e)

- (2) (b), (c) and (e)
- (3) (a), (b) and (c)
- (4) (a), (b) and (d) Answer: 2

283. From the list given below identify the learner characteristics which would facilitate teaching learning system to become effective. Choose the correct code to indicate your answer.

- (a) Prior experience of learner
 - (b) Learner's family lineage
 - (c) Aptitude of the learner
 - (d) Learner's stage of development
 - (e) Learner's food habits and hobbies
 - (f) Learner's religious affiliation
- Code:
 (1) (a), (c) and (d)
 (2) (d), (e) and (f)
 (3) (a), (d) and (e)
 (4) (b), (c) and (f) Answer: 1

284. Assertion (A): All teaching implies learning. Reason (R): Learning to be useful must be derived from teaching. Choose the correct answer from the following:

- (a) Both (A) and (R) are true and (R) is the correct explanation of (A).
- (b) Both (A) and (R) are true but (R) is not the correct explanation of (A).
- (c) (A) is true, but (R) is false.
- (d) (A) is false, but (R) is true. Answer: 3

285. On the basis of summative tests, a teacher is interpreting his/her students, performance in terms of their wellness life style evident in behaviour. This will be called:

- (a) Formative testing
- (b) Continuous and comprehensive evaluation
- (c) Norm - referenced testing
- (d) Criterion - referenced testing Answer: 4

286. Which one of the following is a key behaviour in effective teaching?

- (a) Using student ideas and contribution
- (b) Structuring
- (c) Instructional variety
- (d) Questioning Answer: 3

287. Which of the following set of statements best describes the nature and objectives of teaching? Indicate your answer by selecting from the code.

- (a) Teaching and learning are integrally related.
- (b) There is no difference between teaching and training.
- (c) Concern of all teaching is to ensure some kind of transformation in students.

- (d) All good teaching is formal innature.
- (e) A teacher is a senior person.
- (f) Teaching is a social act whereas learning is a personal act.

Code:

- (1) (a), (b) and (d)
- (2) (b), (c) and (e)
- (3) (a), (c) and (f)
- (4) (d), (e) and (f) Answer: 3

288. Which of the following learner characteristics is highly related to effectiveness of teaching?

- (a) Prior experience of the learner
- (b) Educational status of the parents of the learner
- (c) Peer groups of the learner
- (d) Family size from which the learner comes. Answer: 1

289. In the two sets given below Set - I indicates methods of teaching while Set - II provides the basic requirements for success/effectiveness. Match the two sets and indicate your answer by choosing from the code: n with student teacher feedback. marks to st. ies the doubtsss itself. rmance of a to parents atnterval. vation is raisedh a question-

Code:	(a)	(b)	(c)	(d)	(2) (b), (c) and (d)
(1)	(i)	(ii)	(iii)	(iv)	(3) (a), (c) and (e)
(2)	(ii)	(iii)	(iv)	(v)	(4) (b), (d) and (f)
(3)	(iii)	(v)	(ii)	(i)	Answer: 4
(4)	(iv)	(ii)	(i)	(iii)	290. Assertion (A): All teaching

Answer: 3

290. From the list of evaluation procedures given below identify those which will be called 'formative evaluation'. Indicate your answer by choosing from the code: (a) A teacher awards grades to students after having transacted the course work. should aim at ensuring learning. Reason (R): All learning results from teaching.

Choose the correct answer from the following code:

- (1) Both (A) and (R) are true, and (R) is the correct explanation of (A).
- (2) Both (A) and (R) are true, but (R) is not the correct explanation of (A).
- (3) (A) is true, but (R) is false.
- (4) (A) is false, but (R) is true. Answer: 3

291. Individual therapy meets the standard of best practices when it includes all of the following EXCEPT

- (a) Theory choice
- (b) Adherence and familiarity with only one theory

- (c) Determination of the cultural relevance of the selected theory
 - (d) Appraisal of the empirical evidence for and against the selected theory for the case at hand.
- Answer: B

292. The interview accomplishes all of the following major social work tasks, EXCEPT:

- (a) The establishment of rapport
 - (b) The gathering of information necessary for assessment
 - (c) The enactment of a therapeutic process
 - (d) The acquisition of declarative knowledge
- Answer: D

293. A generic planned change process of social work practice consists of:

- (a) Rapport (establishment of a working relationship)
 - (b) Assessment
 - (c) Contracting
 - (d) Goal Setting
 - (e) All of the above
- Answer: E

294. Historically direct social work practice has been conceptualized in all of the following ways EXCEPT:

- (a) Casework
 - (b) Case Management
 - (c) Individual psychotherapy
 - (d) Generalist practice
 - (e) Policy practice
- Answer: E

295. Therapy has been informed by all of the following theories EXCEPT

- (a) Pharmacological
 - (b) Psychodynamic
 - (c) Cognitive-Behavioral
 - (d) Narrative
 - (e) All of the above
- Answer: E

296. Indirect practice has been conceptualized over time in all of the following ways EXCEPT:

- (a) As private practice
- (b) As administrative or management practice

- (c) As planning and organizational practice
 - (d) As community organizing and social action practice
 - (e) As policy practice
- Answer: A

297. According to Biesteck, all of the following are core values in direct social work practice, EXCEPT:

- (a) Acceptance
 - (b) Non-judgmental attitude
 - (c) Confidentiality
 - (d) Client self-determination
 - (e) All of the above
- Answer: E

298. Declarative knowledge consist of all of the following, EXCEPT:

- (a) Intuitive and creative knowing in the therapeutic moment
 - (b) A cognitive map of learned (taught) concepts
 - (c) Causal knowledge of individual resilience
 - (d) Causal knowledge of individual vulnerability
- Answer: A

299. All of the following are aspects of tacit knowing EXCEPT:

- (a) Use of highly disciplined and automatic procedural knowing
 - (b) Self-regulated ability to reflect and adjust performance in the therapeutic moment
 - (c) Ability to reflect on action
 - (d) Ability to reflect in action
- Answer: C

300. Managing transference and counter-transference is critical in which one of the following theory-based models of therapy?

- (a) Behavior modification
 - (b) Cognitive-behavioral therapy
 - (c) Psychodynamic models of therapy
 - (d) Solution-focused models of therapy
- Answer: C

301. Emphasis on the construction of reality is emphasized in which one of the following theory-based models of therapy?

- (a) Behavior-Modification
- (b) Strengths-based model

- (c) Psychodynamic models
- (d) Power alignments Answer: C

302. All of the following are indicators that the helping relationship or therapeutic process is not going well EXCEPT:

- (a) The client frequently misses, cancels, or is tardy to appointments
- (b) The client asks questions and seeks information about which the worker is not knowledgeable
- (c) The client rambles on at length; focuses on irrelevant matters or details
- (d) The client minimizes the problem or claims miraculous improvement Matching Answer: B

303. Some of the greatest advances in human civilization in the 20th century have been:

- A. the discovery of antibiotics
- B. the discovery of DNA
- C. the marked lengthening of the average life span
- D. the improvement of public health
- E. all of the above Answer: E

304. At present, the longest living human, has lived the following number of years:

- A. 122
- B. 114
- C. 130
- D. 150
- E. none of the above Answer: A

305. Currently, the major cause of death in old age, in the US is:

- A. cardiovascular diseases: heart disease and stroke
- B. cancer
- C. pneumonia
- D. diabetes
- E. dementia Answer: A

306. By "rectangularization" of the survivorship curve, we mean:

- A. compression of morbidity
- B. expansion of morbidity
- C. worse performance of the ADLs
- D. better performance of the IADLs
- E. none of the above Answer: A

307. There are some ethnic/gender differences in the causes of death in the US population EXCEPT:

- A. Alzheimer's dementia is more frequent in women than men irrespective of ethnicity

- B. in men, diabetes is more frequent in American Indians and Alaska natives than whites
- C. in men, hypertension is more frequent in African Americans than in all other ethnic groups
- D. cancer is more frequent in whites than in all other groups
- E. the frequency of heart disease is the same across all ethnic groups Answer: D

308. Which of the following is DIRECTLY CORRELATED with longevity:

- A. Basal Metabolic Rate
- B. Stress
- C. Length of Growth Period
- D. Reproductive Fecundity
- E. All of the Above Answer: C

309. Which of the following can induce Cellular Senescence:

- A. Replicative Senescence
- B. DNA Damage
- C. Oncogene Expression
- D. Super-Mitogenic Signals
- E. All of the Above Answer: E

310. Which of the following is NOT a source of free radicals:

- A. p450 enzyme
- B. Macrophages and Neutrophils
- C. Alloxan
- D. Lipid Peroxidation
- E. None of the Above Answer: D

311. Which of the following

is generally true for sex differences after 65 years of age:

- A. men live longer but have more physical trauma injuries than women
- B. women live longer but have greater dependency (more disabilities) than men
- C. women live longer and have fewer disabilities than men
- D. there is no difference in life expectancy but women have fewer disabilities
- E. none of the above Answer: B

312. How have the major causes of death in the U.S. changed over the past century:

- A. shift from accidents and natural disasters (e.g. floods, earthquakes, etc.) toward microbial diseases
- B. the major causes of death have remained unchanged
- C. shift from microbial diseases and cancer toward natural disasters and food-borne illnesses
- D. shift from microbial diseases toward cardiovascular disease and cancer
- E. shift from cancer and accidents toward microbial diseases Answer: D

313. What happens when telomere length is critically shortened?

- A. cells undergo irreversible arrest of cell proliferation
- B. they show altered function
- C. alteration in function is universal
- D. alteration in function is cell-type specific
- E. all of the above

Answer: A

314. All the following statements regarding telomerase are true, EXCEPT:

- A. somatic cells have telomerase activity throughout their lives because of their high activity levels
- B. germline cells have telomerase activity because of the importance of retaining all their genetic information
- C. telomerase is expressed in 80% of tumor cells
- D. telomerase is expressed in some stem cells but it is highly regulated
- E. telomerase overcomes telomere shortening

Answer: A

315. How are anti-oxidants believed to be helpful to our bodies?

- A. they antagonistically bind to oxygen molecules, thus preventing aerobic pathways
- B. they enhance free-radical formation, thus increasing the efficiency of cellular processes
- C. they "quench" the reactivity of reactive oxygen species, thus preventing their detrimental interactions with other cellular activities
- D. they complex with vitamins in our bodies to produce reactive oxygen species, which are then used to enhance aerobic pathways
- E. none of the above

Answer: C

316. Ageism

- A. has the same meaning as senescence
- B. is a term indicating discrimination or prejudice against the elderly
- C. has the same meaning as aging
- D. none of the above
- E. all of the above

Answer: B

317. In elderly humans, "successful aging" is characterized by:

- A. presence of illnesses but no decline in function
- B. absence of illnesses and absence of decline in function
- C. decline in function but no illnesses
- D. changes in chronological age but not physiological age
- E. none of the above

Answer: B

318. Functional competence and, inversely, degree of disability in the elderly may be measured by:

- A. Counting the number of activities of day living that the old person can perform

- B. Counting the number of instrumental activities of day living that the old person can perform
 - C. Evaluating the degree of performance in both activities and the absence of disabilities
 - D. Estimating the degree of functional independence that allows the old person not to be institutionalized in a nursing home
 - E. all of the above
- Answer: E

319. The number of centenarians, in the last century as compared to the previous centuries has:

- A. remained unchanged worldwide
 - B. increased in developed countries
 - C. increased in developing countries
 - D. decreased in developing countries
 - E. decreased in developed countries
- Answer: B

320. Mice with cells that do not senesce die young of cancer because:

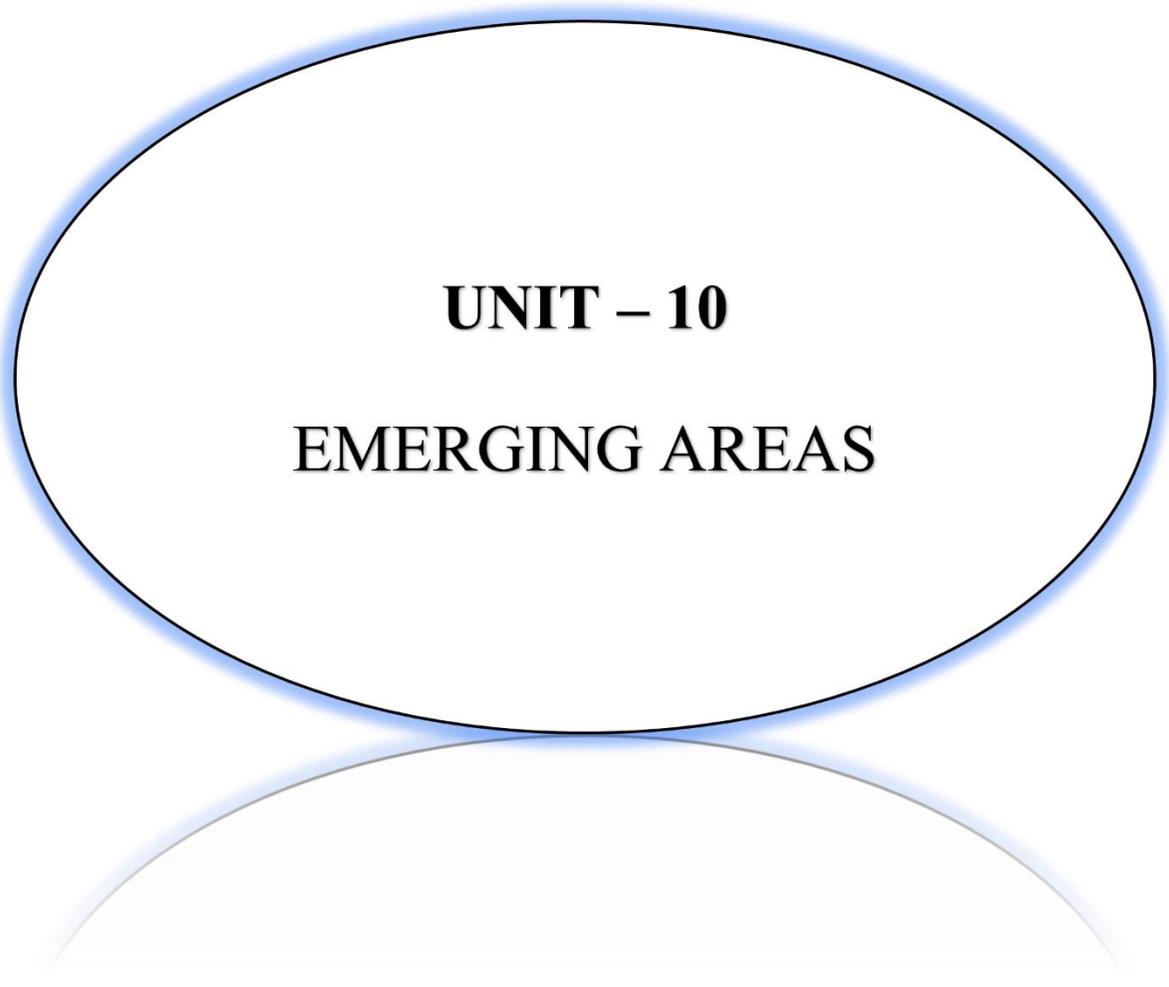

- A. Cellular senescence represents an important tumor suppression mechanism
 - B. tumor cells may be considered immortal
 - C. tumor cells continue to divide and cause death of the host organism
 - D. the two most important tumor suppressor pathways (p53 & pRB) are missing
 - E. all of the above
- Answer: E

321. Disease in the elderly has the following characteristics, EXCEPT:

- A. symptoms are vague and atypical
 - B. diseases are chronic as opposed to acute
 - C. diseases are acute as opposed to chronic
 - D. Diseases often affect many systems simultaneously
 - E. diseases may induce responses to treatment different from those of young & adult persons
- Answer: C

322. Aging and disuse have many similarities; in both cases the following responses occur EXCEPT:

- A. maximum oxygen consumption decreases
 - B. cardiac output decreases
 - C. blood pressure increases
 - D. in all cases, only young people are able to benefit from exercise
 - E. in all cases both young and old people are able to benefit from exercise.
- Answer: D

WHAT IS ISSUES OF GENDER, POVERTY, DISABILITY, AND MIGRATION: CULTURAL BIAS AND DISCRIMINATION. STIGMA, MARGINALIZATION, AND SOCIAL SUFFERING; CHILD ABUSE AND DOMESTIC VIOLENCE?

ISSUES OF GENDER, POVERTY, DISABILITY, AND MIGRATION: CULTURAL BIAS AND DISCRIMINATION. STIGMA, MARGINALIZATION, AND SOCIALSUFFERING; CHILD ABUSE AND DOMESTIC VIOLENCE

Issues of Gender

ANNCREASE GENDER REPRESENTATION/ GENDER BALANCE

One of the main objectives set by UNI Global Union, through its Equal Opportunities Department has been to attain productive development based on gender equality. We regard this principle as essential to achieving sustainable development and true social justice for everyone.

The Equal Opportunitites Department carries out programmes, campaigns and other activities in order to fulfil this goal, both within the organization and among our affiliates.

VIOLENCE AGAINST WOMEN

The socially and culturally built hierarchy between the genders holds certain power relationships. Any power relationship is asymmetrical by definition, i.e. one of the subjects of the relationship has power and the other one does not.

Usually, men are socially regarded as being of higher value. This asymmetrical situation is present in many areas of social life and can lead to violence (physical, verbal, or psychological). Studies show that more than 1/3 of the women around the world have experienced violence at some point in their lives and it can happen at the workplace.

SEXUAL HARASSMENT

Sexual harassment is a form of violence that through a show of power intimidates, humiliates, and affects another person's dignity. This behavior is sexual in nature (physical contacts, sexual advances, comments and jokes with sexual content, exhibiting pornographic material or making inappropriate comments) and undesired; it is perceived by the victim as a condition to keep the job, or as one that creates a hostile, intimidating, and humiliating work environment.

THE WAGE GAP

One of the areas at the workplace where gender differences are seen is the difference in the remuneration that men and women workers receive for work of equal value. A study by the International Labour Organization in 2013 shows that the global wage gap is 23%.

However, this number does not account for the millions of women working in the informal economy with no protection. Also, many countries lack reliable statistics to prepare more accurate reports, therefore, this already high figure will be even higher. Access to education continues to be key to bridging the wage gap. However, it is not the only instrument, since women with higher education are at the ends of the gap with their male peer. For that reason, UNI has pledged to work to make ILO Convention 100 requiring equal remuneration for men and women workers for work of equal value effective in every work site.

WOMEN'S HEALTH

Health is a universal human right. That's why, irrespective of religion, age or where we live, we have a right to the information and the healthcare services that allow us to care for our bodies and our quality of life.

It is not just being free of illnesses, but also having access to reasonable standards of living, housing, food, decent work, as well as appropriate level of medical assistance so that we can develop our full potential as individuals.

To be able to truly achieve gender equality, we need to look at the health and well-being of women. This is a precondition for the promotion of the sustainable growth of our communities.

WORK - LIFE BALANCE

Globalization of the economy has brought about changes in the labour market structure and labour organization, which had remained stable throughout the 20th century. The traditional model of sexual division of labour had placed productive tasks (supporting and providing for the family) in the hands of men and reproductive ones in the hands of women (caring for children and the elderly, housekeeping chores.)

Today, women increasingly share the provider role with men. However, there has not been a similar change in the distribution of domestic work. For that reason, women with both roles (productive and reproductive) work more hours than men, get less rest, and are burdened with a heavy workload that puts their health at risk and limits their chances of developing a professional career.

We must then reflect upon these issues and devise policies intended to balance work and family life to overcome gender inequalities, so that both men and women may have access to a full family life and a professional career.

In many parts of the world, technological innovations such as artificial intelligence (AI), robotics and machine learning are impacting society. These new technologies allow us to communicate faster, share information and feel closer to each other. They are, today, an essential part of our lives and provide us with unprecedented opportunities to advance in areas ranging from education to political participation.

Its use and dissemination is so common that we do not see the impact they have on women. Technology is a reflection of reality, and if we do not work to eradicate the inequalities and prejudices that they transmit, we will continue to widen those gaps we want to close today.

The UNI Equal Opportunities department has begun to address the issue of the impact of digitalization on women by writing conceptual documents that will help continue discussions on this issue.

Our first document: "Digitization from a gender perspective", was intended to explain what digitalization means, and how it will affect the world of work, in particular, working women.

A second document: "The road to digitalization without gender" was written as part of a

collaboration with the European group of experts "Friends of Europe" for its report "Policy options for a digital era". This second document explores further the impact of technology and artificial intelligence on women, the prejudices that permeate the development of these technologies and how they contribute to the gender gap, promoting possible solutions to these issues.

GENDER ISSUES IN INDIA:

Political Economy

In 2016, India ranked 130 out of 146 in the Gender Inequality Index released by the UNDP. It is evident that a stronger turn in political discourse is required, taking into consideration both public and private spaces. The normalization of intra-household violence is a huge detriment to the welfare of women. Crimes against women have doubled in the period between 1991 and 2011. NFHS data reports that 37 per cent of married women in India have experienced physical or sexual violence by a spouse while 40 per cent have experienced physical, sexual or emotional violence by a spouse. While current policy discourse recommends employment as a form of empowerment for women, data presents a disturbing correlation between female participation in labour force and their exposure to domestic violence. The NFHS-3 reports that women employed at any time in the past 12 months have a much higher prevalence of violence (39-40 per cent) than women who were not employed (29 per cent). The researchers advocate a multi-faceted approach to women's empowerment beyond mere labour force participation, taking into consideration extra-household bargaining power.

Gender inequality extends across various facets of society. Political participation is often perceived as a key factor to rectify this situation. However, gender bias extends to electoral politics and representative governance as well. The relative difference between male and female voters is the key to understanding gender inequality in politics. While the female voter turnout has been steadily increasing, the number of female candidates fielded by parties has not increased. More women contest as independents, which does not provide the cover for extraneous costs otherwise available when they are part of a political party.

However, women also act as agents of political change for other women. In the Bihar elections in 2005, when re-elections were held, the percentage of female voters had increased from 42.5 to 44.5 percent while those of male voters declined from 50 to 47 per cent in the interim period of eight months. As a direct result, 37 per cent of the constituencies saw anti-incumbency voting. The average growth rate of women voters was nearly three times in those constituencies where there was a difference in the winning party. District-wise disaggregation of voter registration also supports this hypothesis in the case of Bihar indicating the percolation of the winds of change. This illustration proves that women are no longer under the complete control of the men in their family in terms of electoral participation. The situation is only bound to improve from here. With the introduction of Electronic Voting Machines (EVMs), vulnerable sections like women now have more freedom of choice in their vote. Further, poll related incidents of violence against women have significantly decreased since the phased introduction of EVMs across multi-level elections in India. Extending the conversation to political representation is the next phase in the conversation. Women make up merely 22 per cent of lower houses in parliaments around the world and in India, this number is less than half at 10.8 per cent in the outgoing Lok Sabha. A steady increase in female voter participation has been observed across India, wherein the sex ratio of voters (number of female voters vis-à-vis male) has increased from 715 in the 1960s to 883 in the 2000s. Our studies have shown that women are more likely to contest elections in states with a skewed gender ratio. In the case of more developed states, they seek representation through voting leading to an

increase in voter participation.

The situation can be rectified by providing focused reservation for those constituencies with a skewed sex ratio. Reducing the entry costs (largely non-pecuniary in nature – cultural barriers, lack of exposure) for women in order to create a pipeline of female leaders is another solution. These missing women, either as voters or leaders point to the gross negligence of women at all ages.

FINANCIAL INCLUSION

In the developing world, women have traditionally been the focus of efforts of financial inclusion. They have proved to be better borrowers (40 per cent of Grameen Bank's clients were women in 1983. By 2000, the number had risen to 90 per cent) – largely attributed to the fact that they are less mobile as compared to men and more susceptible to peer pressure. However, institutions in microfinance are exposed to the trade-off between market growth and social development since having more female clients lead to the inevitable drip-down of social incentives. As an attempt to overcome this hurdle, a larger role can be played by donors with a gender driven agenda, for the financial inclusion sector will drive the idea further.

Gendered contextualisation of products is highly necessary for microfinance institutions (MFIs) – men and women do not ascribe to choices in a similar fashion. Trends emerging from prior research indicates that when health insurance coverage was held under the MFI sector, by both men and women, women benefited from the coverage only so far as they were the holders and not using spousa status (if their husbands were insured). Thus healthcare seeking behaviour becomes an important factor to be considered in insurance coverage under the MFIs.

The JAM trinity – Jan Dhan Yojana, Aadhar, Mobile – can be used to improve financial inclusion from a gender perspective as well. The metrics to consider would be the number of Jan Dhan accounts held by women, percentage of women holding Aadhar cards and access to mobile connectivity for women.

HEALTH

In terms of healthcare focusing on women, the Janani Suraksha Yojana (JSY) and National Health Mission are vital to the policy landscape. The JSY has improved maternal healthcare in India through the emphasis on institutional deliveries. Increase of 22 per cent in deliveries in government hospitals, was mirrored by an 8 per cent decline in childbirth at private hospitals and a 16 per cent decline in childbirth at home. The National Health Mission's ASHA led to greater awareness and education of pregnant women as well as an increase in institutional maternal and neonatal healthcare. Improved infrastructure for maternal and neo-natal has been observed in community hospitals, in addition to the introduction of ambulance services.

A gendered increase in seek care is observed with a large 13 per cent increase in the number of women who report being sick in the last 15 days, driving the overall reportage. Further, an eight per cent decline in rural women seeking private healthcare, has been reported, while a 58 per cent increase in women seeking hospitalization has been reported. Further disaggregated, the data shows a 75.7 per cent increase for rural women seeking healthcare. The overall increase in usage of public hospitals is almost entire driven by rural women who saw an increase of 24.6 per cent in utilisation of public hospitals over the 10 years (2004-2014). Our results show that the JSY had a significant, positive impact on overall hospitalisation of women in India. It increased the probability of a woman being hospitalised by approximately 1.3 per cent.

The healthcare sector in India has largely focused on maternal healthcare for women. The importance of research on mental health has been ignored in policy discourse. The significant relationship that mental health bears on violence has also been explored in further research. Every fifth suicide in India is that of a housewife (18 per cent overall) – the reportage of suicide deaths has been most consistent among housewives as a category, than other categories. India is the country with the largest rate of female deaths due to ‘intentional violence’.

Our work on childhood violence shows that girls are twice more likely to face sexual violence than boys before the age of 18. Larger the population of educated females in the country, lesser is the incidence of childhood violence at home – including lesser violent discipline, physical punishment as well as psychological aggression. Additionally, the lifetime experience of sexual violence by girls is strongly correlated with the adolescent fertility rate in a country. Further, a strong relationship is observed between female experience of sexual violence and female labour force participation within a country. The results show that the higher the labour force participation by women in a country, the higher is the incidence of sexual violence against them. This could be indicative of adverse working conditions within labour markets, and the difficulty of access to labour markets by young women in a country

POVERTY IN INDIA

Two-thirds of people in India live in poverty: 68.8% of the Indian population lives on less than \$2 a day. Over 30% even have less than \$1.25 per day available - they are considered extremely poor. This makes the Indian subcontinent one of the poorest countries in the world; women and children, the weakest members of Indian society, suffer most.

India is the second most populous country after China with about billion people and is the seventh largest country in the world with an area of 3,287,000 km². The highly contrasted country has enjoyed growth rates of up to 10% over many years and is one of the largest economies in the world, with a gross domestic product (GDP) of 1,644 billion US dollars. But only a small percentage of the Indian population has benefited from this impressive economic boom so far, as the majority of people in India are still living in abject poverty.

Poverty in India: from the village to the slum

More than 800 million people in India are considered poor. Most of them live in the countryside and keep afloat with odd jobs. The lack of employment which provides a livable wage in rural areas is driving many Indians into rapidly growing metropolitan areas such as Bombay, Delhi, Bangalore or Calcutta. There, most of them expect a life of poverty and despair in the mega-slums, made up of millions of corrugated ironworks, without sufficient drinking water supply, without

garbage disposal and in many cases without electricity. The poor hygiene conditions are the cause of diseases such as cholera, typhus and dysentery, in which especially children suffer and die.

Poverty in India impacts children, families and individuals in a variety of different ways through:

- High infant mortality
- Malnutrition
- Child labour
- Lack of education
- Child marriage
- HIV / AIDS

The high infant mortality

1.4 million children die each year in India before their fifth birthday. In addition to Nigeria, Pakistan, the Democratic Republic of the Congo and China, India is one of the countries with the highest child mortality rates. Pneumonia, malaria and diarrheal diseases as well as chronic malnutrition are the most frequent causes of death.

Malnutrition - not even a bowl of rice a day India is one of the world's top countries when it comes to malnutrition: More than 200 million people don't have sufficient access to food, including 61 million children. 7.8 million infants were found to have a birth weight of less than 2.5 kilograms - alarming figures for a country commonly referred to as the emerging market.

Child labour - no time to play and learn

Although child labour for children under the age of 14 in India is prohibited by law, according to official figures, 12.5 million children between the ages of 5 and 14 are working. Aid agencies assume that in reality, there are many more estimating that 65 million children between 6 and 14 years do not go to school. Instead, in order to secure survival, it is believed that Indian children contribute to the livelihood of their families; they work in the field, in factories, in quarries, in

private households and in prostitution

Lack of education - no opportunities without education

According to UNICEF, about 25% of children in India have no access to education. The number of children excluded from schools is higher among girls than boys. Although women and men are treated equally under Indian law, girls and women, especially in the lower social caste, are considered inferior and are oppressed by their fathers, brothers and husbands. Without education, the chance of finding a living wage from employment in India is virtually hopeless.

Child marriage - the early end of childhood

In spite of banning minors from marrying in 2006, it is still widespread in many regions of India. The main leaders in this practice are young girls, who are still children themselves and become mothers too early. Many of them die at birth. According to an investigation by the medical journal The Lancet, 44.5% of girls are still married in India before they are of legal age. Due to poverty, many parents encourage early marriages for their daughters in hopes of better lives for them.

DISABILITY IN INDIA

As per Census 2011, in India, out of the 121 Cr population, about 2.68 Cr persons are 'disabled' which is 2.21% of the total population. In an era where 'inclusive development' is being emphasised as the right path towards sustainable development, focussed initiatives for the welfare of disabled persons are essential. This emphasises the need for strengthening disability statistics in the Country.

There are ample reasons for developing a sound national disability statistics. Information on their

socio - demographic profile is essential for welfare of disabled persons. Information about their functional status is important to identify needs since two individuals with the same impairment may face different types of difficulties in undertaking certain activities, and so have different needs that require different kinds of interventions.

Functional status data is essential for determining the broader social needs of persons with disabilities, such as provision of assistive technology for use in employment or education or broader policy and laws. Population disability data is essential for monitoring the quality and outcomes of policies for persons with disabilities. In particular, these data help to identify policy outcomes that maximize the participation of persons with disabilities in all areas of social life from transportation and communication, to participation in community life. Finally, with complete and reliable disability statistics, state agencies will have the tools for assessing the cost-effectiveness of policies for persons with disabilities, which in turn can provide the evidence to persuade governments of their ultimate benefit for all citizens.

The National Policy for Persons with Disabilities (2006) recognizes that Persons with Disabilities are valuable human resource for the country and seeks to create an environment that provides equal opportunities, protection of their rights and full participation in society. To facilitate the national objective, there is a need for collection, compilation and analysis of data on disability.

A number of International commitments and guidelines came into effect in the recent past targeting the welfare of the disabled persons. India is a signatory to the 'Declaration on the Full Participation and Equality of People with Disabilities in the Asia Pacific Region' (2000). India has ratified the 'UN Convention on the rights of Persons with Disabilities' (2008). India is also a signatory to the 'Biwako Millennium Framework' (2002) for action towards an inclusive, barrier free and rights based society.

The 'Biwako Plus Five (2007): further efforts towards an inclusive, barrier-free and rights-based society for persons with disabilities in Asia and the Pacific' added the emphasis. The Incheon Strategy to "Make the Right Real" for Persons with Disabilities in Asia and the Pacific (2012) provides the Asian and Pacific region and the world with the first set of regionally agreed disability inclusive development Goals. The Incheon strategy will enable to track progress towards improving the quality of life, and the fulfilment of the rights, of the region's persons with disability. The Sustainable Development Goals (2015) pledges for 'leaving no one behind'. Recognizing that the dignity of the human being is fundamental, the SDGs wish to see the Goals and targets met for all nations and peoples and for all segments of society and to endeavour to reach the furthest behind first.

The implementation and monitoring of these international commitments demand sound database of disabled persons. Issues in measuring disability Some of the important issues being faced while developing a strong disability statistics are as follows:

DEFINING DISABILITY:

The definition of the population with disabilities is a key element in the design of a data collection activity, for it sets the scope and coverage of the whole data collection process. From the conceptual point of view, there is no universal definition of what constitutes a disability or of who should be considered as having a disability. Moreover, there is no one static condition of disability. A disability is a result of the interaction between a person with a health condition and a particular

environmental context. Individuals with similar health conditions may not be similarly disabled or share the same perception of their disability, depending on their environmental adaptations. For example, having access to technical aids, services or medication, or physical adaptation to the environment may allow individuals to overcome their disabling conditions. Disability is not an all-or-nothing phenomenon but involves degrees of difficulty, limitation or dependence, ranging from slight to severe. Questions should be designed to capture those with severe as well as those with less severe forms of disabling conditions and should take into account any assistive devices or accommodations that the person may have. Coverage: Different purposes require different disability data. Eliciting information:

In places where disability is a stigma, people may be reluctant to report it. Also, this being a very sensitive question, the investigators need to be adequately trained to collect data on disabilities. The design of questions to identify persons in the population with disabilities presents complex problems. But efforts are to be made to design the questionnaire in such a manner that, all the target population could be correctly identified. Emerging data requirements in the context of recent international commitments Incheon Strategy to “Make the Right Real” for Persons with Disabilities in Asia and the Pacific The Governments of the ESCAP region gathered in Incheon, Republic of Korea, from 29 October to 2 November 2012 to chart the course of the new Asian and Pacific Decade of Persons with Disabilities for the period 2013 to 2022 and adopted the Incheon strategy which comprises 10 goals, 27 targets and 62 indicators. The Incheon strategy builds on the Convention on the Rights of Persons with Disabilities (CRPD) and the Biwako Millennium Framework for Action and Biwako Plus Five towards an Inclusive, Barrier – free and Rights - based Society for Persons with Disabilities in Asia and the Pacific. This will enable the region to track the progress towards improving the quality of life, and the fulfilment of the rights of the region’s persons with disabilities. Goal 8 of the Incheon strategy specifically aims to ‘Improve the reliability and comparability of disability data’.

MEASURING DISABILITY IN INDIA

The UN convention on the Persons with disabilities and its Optional Protocol was adopted on 13 December, 2006 at the United Nations Headquarters in New York. The Convention came into effect on 3 May, 2008. The Convention is intended as a human rights instrument with an explicit, social development dimension. It adopts a broad categorisation of persons with disabilities and reaffirms that all persons with all types of disabilities must enjoy all human rights and fundamental freedoms.

It clarifies and qualifies how all categories of rights apply to persons with disabilities and identifies areas where adaptations have to be made for persons with disabilities to effectively exercise their rights and areas where their rights have been violated, and where protection of rights must be reinforced.

The purpose of the UN Convention on the Rights of Persons with Disabilities (UN CRPD) is to promote, defend and reinforce the human rights of all persons with disabilities. International Classification of Functioning, Disability and Health (ICF) The International Classification of Functioning, Disability and Health, known more commonly as ICF, provide a standard language and framework for the description of health and health-related states. Like the first version published by the World Health Organization for trial purposes in 1980, ICF is a multipurpose classification intended for a wide range of uses in different sectors. It is a classification of health and health-related domains – domains that help us to describe changes in body function and structure, what

a person with a health condition can do in a standard environment (their level of capacity), as well as what they actually do in their usual environment (their level of performance).

SAMPLE SURVEYS ON DISABILITY BY NSSO

National Sample Survey Office (NSSO), made its first attempt to collect

- information on the number of physically handicapped in its 15th round (July 1959- June 1960) which was confined to rural areas only. In NSSO 16th round (July 1960 – June 1961) the coverage was extended to
- urban areas. The subject was again taken up for nationwide survey in its 24th round (July 1969- June 1970) and 28th round (October 1973- June 1974). The physical handicaps covered in the above mentioned surveys were not
- always same and information was collected through survey schedules meant for other subjects. First comprehensive survey in NSS 36th round (July- Dec 1981) followed by a
- survey in 47th round (July- December 1991) to cover all persons with one or more of the three physical disabilities – visual, communication (ie. Hearing and or speech) and locomotor. The last survey was carried out by NSS in its 58th round (July- December
- 2002), which extended the coverage by mental disability in addition to the three physical disabilities (visual, communication an
- locomotor). Along with the particulars of physical and mental disabilities, the socio economic characteristics of the disabled such as their age, literacy, employment, vocational training etc were collected.

SOCIOCULTURAL BIASES AND DISCRIMINATION

The presence and persistence of sociocultural biases and discriminatory attitudes and practices can be readily identified as major contributors to vulnerability. Bias and discrimination are in a sense acts of social exclusion, as they prevent the groups that are the victims of those acts from fully participating in and benefiting from the wealth, power, knowledge and decision-making capacities of the larger society.

At their worst, socio-economic biases and discrimination can produce feelings of disempowerment, hopelessness and despair for the future, further exacerbating vulnerability among the excluded groups. The inability to provide input to important policy decisions leaves them powerless and voiceless, resulting in their legitimate interests not being protected. Consequently, national policies and development programmes do not necessarily benefit those that are disenfranchised.

Still, worse, their interests may even be sacrificed in the pursuit of such policies and programmes. As a result, social groups, households and individuals subject to such misperception and discrimination experience greater vulnerability to social exclusion. 206. The following are presented below as illustrations of the negative effects of bias and discrimination: the images and misperceptions of older persons; the vulnerabilities experienced by migrants; discrimination against the disabled; groups particularly a risk in situations of conflict; and the lack of respect for traditional knowledge and cultures of indigenous persons.

IMAGES AND MISPERCEPTIONS OF OLDER PERSONS

On one level, perceptions of older persons follow the trajectory of a society's culture, religion, language, history and level of development. On another, they follow social conventions that adhere to established precedents and, once rooted, are difficult to alter. The social convention of

classifying people on the basis of their age has enduring consequences that can create significant barriers to access and participation. Older persons are critical and active partners in families and societies through the care they provide to family members who might otherwise require more formal treatment; through the care and education they provide to children whose parents cannot afford childcare or who migrate elsewhere for work; through the countless other forms of volunteer work that they perform in communities and institutions everywhere; and through their help in conflict resolution and the rebuilding of communities following emergencies. In addition, older persons possess traditional knowledge and overall survival strategies accumulated over a lifetime of experience.

Paradoxically, however, older persons are cast in distorted images that inflate their physical and mental deterioration and dependence. The outcome is an anachronistic message that, on the broader level, colours an entire phase of life. It obscures older persons' contributions and generates ageism, discrimination and exclusion and, ultimately, contributes to a loss of rights in the social, economic and political spheres. Routine media misrepresentation that idolizes youth and views ageing as a time of incapacity and stagnation is particularly damaging to older persons, who already suffer greater exclusion, especially in an era of rapid technological change in which authority is often passed to younger members of society. Significantly, such images are not lost on centres of influence and power, such as employers, donors and policy makers – decision makers who can have an impact on older persons' access to structures and resources and therefore mitigate or increase vulnerability.

Globalization of the media has contributed to spreading ageism to societies in which it was traditionally unknown. The forces of globalization that have ushered in consumerism and individualism in developing countries have compounded the devaluation of the status of older persons, encouraging the view that they are burdens and a financial drain. The effects are becoming visible far beyond the local level, with a lack of opportunities for older persons, combined with the absence of economic assets and added responsibilities owing to the outmigration of younger adults, conspiring to force older persons into greater economic and social dependence. Negative self-image is inextricably bound up with stereotypes and is another factor that leads to social exclusion. Older persons with strong tendencies towards a negative self-image are also those who are in the greatest need of support. Those in poverty and conflict show a marked decline in self-esteem as they age and tend to share a view of ageing as a time of worthlessness, incapacity and loss of status that leads to dependence. For many, fears and self-doubt accumulate to such an extent that what is feared – exclusion and greater physical and economic dependence – becomes more likely. Low self-esteem becomes a risk in itself and helps to foster an image of a population with whom no one, including older persons themselves, wants to identify.

The perpetuation of misperceptions of ageing has a political impact as well. The expression "intergenerational conflict", which has appeared in the public discourse, suggests that, if steps are not taken, individual old-age pension and health-care security, or worse, national or even global financial stability, may be threatened with disruption. Such messages suggest a need to assign responsibility and ultimately serve as a pretext for cutting back on old-age provisions. Perceptions that an ageing society will deepen social conflict, however, are not so rooted in prejudices as to hold any particular age group responsible. Rather, social, economic and politically uncertain environments, with the support of the media, are reshaping attitudes about society's unpreparedness to adjust to a changed demographic structure that has no precedent and therefore no previous

basis from which to proceed.

Women and men move through the ageing process in different ways and encounter different obstacles and relative disadvantages en route. For women, balancing work and family responsibilities can be all-consuming. Their role as principal caregiver in the family often lingers into old age, when they care for their spouses and/or, in areas ravaged by poverty and disease, including HIV/AIDS, for their grandchildren and other family members who are orphaned or sick.

MIGRANTS' VULNERABILITIES

Migration is a pervasive issue that has a bearing on the economy, the social fabric and the political life of many countries. Viewpoint on migration are polarized to the degree that it is difficult to hold a rational debate on the issue. Against such a background of contention, the human dimension of international migration has often been missing from the policy agenda, and many migrants have increasingly found themselves vulnerable

First, in the course of the migration process, individuals lose the security of essential family-, community- and nation-based support structures, including traditional institutions that regulate power, decision-making and protection, while at the same time they are exposed to a host of hazards for which they are largely unprepared. To a significant extent, the vulnerability of migrants stems from the nature of the immigration process, which remains, in much of the world – apart from a handful of traditional countries of immigration – long, challenging and poorly organized. During the course of the immigration process, migrants often receive little assistance from the host country and end up relying on immigrant communities and immigration networks of questionable legitimacy. In trying to circumvent admissions delays and restrictions, an increasing number of migrants are putting themselves at risk by electing to be smuggled.

STIGMA

Stigma is when someone views you in a negative way because you have a distinguishing characteristic or personal trait that's thought to be, or actually is, a disadvantage (a negative stereotype). Unfortunately, negative attitudes and beliefs toward people who have a mental health condition are common.

Stigma can lead to discrimination. Discrimination may be obvious and direct, such as someone making a negative remark about your mental illness or your treatment. Or it may be unintentional or subtle, such as someone avoiding you because the person assumes you could be unstable, violent or dangerous due to your mental illness. You may even judge yourself.

Some of the harmful effects of stigma can include:

- Reluctance to seek help or treatment
- Lack of understanding by family, friends, co-workers or others
- Fewer opportunities for work, school or social activities or trouble finding housing
- Bullying, physical violence or harassment
- Health insurance that doesn't adequately cover your mental illness treatment
- The belief that you'll never succeed at certain challenges or that you can't improve your situation

STEPS TO COPE WITH STIGMA

Here are some ways you can deal with stigma:

- **Get treatment.** You may be reluctant to admit you need treatment. Don't let the fear of being labeled with a mental illness prevent you from seeking help. Treatment can provide relief by identifying what's wrong and reducing symptoms that interfere with your work and personal life.
- **Don't let stigma create self-doubt and shame.** Stigma doesn't just come from others. You may mistakenly believe that your condition is a sign of personal weakness or that you should be able to control it without help. Seeking counseling, educating yourself about your condition and connecting with others who have mental illness can help you gain self-esteem and overcome destructive self-judgment.
- **Don't isolate yourself.** If you have a mental illness, you may be reluctant to tell anyone about it. Your family, friends, clergy or members of your community can offer you support if they know about your mental illness. Reach out to people you trust for the compassion, support and understanding you need.
- **Don't equate yourself with your illness.** You are not an illness. So instead of saying "I'm bipolar," say "I have bipolar disorder." Instead of calling yourself "a schizophrenic," say "I have schizophrenia."
- **Join a support group.** Some local and national groups, such as the National Alliance on Mental Illness (NAMI), offer local programs and internet resources that help reduce stigma by educating people who have mental illness, their families and the general public. Some state and federal agencies and programs, such as those that focus on vocational rehabilitation and the Department of Veterans Affairs (VA), offer support for people with mental illness.
- **Get help at school.** If you or your child has a mental illness that affects learning, find out what plans and programs might help. Discrimination against students because of a mental illness is against the law, and educators at primary, secondary and college levels are required to accommodate students as best they can. Talk to teachers, professors or administrators about the best approach and resources. If a teacher doesn't know about a student's disability, it can lead to discrimination, barriers to learning and poor grades.
- **Speak out against stigma.** Consider expressing your opinions at events, in letters to the editor or on the internet. It can help instill courage in others facing similar challenges and educate the public about mental illness.

Others' judgments almost always stem from a lack of understanding rather than information based on facts. Learning to accept your condition and recognize what you need to do to treat it, seeking support, and helping educate others can make a big difference.

SOCIAL DETERMINANTS OF CHILD ABUSE

Globally, child abuse (or child maltreatment) is a significant public health problem extending beyond culture, social context and race. Child abuse consists of any acts of commission or omission by a parent, caregiver or other adult resulting in harm, potential for, or threat of harm to a child (0-18 years of age) even if the harm is unintentional. The World Health Organization (WHO) estimates that 40 million children aged 0-14 years globally suffer from abuse and neglect that require health and social care.

The extent and trend of national or global rates, and determinants of child abuse are largely unknown. Studies in Egypt are sparse, estimating that 37% of children in Egypt suffer physical punishment with varying degrees of severity; ⁵ these acts of punishment, presumably committed as acts of child discipline, are engendered by a culture that places a high premium on child

obedience and the positive effects of discipline

Social determinants of health (SDH) are conditions in which people are born, grow, live, work and age, including the health system. These conditions provide the freedom people need to live lives they value, and are shaped by the distribution of money, power and resources at global, national and local levels. SDH that perpetuate child abuse can be avoided by reasonable societal level action; however, that they are not avoided indicates that they are unfair, unnecessary, unjust, and therefore inequitable. Given children's need for safe, healthy, nurturing, and responsive living environments, the SDH that perpetuate child abuse are numerous, and need to be examined to understand the association between child abuse and intimate partner violence (IPV).

Children exposed to child abuse are often exposed to co-occurring domestic violence (DV) and environmental stressors. Households frequently experiencing IPV are commonly poor, undergo marital problems, life stressors, and other negative aspects of family life, including low parental education, unemployment, insufficient income, and substance abuse. Other factors associated with increased risk for child abuse include young child age, minority status, and parental stress, immigrant families, single-parent families, stepfamilies, families with three or more children, children 0 - 3 years old, female sex, and older adolescence. Perpetrator-related risk factors such as parental mental health, chronic illness, criminal history, alcohol or drug abuse, and parental skills have also been implicated with child abuse and IPV.

Knowledge of how the social determinants of child abuse operate and interact is an important first step towards developing interventions and policy-level change needed to improve the lives of affected children and families. To assess for associations, the following hypotheses were tested

Hypothesis I: The risk of experiencing child abuse will be higher for children exposed to domestic violence, even after controlling for potential confounders;

Hypothesis II: Mothers with tolerant attitudes towards wife beating will be more likely to abuse their child than those who do not tolerate wife beating;

Hypothesis III: Women exposed to generational IPV i.e. who had witnessed domestic violence in childhood, will be more likely to perpetrating child abuse, compared to those who were not so exposed; and

Hypothesis IV: Children in families of higher socio-economic position (SEP), as indicated by educational level of respondent or partner, and household wealth index, will be at lower risk of experiencing abuse compared to those of lower SEP.

The aim of this study was two-fold:

- i. to determine the prevalence of child abuse in Egypt; and
- ii. to investigate factors associated with maternal abuse as social determinants of child abuse.

DOMESTIC VIOLENCE

Domestic violence (also called intimate partner violence (IPV), domestic abuse or relationship abuse) is a pattern of behaviors used by one partner to maintain power and control over another partner in an intimate relationship

Domestic violence does not discriminate. Anyone of any race, age, sexual orientation, religion or gender can be a victim – or perpetrator – of domestic violence. It can happen to people who are married, living together or who are dating. It affects people of all socioeconomic backgrounds and education levels.

Domestic violence includes behaviors that physically harm, arouse fear, prevent a partner from doing what they wish or force them to behave in ways they do not want. It includes the use of physical and sexual violence, threats and intimidation, emotional abuse and economic deprivation. Many of these different forms of domestic violence/abuse can be occurring at any one time within the same intimate relationship.

Think of the wheel as a diagram of the tactics an abusive partner uses to keep their victim in the relationship. While the inside of the wheel is comprised of subtle, continual behaviors, the outer ring represents physical, visible violence. These are the abusive acts that are more overt and forceful, and often the intense acts that reinforce the regular use of other more subtle methods of abuse.

Although this Power & Control Wheel uses she/her pronouns for the victim and assumes a male perpetrator, abuse can happen to people of any gender in any type of relationship

IT'S NOT ALWAYS EASY TO TELL AT THE BEGINNING OF A RELATIONSHIP IF IT WILL BECOME ABUSIVE.

In fact, many abusive partners may seem absolutely perfect in the early stages of a relationship. Possessive and controlling behaviors don't always appear overnight, but rather emerge and intensify as the relationship grows.

Domestic violence doesn't look the same in every relationship because every relationship is different. But one thing most abusive relationships have in common is that the abusive partner does many different kinds of things to have more power and control over their partner.

Some of the signs of an abusive relationship include a partner who:

- Tells you that you can never do anything right
- Shows extreme jealousy of your friends and time spent away
- Keeps you or discourages you from seeing friends or family members
- Insults, demeans or shames you with put-downs
- Controls every penny spent in the household
- Takes your money or refuses to give you money for necessary expenses
- Looks at you or acts in ways that scare you
- Controls who you see, where you go, or what you do
- Prevents you from making your own decisions
- Tells you that you are a bad parent or threatens to harm or take away your children
- Prevents you from working or attending school
- Destroys your property or threatens to hurt or kill your pets
- Intimidates you with guns, knives or other weapons
- Pressures you to have sex when you don't want to or do things sexually you're not comfortable with
- Pressures you to use drugs or alcohol

Explore the tabs below to learn some of the common warning signs of each type of abuse. Experiencing even one or two of these behaviors in a relationship is a red flag that abuse may be present. Remember, each type of abuse is serious, and no one deserves to experience abuse of any kind, for any reason. If you have concerns about what's happening in your relationship, contact us. We're here to listen and support you!

PHYSICAL ABUSE

You may be experiencing physical abuse if your partner has done or repeatedly does any of the following tactics of abuse:

- Pulling your hair, punching, slapping, kicking, biting or choking you
- Forbidding you from eating or sleeping
- Hurting you with weapons
- Preventing you from calling the police or seeking medical attention
- Harming your children
- Abandoning you in unfamiliar place
- Driving recklessly or dangerously when you are in the car with them
- Forcing you to use drugs or alcohol (especially if you've had a substance abuse problem in the past)

Abuse Defined You are here:

What Is Domestic Violence?

DOMESTIC VIOLENCE (ALSO CALLED INTIMATE PARTNER VIOLENCE (IPV), DOMESTIC ABUSE OR RELATIONSHIP ABUSE) IS A PATTERN OF BEHAVIORS USED BY ONE PARTNER TO MAINTAIN POWER AND CONTROL OVER ANOTHER PARTNER IN AN INTIMATE RELATIONSHIP.

Domestic violence does not discriminate. Anyone of any race, age, sexual orientation, religion or gender can be a victim – or perpetrator – of domestic violence. It can happen to people who are married, living together or who are dating. It affects people of all socioeconomic backgrounds and education levels.

Domestic violence includes behaviors that physically harm, arouse fear, prevent a partner from doing what they wish or force them to behave in ways they do not want. It includes the use of physical and sexual violence, threats and intimidation, emotional abuse and economic deprivation. Many of these different forms of domestic violence/abuse can be occurring at any one time within the same intimate relationship.

Here at The Hotline, we use the **Power & Control Wheel*** to describe most accurately what occurs in an abusive relationship.

Think of the wheel as a diagram of the tactics an abusive partner uses to keep their victim in the relationship. While the inside of the wheel is comprised of subtle, continual behaviors, the outer ring represents physical, visible violence. These are the abusive acts that are more overt and forceful, and often the intense acts that reinforce the regular use of other more subtle methods of abuse.

*Although this Power & Control Wheel uses she/her pronouns for the victim and assumes a male perpetrator, abuse can happen to people of any gender in any type of relationship. Click image to enlarge. Warning Signs of Domestic Violence

IT'S NOT ALWAYS EASY TO TELL AT THE BEGINNING OF A RELATIONSHIP IF IT WILL BECOME ABUSIVE.

In fact, many abusive partners may seem absolutely perfect in the early stages of a relationship. Possessive and controlling behaviors don't always appear overnight, but rather emerge and intensify as the relationship grows.

Domestic violence doesn't look the same in every relationship because every relationship is different. But one thing most abusive relationships have in common is that the abusive partner does many different kinds of things to have more power and control over their partner.

Some of the signs of an abusive relationship include a partner who:

- Tells you that you can never do anything right
- Shows extreme jealousy of your friends and time spent away
- Keeps you or discourages you from seeing friends or family members
- Insults, demeans or shames you with put-downs
- Controls every penny spent in the household
- Takes your money or refuses to give you money for necessary expenses
- Looks at you or acts in ways that scare you
- Controls who you see, where you go, or what you do
- Prevents you from making your own decisions
- Tells you that you are a bad parent or threatens to harm or take away your children
- Prevents you from working or attending school
- Destroys your property or threatens to hurt or kill your pets
- Intimidates you with guns, knives or other weapons
- Pressures you to have sex when you don't want to or do things sexually you're not comfortable with
- Pressures you to use drugs or alcohol

EMOTIONAL ABUSE

You may be in an emotionally/verbally abusive relationship if your partner exerts control

through:

- Calling you names, insulting you or continually criticizing you
- Refusing to trust you and acting jealous or possessive
- Trying to isolate you from family or friends
- Monitoring where you go, who you call and who you spend time with
- Demanding to know where you are every minute
- Trapping you in your home or preventing you from leaving Using weapons to threaten to hurt you
- Punishing you by withholding affection
- Threatening to hurt you, the children, your family or your pets
- Damaging your property when they're angry (throwing objects, punching walls, kicking doors, etc.)
- Humiliating you in any way
- Blaming you for the abuse
- Gaslighting
- Accusing you of cheating and being often jealous of your outside relationships
- Serially cheating on you and then blaming you for his other behavior
- Cheating on you intentionally to hurt you and then threatening to cheat again
- Cheating to prove that they are more desired, worthy, etc. than you are
- Attempting to control your appearance: what you wear, how much/little makeup you wear, etc.
- Telling you that you will never find anyone better, or that you are lucky to be with a person like them

SEXUALLY ABUSIVE METHODS OF RETAINING POWER AND CONTROL INCLUDE AN ABUSIVE PARTNER:

- Forcing you to dress in a sexual way Insulting you in sexual ways or calls you sexual name
- Forcing or manipulating you into to having sex or performing sexual acts
- Holding you down during sex
- Demanding sex when you're sick, tired or after hurting you
- Hurting you with weapons or objects during sex
- Involving other people in sexual activities with you against your will
- Ignoring your feelings regarding sex
- Forcing you to watch pornography
- Purposefully trying to pass on a sexually transmitted disease to you

SEXUAL COERCION

Sexual coercion lies on the 'continuum' of sexually aggressive behavior. It can vary from being egged on and persuaded, to being forced to have contact. It can be verbal and emotional, in the form of statements that make you feel pressure, guilt, or shame. You can also be made to feel forced through more subtle actions. For example, an abusive partner:

- Making you feel like you owe them — ex. Because you're in a relationship, because you've had sex before, because they spent money on you or bought you a gift
- Giving you drugs and alcohol to "loosen up" your inhibitions Playing on the fact that you're in a relationship, saying things such as: "Sex is the way to prove your love for me," "If I don't get sex from you I'll get it somewhere else
- Reacting negatively with sadness, anger or resentment if you say no or don't immediately agree to something

- Continuing to pressure you after you say no
- Making you feel threatened or afraid of what might happen if you say no
- Trying to normalize their sexual expectations: ex. “I need it, I’m a man”

Even if your partner isn’t forcing you to do sexual acts against your will, being made to feel obligated is coercion in itself. Dating someone, being in a relationship, or being married never means that you owe your partner intimacy of any kind.

REPRODUCTIVE COERCION IS A FORM OF POWER AND CONTROL WHERE ONE PARTNER STRIPS THE OTHER OF THE ABILITY TO CONTROL THEIR OWN REPRODUCTIVE SYSTEM. IT IS SOMETIMES DIFFICULT TO IDENTIFY THIS COERCION BECAUSE OTHER FORMS OF ABUSE ARE OFTEN OCCURRING SIMULTANEOUSLY.

Reproductive coercion can be exerted in many ways:

- Refusing to use a condom or other type of birth control
- Breaking or removing a condom during intercourse
- Lying about their methods of birth control (ex. lying about having a vasectomy, lying about being on the pill)
- Refusing to “pull out” if that is the agreed upon method of birth control
- Forcing you to not use any birth control (ex. the pill, condom, shot, ring, etc.)
- Removing birth control methods (ex. rings, IUDs, contraceptive patches)
- Sabotaging birth control methods (ex. poking holes in condoms, tampering with pills or flushing them down the toilet)
- Withholding finances needed to purchase birth control
- Monitoring your menstrual cycles
- Forcing pregnancy and not supporting your decision about when or if you want to have a child
- Forcing you to get an abortion, or preventing you from getting one
- Threatening you or acting violent if you don’t comply with their wishes to either end or continue a pregnancy
- Continually keeping you pregnant (getting you pregnant again shortly after you give birth)

Reproductive coercion can also come in the form of pressure, guilt and shame from an abusive partner. Some examples are if your abusive partner is constantly talking about having children or making you feel guilty for not having or wanting children with them especially if you already have kids with someone else.

ECONOMIC OR FINANCIAL ABUSE IS WHEN AN ABUSIVE PARTNER EXTENDS THEIR POWER AND CONTROL INTO THE AREA OF FINANCES. THIS ABUSE CAN TAKE DIFFERENT FORMS, INCLUDING AN ABUSIVE PARTNER:

Giving an allowance and closely watching how you spend it or demanding receipts for purchase

- Placing your paycheck in their bank account and denying you access to it
- Preventing you from viewing or having access to bank accounts
- Forbidding you to work or limiting the hours that you can work
- Maxing out credit cards in your name without permission or not paying the bills on credit cards, which could ruin your credit score
- Stealing money from you or your family and friends
- Using funds from children’s savings accounts without your permission
- Living in your home but refusing to work or contribute to the household

- Making you give them your tax returns or confiscating joint tax returns
- Refusing to give you money to pay for necessities/shared expenses like food, clothing, transportation, or medical care and medicine

DIGITAL ABUSE IS THE USE OF TECHNOLOGIES SUCH AS TEXTING AND SOCIAL NETWORKING TO BULLY, HARASS, STALK OR INTIMIDATE A PARTNER. OFTEN THIS BEHAVIOR IS A FORM OF VERBAL OR EMOTIONAL ABUSE PERPETRATED ONLINE. YOU MAY BE EXPERIENCING DIGITAL ABUSE IF YOUR PARTNER:

Tells you who you can or can't be friends with on Facebook and other sites

- Sends you negative, insulting or even threatening emails, Facebook messages, tweets, DMs or other messages online.
- Uses sites like Facebook, Twitter, foursquare and others to keep constant tabs on you.
- Puts you down in their status updates.
- Sends you unwanted, explicit pictures and demands you send some in return.
- Pressures you to send explicit videos.
- Steals or insists on being given your passwords.
- Constantly texts you and makes you feel like you can't be separated from your phone for fear that you will be punished.
- Looks through your phone frequently, checks up on your pictures, texts and outgoing calls.
- Tags you unkindly in pictures on Instagram, Tumblr, etc.
- Uses any kind of technology (such as spyware or GPS in a car or on a phone) to monitor you. You never deserve to be mistreated, online or off. Remember:
- Your partner should respect your relationship boundaries.
- It is ok to turn off your phone. You have the right to be alone and spend time with friends and family without your partner getting angry. You do not have to text any pictures or statements that you are uncomfortable sending, especially nude or partially nude photos, known as "sexting."
- You lose control of any electronic message once your partner receives it. They may forward it, so don't send anything you fear could be seen by others.
- You do not have to share your passwords with anyone.
- Know your privacy settings. Social networks such as Facebook allow the user to control how their information is shared and who has access to it. These are often customizable and are found in the privacy section of the site. Remember, registering for some applications (apps) require you to change your privacy settings.
- Be mindful when using check-ins like Facebook Places and foursquare. Letting an abusive partner know where you are could be dangerous. Also, always ask your friends if it's ok for you to check them in. You never know if they are trying to keep their location secret.
- You have the right to feel comfortable and safe in your relationship, even online.

WHAT IS PEACE PSYCHOLOGY: VIOLENCE, NON-VIOLENCE, CONFLICT RESOLUTION AT MACRO LEVEL, ROLE OF MEDIA IN CONFLICT RESOLUTION?

Peace psychology

Peace psychology, area of specialization in the study of psychology that seeks to develop theory and practices that prevent violence and conflict and mitigate the effects they have on society. It also seeks to study and develop viable methods of promoting peace.

The roots of peace psychology are often traced to William James and a speech he gave at Stanford University in 1906. With World War I on the horizon, James talked about his belief that

war satisfies a deeply felt human need for virtues such as loyalty, discipline, conformity, group cohesiveness, and duty. He also observed that individuals who belong to a group, whether military or otherwise, experience a boost in self-pride when they are proud of their group. Most important, he argued that war is not likely to be eliminated until humans have created a "moral equivalent of war," such as public service that allows people to experience the virtues that were associated with war making.

Many other psychologists and philosophers wrote about the psychology of peace. A partial list includes Alfred Adler, Gordon Allport, Jeremy Bentham, James McKeen Cattell, Mary Whiton Calkins, Sigmund Freud, William McDougall, Charles Osgood, Ivan Pavlov, and Edward Tolman. Even Pythagoras would qualify, because of his writings on nonviolence and appreciation for the more-insidious form of violence called structural violence, which kills people slowly by depriving them of basic need satisfaction (e.g., poverty).

A recurrent theme among peace psychologists has been that war is built, not born, and the related idea that war is biologically possible but not inevitable. Those ideas are captured in a number of manifestos issued by psychologists. One statement was signed by almost 4,000 psychologists after World War II. Another, the Seville Statement, was issued in 1986 by 20 highly respected scientists during the United Nations International Year of Peace. Because war is built or constructed, a great deal of research in peace psychology has sought to identify environmental conditions that are linked to violence and peaceful behaviour.

Peace psychology was given a significant boost during the Cold War (c. mid-1940s through the early 1990s), when the conflict between the United States and Soviet Union heated up and the threat of nuclear annihilation seemed imminent, leading psychologists to create concepts to better understand intergroup conflict and its resolution. Also important was the establishment of the 48th division of the American Psychological Association, called Peace Psychology, in 1990. Shortly thereafter, a journal was established, *Peace and Conflict: Journal of Peace Psychology*. Since then, doctoral-level training programs in peace psychology have been established around the world. Peace psychology is now global in scope. It recognizes that violence can be cultural, which occurs when beliefs are used to justify either direct or structural violence. Direct violence injures or kills people quickly and dramatically, whereas structural violence is much more widespread and kills far more people by depriving them of satisfaction of their basic needs. For example, when people starve even though there's enough food for everyone, the distribution system is creating structural violence. If a person justifies the deaths of starving people by blaming them for their situation (called blaming the victim), that person is engaging in cultural violence. Direct violence is supported by the culturally violent notion of just war theory, which argues that under certain conditions, it is acceptable to kill others (e.g., defense of the homeland, using war as a last resort). One of the main challenges for peace psychology is to deepen understanding of the structural and cultural roots of violence, a problem that is particularly important when security concerns revolve around the prevention of terrorism.

PSYCHOLOGY'S ROLE IN WORLD WAR I AND II

The concerns of peace psychologists are deeply rooted in the field of psychology, not only because the promotion of human well-being is central to the mission of psychology (APA Bylaws) but also because psychologists have long been concerned about war and peace. William James, a founder of psychology in the United States, has been regarded as the first peace psychologist (Deutsch, 1995). Just prior to World War I, James gave an address on "the moral equivalent of war"

in which he highlighted the enthusiastic readiness of humans to rally around the military flag (James, 1995), a social psychological phenomena akin to “nationalism” that has played out repeatedly for generations, especially when relations between nations become hostile. James argued that militaristic urges are deeply rooted in humans and that societies must learn to channel the satisfaction of their needs in productive directions. Psychologists did not follow James’ advice, but they did become involved in U.S. military affairs during the First World War.

Among the more important contributions of psychologists to the war effort was the development of group intelligence tests that were used to select and classify new recruits, a development that “put psychology on the map” (Smith, 1986, p.24). Psychologists had even greater involvement during the Second World War. A number of specialties in psychology emerged and supported the war effort. Clinical psychologists developed and administered tests to place personnel within the military establishment and they also treated war-related emotional problems. Social psychologists contributed their expertise, developing propaganda designed to promote the war effort by boosting morale at home and demoralizing the enemy abroad.

A number of psychologists worked with the Office of Strategic Services, the precursor of the Central Intelligence Agency, selecting and training people involved in “undercover” activities in Europe and the Far East. Human factors psychologists participated in the design of weaponry and other instruments used by the military, and experimental psychologists trained nonhumans to perform human tasks.

The best-known example of the latter was B. F. Skinner’s research in which he trained pigeons to guide pilotless missiles to targets, a program that was ultimately discarded (Herman, 1995). In all these activities, psychologists were enthusiastic participants in the effort to win World War II, a war that was regarded by most people as a just war.

PSYCHOLOGY’S ROLE IN THE COLD WAR

The ideology of Realpolitik has guided the conduct of foreign policy worldwide for nearly three centuries (Klare & Chandrani, 1998). Realpolitik is the belief that politics is reducible to three basic goals: keeping power, increasing power, and demonstrating power (Morganthau, 1972). The international politics of the United States was, and continues to be, primarily guided by the ideology of Realpolitik. From a Realpolitik perspective, one sees security in the international system as the balanced capacity among states to use coercive power. Furthermore, because it is assumed that all sovereign states seek to maximize their power, and they operate within an international structure that is anarchical, the best way to ensure security is to be militarily strong and to adopt a policy of deterrence. According to the logic of deterrence, each state can best ensure its security by threatening any would-be aggressor with a retaliatory blow that would be unbearably costly to the aggressor. By the conclusion of World War II, a tidy bipolar superpower arrangement had emerged in the world. The United States and Soviet Union were locked into an adversarial relationship in which they competed and concentrated their resources in an arms race, a Cold War that resulted in enormous stockpiles of conventional and nuclear weapons. During the early years of the Cold War, psychologists continued to support the policies of the U.S. government.

Tensions between the United States and Soviet Union grew, as did the arsenals of nuclear weapons that were aimed at each other. There were scattered attempts by committees of the American Psychological Association (APA) and the Society for the Psychological Study of Social Issues (SPSSI) to analyze the implications of the new atomic warfare capability on future international

relations, as well as the potential psychological effects on populations experiencing atomic bombardment. Generally, these early committees lacked focus but agreed that the major psychological concern was citizens' attitudes toward atomic warfare and energy. They "emphasized the need to accurately assess and control public opinion in order to achieve public consensus regarding foreign relations and atomic war" (Morawski & Goldstein, 1985, p. 278).

THE POST-COLD WAR ERA: PEACE PSYCHOLOGY COMES OF AGE

THE COLD

War was a power struggle of global proportions that made certain categories of violence salient. Using the state as the focal unit of analysis, scholars concentrated their attention on interstate wars, wars of liberation, secessionist movements, civil wars, and wars in which the superpowers directly intervened militarily (i.e., interventionist wars). Although many other forms of violence were prevalent, from a state-centered perspective, what mattered most were those struggles that had a direct bearing on the strategic, U.S.–Soviet balance of power (George, 1983). Since the end of the Cold War in the late 1980s, the planet's bipolar superpower structure has reconfigured dramatically and entirely new categories of security concerns have emerged.

To be sure, the sovereign states of the international system will still have conflicts to manage, but increasingly, patterns of violence are not neatly following the contours of our inherited system of sovereign states. In the post–Cold War era, a complex pattern of interlacing schisms is emerging, which divides people not so much by state boundaries but by ethnicity, religion, economic well being, population density, and environmental sustainability (Klare, 1998).

A small sample of what we are now observing globally is the outbreak of ethnic violence and other forms of identity group conflict and violence, a growing number of economic and political refugees, ecological devastation and pockets of food insecurity, concentrations of drug-related violence, and international terrorism. These problems are within and across international boundaries and underscore the need to reorient peace psychology and enlarge its scope of practice. The current volume was conceived within the context of these new challenges and represents an attempt to reinvigorate the search for psychological analyses that can inform theory and practice in peace psychology for the twenty-first century.

ORGANIZATION OF THE BOOK: THE FOUR-WAY MODEL

Section I: Direct Violence The current volume retains the traditional focus of peace psychology on international relations by applying psychological concepts and theory to problems of interstate violence and the threat of nuclear war. In addition, because direct violence does not neatly follow the contours of the sovereign state system, chapters in Section I reflect a wider radius of violent episodes that vary in scale from two-person intimate relations to the large-scale violence of genocide. While different in scale and complexity, these varied forms of violence share several features: They all engender direct, acute insults to the psychological or physical well-being of individuals or groups, and they erupt periodically as events or episodes. The analytic tools of peace psychologists are central to understanding many forms of direct violence. For instance, in Section I, many of the contributors from around the world underscore the importance of social identity processes, which are manifest when individuals begin to identify with particular groups and favor their ingroups over outgroups. Quite naturally, the basic need to have a sense of who we are is inextricably woven into the fabric of our identity groups. Conflict and violence often erupts when two or more groups of individuals have different identities and see each other as threats to

their identity group's continued existence.

These identity-based conflicts are central to many forms of violence including hate crimes, gang violence, ethnic conflicts, and even genocide. Sovereign states have been woefully inadequate in dealing with identity-based problems. Also reflected throughout the text is peace psychologists' growing appreciation for the structural roots of violent episodes. For example, patriarchal structures in which males dominate females play a role in intimate violence. Similarly, cultural narratives that denigrate gays, lesbians, and other marginalized identity groups are predisposing conditions for direct violence. Section II looks closer at some forms of violence that are deeply rooted in the structures of a society, what we are calling "structural violence." Section II: Structural Violence Today, an increasing number of peace psychologists are concerned about structural violence (Galtung, 1969), an insidious form of violence that is built into the fabric of political and economic structures of a society (Christie, 1997; Pilisuk, 1998; Schwebel, 1997).

Structural violence is a problem in and of itself, killing people just as surely as direct violence. But structural violence kills people slowly by depriving them of satisfying their basic needs. Life spans are curtailed when people are socially dominated, politically oppressed, or economically exploited.

Structural violence is a global problem in scope, reflected in vast disparities in wealth and health, both within and between societies. Section II examines a number of forms of structural violence, all of which engender structure-based inequalities in the production, allocation, and utilization of material and non-material resources. Galtung (1969) proposed that one way to define structural violence was to calculate the number of avoidable deaths. For instance, if people die from exposure to inclement conditions when shelter is available for them somewhere in the world, then structural violence is taking place. Similarly, structural violence occurs when death is caused by scarcities in food, inadequate nutrition, lack of health care, and other forms of deprivation that could be redressed if distribution systems were more equitably structured. The chapters in Section II make it clear that structural violence is endemic to economic systems that produce a concentration of wealth for some while exploiting others, political systems that give access to some and oppress others, and hierarchical social systems that are suffused with ethnocentrism and intolerance.

CONFLICT RESOLUTION AND MANAGEMENT: THE MACRO PERSPECTIVE

Conflicts arise from the pursuit of divergent interests, goals and aspirations by individuals or groups in a defined social and physical environment. According to

[1] changes in the social environment such as contestable access to new political positions or perceptions of new resources arising from development in the physical environment are fertile grounds for conflicts involving individuals and groups, who are interested in using the new resources to achieve their goals. The past ten to fifteen years were characterized by the occurrence of some of the most violent conflicts among several ethnic and religious communities in different regions and states of Nigeria. As in

[2] hardly was any region spared some of these conflicts, even though the conflicts differed either in prevalence and intensity, or their protracted or nonprotracted nature. By definition, it implies that conflict is natural to human nature. That is, all humans or groups of humans have goals and interests which may be different with the goals and interests of other groups.

This makes conflict inevitable. Change is a natural phenomenon that produces the major social

forces that shape societies. When these changes occur, especially at the middle and micro levels where their effects are individually or personally experienced, they do not happen quickly but are gradual in altering the ecological order, the system of stratification and the social institutions of an entire society causing societies to undergo industrial, political and urban revolution leaving in its wake social problems such as political and economic exclusion of some groups, injustice, poverty, exploitation, diseases, inequality etc.

These conditions place some people or group at an advantage over others and the inability of the social structures in place to bridge this gap and where possible reduce the disparity can cause frustrations and acts of aggression from the disadvantaged individuals or groups.

Where these shows of frustration and aggression are ignored and not nipped at the bud, they most often are excuses to violently play out the hostility towards the exploitative group or groups and may escalate to become larger than the small groups or individuals involved to include an entire ethnic groups or organizations.

OVERVIEW OF CONFLICT

Conflict is an inevitable phenomenon in this universe. As long as humankind exists, there must be conflict. Conflict has been variously defined by different authors but it is technically seen as an opposition among social entities directed against each other [3]. Similarly, [4] sees conflict as a political process that generates from diversity of choices and distribution of scarce resources in the society. [5] further adds that the occurrence of cheat and aggressive behavior on the part of individuals or groups that lead to the frustration of others may cause conflict. Also [6] states that conflict is the struggle over values or claims to states, power and scarce resources which the aims of the group or individuals involved are not only to obtain the desired values but are to neutralize, injure or eliminate rivals. Thus, conflict is present when two or more parties perceive that their interests are incompatible, express hostile attitudes, or take, pursue their interests through actions that damage the other parties. These parties may be individuals, small or large groups, and countries. From the foregoing, it can be deduced that opposition is the order of contrast to cooperation. Meaning that wherever and whenever cooperation and understanding is lacking opposition sets in.

Therefore, conflict can be explained to be an adversarial relationship involving at least two individuals or collective actors over a range or series of issues such as resources control, power, status, values, goals interest etc. Conflict is a social situation in which at least two parties are involved who strive for goals, making it goal oriented or directed activity designed to improve the position of one party at the expense of the other.

It is a perceived state of incompatibility between two or more people or groups and among values where the achievement of one value can be realized only at the expense of the other values. Conflict is an escalated competition between two or more parties each of which aims to gain advantage of some kind and at least one of the parties believes that the conflict is over a set of mutually incompatible goals. Conflicts may or may not be expressed in behaviours. It is one of the energies of life and thus common, natural and unavoidable but its pattern of expression can make or mar any relationship.

3. CONCEPT OF MACRO

Conflict When individuals or groups who had previously been latent over their grievances,

oppressions, deprivation, injustices etc suddenly or gradually begin to express these feelings through certain obnoxious behaviours in order to call for attention to their situation which escalates to an entire group, ethnic, state or even national and international, macro conflict has occurred. Macro level conflicts are expression of existing adversary's relationships through aggressive behaviours as a result of unresolved incompatible interest in the social structure of the system or organization. These lapses in the structural functionalism of a society make it difficult for the rules and status that exists to provide social control or social order which is necessary for survival.

Macro conflicts are open or external expression of dissatisfaction of the aggrieved group which is aimed at injuring the other party or reducing it if not totally eliminating the existing relationship between both groups. Conflict that has degenerated to macro level becomes difficult and complex for the parties involved to personally resolve their differences alone without the aid of external assistance. Most times the aggrieved parties may not even be able to state the immediate or direct cause of conflict as they usually lose track of the original causes of grievance.

Again, conflicts can escalate to its macro level as a result of the presence of indirect or secondary parties to the conflict. These groups of persons or organizations complicate conflict situations and are difficult to identify because their involvements are by proxy through provisions of war aid and weapons, financial support etc.

They are known as "shadow" parties in conflict. Macro conflicts focus on the broader impacts or effects of conflict or its lack thereof. It considers a wider aspect in conflict such as an entire society, age group or age bracket, population groups, countries, economies, social class etc. Macro conflict goes beyond an individual or organization and conflict at the macro level changes social stratification, economic power and diplomatic stance of a society and thereby its future.

Causes of Macro Conflict Resources

Conflicts can emerge due to resources. These conflicts arise when two or more groups aspire for the same scarce resources and where the aspiring parties demanding for these resources are more than the available scarce resources. The desire for control of the available scarce resources by a privileged group to the disadvantage of the other aspirants can cause conflicts e.g. the Niger Delta Region crises in Nigeria. Values: Conflicts may arise due to differences in the value of the people or organization. Values here include philosophy, ideologies, religions etc.

The value a group of people or ethnic nationality places on another group may be a constant cause for conflict especially where these values or perceptions are discriminatory and undermines the other group thereby limiting the prospects in certain areas of their lives or hindering their access to certain self actualizing opportunities. Values can bring about oppressive and unequal social structures.

e.g Fulani Cattle Herdsmen and some indigent communities in Northern Nigeria, the Igbo cast system.

MACRO CONFLICT RESOLUTION AND MANAGEMENT

Conflict at the macro level has most often gone beyond the control of the conflicting parties, so even when they see the need for peace, may require the presence and assistance of a third party to

initiate the peace move. The third party usually provides neutral ground that are safe enough for peace talk and unbiased opinions for conflicting parties to consider and upon which their decision can be based. Also, warring or conflicting groups may want to enter into peace talks through representative bodies who are expected to, if possible find lasting solution to the existing strives. Conflict resolution is seen by [10] as a variety of approaches aimed at terminating conflict through the constructive solving of problem while conflict management is defined as the process of reducing the negative and destructive capacity of conflict through a number of measures and by working with and through the parties involved in the conflict. For the purpose of this paper, conflict resolution and management is defined as constructive processes or procedures adopted for solving problems which are aimed at terminating conflicts or reducing its negative and destructive effects by working with and through the conflicting parties.

This means that some conflicts can be permanently resolved when the basic needs of the parties have been met with all necessary satisfiers and their fears allayed and there are non-resolvable conflicts and these can be transformed, regulated or managed e.g. values. Management of conflicts covers the entire handling of conflict positively through its different stages, including efforts made towards prevention by being proactive, conflict limitation, containment and litigation. According to [7], conflict management promotes conditions in which collaborative and values relationships control the behaviour of conflicting parties

CONCLUSION

Conflicts are natural phenomenon in human society. Depending on their intensity, conflicts are expressed sometimes in violent or non-violent ways. They are social situations in which at least two parties with incompatible goals strive to achieve these goals at the expense of each other. Conflicts occur at all levels of human interaction. Macro conflicts focus on the broader impacts of conflict on entire groups or social strata.

The causes of conflict are varied and includes resources, values, oppressive social order, mismanagement of information etc. and these could be permanently resolved but where this is impossible will be managed through collaboration, alternative dispute resolution (ADR), negotiation, conciliation, mediation, arbitration, adjudication, crisis management and multi-track approach methods. Conflict is an inevitable occurrence in every human existence, at all levels and takes different forms which could be either violent or non-violent ways.

THE ROLE OF THE MEDIA IN PEACE BUILDING, CONFLICT MANAGEMENT, AND PREVENTION

Information is power and insight can impact on public discourse. This way, perceptions can be changed by access to media. Different types of media are utilised globally to distribute knowledge and idealistically, free mass media is a tool of and signpost for democracy. Freedom of expression is not only the core of a healthy media but also a fundamental human right and vital for a democratic structure. It stands for freedom of speech, the right to information and the representation of different opinions in a heterogeneous society. In any culture of prevention, effective and democratic media are an essential part and indispensable for societies trying to make a transition towards peace and democracy. Harry S. Truman once said "You can never get all the facts from just one newspaper, and unless you have all the facts, you cannot make proper judgements about what is going on this statement reflects the need for free access to unbiased information. Not giving people the possibility of political participation and not allowing them to express themselves freely is a significant cause of conflict. On the one hand free, independent and

pluralistic media provide a platform for debate and different opinions. On the other hand, media can be misused for propaganda purposes, to incite hatred and spread rumours and therefore artificially create tensions.

The transmission of ideas is also not limited to conventional media such as newspapers, TV or radio.

Lack of information can, at any stage of a conflict, make people desperate, restless and easy to manipulate. The ability to make informed decisions strengthens societies and fosters economic growth, democratic structures and the positive outlook on the future. For this very reason, the United Nations Millennium Declaration stressed the need "to ensure the freedom of the media to perform their essential role and the right of the public to have access to information.

Journalism does not need justification for its existence. Its service to society is justification in itself. Journalism can not only help to distribute information but also counter hate-speech and create an environment of balanced opinions, an information equilibrium]. For the media it can be problematic to find a balance between preventing harm caused by speech and protecting individual expression. Being able to find this balance, however is important especially in conflict situations. Responsible journalism does not just re-publish press releases but is truly concerned with a truthful, balanced and fair account of events. In order to achieve this journalists have to stay clear of judgemental representations and describe reality without embellishment]. If democracy is to work properly, society needs access to news and information; analysis of the status quo, debate, practical information and exchange as well as entertainment are needed and provided by the media. The definition of conflict and defining conflict areas is not easy and no two places are alike. Journalists need to know what they can expect on sight in order to define the objectives of their project.

In case of a crisis or a conflict, the international media can attract worldwide attention. The mass media is a pervasive part of daily life especially in industrialised countries and thus able to shine a light on conflicts anywhere in the world. Since most armed conflicts these days have governmental and not territorial reasons; the parties are often concerned with making sure that the majority of people are on "their" side, which bears a lot of potential for misrepresenting facts and trying to seize control over the distribution of information. For this very reason the intervention of unbiased and free global media is important not only for the world public but also for the people directly affected. The number of conflicts, however, that gets international attention is small; therefore local media is vital in this context.

Broadcasting news by using community radios can help reach people in different areas, even with different languages more easily. This way people can be addressed directly and their own personal experiences and lives can be incorporated much better, than with foreign media. The danger of manipulation and inflammation of ethnic tensions, however, cannot be ignored. Another advantage of local media, especially radio is that in border areas it is possible to convey peace messages to passing fighters and refugees alike]. Democratic media structures need more than this; it is vital that the use of information within a society is not solemnly passive but that the population gets actively involved in creating content and broadcasting it[

WHAT IS WELLBEING AND SELF-GROWTH: TYPES OF WELLBEING [HEDONIC AND EUDEMONIC], CHARACTER STRENGTHS, RESILIENCE AND POST-TRAUMATIC GROWTH?

WELLBEING

Well-being is the experience of health, happiness, and prosperity. It includes having good mental health, high life satisfaction, a sense of meaning or purpose, and ability to manage stress. More generally, well-being is just feeling well (Take this quiz to discover your level of well-being.) Well-being is something sought by just about everyone, because it includes so many positive things — feeling happy, healthy, socially connected, and purposeful. Unfortunately, well-being appears to be in decline, at least in the U.S. And increasing your well-being can be tough without knowing what to do and how to do it.

These are some of the reasons why I founded The Berkeley Well-Being Institute — an organization that translates the science of well-being into simple tools and products that help you build your well-being. And they are the reasons why I wrote *Outsmart Your Smartphone: Conscious Tech Habits for Finding Happiness, Balance, and Connection IRL*, which helps people tackle new challenges that interfere with our well-being in the technology age.

Can You Actually Improve Your Well-Being

Increasing your well-being is simple; there are tons of skills you can build. But increasing your well-being is not always easy: Figuring out what parts of well-being are most important for you and figuring out how, exactly, to build well-being skills usually require some extra help.

How Long Does It Take to Improve Well-Being?

Usually when people start consistently using science-based techniques for enhancing well-being, they begin to feel better pretty quickly. In the studies I've conducted and read, most people show significant improvements within five weeks.

But you have to stick to it. If you are feeling better after five weeks, you can't just stop there. Why? Well, you probably already know that if you stop eating healthy and go back to eating junk food, then you'll end up back where you started. It turns out that the exact same thing is true for different types of well-being. If you want to maintain the benefits you gain, you'll have to continue to engage in well-being-boosting practices to maintain your skills. So it's really helpful to have strategies and tools that help you stick to your well-being goals — for example, a happiness and well-being plan or a well-being boosting activity that you can continue to use throughout your life.

Here's what you need to know:

Where Does Well-Being Come From?

Well-being emerges from your thoughts, actions, and experiences most of which you have control over. For example, when we think positive, we tend to have greater emotional well-being. When we pursue meaningful relationships, we tend to have better social well-being. And when we lose our job — or just hate it — we tend to have lower workplace well-being. These examples start to reveal how broad well-being is, and how many different types of well-being there are.

Because well-being is such a broad experience, let's break it down into its different types.

5 MAJOR TYPES OF WELL-BEING

- Emotional Well-Being. The ability to practice stress-management techniques, be resilient, and

generate the emotions that lead to good feelings.

- Physical Well-Being. The ability to improve the functioning of your body through healthy eating and good exercise habits.
- Social Well-Being. The ability to communicate, develop meaningful relationships with others, and maintain a support network that helps you overcome loneliness.
- Workplace Well-Being. The ability to pursue your interests, values, and purpose in order to gain meaning, happiness, and enrichment professionally.
- Societal Well-Being. The ability to actively participate in a thriving community, culture, and environment.

To build your overall well-being, you have to make sure all of these types are functioning to an extent.

Think of it like this: Imagine you are in a car. Your engine works great, and maybe your transmission works pretty well, too, but your brakes don't work. Because your brakes don't work, it doesn't really matter how well your engine works; you're still going to have trouble going about your life.

The same is true for your well-being. If everything else in your life is going great, but you feel lonely, or you're eating unhealthfully, other areas of your life will be affected, and you likely won't feel as well as you want to.

Because each part of well-being is important to your overall sense of well-being, let's talk about how to build each type of well-being:

Emotional Well-Being. To develop emotional well-being, we need to build emotional skills — skills like positive thinking, emotion regulation, and mindfulness, for example. Often, we need to build a variety of these skills to cope with the wide variety of situations we encounter in our lives. When we have built these emotional well-being skills, we can better cope with stress, handle our emotions in the face of challenges, and quickly recover from disappointments. As a result, we can enjoy our lives a bit more, be happier and pursue our goals a bit more effectively.

Here are some of the skills that research suggests contribute to emotional well-being:

- Happiness Skills
- Mindfulness Skills
- Positive Thinking Skills
- Resilience Skills

Physical Well-Being. To develop our physical well-being, we need to know what a healthy [diet](#) and exercise routine looks like, so that we can implement effective strategies in our daily lives. When we improve our physical well-being, not only do we feel better, our newfound health can also help prevent many diseases, heal our guts, boost our emotional well-being, and limit the number of health challenges we have to deal with in our lives.

Here are some of the things that can help you boost your physical well-being:

- Eating for Health
- Detoxing Your Body
- Correcting Nutritional Deficiencies
- Removing Plastic From Your Home

Unfortunately, it's possible to eat healthy but still be unhealthy. We can accidentally miss important foods or nutrients. Or we can overburden ourselves with toxins from plastic or processed food. As a result, we may need to eat additional foods, detox our bodies, or prevent these toxins from entering our bodies again. This is why it's essential to learn about health, so that we can make the right changes – those that lead to long-term health and well-being.

Social Well-Being. To develop social well-being, we need to build our social skills, like gratitude, kindness, and communication. Social skills make it easier for us to have positive interactions with others, helping us to feel less lonely, angry, or disconnected. When we have developed our social well-being, we feel more meaningfully connected to others.

Here are some of the skills that research suggests contribute to better social well-being:

- Practicing Gratitude
- Building Meaningful Social Connections
- Managing Your Relationship with Technology

It's important to know that building social well-being is one of the best ways to build emotional well-being. When we feel socially connected, we also tend to just feel better, have more positive emotions, and we are able to cope better with challenges. This is why it's essential to build our social well-being.

Workplace Well-Being. To develop our workplace well-being, we need to build skills that help us pursue what really matters to us. This can include building professional skills which help us to advance more effectively, but it also includes things like living our values and maintaining work-life balance. These skills let us enjoy our work more, helping us to stay focused, motivated, and successful at work. When we have developed workplace well-being, our work, and therefore each day, feels more fulfilling.

Here are some of the key skills you need for workplace well-being:

- Maintaining Work-Life Balance
- Finding Your Purpose

Because we spend so much time at work, building our workplace well-being has a big impact on our overall well-being.

Societal Well-Being. To develop societal well-being, we need to build skills that make us feel interconnected with all things. We need to know how to support our environment, build stronger local communities, and foster a culture of compassion, fairness, and kindness. These skills help us feel like we're part of a thriving community that really supports one another and the world at large. When we cultivate societal well-being, we feel like we are a part of something bigger than just ourselves and live happily.

Although each of us only makes up a tiny fraction of a society, it takes all of us to create societal well-being. If each of us did one kind act for someone else in our community, then we would live in a very kind community. Or if all of us decide we are going to recycle, then suddenly we create a world with significantly less waste. In order to live in a healthy society, we too need to contribute to making a healthy society.

Here are some of the skills you can build for greater societal well-being:

- Living Your Values
- Creating a Plastic-Free Home
- Making Positive Impacts in Other People's Lives
- Kindness

Who Benefits Most from Building Well-Being?

Not everyone experiences the same benefits from building their well-being. For example, lots of research suggests that the more motivated you are to build well-being skills, the greater the impact. Perhaps this is not surprising.

Still other research shows that having skills like a growth mindset or a positive attitude can actually help you build your other well-being skills more easily. This is why I tend to encourage people to build these skills first – afterward, you may be able to increase the other types of well-being more easily. In addition, building well-being skills is perhaps most beneficial for people struggling the most, particularly if they've recently undergone something stressful. It may be harder to build well-being during this time, but the impact may be greater, because there is more room for improvement.

There Is No Magic About Building Well-Being

Keep in mind, it takes time and effort to build any new skill set – that includes well-being skills. It's important to be realistic with yourself about what you can reasonably accomplish in a given amount of time. Having unrealistic expectations can lead you to give up before you've reached your well-being goals. So it's key to create a realistic plan for your well-being, stick to it, and take small actions every day that add up to big improvements up over time.

If you've read my earlier posts, you might know that I too have struggled with aspects of my well-being, particularly with maintaining work-life balance. The truth is, we all struggle, and new struggles can and will pop up, even if you're doing well. But the longer we've worked on strengthening our well-being skills, the easier it is to be resilient, take the actions needed to bounce back, and continue moving forward.

Growing your well-being is a lifelong pursuit, but it is totally worth it.

HEDONIC AND EUDAIMONIC WELL-BEING

Hedonic versus Eudaimonic Conceptions of Well-being: Evidence of Differential Associations with Self-reported Well-being Conceptions of well-being are individuals' cognitive representations of the nature and experience of well-being. Numerous professional thinkers from a broad range of disciplines have theorized about the nature of well-being and "the good life", providing explicit conceptualizations of the experience of well-being. Contemporary psychological research has also begun to examine how laypersons conceptualize and think about the nature of well-being (e.g., King and Napa 1998; McMahan and Estes 2010; Ng et al. 2003), often focusing on the degree to which individuals define well-being in hedonic (e.g., the experience of pleasure) and eudaimonic (e.g., the experience of meaning) terms.

As a fundamental representation of wellness, these conceptions likely exert a pervasive influence on behavior and psychological functioning. In two studies, the above research is extended by investigating the relative effects of both hedonic and eudaimonic dimensions of individual conceptions of well-being on several aspects of experienced well-being.

Formal and Lay Conceptions of Well-being Well-being refers to optimal functioning and experience (Ryan and Deci 2001). The precise nature of optimal functioning is not necessarily clear, however, and many philosophers and psychologists provide differing conceptions of well-being. Although numerous and sometimes complex, these conceptions tend to revolve around two distinct, but related philosophies:

- (1) hedonism and
- (2) eudaimonism.

A hedonic view of well-being equates well-being with pleasure and happiness (Kahneman et al. 1999; Ryan and Deci 2001). Alternatively, a eudaimonic view of well-being conceptualizes well-being in terms of the cultivation of personal strengths and contribution to the greater good (Aristotle, trans. 2000), acting in accordance with one's inner nature and deeply held values (Waterman 1993), the realization of one's true potential (Ryff and Keyes 1995), and the experience of purpose or meaning in life (Ryff 1989). Hedonic and eudaimonic approaches to well-being can be further distinguished by the degree to which they rely on subjective versus objective criteria for determining wellness.

To illustrate, determinations of wellness from the hedonic approach center around the experience of pleasure, a subjectively-determined positive affective state. From a eudaimonic perspective, well-being is achieved by meeting objectively-valid needs which are suggested to be rooted in human nature and whose realization is conducive to human growth (Fromm 1947). In short, the hedonic approach focuses on subjectively-determined positive mental states, whereas the eudaimonic approach focuses on experiences that are objectively good for the person (Kagan 1992).

Contemporary research within psychology further indicates that laypeople may also hold conceptions of well-being that are similar to those advocated by professionals (e.g., King and Napa 1998; McMahan and Estes 2010; Ng et al. 2003; Pflug 2009; Tseng 2007). For example, research has found that lay conceptions of well-being incorporate both hedonic and eudaimonic aspects (King and Napa 1998), and individuals differ in the degree to which they conceptualize well-being in hedonic and eudaimonic terms (McMahan and Estes 2010).

Additionally, pleasure and meaning are consistently included in individuals' conceptions of well-being, but highly valued items that are theoretically not considered to be definitive of well-being, such as material wealth, are typically not included (King and Napa 1998; Tseng 2007). In general, laypersons' conceptions of well-being seem to mirror the conceptions of well-being provided by philosophers and psychologists, and laypeople seem to similarly differ in terms of the degree to which they advocate a more hedonic or eudaimonic definition of well-being.

HEDONIC VERSUS EUDAIMONIC APPROACHES TO WELL-BEING

The degree to which individuals define well-being in hedonic and eudaimonic terms has large practical implications and likely influences behavior in several domains of functioning, particularly those relevant to the experience of well-being (Ryan and Deci 2001). Implicit in theorizing on hedonic versus eudaimonic approaches to well-being is the assumption that these approaches are differently associated with positive psychological functioning. Specifically, eudaimonic theories maintain that many desired outcomes which are pleasurable may not necessarily be good for the individual and would thus not promote wellness (Ryan and Deci 2001).

To illustrate, dining at a fine restaurant and running a marathon may yield experiences of a similar hedonic quality, such as the experience of enjoyment and pleasure. However, running a marathon likely provides more opportunity for personal growth, self-development, and feelings of competency than dining at a fine restaurant and would thus likely yield increased well-being. Additionally, eudaimonic approaches to well-being, because they involve activities that are inherently good for the individual, are likely associated with long-term and enduring well-being, whereas the sense of well-being derived from the experience of simple pleasures likely dissipates in the short-term (Steger et al. 2008). In support, research indicates that physical pleasure is associated with life satisfaction in the short-term (i.e., within a day), but not in the long-term (i.e., over several weeks) (Oishi et al. 2001). Further, the positive effects of eudaimonic activity during a single day are associated with subsequent reports of well-being over several days (Steger et al. 2008).

PERSONALLY-EXPRESSIVE ACTIVITIES

(Waterman 2005; Waterman et al. 2008), and psychological well-being (Ryff 1989; Ryff and Singer 1998), have found that behaviors and cognition indicative of a eudaimonic approach are generally associated with positive psychological functioning. Research also indicates that in some cases, behaviors and cognition indicative of a hedonic approach may actually be detrimental to well-being. For example, sensation-seeking has been associated with a number of negative outcomes, including substance use (Carroll and Zuckerman 1977; Zuckerman 1994) and risky behaviors (Zuckerman 2009).

Although a great deal of research has documented the positive effects of eudaimonic activities, less research has examined the relative impact of both hedonic and eudaimonic approaches on well-being. Existing empirical research suggests, however, that eudaimonic approaches may be relatively more important for well-being than hedonic approaches. For example, daily eudaimonic activity was found to be more robustly associated with well-being than behaviors aimed at experiencing pleasure or obtaining material goods (Steger et al. 2008). Similarly, orientation to happiness, a construct measuring the degree to which individuals attempt to achieve happiness through pleasure, meaning, or engagement, has been found to be positively associated with life satisfaction (Peterson et al. 2005). Specifically, orientations to meaning and to engagement, representing eudaimonic approaches to well-being, have been found to be more robustly associated with life satisfaction than an orientation to pleasure in both national (e.g., Peterson et al. 2005) and cross-national studies (Park et al. 2009). Further, lay conceptions of well-being have been found to be associated with multiple self-report indicators of well-being, including satisfaction with life, vitality, positive affect, and meaning in life, with eudaimonic dimensions indicating more numerous and generally stronger associations with well-being than hedonic dimensions (McMahan and Estes 2010).

CHARACTER STRENGTHS

Character Strengths and Virtues is a groundbreaking handbook compiling the work of **researchers** to create a classification system for widely valued positive traits.

This handbook also intends to provide an empirical theoretical framework that will assist positive psychology practitioners in developing practical applications for the field.

There are 6 classes of virtues that are made up of 24 character strengths:

1. **Wisdom** and Knowledge
2. Courage Humanit
3. Justice
4. Temperance
5. Transcendence

Researchers approached the measurement of “good character” based on the strengths of authenticity, persistence, kindness, gratitude, hope, humor, and more.

Before you read on, we thought you might like to **download our 3 Positive Psychology Exercises for free**. These science-based exercises will explore fundamental aspects of positive psychology including strengths, values and self-compassion and will give you the tools to enhance the wellbeing of your clients, students or employees.

Cultures around the world have valued the study of human strength and virtue. Psychologists have a particular interest in it as they work to encourage individuals to develop these traits. While all cultures value human virtues, different cultures express or act on virtues in different ways based on differing societal values and norms.

Martin Seligman and his colleagues studied all major religions and philosophical traditions and found that the same six virtues (i.e. courage, humanity, justice, etc.) were shared in virtually all cultures across three millennia.

Since these virtues are considered too abstract to be studied scientifically, positive psychology practitioners focused their attention on the strengths of character created by virtues, and created tools for their measurement.

The main assessment instruments they used to measure those strengths were

- Structured interviews
- Questionnaires
- Informant Reports
- Behavioral Experiments
- Observations

The main criteria for characters strengths that they came up with are that each trait should:

- Be stable across time and situations
- Be valued in its own right, even in the absence of other benefits
- Be recognized and valued in almost every culture, be considered non-controversial and independent of politics.
- Cultures provide role models that possess the trait so other people can recognize its worth.
- Parents aim to instill the trait or value in their children.

THE CSV HANDBOOK’S LIST

The Handbook delves into each of these six traits. We’ve summarized key points here.

1. VIRTUE OF WISDOM AND KNOWLEDGE

The more curious and creative we allow ourselves to become, the more we gain perspective and wisdom and will, in turn, love what we are learning. This is developing the virtue of wisdom and knowledge. Strengths that accompany this virtue involve acquiring and using knowledge:

- Creativity (e.g. Albert Einstein's creativity led him to acquire knowledge and wisdom about the universe)
- Curiosity
- Open-mindedness
- Love of Learning
- Perspective and Wisdom (Fun fact: many studies have found that adults' self-ratings of perspective and wisdom do not depend on age, which contrasts the popular idea that our wisdom increases with age).

2. VIRTUE OF COURAGE

The braver and more persistent we become, the more our integrity will increase because we will reach a state of feeling vital, and this results in being more courageous in character.

Strengths that accompany this virtue involve accomplishing goals in the face of things that oppose it:

- Bravery
- Persistence
- Integrity
- Vitality

3. VIRTUE OF HUMANITY

There is a reason why Oprah Winfrey is seen as a symbol of virtue for humanitarians: on every show, she approaches her guests with respect, appreciation, and interest (social intelligence), she practices kindness through her charity work, and she shows her love to her friends and family.

Strengths that accompany this virtue include caring and befriending others:

- Love
- Kindness
- Social intelligence

4. VIRTUE OF JUSTICE

Mahatma Gandhi was the leader of the Indian independence movement in British-ruled India. He led India to independence and helped create movements for civil rights and freedom by being an active citizen in nonviolent disobedience. His work has been applied worldwide for its universality. Strengths that accompany this virtue include those that build a healthy and stable community:

- Being an active citizen who is socially responsible, loyal, and a team member.
- Fairness
- Leadership

5. VIRTUE OF TEMPERANCE

Being forgiving, merciful, humble, prudent, and in control of our behaviors and instincts prevents us from being arrogant, selfish, or any other trait that is excessive or unbalanced. Strengths that are included in this virtue are those that protect against excess:

- Forgiveness and mercy
- Humility and modesty
- Prudence
- Self-Regulation and Self-control

6. VIRTUE OF TRANSCENDENCE

The Dalai Lama is a transcendent being who speaks openly why he never loses hope in humanity's potential. He also appreciates nature in its perfection and lives according to what he believes is his intended purpose.

Strengths that accompany this virtue include those that forge connections to the larger universe and provide meaning:

- Appreciation of beauty and excellence
- Gratitude
- Hope
- Humor and playfulness
- **Spirituality**, or a sense of purpose

POSITIVE PSYCHOLOGY & CHARACTER STRENGTHS AND VIRTUES

Positive psychology practitioners can count on practical applications to help individuals and organizations identify their strengths and use them to increase and maintain their levels of well-being. They also emphasize that these character strengths exist on a continuum; positive traits are regarded as individual differences that exist in degrees rather than all-or-nothing categories.

In fact, the handbook has an internal subtitle entitled “A Manual of the Sanities” because it is intended to do for psychological well-being what the DSM does for psychological disorders: to add systematic knowledge and ways to master new skills and topics.

Research shows that these human strengths can act as buffers against mental illness. For instance, being optimistic prevents one’s chances of becoming depressed. The absence of particular strengths may be an indication of psychopathology. Positive psychology therapists, counselors, coaches, and other psychological professions use these new methods and techniques to help build people’s strength and broaden their lives.

It should be noted that many researchers are advocating grouping these 24 traits into just four classes of strength (Intellectual, Social, Temperance, and Transcendence) or even three classes (excluding transcendence), as evidence has shown that these classes do an adequate job of capturing all 24 original traits.

Others caution that people occasionally use these traits to excess, which can become a liability to the person. For example, some people may use humor as a defense mechanism in order to avoid dealing with a tragedy or coma.

WHAT STRENGTHS DO WOMEN SCORE HIGHER?

There’s an interest in identifying dominant character strengths in genders and how it is developed. As Martin Seligman and his colleagues studied all major religions and philosophical traditions to find universal virtues, much of the research on gender and character strengths have been cross-cultural also.

In a study by Brdar, Anic, & Rijavec on gender differences and character strengths, women scored highest on the strengths of honesty, kindness, love, gratitude, and fairness.

Life satisfaction for women was predicted by zest, gratitude, hope, appreciation of beauty/excellence, and love for other women. A recent study by Mann showed that women tend to score higher on gratitude than men. Alex Linley and colleagues reported in a UK study that women not only scored higher in interpersonal strengths, such as love and kindness, but on social intelligence, too.

In a cross-cultural study in Spain by Ovejero and Cardenal, they found that femininity was positively

correlated with love, social intelligence, appreciation of beauty, love of learning, forgiveness, spirituality, and creativity. The more masculine a man was, the more he correlated negatively with these character strengths.

WHAT STRENGTHS DO MEN SCORE HIGHER?

Brdar, Anic & Rijavac reported that men score highest on honesty, hope, humor, gratitude, and curiosity.

Their life satisfaction was predicted by creativity, perspective, fairness, and humor. Alex Linley and colleagues study showed that men scored higher than females on creativity.

Miljković and Rijavec's study found sex differences in a sample of college students. Men not only scored higher in creativity, but also leadership, self-control, and zest. These findings are congruent with gender stereotypes, as the study by Ovejero and Cardenal in Spain showed that men did not equate typical masculine strengths with love, forgiveness, love of learning, and so on.

In a Croatian sample, Brdar and colleagues found that men viewed cognitive strengths as a greater predictor for life satisfaction. Men saw strengths such as teamwork, **kindness**, perspective, and courage to be a stronger connection to life satisfaction than other strengths. There is an important limitation to this sample population, as most of the participants were women.

WHAT CAN WE LEARN FROM BOTH?

While there are differences in character strengths between men and women, there are many that they share. Both genders saw gratitude, hope, and zest as being related to higher life satisfaction, as well as the tendency to live in accordance with the strengths that are valued in their particular culture.

Studies confirm that there is a duality between genders, but only when both genders identify strongly with gender stereotypes. It makes one wonder if men and women are inherently born with certain strengths, or if the cultural influence of certain traits prioritizes different traits based on gender norms.

Development of Character Strengths in Children

Peterson and Seligman's, Character Strengths in Action handbook (2004) theorized that it is not common for some young children to demonstrate gratitude, open-mindedness, authenticity, and forgiveness.

Park and Peterson's study (2006) confirmed this theoretical speculation, concluding that these sophisticated character strengths usually require a degree of cognitive maturation that develops during adolescence. So although gratitude is associated with happiness in adolescents and adulthood, this is not the case in young children.

Park and Peterson's study found that the association of gratitude with happiness starts at age seven "Gratitude is seen as a human strength that enhances one's personal and relational well-being and is beneficial for society as a whole." – Simmel

Although most young children are not yet cognitively mature enough for sophisticated character strengths, there are many fundamental character strengths that are developed at a very early stage. The strengths of love, zest, and hope are associated with happiness starting at a very young age. The strengths of love and hope are dependent on the infant and caregiver relationship. A secure attachment to the caregiver at infancy is more likely to result in psychological and social well adjustment throughout their lives.

The nurturing of a child plays a significant role in their development, and role modeling is an important way of teaching a child certain character strengths as they imitate behavior and can then embrace the strength as one of their own.

Most young children don't have the cognitive maturity to display gratitude but have the ability to display love and hope. Therefore, gratitude must not be expected from a young child but must be taught.

Positive education programs have been developed to help children and adolescents focus on character strengths. There are certain character strengths in adolescents that have a clearer impact on psychological well-being. These strengths must be fostered to ensure life long

fulfillment and satisfaction.

“Character strengths are influenced by family, community, societal, and other contextual factors. At least in theory, character strengths are malleable; they can be taught and acquired through practice.” – Gillham, et al

CHARACTER STRENGTHS AND WELL-BEING IN ADOLESCENTS

The majority of the research today on character strengths focuses on adults, despite the known importance of childhood and adolescence on character development.

Research into character strengths shows which promote positive development and prevent psychopathology.

Dahlsgaard, Park, and Peterson discovered that adolescents with higher levels of zest, hope, and leadership displayed lower levels of anxiety and depression in comparison to their peers with lower levels of these strengths. Other research findings suggested that adolescent character strengths contribute to well-being (Gillham, et al, 2011).

The research suggests that transcendence (eg. gratitude, meaning, and hope) predicts life satisfaction, demonstrating the importance of adolescents developing positive relationships, creating dreams, and finding a sense of purpose.

VIA CHARACTER STRENGTHS YOUTH SURVEY

Parents, educators, and researchers have requested the VIA: institute on character strengths to develop a VIA survey that is especially aimed at youths. Take the **VIA psychometric data – youth survey** if you are between the ages of 10-17.

CONCLUSION

The measurement of character strengths and the different traits that go into making them have many applications, from life satisfaction to happiness and other well-being predictors. These measurement tools have been used to study how these strengths have been developed across genders and age groups.

What strengths do you possess? What implications can you see this research having in our world today? Can you see how it may apply to your own life?

Please share your thoughts in the comment section below. We hope you enjoyed reading this article. Don't forget to **download our 3 Positive Psychology Exercises for free**. If you wish for more, our **Positive Psychology Toolkit**© contains over 300 science-based positive psychology exercises, interventions, questionnaires and assessments for practitioners to use in their therapy, coaching or workplace.

RESILIENCE AND POST-TRAUMATIC GROWTH

Resilience: How we piece ourselves back together Resilience is a broad and complex concept that encompasses all the patterns of behavior which contribute to a person adapting to distressing life circumstances. Resilience is the ability to cope with negative emotions that arise from a stressful experience and function at normal or close to normal capacity; resilience then is a demonstration of survival in the face of overwhelming life circumstances. A range of factors have been identified

that are linked to resiliency—they encompass attributes of a person, such as being sociable, having a sense of humor and being hopeful; as well as social dimensions such as experiences of parental warmth, nurturing in the family unit, support at school and success in at least one area of life .

Resilience in a specific area of one's life does not guarantee resilience across all functional areas. Indeed, research into, and theories of resilience indicate that resilience in one area of life can co-exist with high risk behaviors, social and emotional withdrawal, and maladaptive survival tactics. Further experience of childhood trauma is associated with lower levels of resilience and PTG following a traumatic event in adulthood.

Yet, people who suffer trauma can be viewed as having enormous potential to survive and the survival tactics used must be seen as normal reactions to abnormal circumstances.

POST TRAUMATIC GROWTH:

Post Traumatic Growth (PTG) refers to positive changes that are experienced by an individual as a result of a struggle with highly challenging life circumstances .

The life circumstances must constitute a trauma, crisis, or highly stressful experience that challenges the way a person sees the world and their place in it. Experiences where one faces death, disabling injury, or significant loss of possessions may cause people to question what is meaningful in life. Research by Tedeschi and Calhoun in the area of PTG has contributed to our understanding of what constitutes PTG and what is needed to achieve it. The researchers identified five types of PTG (2)

1. Greater appreciation for life, which may include a shift in priorities, seeing pleasure in things that were once taken for granted.
2. Closer, more intimate relationships with others, characterized by increased compassion and empathy for others.
3. Seeing new opportunities in life and setting new life goals. This often requires the person to let go of the possibilities and goals that were part of their life before the trauma.
4. A sense of increased personal strength - recognizing that bad experiences happen, we are vulnerable, but survival is possible.
5. Positive spiritual change such as greater affinity with one's faith and more engagement with the bigger questions about one's existence and humanity. It's important to keep in mind that growth does not occur as a direct consequence of the traumatic experience but in the aftermath of it and the struggle to find a new normal. Growth can, and usually does, happen during the same period of time that unpleasant psychological and emotional reactions are present. How does growth happen? Growth is considered to be both an outcome and a process.

Two main processes are involved in achieving growth:

EMOTIONAL PROCESSING:

In the time following a traumatic experience individuals are often consumed by overwhelming emotion which can be described as intrusive and distressing. Being aware of those emotions, having a willingness to feel the feelings and expressing/disclosing the emotions are critical to moving toward growth. When a person is able to identify those distressing emotions yet still be able to experience positive emotions, then growth from the experience is much more likely. Emotional processing then requires a level of literacy about emotions in order to engage in the

cognitive processes and to make meaning of the experience. This is often a lengthy process.

COGNITIVE PROCESSING

involves recognizing that life has changed and now must be restructured with a new identity. The traumatic experience becomes part of this new identity and a new life purpose is established. Resilience is required for growth to occur; you have to be able to survive the initial distress in order to achieve positive growth. Being resilient, however, does not necessarily ensure growth will happen.

WHAT IS HEALTH: HEALTH PROMOTING AND HEALTH COMPROMISING BEHAVIORS, LIFE STYLE AND CHRONIC DISEASES [DIABETES, HYPERTENSION, CORONARY HEART DISEASE], PSYCHONEUROIMMUNOLOGY [CANCER, HIV/AIDS]?

HEALTH

Health psychology is a specialty area that focuses on how biology, psychology, behavior, and social factors influence health and illness. Other terms including medical psychology and behavioral medicine are sometimes used interchangeably with the term health psychology.

Health and illness are influenced by a wide variety of factors. While contagious and hereditary illness are common, many behavioral and psychological factors can impact overall physical well-being and various medical conditions.

The field of health psychology is focused on promoting health as well as the prevention and treatment of disease and illness. Health psychologists also focus on understanding how people react to, cope with, and recover from illness. Some health psychologists work to improve the health care system and the government's approach to health care policy.

Illnesses Related to Psychological and Behavioral Factors

- Stroke
- Heart disease
- HIV/AIDS
- Cancer
- Birth defects and infant mortality
- Infectious diseases

Division 38 of the American Psychological Association is devoted to health psychology. According to the division, their focus is on a better understanding of health and illness, studying the psychological factors that impact health, and contributing to the health care system and health policy.

The field of health psychology emerged in the 1970s to address the rapidly changing field of healthcare. Life expectancy was much lower then, due to lack of basic sanitation and the prevalence of infectious diseases. Today, life expectancy in the U.S. is around 80 years, and the leading causes of mortality are chronic diseases often linked to lifestyle.² Health psychology helps address these changes in health.

By looking at the patterns of behavior that underlie disease and death, health psychologists hope to help people live better, and healthier, lives.

How Is Health Psychology Unique?

Because health psychology emphasizes how behavior influences health, it is well positioned to help people change the behaviors that contribute to health and well-being. For example, psychologists who work in this field might conduct applied research on how to prevent unhealthy behaviors such as smoking and look for new ways to encourage healthy actions such as exercising.

For example, while most people realize that eating a diet high in sugar is not good for their health, many people continue to engage in such behaviors regardless of the possible short-term and long-term consequences. Health psychologists look at the psychological factors that influence these health choices and explore ways to motivate people to make better health choices.³

The US Centers for Disease Control National Center for Health Statistics compiles data regarding death in the nation and its causes. Congruent with data trends throughout this century, nearly half of all deaths in the United States can be linked to behaviors or other risk factors that are mostly preventable. Specifically, in the most recent CDC report (2012), the rate of death has declined for all leading causes except suicide; life expectancy is at an all-time high (78.8 years); and yet every hour about 83 Americans die from heart disease and stroke. More than a quarter of those deaths are preventable.

Cancer remained second; followed chronic lower respiratory diseases, primarily chronic obstructive pulmonary diseases (COPD) such as emphysema and chronic bronchitis; followed by drug poisonings including overdoses and then fatal falls among an increasingly elder population.)⁴ Current Issues in Health Psychology Health psychologists work with individuals, groups, and communities to decrease risk factors, improve overall health, and reduce illness. They conduct research and provide services in areas including:

- Stress reduction
- Weight management
- Smoking cessation
- Improving daily nutrition
- Reducing risky sexual behaviors
- Hospice care and grief counseling
- Preventing illness
- Understanding the effects of illness
- Improving recovery

Teaching coping skill

The Biosocial Model in Health Psychology

Today, the main approach used in health psychology is known as the biosocial model. According to this view, illness and health are the results of a combination of biological, psychological, and social factors.⁵

- **Biological factors** include inherited personality traits and genetic conditions.
- **Psychological factors** involve lifestyle, personality characteristics, and stress levels.
- **Social factors** include such things as social support systems, family relationships, and cultural beliefs.

Health Psychology in Practice

Health psychology is a rapidly growing field. As increasing numbers of people seek to take control of their own health, more and more people are seeking health-related information and resources. Healthpsychologists are focused on educating people about their ownhealth and well-being, so they are perfectly suited to fill this rising demand.

Many health psychologists work specifically in the area of prevention, focusing on helping people stop health problems before they start.

This may include helping people maintain a healthy weight, avoid risky or unhealthy behaviors, and maintain a positive outlook that can combat stress, depression, and anxiety.

Another way that health psychologists can help is by educating and training other health professionals. By incorporating knowledge fro health psychology, physicians, nurses, nutritionists, and other healthpractitioners can better incorporate psychological approaches into how they treat patients.

HEALTH PROMOTION

Health promotion is among the foremost concerns of modern society. As with many problems of considerable social significance, most health problems are caused by what people do and what people do not do. People eat too much, exercise too little, and visit healthcare providers too infrequently, among many other things.

Understanding and solving these problems is a task for the behavioral sciences, and applied behavior analysts have been addressing problems related to health and fitness since the earliest days of the field.

The primary focus of this chapter is on applied behavior analysis research related to health promotion through diet, exercise,and medication adherence, as addressing these issues would significantly improve health across many populations.

Health promotion is the process of enabling people and communities to increase control over factors that influence their health, and thereby to improve their health (adapted from the Ottawa Charter of Health Promotion, 1986; Box 2.7). Health promotion is a guiding concept involving activities intended to enhance individual and community health and well-being (Box 2.8). It seeks to increase involvement and control by the individual and the community in their own health. It acts to improve health and social welfare, and to reduce specific determinants of diseases and risk factors that adversely affect the health, well-being, and productive capacities of an individual or society, setting target based on the size of the problem but also the feasibility of successful intervention, in a cost-effective way. This can be through direct contact with the patient or risk group, or act indirectly through changes in the environment, legislation, or public policy. Control of AIDS relies on an array of interventions that promote change in sexual behavior and other contributory risks such as sharing of needles among drug users, screening of blood supply, safe hygienic practices in health care settings, and education of groups at risk such as teenagers, sex workers, migrant workers, and many others. Control of AIDS is also a clinical problem in that patients need antiretroviral therapy (ART), but this becomes a management and policy issue for making these drugs available and at an affordable price for the poor countries most affected. This is an example of the challenge and effectiveness of health promotion and the New Public Health.

HEALTH PROMOTION INTERVENTIONS

Health promotion interventions have also been shown to have beneficial effects on PCMDs. These interventions include developing skills to improve perinatal health, teaching women about infant development, engaging and stimulating infants, and encouraging sensitivity and responsiveness toward infants. These types of interventions aim to improve mother-infant interaction and maternal self-efficacy and satisfaction (Rahman et al., 2013) and often give women an opportunity to share concerns and feelings, and receive social support from a group (Clarke et al., 2013).

The systematic reviews of PCMD treatment reported that health promotion interventions brought about improvements in PCMDs compared with usual care but with smaller effect sizes than the psychological interventions (Clarke et al., 2013). These studies included those conducted by Cooper et al. (2002, 2009), Baker-Henningham, Powell, Walker, and Grantham-McGregor (2005), Rahman, Iqbal, Roberts, and Husain (2009), Tripathy et al. (2010), Morris et al. (2012), Langer et al. (1996), le Roux et al. (2013), Robledo-Colonia, Sandoval-Restrepo, Mosquera-Valderrama, Escobar-Hurtado, and Ramírez-Vélez (2012), and Aracena et al. (2009). Clarke et al. examined seven of these health promotion interventions and reported a pooled effect size of -0.15 ; (95% CI: -0.27 and -0.02) on PCMDs. This effect size is much smaller than for psychological interventions but still larger than for no treatment.

HEALTH PROMOTION IN SCHOOLS

Health promotion in schools is a topic of both practical and empirical interest. Schools which provide comprehensive school health promotion programs are more effective in encouraging children to adopt health-enhancing behaviors and reducing health-compromising behaviors than schools that provide health education alone. Quantitative reviews of prevention and intervention programs targeting adolescent drug use, smoking, and alcohol consumption were presented. Research into the effectiveness of comprehensive school health programs provides evidence of the positive influence that such programs can exert on student health behaviors. However, conditions that enable effective school health promotion programs to be initiated and maintained depend on several school organizational and program implementation factors.

These strategies are supported by five priority action areas as outlined in the Ottawa Charter for health promotion

- Build healthy public policy.
- Create supportive environments for health.
- Strengthen community action for health.
- Develop personal skills.
- Reorient health services.

1. Address the population as a whole in health-related issues, in everyday life as well as people at risk for specific diseases.
2. Direct action to risk factors or causes of illness or death.
3. Undertake activist approach to seek out and remedy risk factors in the community that adversely affect health.
4. Promote factors that contribute to a better condition of health of the population.
5. Initiate actions against health hazards, including communication, education, legislation, fiscal measures, organizational change, community development, and spontaneous local activities.
6. Involve public participation in defining problems and deciding on action.
7. Advocate relevant environmental, health, and social policy.
8. Encourage health professional participation in health education and health advocacy.

9. Advocate for health based on human rights and solidarity.
10. Invest in sustainable policies, actions, and infrastructure to address the determinants of health.
11. Build capacity for policy development, leadership, health promotion practice, knowledge transfer and research, and health literacy.
12. Regulate and legislate to ensure a high level of protection from harm and enable equal opportunity for health and well-being for all people.
13. Partner and build alliances with public, private, non-governmental, and international organizations and civil society to create sustainable actions.
14. Make the promotion of health central to the global development agenda.

Salutogenesis

Health promotion is the process by which people increase their control over the determinants of their own health, thereby improving health and quality of life. In this context, quality of life refers to the perception that one is capable of managing one's health and life, that one's needs are being met, and that one is not being denied opportunities to achieve happiness and life satisfaction, regardless of eventual health, social, or economic limitations (World Health Organization, 1986). This perspective calls for a model of health promotion that emphasizes the development of empowerment and it is coherent with Aaron Antonovsky's concept of salutogenesis in which individuals are responsible, active, and participative (Eriksson & Lindström, 2006).

The theory of salutogenesis, or the salutogenic model (Antonovsky, 1996), represents a paradigm change in health promotion because it focuses on the factors that facilitate or optimize health rather than on the treatment or prevention of diseases (ie, the pathogenic model). Antonovsky suggested that health promotion has been overly concerned with risk factors rather than attempting to understand how people move in the direction of health. The salutogenic approach underlines the need for people to understand the factors that actively promote health instead of concentrating efforts and resources on negative outcomes. Hence, the assets model attempts to synthesize evidence based on the combination of factors that protect or promote health, well-being, and achievement (Morgan & Ziglio, 2007).

Antonovsky (1996) developed his salutogenic model during the Second World War, trying to determine what helps people maintain health under dramatic situations and how they recover from such situations. He suggested that those who have more favorable biological, psychosocial, and material resources, so-called general life resources (eg, money, social capital, cultural capital, intelligence), are more successful in dealing with life's challenges and recovering from life's problems than those who have fewer such resources (Rivera, Ramos, & Moreno, 2011).

Furthermore, Antonovsky (1996) referred to the importance of what he called the (internal) sense of coherence (SOC): a "generalized orientation towards the world, which perceives it, in a continuum, as comprehensible, manageable and meaningful" (p. 15). The SOC has three dimensions: the cognitive dimension or comprehensibility; the behavioral dimension or manageability, and the motivational dimension or meaningfulness. The SOC is thought to facilitate movement toward health because it provides the individual with the sense that the world and life events are understandable, ordered, and even predictable (ie, comprehensibility), the belief that one has the necessary resources to cope and manage events (ie, manageability), and the belief that life's challenges are worthy of investment of effort and resources (ie, meaningfulness; Rivera, Garcia-Moya, Moreno, & Ramos, 2013).

Psychosocial correlates of health compromising

The major causes of adolescent mortality are not diseases, but are primarily related to preventable social, environmental and behavioral factors (Irwin and Millstein, 1986; Millstein, 1989). The three primary causes of mortality during adolescence are injuries, homicide and suicide; together they are responsible for 75% of all adolescent deaths (Millstein et al, 1993).

Major sources of morbidity include injury and disability associated with the use of motor or recreational vehicles, pregnancy complications, sexually transmitted diseases and consequences of substance abuse (Millstein et al., 1993).

Among adolescent females, eating disorders are another significant source of morbidity, and the use of unhealthy weight loss methods may have numerous psychological and physical health consequences (Nylander, 1971; Pugliese et al., 1983; French and Jeffery, 1994; Neumark-Sztainer, 1995).

To improve adolescent health it is essential to reduce the frequency, delay the onset and aim towards the prevention of behaviors associated with morbidity and mortality among youth. Following the identification of health-compromising behaviors to be targeted for intervention, the next step in building effective prevention programs is to understand the factors associated with these behaviors among adolescents at different stages of development.

Numerous studies on health-compromising behaviors among adolescents indicate that these Social Cognitive Theory (SCT) discusses the importance of personal, socio-environmental and behavioral factors on behavior and the reciprocal relations between all of these factors (Bandura, 1977, 1986). SCT has particular relevance for explaining involvement in health-compromising behaviors among youth. Jessor has developed a model specifically aimed at explaining adolescent risk behavior/lifestyle which incorporates a number of principles similar to those in SCT (Jessor, 1991, 1992, 1993). Personal, socio-environmental and behavioral factors are shown to influence adolescent risk behavior with reciprocal relationships among all of the factors.

1). Personal factors include those from the psychological domain: self-esteem, emotional well-being and risk-taking disposition. Socioenvironmental factors include both actual and perceived components such as family structure and family connectedness, school connectedness, and stressful life experiences such as past physical and sexual abuse.

Behavioral factors include school achievement, involvement in extracurricular activities and attendance at religious services. It should be noted that the placement of these variables into these larger categories is not clearcut as most of these variables have personal, Health-compromising behaviors Unhealthy weight loss behaviors Respondents indicated involvement in any of the following behaviors for weight control purposes: laxative use, water pills (diuretics), diet pills and vomiting. Internal consistency as measured by Cronbach's α was 0.60. Scores ranged from 0 to 4, for the number of methods used.

SUBSTANCE ABUSE BEHAVIORS RESPONDENTS

indicated frequency and quantity of consumption for cigarettes, alcohol and marijuana. Responses to six questions were summed ($\alpha = 0.81$).

Delinquent behavior

Adolescents reported the frequency with which they had damaged or destroyed property; hit or beat up another person; or taken something from a store without paying for it, over the past 12 months. Responses were summed ($\alpha = 0.84$).

SEXUAL ACTIVITY

Adolescents in the ninth and 12th grades indicated: whether they ever had sexual intercourse, number of opposite gender partners over the past 12 months and frequency of birth control use. Responses were summed with higher scores indicating higher risk sexual activity (more partners and less use of birth control) ($\alpha = 0.98$). Data on sexual behaviors were not collected on sixth graders.

SUICIDE ATTEMPTS

Adolescents completed two questions regarding suicidal ideation and behaviors, and indicated whether they had thought about, or attempted suicide, over a year ago, during the past year, both or never. Responses were summed with higher scores indicating increased suicidal risk ($\alpha = 0.54$). Strength of association between psychosocial variables and health-compromising behaviors were examined with Pearson's correlation coefficients separately among males and females.

Associations between psychosocial variables were also examined using Pearson's correlation coefficients. Multiple stepwise linear regressions were employed in analyzing associations between psychosocial variables and health-compromising behaviors.

Health-compromising behaviors were the dependent variables, and separate regressions were run on each behavior for the different age and gender groups. The contribution of each psychosocial variable to the total explained variance in the behaviors and the total percent of variance explained by all of the psychosocial variables included in the analyses was determined.

LIFESTYLE, AND HEALTH

Few would deny that today's college students are under a lot of pressure. In addition to many usual stresses and strains incidental to the college experience (e.g., exams, term papers, and the dreaded freshman 15), students today are faced with increased college tuitions, burdensome debt, and difficulty finding employment after graduation. A significant population of non-traditional college students may face additional stressors, such as raising children or holding down a full-time job while working toward a degree.

Of course, life is filled with many additional challenges beyond those incurred in college or the workplace. We might have concerns with financial security, difficulties with friends or neighbors, family responsibilities, and we may not have enough time to do the things we want to do. Even minor hassles—losing things, traffic jams, and loss of internet service—all involve pressure and demands that can make life seem like a struggle and that can compromise our sense of well-being. That is, all can be stressful in some way.

Scientific interest in stress, including how we adapt and cope, has been longstanding in psychology; indeed, after nearly a century of research on the topic, much has been learned and many insights have been developed. This chapter examines stress and highlights our current understanding of the phenomenon, including its psychological and physiological natures, its causes and consequences, and the steps we can take to master stress rather than become its victim.

All lifestyle factors were associated with the mental health outcomes. Better mental health was linked to higher frequency of physical and mental activity, moderate alcohol consumption (i.e. not increased or no alcohol consumption), non-smoking, a body mass index within the range of normal to overweight (i.e. not underweight or obese) and a regular life rhythm. The more healthy lifestyle choices an individual makes, the higher life satisfaction and lower psychological distress he or she tends to have.

CHRONIC DISEASES [DIABETES, HYPERTENSION, CORONARY HEART DISEASE],

A chronic illness is “a long-lasting condition that can be controlled but not cured” (University of Michigan Center for Managing Chronic Disease, 2011). Examples in children include asthma, diabetes, cancer and organ failure. Most children and their families adapt well to living with a chronic illness. Some have greater difficulty with adjustment and coping, however. Adjustment problems can occur at the time of diagnosis, or may arise later on, as the result of the chronic stress of living with an illness. Adjustment problems are also more likely in children who had prior behavioral or psychological problems, or in families with higher levels of conflict.

Children or families who are having difficulty coping with medical illness can be seen by Texas Children’s experts in [Psychology](#).

Adjustment at diagnosis

When a child is first diagnosed with a chronic illness, all families experience some combination of shock, disbelief, anger, fear and worry. Children may ask, “Why me?” And parents will ask, “Why did this happen to my child?” These are normal reactions to diagnosis and usually lessen with time. However, diagnosis of a chronic illness can be **traumatic** for some children and their parents. As many as 1 in 5 children and parents experience acute stress at the time of diagnosis that may benefit from additional support.

You may want to speak with a pediatric health psychologist or another mental health professional if you or your child:

- can’t stop thinking about the diagnosis or worrying about the illness and its complications
- can’t sleep, can’t concentrate, feel overly jittery or stressed
- avoid any reminders of the illness
- one or more of these symptoms lasts for more than 1-2 weeks

Many parents also **feel guilty** and worry that they did something to cause their child’s illness. It is important to understand that there was nothing anyone did to cause the illness, and almost certainly nothing anyone could have done to prevent it.

CHRONIC ILLNESS AS CHRONIC STRESS

After diagnosis, families find that they have to make many changes to their daily routines to manage the illness effectively. Children may start to think of themselves differently, and parents have to face a new set of worries. Living with a chronic illness can bring many challenges, including: physical symptoms such as discomfort or pain

- treatments that can be unpleasant or difficult to follow consistently
- lifestyle changes, such as having to follow dietary restrictions
- the need for high levels of parental monitoring
- the need for more frequent medical attention, possibly including repeated hospitalizations

- disruptions to normal life, such as missing school, or having restrictions on activities
- uncertainty regarding complications, long-term outcomes, or (in the case of an illness like cancer) possible recurrence

All of these factors can cause significant **chronic stress** for the child, the parents, and other family members. Stress, in turn, can take a psychological toll on children and families. Psychological difficulties experienced by children with chronic illness include:

- persistent worries and fears about the illness and its long-term effects
- fear of dying
- fear of the hospital or medical procedures
- persistent sadness, anger, irritability, or excessive moodiness
- changes in self esteem
- concerns about physical appearance and body image issues
- behavior problems social difficulties, especially getting teased

You may want to speak with a pediatric health psychologist or another mental health professional if any of the problems above last for more than a week or 2, and either:

- cause your child distress
- disrupt sleep
- cause a loss of interest in fun things or activities
- create conflict with other people

PARENTING A CHILD WITH A CHRONIC ILLNESS

Parenting a child with a chronic illness can also be a source of significant stress for caregivers. It is important for parents to make sure to take care of themselves as well as their child, to manage daily stress, and to seek help from family, friends, community organizations, or mental health professionals when needed.

Chronic illness can also change how caregivers parent. Parents may become overprotective because of increased fears of their child's vulnerability. They may also become more reluctant to set limits for a child's behavior, especially if the child has experienced a life-threatening emergency or an extended period of hospitalization or treatment. In general, parents can help their child cope by:

- setting the same clear, consistent limits for behavior they would for any other child
- expressing warmth and support
- fostering as normal a life as possible

Developmental issue

Having a chronic illness can affect the normal course of a child's development in different ways. A chronic illness may limit the child from engaging in activities that contribute to development. For example, some children being treated for cancer may not be able to attend school or see friends during treatment due to reduced immune system functioning; a child with a heart transplant may not be allowed to participate in sports; or a child with type 1 diabetes may not be allowed by parents to go on sleepovers at a friend's house due to concerns that the other parents will not know how to manage the illness. Sometimes these limits are set by the child's medical provider; at other times, limits are set by parents who may have become overprotective.

- It is very important to help a child with a chronic illness have as normal a life as possible, within

the bounds set by the medical team.

- Ask the medical team if you have any questions about whether an activity is okay for your child.
- If you remain concerned about an approved activity, try to think through ways in which the possible risks can be minimized so that your child can participate safely.
- Seek out alternative activities that can provide similar experiences.

EFFECTS ON LEARNING

Some chronic conditions can be associated with learning problems. This can occur because the child misses a lot of school due to health problems or for extended periods of medical treatment. Parents should speak to their child's school about developing a **504 Plan** for their child to ensure appropriate accommodations are made so that their child can still access and receive a free and appropriate public education.

Some conditions and their treatment can also more directly result in learning or attention problems. Children with a chronic illness who are having difficulty with learning or attention can be seen by Texas Children's experts in Neuropsychology.

DEVELOPING AUTONOMY

For adolescents, chronic illness may disrupt changing relationships with parents and friends and interfere with the process of gaining independence and autonomy. An adolescent with a chronic illness may be less comfortable with becoming less dependent on parents. On the other hand, parents may become more resistant to the adolescent's efforts to act independently.

Some ways to address the conflict between normal development of independence, while still addressing health care needs of the chronic illness, include the following:

- Involve adolescents in health-related discussions (for example, current concerns about their illness, treatment choices).
- Teach adolescents self-care skills related to their illness.
- Encourage adolescents to monitor and manage their own treatment needs.
- Encourage the development of coping skills to address problems or concerns that might arise related to their illness.
- Encourage older adolescents to begin to meet with their healthcare providers themselves.

Continued parent involvement

While it is important to encourage adolescents' increased autonomy, it is also important for parents to maintain continued involvement in illness management. Youth whose parents stay involved in chronic illness management in developmentally-appropriate ways tend to have much better control of their illnesses and their symptoms. The challenge is finding a good balance between parent involvement and youth independence, which parents can foster by:

- Communicating openly. Allow the teen to openly express thoughts, feelings, preferences, problems and concerns related to illness management, and listen without judgment.
- Working together to think through and solve problems related to illness management.
- Not pushing independence before the adolescent is ready for it. Instead, ask what the adolescent wants to do more independently, and ask what you can do to help.

You might want to speak with a pediatric health psychologist if significant parent-child conflict arises around illness management.

RELATIONSHIPS WITH PEERS

Chronic illness and treatment may also interfere with time spent with peers or in the school setting, which is the adolescent's primary social environment. Self-esteem issues related to acceptance of one's self and concerns about acceptance by others can be intensified by chronic illness and related treatment needs. To address these concerns, consider the following:

Encourage spending time with friends. Help problem-solve any potential barriers

- Discuss concerns about what information to share with friends.
- Support children and adolescents who are bullied by peers. Enlist school personnel to address the bullying.
- Encourage and assist friends in being supportive. Involve friends' parents in this as needed.

ADHERENCE TO TREATMENT AND LIFESTYLE CHANGES

As adolescents with chronic illness learn more about their illness and take more responsibility for its management, they will begin to make their own decisions about management. They may also experiment. For example, trials of decreasing their medication or not taking it without consulting healthcare providers may occur. Teens may also make different decisions when they are alone versus when they are with friends; in general, they are less likely to complete illness management tasks when with friends. While these behaviors are developmentally normal, they create the need for continued parental monitoring and support.

- Encouraging open discussions with teens around treatment choices, and taking a nonjudgmental approach to the choices they make, is crucial if parents want to continue to have an influence over these decisions.
- Parents should view these attempts as opportunities for discussion and active problem-solving with their teen, rather than as deviations to be punished. If an adolescent does not complete a treatment task (like taking medication), encourage discussion of what happened and why and what can be done in the future, rather than reprimanding the teen
- Teach and encourage use of problem-solving skills related to their illness. Ask questions, such as: "What do you think you would do if...?" or "What do you think would happen if...?" Encourage adolescents to ask you the same kinds of questions.
- Encourage teens to share their ideas and concerns with their healthcare providers.
- Work on "team building" between the adolescent, parents, and healthcare providers.

BURNOUT

Angry or self-conscious feelings related to having a chronic illness can significantly affect adherence with recommended treatment or management techniques. Adherence may also decline over time due to disease management burnout, which is very common, especially among teens. Teens may come to feel discouraged, especially if it has proven difficult to gain good illness control, and this can progress to feelings of helplessness and hopelessness. To help:

- Recognize how difficult and frustrating it can be to live with and manage a chronic illness.
- Ask if the youth feels burned out or discouraged about illness management.
- Ask if the youth is getting the support he/she needs, and what parents and healthcare providers can do to help "lessen the load."

You might want to speak with a pediatric health psychologist if the youth

- seems helpless or hopeless around illness management
- is distressed about the illness or its management
- seems sad more days than not

- shows changes in sleep, appetite, interest, or grades
- becomes withdrawn

TREATMENT AND CARE

Almost all families hit “bumps in the road” when living with a chronic illness. **Pediatric health psychologists** are experts in behavioral health, illness management, and adherence difficulties who use evidence-based treatment strategies to help children and their families cope with the difficulties of living with a chronic illness. Children, adolescents, and their families can be seen for a one-time consultation around illness management difficulties, brief behavioral therapies, or longer-term individual or family outpatient therapy as needed.

DIABETES

Having diabetes can take its toll, with the different aspects of self- management often feeling overwhelming. The responsibility for managing diabetes lies almost entirely in the hands of the person with this life-long condition.

People with different types of diabetes often have distinctive psychosocial needs. This article focusses on type 2 diabetes which is the most common form of the condition

IMPACT ON QUALITY OF LIFE

The personal costs for those with type 2 diabetes are many. It can impact on relationships, on working and social life, and on psychological well-being, with a consequent effect on overall quality of life.

Constant monitoring, following a healthy diet and finding time for exercise can all lead to improved mental and emotional health.

People with diabetes are up to three times more likely to report symptoms of depression and these can be debilitating. For type 2 diabetes, £1.8 billion of additional costs to the NHS can be attributed to poor mental health. However, less than 15% of people with diabetes have access to psychological support, in spite of the fact that psychological support improves health and cuts costs by 25%.

Poor mental and emotional well-being can lead to feeling less inclined to monitor blood glucose levels which then impact on self- management and diabetes control. People who feel depressed often feel lethargic and so are less likely to exercise. Diet is also very often affected with less healthy foods and more alcohol consumed. In addition, sleep is often affected (problems sleeping are one of the symptoms of depression), which can have a serious impact on overall quality of life.

SYMPTOMS OF DEPRESSION INCLUDE:

- Feeling sad/depressed mood Lack of interest/enjoyment in daily activities
- Inability to sleep
- Early waking
- Tiredness/lack of energy
- Loss of appetite
- Feelings of guilt/worthlessness
- Recurrent thoughts about death/suicide

EMOTIONAL DISTRESS

People with diabetes may also experience diabetes-related emotional distress and although there is a strong association between distress and depression, many people only report one or the other. Symptoms of diabetes-related distress include constantly worrying about blood glucose levels or the risk of getting diabetes complications, feeling angry about living with diabetes, and feeling guilty when going off track with managing diabetes self-care.

Distinguishing between symptoms of depression or diabetes-related distress through discussion with the diabetes nurse or GP, can help to decide what the most appropriate follow-up care should be offered.

For example a referral for counselling or other 'talking therapies', or diabetes education. The 'vicious cycle' (as described in **figure 1**) can be broken if appropriate support is given.

IMPORTANCE OF WELL-BEING

The importance of psychological and emotional well-being has now been recognised by not only Diabetes UK, but the National Institute for Health and Care Excellence (NICE) and there are guidelines for the management of diabetes and depression when they occur together.

NHS England has also recognised the importance of good mental health, advocating a holistic approach to care for people with diabetes which includes consideration of mental and emotional well-being as well as physical health (NHS England 2018). Diabetes UK has recommended that every person with diabetes should be in receipt of 15 healthcare essentials - including getting psychological and emotional support, and that receiving more integrated care would improve outcomes and quality of life. This, they say, would also subsequently reduce healthcare costs. A 'stepped care' approach to treating depression has been recommended by NICE which organises provision according to what is seen as the patient's specific needs.

IDENTIFYING THE SYMPTOMS

When someone goes to their GP to discuss feeling depressed or anxious, identification of symptoms starts with two questions:

1. During the last month, have you often been bothered by feeling down, depressed or hopeless?
2. During the last month, have you often been bothered by having little interest or pleasure in doing things?

If the answer is 'yes' to either of these questions, then further questions are asked in order to decide on the next step, and this is usually based on the severity of symptoms.

What support is available

A service available to all those identified as having depressive symptoms is the **Improving Access to Psychological Therapies** (IAPT) service. GPs usually make the referral, however self-referral is also an option. The IAPT service consists of talking therapies such as cognitive behavioural therapy.

NICE guidelines, based on existing evidence, also recommend the use of physical activity groups, motivational interviewing, and group or family therapy.

Some people prefer group rather than individual support as it can promote a sense of belonging, sharing stories and feeling less isolated.

A recent systematic review of studies investigating the impact of different treatments in people with diabetes found that both psychological and pharmacological interventions had a moderate effect on depressive symptoms, but had no impact on quality of life. NICE are currently updating their guidance and evaluating the evidence which can inform their recommendations.

Specific guidelines for supporting people with long-term conditions (including diabetes) have only very recently (April 2018) been developed and are yet to be widely available. At the same time, direct access to psychological support in primary or secondary diabetes clinics remains scarce.

There is often a lack of confidence in talking about depression or other psychological and emotional problems, on the part of both the GP and the person with diabetes.

The treatment of diabetes and its physiological consequences is often seen as the main priority of care, with psychological well-being further down the list, and worries about the most appropriate service to offer or receive are common.

DON'T BE AFRAID TO ASK FOR HELP

Asking for help with psychological problems can be difficult. Mental health problems still carry a stigma which can influence whether or not symptoms are expressed.

The language used within clinical settings can also influence the discussions. Using words such as 'adherence' or 'compliance' with treatment can have serious negative effects. Conversely, using non-discriminatory words can open up conversations and help identify the particular needs of the person with diabetes.

MORE SUPPORT IS NEEDED

In summary, diabetes can have a serious psychological and emotional impact, and can affect self-management as well as the individual's quality of life. A range of psychological problems can occur including depression, anxiety and diabetes-related distress.

Diabetes care service providers have acknowledged the extent of this problem and advocate a holistic approach to care which includes consideration of both physical and mental health.

It is recommended that psychological well-being is addressed in clinical consultations so that the most appropriate and person-centred care is provided, however there remains a shortage of specialist support.

Hypertension and Psychological Health

High blood pressure (HBP) is also known as hypertension. It is becoming too common in the 21st century despite the fact people are more health conscious []. Research proves healthy diet and exercise are effective in lowering HBP []. However, the diagnosis of hypertension is not decreasing. The concept of a healthy life style must be holistic and consider all factors that contribute to hypertension. This requires identifying the connection of the systolic (top number) and diastolic (bottom number) pressure to the cause when developing a holistic treatment plan for each patient. Perhaps the 21st century treatment for hypertension patients includes total mind, body and soul.

KNOW YOUR NUMBERS

High blood pressure is a silent killer because it leads to heart attacks and strokes. Hospitals and doctor's office staff measure each patient's blood pressure to break the silent attack of HBP []. A patient hears their numbers and information about a healthy blood pressure reading during their

visits to the doctor. A blood pressure (BP) reading has a top and bottom number referred as systolic and diastolic pressure []. In adults, a good systolic pressure is 120 mm Hg and a good diastolic pressure 80 mm Hg or less []. Each number is a snapshot of each patient's healthcare needs.

Doctors rely on the BP measurement to guide them in developing an appropriate treatment plan for each patient. The systolic pressure is the measurement of the arteries contractions as the heart is compressing and a high number indicates stress on the arteries []. The diastolic pressure is the resting pressure the measurement of blood flow between each heartbeat and a high number indicates an elevation in pulse rate []. The differences between systolic and diastolic pressure is simply physical cause and mental causes. Therefore, a patient should know their numbers to make adequate lifestyle changes to have a good BP reading.

HEALTHY LIFE STYLE CHANGES

High blood pressure shakes the core of all patients and they want to correct the problem by any means necessary. Doctors prescribe medication, a healthy diet, and exercise to their patients and many follow the doctor's orders []. This treatment is effective in many patients. However, there are some patients living a healthy lifestyle and still have a high diastolic pressure []. The question they ask in frustration is what is causing a high diastolic pressure despite a healthy life style of diet and exercise. This leads to the analysis of stress and physical health [].

Psychological health includes stress and anxieties. Therefore, it is necessary for a patient to seek the professional care of a psychiatrist to identify the stressors and develop a treatment plan []. There are also mechanics in psychiatric care because the endocrine system plays a vital role in releasing cortisol that affect the resting BP []. The 21st century is the era of holistic healthcare. Therefore, proper treatment for HBP should include psychiatric care. Medication is not the only treatment for HBP in regards to physical healthcare or psychological health care [].

A holistic care plan should use medications as the last option and if used it should be temporary as the patient makes their holistic care life style changes. A holistic plan of care for HBP is mind, body, and soul.

The mind, body, and soul treatment should align with the patient's beliefs. Many doctors and psychiatrist agree people become healthier when they reduce their exposure to a busy and noisy environment []. Therefore, spending time in nature enjoying its serene sounds is therapeutic and reduces the cortisol levels causing elevations in diastolic pressure that will increase with time of systolic pressure []. A healthy life style goes beyond diet and exercise. The mind, body, and soul are a lifelong preventive care plan and an effective treatment plan for HBP.

CONCLUSION

Patients' lifestyles have an impact on their BP. Doctors need to assess holistically the cause of patient's HBP to provide an appropriate treatment plan. In the 21st century, medication is not the first choice of treatment for HBP. Doctors encourage their patients to switch to a healthy diet, exercise, and relax []. However, relaxing is the most difficult part of the treatment plan for most patients who do not know the cause of their stress. In conclusion, physicians should recommend psychiatric care within their HBP treatment plan.

PSYCHOLOGICAL TREATMENTS FOR CORONARY HEART DISEASE

Coronary heart disease is a common term for the buildup of plaque in the heart's arteries that could lead to heart attack. But what about coronary artery disease? Is there a difference? The short answer is often no – health professionals frequently use the terms interchangeably. However, coronary heart disease, or CHD, is actually a result of coronary artery disease, or CAD, said Edward A. Fisher, M.D., Ph.D., M.P.H., an American Heart Association volunteer who is the Leon H. Charney Professor of Cardiovascular Medicine and also of the Marc and Ruti Bell Vascular Biology and Disease Program at the NYU School of Medicine.

With coronary artery disease, plaque first grows within the walls of the coronary arteries until the blood flow to the heart's muscle is limited. View an illustration of coronary arteries. This is also called ischemia. It may be chronic, narrowing of the coronary artery over time and limiting of the blood supply to part of the muscle. Or it can be acute, resulting from a sudden rupture of a plaque and formation of a thrombus or blood clot.

The traditional risk factors for coronary artery disease are high LDL cholesterol, low HDL cholesterol, high blood pressure, family history, diabetes, smoking, being post-menopausal for women and being older than 45 for men, according to Fisher. Obesity may also be a risk factor. "Coronary artery disease begins in childhood, so that by the teenage years, there is evidence that plaques that will stay with us for life are formed in most people," said Fisher, who is former editor of the American Heart Association journal, *ATVB*. "Preventive measures instituted early are thought to have greater lifetime benefits. Healthy lifestyles will delay the progression of CAD, and there is hope that CAD can be regressed before it causes CHD."

Living a healthy lifestyle that incorporates good nutrition, weight management and getting plenty of physical activity can play a big role in avoiding CAD.

"Coronary artery disease is preventable," agreed Johnny Lee, M.D., president of New York Heart Associates, and an American Heart Association volunteer. "Typical warning signs are chest pain, shortness of breath, palpitations and even fatigue.

PSYCHONEUROIMMUNOLOGY [CANCER, HIV/AIDS]

In a nutshell, PNI studies the connection between psychological processes and the nervous and immune systems of the body. A more detailed description of PNI was given in an interview with Dr. Robert Ader, a Distinguished University Professor at the University of Rochester School of Medicine and Dentistry, and one of the pioneers of this rapidly growing branch of research. It reads as follows:

"Psychoneuroimmunology refers, most simply, to the study of the interactions among behavioral, neural and endocrine (or neuroendocrine), and immunologic processes of adaptation. Its central premise is that homeostasis is an integrated process involving interactions among behavior and the nervous, endocrine, and immune systems."

History

The field grew from the work of Russian psychologist Ivan Pavlov and his classical conditioning model. Pavlov was able to condition dogs to salivate when they heard the ring of a bell by ringing a bell when they were given food. Eventually, they came to automatically associate the sound of the bell with the act of eating, so that when the food was no longer given, the sound of the bell would automatically cause them to salivate.

With PNI, Russian researchers conducted a series of experiments that showed that the body's other systems may be altered by conditioning as well. Although their research does not live up to today's rigorous standards, they were able to cause immunologic reactions in animals in much the same way that Pavlov created salivation in his dogs.

American researchers like Ader took the research further in the United States, and we now know for certain that immune responses can be enhanced or suppressed with a wide variety of conditioned cues. We also have a deeper understanding of the placebo effect— some researchers are beginning to believe that it might be a conditioned response as well.

PSYCHONEUROIMMUNOLOGY APPLICATIONS

Psychoneuroimmunology research sheds a great deal of light on many aspects of wellness and provides important research on stress. PNI studies have found many correlations between life events and health effects.

As PNI has gained greater acceptance in the scientific community, the finding that emotional states can affect immunity has been an important one, and research in this area helps us to gain a clearer understanding of stress and its effects on health. We are gaining a clearer understanding of the links between lifestyle and personality factors and immunity as research continues.

PSYCHONEUROIMMUNOLOGY: IMPLICATIONS FOR CANCER PROGRESSION AND TREATMENT

Research that has attempted to link psychosocial stressors with tumour development or progression has faced many obvious difficulties [1]. For example, stage of disease can have a profound effect on how patients feel, and cancer treatments such as chemotherapy and radiation are associated with a number of side-effects, including immunological alterations. One obvious area of interest is the possibility of influencing the course of cancer through behavioural interventions. Properly designed intervention studies provide a powerful tool for examining psychosocial factors. By random assignment of patients who have the same kind of stage of cancer to control and intervention conditions, researchers can assess psychological, immunological and disease changes. Following the initial demonstration of behaviourally mediated immune enhancement among older adults [21], a number of researchers have confirmed our finding that stress-reducing interventions can improve immune function [41].

One of the best studies in this area evaluated both the immediate and longer-term effects of a 6-week structured group intervention that consisted of health education, enhancement of problem-solving skills regarding diagnosis, stress management techniques such as relaxation, and psychological support [42, 43].

The patients had stage I or II malignant melanoma, and they had not received any treatment after surgical excision of the cancer. Noteworthy effects included reduced psychological distress and significant increases in the per cent of NK cells, as well as an increase in NK cell cytotoxicity, compared with controls.

A 6-year follow-up of these patients showed a trend towards greater recurrence, as well as a significantly higher mortality rate in the control group than in intervention patients. The group differences remained significant after adjusting for the size of the initial malignant melanoma

lesion, a key risk factor.

Consistent with results of the intervention study with melanoma patients, Spiegel and colleagues [44] showed that a year of weekly supportive group therapy sessions with self-hypnosis for pain was associated with extended survival time in women with metastatic breast cancer. It is not known if these data reflect immunological alterations that influenced the course of the cancer, and a number of other interpretations are plausible. As the authors note, patients in the intervention condition could have been more compliant with medical treatment, and/or they might have had better health behaviours such as exercise and diet. Such behavioural differences could contribute to the observed outcome.

receiving chemotherapy for ovarian cancer. Comparisons of data obtained at home several days before a scheduled treatment showed greater lymphocyte proliferation when compared with samples drawn in the hospital just prior to the treatment, even after controlling for increased activity. Consistent with the interpretation of the process as conditioned immune suppression, patients also demonstrate

Other researchers have linked stress to poorer immune function in cancer patients whose immune systems are already affected by disease. Among 116 women recently treated surgically for invasive breast cancer, greater stress (assessed via a self-reported measure of intrusive and avoidant thoughts and behaviours related to cancer) was associated with lower proliferative responses of PBLs to mitogens and to a monoclonal antibody against the T cell receptor [2]. Importantly, stress was also related to lower NK cell lysis, as well as diminished responsiveness of NK cells to rIFN- γ .

Earlier studies from Levy and Herberman and colleagues [4, 5] had shown that three variables accounted for 51% of variance in baseline NK cell activity among women with breast cancer: patient 'adjustment', lack of social support and fatigue/depressive symptoms. On reassessment of NK cell activity after 3 months, the investigators found that they could account for 30% of the variance on the basis of baseline NK cell activity, fatigue/depression and lack of social support. Most importantly, NK cell activity remained markedly lower in patients with positive nodes than in patients with negative nodes, that is average levels of NK cell activity were lower for patients with greater tumour burden. Even though neither radiation nor chemotherapy appeared to be related to subsequent NK cell activity, tumour burden was again associated with NK cell activity.

Additional data collected from breast cancer patients were consistent with evidence described earlier linking NK cell activity with social support in healthy individuals [46]. Among women with stage I or II cancer, higher NK cell activity was associated with the perception of high-quality emotional support from a spouse or significant other, perceived social support from the patient's physician, oestrogen receptor negative tumour status, having an excisional biopsy as surgical treatment, and actively seeking social support as a major coping strategy.

PSYCHONEUROIMMUNOLOGY AND HIV DISEASE PROGRESSION HIV / AIDS - A TABOO IN INDIAN SOCIETY

million Indians are infected with the HIV virus; about 220,000 of them are children, with the tendency rising. The lack of education and the lack of condoms mean that the virus is spreading faster and faster and more and more people are dying of AIDS - especially in the slums of the growing cities. More and more children are living there as so-called AIDS orphans, often being

infected with the virus as well. Among psychiatrists who treat patients with HIV/AIDS, the question of how psychosocial distress affects the progression of HIV disease is likely to arise. Even for healthy individuals, we are only beginning to clarify the complex pathways by which thoughts and emotions impact immune function. Due to the bidirectionality of the communications of the brain and the immune system, this is a complicated scenario. The fact that HIV alters the function of the immune system during the course of its progression creates greater confounds to the understanding of these systems. We will address the rationale that progression from HIV infection to AIDS may be modulated by psychosocial factors, discuss possible reasons for conflicting findings and posit some clinically relevant recommendations drawn from research findings.

Among psychiatrists who treat patients with HIV/AIDS, the question of how psychosocial distress affects the progression of HIV disease is likely to arise. Even for healthy individuals, we are only beginning to clarify the complex pathways by which thoughts and emotions impact immune function. Due to the bidirectionality of the communications of the brain and the immune system, this is a complicated scenario. The fact that HIV alters the function of the immune system during the course of its progression creates greater confounds to the understanding of these systems. We will address the rationale that progression from HIV infection to AIDS may be modulated by psychosocial factors, discuss possible reasons for conflicting findings and posit some clinically relevant recommendations drawn from research findings.

PSYCHOSOCIAL VARIABLES: MODULATORS OF HIV DISEASE PROGRESSION?

The progression of HIV disease is highly variable among individuals. Factors known to play a role in determining the rate of progression include the viral strain, genetic characteristics of the host immune system, co-infections with other pathogenic organisms (Zorilla et al., 1996) and health maintenance habits (e.g., diet, exercise, medical treatment). However, these factors do not fully explain the extreme degree of variability noted in the course of HIV disease (Cole and Kemeny, 1997).

Given that certain immune parameters are modulated by physiologic mediators of the stress response (i.e., catecholamines and glucocorticoid hormones), it would seem logical to investigate the role of stress and other psychosocial factors in the progression of HIV infection. In fact, changes in immune function and disease susceptibility have been well documented in healthy individuals during times of psychic distress (Ader et al., 1995; Miller et al., 1997), and studies over the past 15 years have shown significant correlations between psychosocial variables and HIV progression. However, there have also been a number of studies showing no such correlation.

Stressful Life Experiences. Studies examining stressful life events and HIV have shown interesting but conflicting results. For example, Rabkin et al. (1991) studied 124 HIV-positive men and found no association between clinician-rated anxiety and CD4+ lymphocyte counts at study entry and at six-month follow-up. However, Evans et al. (1995), performing a similar cross-sectional study of HIV-positive men, did show a significant correlation between increased frequency of negative life events over the six months prior to interview and decreased CD8+ cytotoxic T-cells. Evans et al. (1997) continued with a two-year prospective study and found that not only were severe life stressors predictive of greater declines in some lymphocyte populations (natural killer [NK] cells and CD8+ cytotoxic lymphocytes), but also that such stressors increased the rate of HIV progression to AIDS. The researchers emphasized that their results were noted only in those experiencing severe life stress, not stresses associated with everyday living. For every severe life stress reported, they found the risk of HIV disease progression to AIDS doubled. In their most recent work, these investigators followed 82 HIV-positive gay men at six-month intervals for up to 5.5 years. They found that more cumulative life stress and less cumulative social support doubled

or tripled the probability of progressing to AIDS (Leserman et al., 1999).

Depression. Studies examining the effect of depression on HIV progression have had variable results. For example, Rabkin et al. (1991) found no correlation in their cross-sectional study between depression and CD4+ lymphocyte count or stage of HIV illness; however, a relationship was found between clinician-rated depression and increased report of HIV-related symptoms. In 1993, Burack et al. reported findings of a five-year prospective cohort study that showed a significant correlation between depressive symptoms and more rapid decline in CD4+ lymphocyte counts, although not with increased HIV/AIDS-related morbidity or mortality. Conversely, in a similar eight-year study of 1,809 HIV-positive gay men, Lyketsos et al. (1993) found no significant relationship between depression and indicators of HIV disease progression or clinical outcome. Likewise, results from a seven-year prospective cohort study of 402 gay men showed that depressed affect was associated with a greater AIDS-related mortality rate, although no correlation was found for measures of CD4+ lymphocytes (Mayne et al., 1996). In a meta-analytic review, Zorilla et al. (1996) concluded that no significant correlations could be made between depressive symptoms and markers of HIV disease progression. There did seem to be a relationship between depression and increased reporting of HIV-related symptoms.

Social Interaction. It is widely accepted that social isolation is a significant risk factor for several disease entities and that significant interruptions in social relationships can have deleterious effects. With regard to HIV/AIDS, this is exemplified among studies examining the death of an intimate partner, an event generally associated with bereavement and social role disruption.

Kemeny et al. (1995) studied 39 HIV-positive gay men who had experienced the death of an intimate partner within the previous 13 months. Looking at various markers of HIV progression pre- and post-bereavement, they found significant increases in serum neopterin (a product of activated monocytes and a predictor of HIV disease progression) in the bereaved group. This finding was independent of ratings of depression, suggesting a qualitative difference between bereavement and depressive disorders. Another study unexpectedly found that greater self-reports of loneliness were associated with a slower decline in CD4+ lymphocytes over a three-year period, but not associated with time to AIDS diagnosis or AIDS-related death (Miller et al., 1997).

Similarly, in a study of socially and independently housed rhesus monkeys, Capatino and Lerche (1998) found that greater social disruption around the time of inoculation with simian immunodeficiency virus correlated with a significantly increased rate of mortality. The rate of mortality also increased after inoculation if the animal was placed in a novel social environment versus individual housing. These findings, although yielding a variability of findings, suggest that social interactions may play an increasingly important role in understanding HIV disease progression.

Coping Responses. There is growing evidence that one's coping style may modulate the progression of HIV infection. For example, in a study by Byrnes et al. (1998), an increased measure of pessimism was related to lower NK-cell cytotoxicity in a group of HIV-seropositive black women at risk for cervical cancer. Furthering this hypothesis, Cole et al. (1996) found in a nine-year study that the degree of "closetedness," or concealment of gay identity, was strongly correlated with more rapid decline of CD4+ lymphocytes, more rapid progression to AIDS diagnosis and more rapid time to AIDS-related mortality. These findings were unrelated to health practices, medical treatment or other demographic differences and suggest a relationship between disease progression, poor coping and the stress of concealing one's sexual orientation.

Examining specific coping styles in a group of 74 gay men diagnosed with AIDS, Reed et al. (1994) showed that higher measures of "realistic acceptance" of their AIDS diagnosis was a significant predictor of decreased survival time. They point out that, in the past, researchers have shown unrealistic optimism to be associated with better psychological adjustment and more active coping styles. Studies of the converse of this idea have found a "fighting spirit" to be associated with reduced progression to AIDS over a 12-month period (Solano et al., 1993). In an examination of the impact of perceived causes of events on HIV progression, Segerstrom et al. (1996) showed that the tendency to attribute negative events to the self was predictive of faster CD4+lymphocyte decline over the 18-month study period

FACTORS CONTRIBUTING TO THE DIFFERENCES OBSERVED IN STUDIES TO DATE

In attempting to compare the studies cited above, confounding elements include both the heterogeneity of the study populations and methodological differences among investigators. The majority of studies have been conducted among groups consisting primarily of Caucasian, well-educated, homosexual men living in metropolitan locations. However, even within this subgroup, there are variables that might skew study data (e.g., age group, unknown time since HIV infection, access to antiretroviral treatment and so forth).

A variety of methodological difficulties deserve mention. HIV/AIDS is an illness with an extraordinarily long latency period, so following patients even for several years may yield no substantive change in disease status. Putative immunologic changes brought about by psychosocial factors tend to be small, necessitating larger samples to reveal significant findings (Cole et al., 1997). Many psychiatric disorders tend to be recurring, time-limited entities, and our measurement techniques for these typically yield only a cross-sectional glimpse of mental health at a given time. These factors could preclude significant findings in a disease like HIV/AIDS, which has a lengthy asymptomatic phase (Zorilla et al., 1996).

Currently, several known laboratory findings correlate with HIV progression, but their predictive value is questionable. The most common marker, the CD4+ lymphocyte, is predictive of increased risk for opportunistic infections once it drops below a critical level. Another promising marker is the plasma viral load. However, with the advent of newer antiretroviral therapies, CD4+ lymphocyte levels can rise markedly and viral load can become undetectable for years

CLINICAL RECOMMENDATIONS AND APPLICATIONS: LENGTHIER STUDIES ARE NEEDED

Many studies give us hope that psychosocial interventions can not only improve our patients' quality of life, but also improve their physical health. For example, a study of 10 HIV-positive men by Taylor (1995), showed that behavioral stress management over a 20-week period significantly slowed the rate of CD4+ lymphocyte decline. These results are tempered by conflicting findings such as those of Mulder et al. (1995). Working with 26 asymptomatic, HIV-positive men in either cognitive-behavioral group therapy or experiential group therapy, these researchers found no significant differences in CD4+ lymphocyte changes between group members and controls over a 24-month period. Lengthier studies of larger populations are clearly needed to elucidate further findings and to translate them from laboratory data into real-world scenarios.

Exercise training has been studied among several HIV-positive cohorts, revealing numerous psychological benefits including decreases in anxiety and depression and increases in active, positive coping styles. In a review of pertinent literature, LaPerriere et al. (1997) concluded that a

typical regimen of aerobic exercise can result in increases in CD4+ lymphocyte counts in all HIV-positive patients, except those with AIDS. However, even among AIDS patients, the CD4+ lymphocyte counts remained stable over an 18-month study (whereas control patients' levels continued to decline).

The impact of HIV on neural tissue remains questionable. There is evidence, at least in the case of depression, that HIV-positive individuals respond to antidepressant therapy at rates similar to seronegative controls. The side-effect profiles of these medications also seem to differ minimally based on HIV status (Rabkin et al., 1994).

A significant finding about HIV and depression in the meta-analysis by Zorilla and colleagues (1996) was that depression was associated with increased reporting of HIV physical symptoms, regardless of objective markers of physical disease. Depressed HIV-positive individuals may have a more painful experience of HIV illness, regardless of objective physical signs and markers. Also, alleviating depression in some cases may facilitate compliance with medication regimens and medical follow-up, improve self-care, and decrease self-destructive behavior—all variables associated with diminished morbidity and mortality (Stober et al., 1997).

Overall, evidence remains inconclusive regarding the role of psychosocial factors in HIV disease progression, as well as the long-term effectiveness of interventions directed at such factors. However, it is certain that psychiatric disorders and social stressors occur frequently during the course of HIV disease. While it is unclear whether specific psychiatric and psychosocial interventions will extend life or improve physical health among HIV/AIDS patients, we do know definitively that treatment can alleviate psychiatric disorders, relieve distress, and improve quality of life and such critical variables as treatment adherence.

With more HIV-positive individuals being seen in general psychiatric practice, one should not underestimate the positive effects of comprehensive psychiatric care

WHAT IS PSYCHOLOGY AND TECHNOLOGY INTERFACE: DIGITAL LEARNING; DIGITAL ETIQUETTE: CYBER BULLYING; CYBER PORNOGRAPHY: CONSUMPTION, IMPLICATIONS; PARENTAL MEDIATION OF DIGITAL USAGE?

PSYCHOLOGY AND TECHNOLOGY INTERFACE:

Human-computer interaction (HCI) is the study of how people interact with computing technology. One major area of work in the field focuses on the design of computer systems. The goal is to produce software and hardware that is useful, usable, and aesthetically pleasing.

A closely aligned area is the evaluation of systems in use. This is of course related to design, because to know if a design is useful or usable requires observing it in use. However, this also extends to the study of the larger social consequences of use. Increasingly, evaluation takes place at multiple levels of analysis: the individual, the group, the organization, and the industry or societal sector.

The methodological and conceptual issues at these different levels of evaluation are quite different. Psychologists are typically most interested in the smaller levels of aggregation, though Landauer (1995) attempted to provide a largely psychological account of the “productivity paradox,” a phenomenon first identified by economists who found a disappointing lack of

correlation between the amount of money invested in information technology and changes in industry productivity measures

This chapter updates and expands the last review of HCI in the Annual Review of Psychology (Carroll 1997). There has been steady growth in the field since then, and in our brief chapter we can only highlight some of the most significant changes. We also give explicit attention to the emergence of research at the group and organizational level, often referred to as computer-supported cooperative work or CSCW.

The field of HCI is fundamentally interdisciplinary. The fields of cognitive, social, and organizational psychology are all important to research in the area, but other social sciences such as sociology and anthropology have played key roles, as have such related fields as communication, management, operations research, and ergonomics.

Also, a variety of technical specialties from computer science are important. Research in HCI requires literacy in the related fields and often involves multidisciplinary collaboration. Some think of HCI as a purely applied field.

However, being applied does not mean lacking in relevance to basic science. Stokes (1997) argued that the quest for fundamental understanding and considerations of use are two separate dimensions of a 2×2 table rather than opposite ends of a continuum. He used Pasteur as an example of research that sought both fundamental understanding and practical solutions. Whereas some research in HCI is close to purely applied, as we hope to show in this review, much of it falls in Pasteur's quadrant.

THE SCIENCE OF HUMAN COMPUTER INTERACTION

Theoretical advances in HCI are proceeding on a number of different fronts. Modeling of the integration of perceptual-cognitive motor processes to illuminate the moment-by-moment behavior people exhibit with computers has become more detailed. At the more social level, there is work on distributed cognition, focusing on the interplay of people with their teammates and the artifacts of their interaction.

Another class of tasks, that of information retrieval, is receiving attention from HCI researchers. What we do not have yet is a detailed model of social interaction or of some of the larger issues of adoption of innovation. There is significant work to be done to understand what might be unique about the adoption of computation as an innovation, because computational artifacts can be designed in so many different ways.

Human Computer Interaction Work on Information Retrieval Whereas most of the theory and applications in HCI of the 1980s and early 1990s focused on computationally supported office applications such as word processors and spreadsheets, one of the major theoretical advances of the late 1990s came in an examination of information-retrieval behavior. Spurred by the advent of the World Wide Web and ubiquitous "surfing" behavior, Pirolli & Card (1999) investigated how people decide to continue in a line of searches and when to jump to a different source or search string.

To model this behavior they drew on foraging theory from biology. They saw the analogy between the movement of animals from one food source to another (a "patch") and people's movement

from one information source to another.

They modeled the moment-by-moment decisions people make in their assessment of the value of what they see in search results to predict when they would pop back up to a high level change in a search string or a completely different source such as stopping searching the web and asking a reference librarian. This work also highlighted the importance of the display of the search results in the way it gives clues (“scents”) as to whether further selection of an item is likely to be valuable (“to bear fruit”). So, for example, if a Google search returns only headers or urls, it has a less informative “scent” than a display of the sentence fragments that surround the words that match the search string.

These bits of information give the user clues as to whether the selection of that item is likely to be useful. The Card and Pirolli information-foraging work is remarkable not only in its novelty of task and approach, but in the variety of methods they bring to play in their work. They motivate the investigation with some descriptions of real people searching for information—a team of MBAs doing an industry analysis and a consultant writing his monthly report on a topic. From phenomena gleaned from these cases, they worked with mathematical foraging theory, applying various concepts and equations to information rather than food-seeking behavior. Of particular relevance here were calculations on the time a person would spend in a fruitful region of information before moving on to another and the factors that drove the decision to move. They then moved to modeling the moment-by-moment behavior of people conducting their search with an ACT-IF model (the ACT-R model applied to information foraging, IF).

The mathematical analyses show aggregate behavioral trends (e.g., average time to linger as a function of richness of the scent), whereas the ACT-IF model allowed them to explore various mechanisms that might account for this behavior. They concluded with an empirical laboratory study of people making such switching decisions in a particular information-retrieval system called the “Scatter/Gather” interface. They made very specific predictions of when someone would stop searching a source (when the average value of a found item dropped below an estimated middle point). They also encouraged designs to give “scent,” hints as to the ultimate value of continuing searching on a particular path, such as meaningful labels and revealing search results.

USER INTERFACE DEVELOPMENTS

As computing technology changes, new user interface challenges arise. For instance, in the early days of personal computing screen displays were mostly command lines in green or yellow on a black background. Editing a manuscript included placing explicit formatting characters in the text. With the emergence of graphical user interfaces (GUIs), whole new classes of issues emerged, as well as new opportunities for tapping into key cognitive and perceptual processes. Much of the design of early GUIs was influenced by psychological research (e.g., Johnson et al. 1989). Such systems have been around long enough that they have achieved some level of stability in design, even across different hardware and software platforms.

Now all kinds of new situations are emerging that are challenges to human-computer interaction specialists. We briefly describe some examples of these and indicate the character of some of the psychological issues involved. As applications move from the desktop to more mobile, immersive environments and to a wider set of users, there remain a number of challenges for basic psychology. How do people understand aspects of the digital world as it is embodied in these various devices? How do we capitalize on the strengths of each human, coupling them with

assistance from computing, to bring about the most in a productive, satisfying life. Mobile Devices In the past decade a wide variety of small mobile devices have appeared. The most common are what are called personal digital assistants or PDAs. These are small handheld devices that have increasingly sophisticated computational capabilities.

The user interface challenges are daunting. These devices typically have small screens, and interactions are with a stylus and a small set of buttons. Some models have optional folding keyboards that allow for more traditional interactions. Despite these user interface challenges, such devices have a number of very useful functions and are very popular. Combinations of mobile devices, such as the merging of PDAs and cell phones, are just appearing. One specialized user interface issue is how to integrate such mobile devices with more traditional computing. For instance, Milewski & Smith (2000) developed a digital address book with location sensors that could be accessed from a regular workstation or from a PDA and that provided information about the availability of others that could be used to coordinate phone calls regardless of where the participants might be. The interface had to be adapted to the capabilities of each device in a way that users found intuitive and natural.

DIGITAL TECHNOLOGY ON LEARNING

Over our first few blogs, let's take a look at the effects of digital technology on learning. We'll begin in the classroom.

Does technology interfere with classroom learning? Yes

According to one teacher survey regarding the problem with technology in schools (Washington Post 2013):

- Nearly 90% of teachers felt technology has created a distracted generation with short attention spans.
- 60% felt it hindered writing and face-to-face communication; i.e., communication with full sentences and longer has lost out to short snippets in writing or media.
- Almost 50% felt it hurt critical thinking and homework ability.
- 76% felt students were conditioned to find quick answers.

In short, technology is changing the way our students learn, and not always for the better.

In another survey, university students were asked how often they use their cell phones while in class for non-class related uses (Baron 2015). The average college student reported such use 11 times daily. 15% of students used their cell more than thirty times during class. All of this activity comes at a price in learning. In one study, students who sent text messages while watching a lecture had exam scores 19% below those who did not text (Thompson 2014).

When students were asked themselves about texting during class time, the following percent of them agreed or strongly agreed:

- 77% felt that receiving text messages hurts my ability to learn during lecture. 72 % felt that sending text messages hurts my ability to learn during lecture
- 37% felt that they get distracted when someone else receives a text during class.
- 31% felt that they get distracted when someone else sends a text during class.

Thus, students recognize that texting in school not only interferes with their own learning, but also interferes with other student's attention—yet 49% of them still felt it was okay to text during class (Rosen, 2012).

Not surprisingly, allowing web access (i.e., not just texting access) to students during a lecture doesn't fare well, either. One group of students was allowed to surf the web during class, and the other kept their laptop closed. Students did indeed look at lecture related sites, but also went shopping, watched videos and caught up on e-mail. Even those students who surfed only on topics related to the lecture showed significantly worse memory of the lecture's content than those who kept their laptop closed (Carr 2011).

Yet, multiple studies reveal that the majority of students say that they use their electronic devices during class to text, browse, or consume media. The results of these studies agree with my own informal survey of my patients who, when asked, almost uniformly say that students are using the classroom laptops/iPads for non-educational activities. Even those who have monitored or limited Internet access still use their laptops for offline gaming. If an adult comes around, they simply hit a button which switches the screen to a legitimate activity. The CD (remember those?) version of MAD magazine even contains a "panic button" which, if pressed when an adult checks in, pulls up a Word document that reads something to the effect that, "I can't believe my parents fell for this again." School systems that are switching to all digital experiences for their students must ask themselves if the advantages are worth the distractions.

Digital etiquette, or netiquette as it is sometimes referred to, is a basic set of rules pertaining to behaviour that needs to be followed to ensure the Internet is better for all users. Basically it means "the use of good manners in online communication such as e-mail, forums, blogs, and social networking sites." Digital etiquette, or netiquette as it is sometimes referred to, is a basic set of rules pertaining to behaviour that needs to be followed to ensure the Internet is better for all users. Basically it means "the use of good manners in online communication such as e-mail, forums, blogs, and social networking sites" (Digital Citizenship, Auburn University. n.d.).

Etiquette, the word, means "The forms required by good breeding or prescribed by authority in social or official life". The origins of the word stem from the French word "ticket"; if you knew the etiquette for the group or society you would have a 'ticket' to gain access (Shea, V. 2004).

Importance of Netiquette

So why is netiquette so important? When we communicate face-to-face, it is important to note that 55% of the communication is made up of body language, 38% is the tone of voice, with the remaining 7% being the actual words (Psychology Today (Thompson, J. 2011)). When communicating on a phone we lose the body language component but the tone is still there to support the message.

However, communicating online, or in the written form, we lost 93% of the communication – the words become the sole mechanism for communication! As a result misunderstandings occur without these non-verbal cues.

So how do we provide these non-verbal cues in digital communication? Informally we use emoticons to aid the message, but formally this is a lot harder. Most formal communication occurs within a business context, so netiquette becomes vital in our communication as businesses rely heavily on building and maintaining relationships.

Netiquette is even more important when we consider the longevity and the reach of the communication. The lack of netiquette can cause substantial problems in the workplace and

schooling.

Although there has been a reduction in poor netiquette, it is still an issue that has ramifications beyond socially acceptable norms. Etiquette and Business. Business is about building relationships, which at times can take years. Creating the rapport is incredibly important in establishing trust, authenticity and credibility. Any disregard for netiquette can break this down with a single email, post or online comment. It is key for businesses to focus on the digital skills of their employees; moreover the focus should be on communication with a nuance on digital communication.

Etiquette and Society

We know that the socio-cultural environment has the deepest, strongest, and perhaps most prevailing effect on social behaviour. In fact etiquette are societal norms, therefore netiquette would be the rules society dictates we utilise when we are online.

The Online Disinhibition Effect

People disclose or act out more frequently, at times more intensely, when they are online. More so than when they are off-line. Because of this loss of inhibition, users show tendencies, such as being more affectionate, more open, and less guarded, in an attempt to achieve emotional well being (Suler, 2004 Role of Rules and Policy We communicate daily, be it in a social, business or academic context, and the way in which we engage will differ. Without any form of 'guidelines' or rather rules and policy on conduct, our interactions will degenerate and result in negative consequences. (N)Etiquette is all about the code of behaviour established for communicating and behaving

Electronic Standards of Conduct

Electronic Standards of Conduct is a set of standards on social, environmental and ethical issues within the context it is provided. Most companies have such standards, often referred to as Acceptable Use Policy (AUP). This is often used as a guideline for employees and users, but also in terms of managing staff. Given that employees represent the company, even outside of their normal working hours, therefore some standards need to be in place.

Employees in breach of these standards may find themselves without a job, as it is seen as part of their contract with the company.

Virginia Shea's Netiquette Guidelines

These guidelines will differ, in terms of the context and the medium available. However, there are some core principles that we need to be aware of and adhere to. According to Shea (1994), an academic who has been dubbed the 'network manners guru', these guidelines are:

1. Remember the Human Never forget that the person reading your communication is actually a person with feelings and can get hurt. Essentially never say anything online that wouldn't say to your reader's face. Adhere to the same standards of behaviour online that you follow in real life. Be ethical in your engagement and know that breaking the law is bad netiquette
2. Know where you are in cyberspace The netiquette required will differ from domain to domain. If you are in a forum of experts, your netiquette should reflect respect. Whereas if you are in a chat room with a group of friends (you know in real life) then the netiquette will differ!
3. Respect other people's time and bandwidth When sharing files or documents, bear in mind the audience's bandwidth. Furthermore, make sure you read the FAQs first before asking mundane questions where the answers already exist. If you disagree with a group's discussion, don't

- waste their (or your) time by telling them how stupid they are: Just stay away.
4. Make yourself look good online Check grammar and spelling before you post. Most people judge others' intelligence based on the use of grammar and spelling. Only post on things you know about, it is not worth it to look like the fool.
 5. Share expert knowledge Offer answers and help others where you can
 7. Help keep flame wars under control Don't respond to flame-bait, don't post spelling or grammar flames, and apologise if you have done so or perpetuated a flame-war.
 8. Respect other people's privacy Don't give out other people's details, online or offline.
 9. Don't abuse your power The more power you have, the more important it is how you use it.
 10. Be forgiving of other people's mistakes We all were once a newb (and no we don't mean noob – those who know little and have no will to learn any more).

Bad Etiquette Examples

- Although these are not the only examples of bad netiquette these examples may give an idea of the things that are taboo: Don't type in CAPS – it is considered shouting
- Don't spam
- Don't use offensive language
- Don't steal other people's identity
- Don't distribute illegal material
- Don't flood
- Don't expect a response straight away
- Don't broadcast only; engage with others Don't 'reply-all' for a personal conversation Don't ask a question that can be found on the site or on Google" (Melin, 2013).

CYBERBULLYING FROM A PSYCHOLOGICAL PERSPECTIVE

The stereotype bully used to be the big kid in the school taking smaller children's dinner money or the colossal 'Miss Trunchball' terrorizing the tiny kids in Roald Dahl's book, 'Matilda'. In recent years the definition of bullying has extended beyond the school playground and we are more likely to recognize that the capacity to bully others is not limited to those with large bodies.

Over the past twenty years, as the internet and mobile phones have become embedded in our lives, we have heard about children and adults who have been targeted by bullies online. We seem to have improved our understanding of how bullies operate and we are more likely to believe the stories of those who have been bullied but we do not seem to have made much progress in preventing bullying or dealing with bullies.

For those of us who are less familiar with social media or do not feel confident in understanding the online context it might feel overwhelming and confusing if, either professionally or personally someone seeks our support or advice on addressing cyberbullying. I hope that the following information serves as a way of familiarizing oneself with some of the issues that might come up and suggest ways we can support people who have experienced cyberbullying.

What is cyberbullying?

'Cyberbullying' is a range of behaviours that people use to intimidate, shame or alienate another person online. Cyberbullying includes, but is not limited to, using offensive or dehumanizing language against someone; blackmail; 'outing' someone; threatening physical violence. In the same way that bullies often try to isolate someone 'in real life' they might also try to rally others to isolate someone else in the online context and/or in 'real life'.

What distinguishes cyberbullying from face to face bullying?

In the past few years there have been several cases of high profile people being bullied online. Most notably, Twitter, has enabled people to communicate with famous people in a way that wasn't previously possible and there are many people who have used this opportunity to express their racist, misogynistic and homophobic beliefs directly at their target.

One of the most striking aspects of these cases is the way that a 'pack' descends onto the scene and, also, how online platforms appear to be ill-equipped to deal with bullying and so people are sometimes 'bullied off' the platform.

The internet also enables a person to bully strangers, without geographical limitations, via social media, comment sections, dating apps etc. in a way that wouldn't have been possible previously. Additionally, a cyberbully can send abusive messages at any moment, not limited by the time restrictions of face to face contact.

Young people who have experienced cyberbullying describe a feeling of not being able to get away from it; that there is no respite. Older people might think that the solution is to disconnect from the online spaces where the bully can send messages or, perhaps, even to disconnect from social media altogether but it seems that young people are usually unwilling to sacrifice the more positive interactions they have in those online contexts in order to avoid the bully. Young people's online lives are often so embedded in their day to day lives telling them to quit social media is like telling them to stop going to the town centre so they can avoid the bully.

WHERE DOES CYBERBULLYING HAPPEN?

The most popular online social media platforms are Facebook, Instagram, Twitter, Snapchat and Tumblr and the most popular mobile phone applications for sending messages and photos are WhatsApp and SnapChat.

However, there are always new platforms coming and going and it's difficult to keep up with the trends in the lesser known platforms and to understand what they entail. The NSPCC website 'net aware' (link in references section below) is very helpful as it provides descriptions of different apps and social media platforms and gives advice on how to use them as safely as is possible.

When we're thinking about how to help or protect others from cyberbullying it's important to be aware that platforms such as Netflix (TV and film streaming service), videogames and music apps (e.g Spotify) that are not necessarily marketed as 'social media' or communication apps also provide the possibility to send message (and therefore provide another platform for bullies to send abusive messages).

AT WHAT AGE DOES CYBERBULLYING BEGIN?

Most of us will have observed, experienced or participated in bullying at primary school, so we know that primary school aged children do have the capacity to bully others face to face. It would therefore follow that primary school aged children who are using social media are not immune from bullying others or being bullied by others online.

Since the emergence of smart phones around 2010 it seems that more and more parents use mobile phones and/or portable devices to entertain or occupy babies and small children. Following

on from this, it seems plausible that a child's first negative online experience must be becoming progressively younger and that it's not unrealistic that their first experience of cyber bullying (whether it is observing, participating or being on the receiving end) could happen whilst they are still attending primary school.

THE PROFILE OF THE CYBERBULLY

Most adults would admit to having engaged in some form of bullying, no matter how briefly, at some point in our lives. And, like in most other areas of human behaviour, it seems unlikely that a person who engages in protracted bullying is categorically different from the rest of us but, rather, is more likely to be at the more severe end of personality traits that we all have: jealousy, obsessionality and lacking empathy (callousness).

As is the same with the face to face context, cyber bullying can provide a way for individuals to project their own feelings of distress into another person. It also seems plausible that a nasty message provides the sender with some temporary excitement or temporarily relieves some feelings of frustration. By sending nasty messages under the cloak of the internet (not necessarily anonymously) the sender is protected from any possible physical backlash from the receiver. However, they have also left an 'electronic trail' that could land them in trouble with their employer, their school, the online platform, or the police. Perhaps this is one of the reasons for the 'pack' behaviour mentioned previously: that bullies have a feeling of 'safety in numbers' and if the pack unleash their anger and frustration on particular individuals they feel that they are less likely to be sanctioned than if they are the sole bully.

A long standing explanation of the behaviour of bullies in face to face contexts is that they are people who are unable to form a positive connection with others and so a negative, destructive communication is more rewarding for them than to be alone or isolated. It seems plausible that this explanation also holds up for cyberbullies.

DRAWING ON PROFESSOR PAUL GILBERT'S THEORIES TO UNDERSTAND CYBERBULLYING

Professor Gilbert's psychological theories have long since drawn on broader social and evolutionary theories to make sense of individual feelings and behaviours. It is useful to be reminded that, as human beings, we are inherently social creatures. It is also helpful to hold in mind that the vast part of our physical and mental evolution occurred during the hundreds of thousands of years prior to the first civilisations; the internet era of the last twenty years is less than a blink of an eye in the big picture of human evolution. Which leaves the question of how well our minds are equipped and/or able to adapt to the rapid technological changes that are happening in our lives. Gilbert (2006) outlines our most basic behaviour displays and defences: courting, sharing, fight, flight, submission and freezing and our basic cognitive competencies: Theory of Mind; symbolic representations of ourselves and others; and meta cognitions and meta presentations. Perhaps one of the reasons why smart phones have become so pervasive is because they draw on so many of our most primitive cognitive and physical capacities.

It seems that many people are emotionally attached to their mobile phones in a more profound way than other electronic devices. This emotional attachment makes sense if the phone is recognised as a device that enables us to meet some of our most primitive needs.

Negotiating our social ranking is the one of the primitive activities that we use mobile phones for.

I remember in 1997 when I was a waitress in Pizza Hut in Manchester and customers first began to put their mobile phones on the tables; when just having a mobile phone was a way to increase social ranking. Now, mobile phones are ubiquitous but provide a way of accessing higher social rank through the popularity or cleverness of the images or information that we share. And for those who have gained social rank via socialmedia, or aspire to gain social rank via social media, it is not surprising that they will try to resist losing that rank if the bullies come along.

It's also helpful to be reminded of Gilbert and McGuire's (1998) work on aggressive and attractive strategies for gaining social rank as, again, the very primitive nature of these behaviours fits well in the context of understanding online behaviour. I think this work helps to explain the polarisation that appears to be endemic to Twitter in particular. Gilbert and McGuire outline how, to gain and maintain social rank, people use either 'attractive' strategies such as showing talent and competence in order to be valued and stimulate positive affect in others or they use 'aggressive' strategies such as authoritarianism, coercion or threats in order to make others fearful, inhibited or submissive.

So far, we have outlined several motivations for why people bully others online: feeling emboldened to express their offensive beliefs because others are doing so; projection of their own unwanted, unpleasant feelings into another person; personality traits on the severe end of the dimensions of jealousy, obsessionality and/or lack of empathy (callousness); attempts to use aggressive tactics to increase their social rank and/or inhibit someone else's social rank.

Supporting those who have been shamed online by bullies

Bullies attempt to shame others in a range of ways; from mocking them to sharing their videos or photos, particularly those of a sensitive nature. In face to face contexts this is bad enough but the permanence and the possibility of wide distribution online make things even worse.

One way of partly relieving shameful feelings is when we meet others who are willing or able to empathise with us. At the end of the Netflix documentary 'Audrie and Daisy' (2016) Daisy meets other teenage girls who were also bullied (online and face to face) by their peers after reporting sexual assaults to the police and the meeting appears to go some way towards relieving feelings of shame for those concerned. Professor Gilbert's book, 'The Compassionate Mind' (2009) is a useful resource for developing self-compassion as an antidote to feelings of shame.

Where bullies have distributed videos or images that are of a sexual nature and there is recourse to legal avenues it seems plausible that obtaining justice through the legal system might help to relieve some of the feelings of shame.

Supporting those who have been frightened by bullies online

When bullies are making threats or have made threats the first step should always be to ensure the person's safety by contacting the police.

Paladin is a UK service offering advice and support to people who are being stalked and also provides advice to professionals who are working with people who are being stalked.

It is also important to contact the support services for the online platforms where the bullying has taken place to ensure that the intimidation is prevented from reoccurring. Each social media platform has its own code of conduct and sanctions if the rules are broken.

In terms of providing emotional support to those who have felt frightened by online bullies the most important priority is to ensure that the person is now safe. If we can be sure the person is now physically safe only then can we support them in processing their feelings of anxiety about what happened in the past.

It is important to take people's emotional reactions to cyber bullying as seriously as we would if the bullying was face to face. It might be that the person continues to feel anxious because they are focused on thoughts of 'what could've happened', 'what could've gone wrong'. In these cases we should validate the person's worries but help them trace the actual chain of events and to focus on the actual outcomes rather than the 'what could have been's'.

THE CONSEQUENCES OF HAVING BEEN BULLIED

I have worked with people in their eighties who continue to experience distressing memories of being bullied in school; for others, maybe the horrible memories do diminish but in every case we should always take the person's experience of being bullied seriously and listen carefully to the details of the particular situation so that we can offer the best and most appropriate support possible.

I have worked with families who have taken their child out of school due to bullying only for it to happen in the new school. In these cases it must be very difficult for the child not to believe that the problem is with them when, in reality, starting a new school is likely to be a moment of vulnerability that bullies are vigilant to. It seems important to ensure that if the decision to change schools is made that the child receives proper support on how to approach starting their new school in light of their previous experiences.

From working across the lifespan we know that people who have experienced face to face bullying continue to experience the consequences for many years after: finding it difficult to trust others, internalising the bully's voice and so on. As online bullying is a relatively new phenomenon only time will tell if the consequences are as longstanding. What we do know is that people who have been bullied in either of these contexts have taken their own lives indicating that the short term impact of cyber bullying can be as devastating as face to face bullying.

CONCLUSION

I've met several young people who have been worried that if they tell someone about the bullying that they're experiencing that 'it will make things worse'. Of course, this plays directly into the hands of the bully who seeks to isolate the person that they're bullying. By listening very carefully, paying attention to the fine details of the situation and providing emotional support to the young person we can work out the most appropriate solutions together.

Schools, social media platforms, families and any other place where people are interacting are vulnerable to the possibility of bullying taking place. In terms of supporting people (of all ages) who are targeted by cyber bullies, I think we should have at least a basic understanding of social media in order to provide appropriate support and advice. As in any other form of tyranny the minority of people who engage in cyber bullying depend on the fragmentation, impassivity and indifference of the wider society. By having a better understanding of social media, even if we do not have a personal interest in it ourselves, we will be better able to provide appropriate support and advice to those who are targeted by cyber bullies.

PORNOGRAPHY

A study of Internet pornography users suggests a person's own feeling of being addicted to online pornography drives mental health distress, not the pornography itself.

Researcher Joshua Grubbs, a doctoral candidate at Case Western Reserve University's Department of Psychological Sciences, said the finding adds a fresh perspective to commonly held concerns that Internet pornography can be a threat to mental health. The research, funded by the John Templeton Foundation, suggests that feeling addicted to Internet pornography is associated with depression, anger, and anxiety, but that actual use of pornography is not.

Grubbs is part of a research team that did a study titled "Perceived Addiction to Internet Pornography and Psychological Distress: Examining Relationships Concurrently and Over Time." The article is now published in *Psychology of Addictive Behaviors*, a journal of the American Psychological Association.

With Grubbs on the research team are Nicholas Stauner and Julie J. Exline, also of Case Western Reserve University; Kenneth I. Pargament of Bowling Green State University, and Matthew J. Lindberg of Youngstown State University.

Grubbs said Internet pornography viewing online is increasingly common, more among adult males than adult females. The study did not involve minors. Data used for the study came from research participants who were granted anonymity. These participants were assigned numerical identities for confidentiality and were paid for their participation. A second group involved psychology undergraduate students at three separate universities in the United States. Those students received course credit for participation. The research team used these two cross-sectional samples and a 1-year longitudinal study.

"Collectively, these findings suggest that perceived addiction to Internet pornography, but not pornography use itself, is related to psychological distress, which runs counter to the narrative that many people have put forth. It doesn't seem to be the pornography itself that is causing folks problems, it's how they feel about it," Grubbs said. Prior research by Grubbs and Exline has shown that perceived addiction to Internet pornography is partially driven by religious beliefs and moral disapproval of pornography.

IMPLICATIONS OF PSYCHOLOGY

Early Years STEM Learning Emerging from the literature review, further research is likely to illuminate how different individuals respond to instruction during early years education. The literature review reveals the fact that children start school with potentially very different levels of ability in some key areas that predict achievement in STEM subjects (including linguistic ability, quantitative ability, spatial ability and executive function). We are beginning to understand the way in which these skills combine to provide a foundation for STEM Learning, but in the future education is likely to benefit from: Improved methods of identifying the individual needs of children. Tests for various abilities are already used in research, but these are not always convenient or appropriate to apply in classroom practice.

This can be due to the time required to administer the tests, or to the need to administer them on a 1-to-1 basis. In the future, novel methods of measuring precursor abilities in classroom contexts,

with good levels of reliability and validity, will provide schools and teachers with new and more effective methods by which to target differentiated support and instruction. Improved methods of supporting children with low levels of precursor skills and abilities. Given that these skills and abilities are strong predictors of future learning, it may be important that children identified as having low levels of particular abilities on entering formal education are supported in ways that focus on these abilities. Research cited in the literature review indicates some limited success has already been demonstrated in raising levels of these precursor skills, but further pursuit of research in this area will help identify more effective interventions for children with different levels of need and at different ages. Some research has already taken seriously the need to focus on individual differences in response to STEM instruction, and to explore interventions that can address diverse needs for support. An excellent example of this approach is Dowker's (2005a; 2005b) componential model of arithmetic, that led to the development of the Catch-Up Numeracy programme. This research was not included in the literature review as its theoretical basis appears more educational than psychological or neuroscientific. However it provides clear evidence that a focus on individual differences in children's learning can lead to improved outcomes. In the next 20 years, improved understanding of discrete predictors of achievement in STEM (e.g. spatial ability, quantitative ability, linguistic ability) and, perhaps more importantly, the ways in which they interact, will stimulate new insights into ways in which curriculum material can best be introduced, and new insights into ways in which material can be differentiated according to children's abilities.

PARENTAL MEDIATION OF DIGITAL USAGE

Most children of the current generation grow up in media-rich homes. Media are present in the majority of households and new technologies, such as tablets and smartphones, have emerged in Euro-American contexts. As indicated in a systematic review of European research (Ólafsson, Livingstone, & Haddon, 2013), most research on children and digital media has focused on children aged 9 and above. However, due to the recent, rapid adoption of touch-screen devices most children use digital media and the internet at an earlier age (Findahl, 2013). Even children aged 3-4 use electronic gadgets and are avid users of technology (Ofcom, 2014). However, children are substantially influenced by their parents and their daily practices. Parental mediation is defined as the parental management of the relationship between children and media, including simple restrictions, conversational and interpretive strategies, and parental monitoring activities (Livingstone & Helsper, 2008). Parental mediation is a key factor in the online lives of young children; however, there is a dearth of research on the parental mediation of young children (Nikken & de Haan, 2015; Shin & Huh, 2011) and we do not know how parental mediation is related to specific risks and opportunities. We also lack a greater understanding of the role of children and their characteristics in the mediation process. Consistent with the new sociology of childhood (Christensen & James, 2008) we consider the child as an active subject who is not only formed by the system of family and exogenous factors, but also plays an active role in the construction of the family and its environment. Children are not passive recipients of parental mediation. They can influence the approaches by which their parents regulate their activities (Prout, 2008). Therefore, in the present research, we sought to understand how parents mediate the online experiences of young children in the family context, what is the role of the child in the mediation, and how parents mediate specific online risks and opportunities.

YOUNG CHILDREN'S ONLINE EXPERIENCES

To understand parenting in the digital age, it is necessary to understand young children's online behavior because the activities that children engage in with digital technologies can lead to

experiencing different kinds of outcomes. Findings related to negative experiences and outcomes (i.e., risks and harm) show that children's technology use can be associated with content risks (e.g., seeing upsetting pictures), contact risks (e.g., receiving unwanted messages from strangers), and conduct risks (e.g., online aggression) (Livingstone, Mascheroni, & Staksrud, 2017). Positive experiences and outcomes (i.e., opportunities and benefits) can also be divided into the same broad areas: content (e.g., learning new information), contact (e.g., enhancing social competencies), and conduct (e.g., identity expressions).

The risks and opportunities for adolescents and youth are well-documented, and to some extent also for the population in middle childhood. There are wide national studies for these ages in the United States (Youth Internet Safety Survey, ages 10-17) and in Europe (EU Kids Online II and III, ages 9-16). They focus on the prevalence, related factors, associated risks and opportunities, and coping strategies for selected online activities. Research on younger children and their use of digital technology is more scarce and has only recently begun to expand; for example, recent research in the USA focuses on the role of media in children's development, especially in the context of education (e.g., Blackwell, Lauricella, & Wartella, 2014). However, most research has mainly been published in descriptive research reports (e.g., Chaudron et al., 2015; Rideout & Katz, 2016) or in reports that have a dominant focus on preschoolers (e.g., Marsh et al., 2015).

Research findings indicate that preschool children (Marsh et al., 2015) and children around 7 years old (Chaudron et al., 2015; Nikken & Jansz, 2014) are engaged in more limited online activities and thus are exposed to different risky situations than the older population – such as different content that is evaluated as uncomfortable, or commercial risks. Children aged 8 and older progressively expand the range of their activities in comparison with younger children (e.g., they start using social networking sites, play online games; Ofcom, 2016), which may lead to experiencing more varied risks as well as opportunities. New activities that children engage in represent unique experiences for children to cope with, but also pose a challenge for the whole family, which must dynamically react to the children's development.

PARENTAL MEDIATION

According to Youn (2008), parental mediation is a form of parental socialization because parents, as the primary socialization agents, influence their children's behaviors and attitudes to become more competent technology users. We defined parental mediation above as parental management of the relation between children and media in line with Livingstone and Helsper (2008). Parental mediation could also be seen as a "specific" or "new" type of parenting. However, many different classifications of parental mediation have been formulated in previous studies (such as Nikken & Jansz, 2014; Zaman, Nouwen, Vanattenhoven, de Ferrer, & Van Looy, 2016; Livingstone, Ólafsson, et al., 2017).

The first studies of parental mediation in children's television viewing identified three main types of parental mediation: active/instructive mediation, restrictive mediation, and co-viewing (Nathanson, 1999; Warren, 2003). Based on previous classifications, Livingstone and Helsper (2008) created four widely-used mediation types specifically for the mediation of children's digital media usage: active co-use, technical restrictions, interaction restrictions, and monitoring. The active co-use category suggests that sharing the media is more active when the child uses the internet than when they watch television. It refers to behavior in which the parent is sitting near the child and talks to them about the online activity. Co-use also involves restrictions associated with the communication of personal information online, shopping online, completing forms, etc. These

restrictions are included in this category because parents can explain and enforce such restrictions during co-use. Diverse restriction strategies were divided into two different categories: technical restrictions and interaction restrictions. The interaction-restriction category is associated with the prohibition of contacting others (e.g., using e-mail, chat, game playing). Technical restrictions represent the installation or use of software that, for example, filter content and prevent access to some websites. The last category, parental monitoring, is connected to checking the child's activities after the child's use of the internet, either covertly or overtly (Livingstone & Helsper, 2008). The previous research on the styles of parental mediation was mostly carried out among families with children 9 years old and older (i.e., Haddon, 2015; Talves & Kalmus, 2015). Research on families with younger children is more scarce. Research on the mediation of younger children was carried out by Nikken and Jansz (2014) with Dutch parents of children aged 2 to 12. The authors revealed the following five mediation styles: co-use (e.g., using the internet together); active mediation (e.g., helping children understand what to do when being harassed online); restrictive mediation of access (e.g., general restrictions, time limitations); restrictive content-specific mediation (e.g., banning certain sites); and supervision (e.g., parent's monitoring of their children's internet use when nearby). The authors identify supervision as a new mediation in the context of online behavior. In contrast to Livingstone and Helsper (2008), Nikken and Jansz (2014) did not find monitoring the child's activities after the child's use of the internet to be a distinct type of mediation. They hypothesized that this kind of mediation applies more to older children.

Zaman et al. (2016) carried out a qualitative, mixed-method study in Belgium that included 24 Flemish parents and their 36 children, aged 3 to 9. They investigated the strategies the parents used to mediate their young children's media use and what contextual factors influenced the parental mediation practices. They identified the following parental mediation practices: restrictive mediation, participatory learning involving co-use plus active mediation, and distant mediation. Restrictions of activities in terms of time, device, content, location, and purchase were found. Two types of co-use emerged in the data when parents behaved as helpers or as buddies. Parents behaving as helpers guided their children when they learned how to use the medium or when problems with usage arose. Parents as buddies shared some media activities with their children purely for enjoyment. Active mediation included discussions between the parents and their children. The distant mediation included "deference" when parents decide not to intervene and to respect the autonomy of their children, and "supervision", which is associated with situations where the parents allow their children to use digital technology independently but under close parental supervision.

Zaman et al. (2016) also revealed several external and internal contextual factors that are associated with parental mediation. Situational factors were related to weather, family composition and schedule, social contact, the disposition of media devices, and the architecture of the house. Internal factors were related to attitudes, digital media, health, and parenting. The authors describe how parental mediation is changing in relation to the contextual demands that evolve over time (such as the popularity of devices) or vary between locations (such as less strict rules in the car).

In the present article, we follow this line of research on the situational factors of parental mediation. We aim to develop an understanding of specific parental mediations in relation to online opportunities and risks in the family context.

FACTORS ASSOCIATED WITH PARENTAL MEDIATION

Recent research has discovered several factors that are associated with the parental mediation of technology use. On the individual level, studies have indicated that parental mediation can be related to demographic variables, such as the age and gender of the parents (Kirwil, Garmendia, Garitaonandia, & Martínez Fernández, 2009; Sonck, Nikken, & de Haan, 2013); the parents' education (Kirwil et al., 2009); the age and gender of the children (Eastin, Greenberg, & Hofschire, 2006; Livingstone & Helsper, 2008); the household socioeconomic status (Livingstone & Helsper, 2008); and the family size (Sonck et al., 2013). Parental mediation is also associated with the parents' perceptions of their children's digital skills (Livingstone, Ólafsson, et al., 2017); the level of the child's (Lee & Chae, 2012) and the parents' media literacy (Mendoza, 2009); the level of the parents' digital skills (Livingstone & Helsper, 2008); the child's motivation to use media; the frequency of media use in the family (Lee & Chae 2007; Livingstone & Helsper, 2008); and the parents' views on the various effects of media content on their children (Sonck et al., 2013). On the socio-cultural level, studies have indicated that parental mediation of their children's internet use is affected by the culture of their country (i.e., countries' individualistic or collectivistic values; Kirwil, 2009) and their country's level of welfare (Kalmus & Roosalu, 2012). These studies focused on factors associated with parental mediation and they were based on investigations within families with children aged 9 and older.

The other relevant factors for families with younger children were investigated even less. One project researched 896 Dutch parents of children under 7 and investigated which factors on both the side of the child and the parent characteristics predicted mediation by the parent (Nikken & Schols, 2015). The authors revealed that children's media use is predicted by the children's skills to use the media and the age of the child. Furthermore, parental mediation strategies depended on the parents' attitudes toward media. Finally, the authors revealed that mediation strategies varied among families with infants, toddlers, preschoolers, and early-childhood children. The study indicated that parental mediation was also associated with the children's media skills and media activities.

RESEARCH GOALS

As we explained above, our research assumed that the child is an active subject in the family system and that the child plays an active role in the process of technology mediation. The role of young children in the mediation process has not been sufficiently investigated in previous research and we aim to fill this gap with our research. In our investigation, we focus on the mediation strategies that parents use to shape the online experiences of 7-8-year-old children and we investigate the parental mediation of specific online opportunities and online risks for young children. We sought also to understand the situational factors that play a role in the parental mediation of technology risks and opportunities, and the active role of the child from the perspective of the parents

METHOD PARTICIPANTS

The sample consisted of 10 families from the Czech Republic ($N_{\text{mother}} = 8$, $N_{\text{father}} = 6$, $N_{\text{children}} = 21$) who had at least one 7-8-year-old child ($N = 10$, $M = 7.5$ years $SD = 0.39$) who used a tablet, PC, or smartphone at least once a week. The parents' ages ranged from 35 to 41. For detailed information see Table 1. Seven families had two parents; three had a single parent (a mother); and one family shared their household with a grandfather. All of the parents were Czech. Their education ranged from vocational to university level. The income of the families also varied from under half of the national median to above the national median. All the families had PC/laptops, smartphones, and mobile phones in the household. Seven families owned at least one tablet. The

children had access to these devices. Some children had possession of their own devices (specified in Table 1). Within this research, we analyzed data from interviews with parents.

PROCEDURE

Our research was part of a research project called “Young Children (0-8) and Digital Technology” carried out by the Joint Research Centre, Institute for the Protection and Security of the Citizen (see Chaudron et al., 2015). The present research is based on a more detailed re-analysis of the data collected in the Czech Republic only. Individual face-to-face interviews – separately with the parent(s) and separately with the child/children – were carried out from September 2014 to October 2014. Interviews took place in the home of the participants. The semi-structured interviews with parents were between 35 and 85 minutes long (60 minutes on average). Parents were interviewed about four main areas: (1) devices employed, activities, and skills; (2) parental mediation; (3) family rules about technology usage; and (4) the parents’ perceptions of new technologies and parental concerns of technologies. The interviewers used an interview guide to follow questions and observation protocol as developed by the Joint Research Centre (for detailed information, see Chaudron et al., 2015).

To find participants, six primary schools in the South Moravia region were sent a request to forward invitations for participation to students of second-year classes, which were then delivered to parents. Approximately 350 invitations were distributed in this way. Thirty families registered to participate in the study and interviews were subsequently held in 10 of them. Families were chosen to create a variable sample – in order to have two- and one-parent families; to have families with one and more children; to have families with child/children who owned a device on their own etc. The parents received gifts for their children provided by the Joint Research Centre and 1,000 CZK (approximately 37 EUR) for participating in the research (the national median monthly income for a two-member family is 24,000 CZK, approximately 888 EUR).

All of the participants were informed about the purpose of the research and they provided written informed consent. The study received ethical approval from the European Commission. For more information, see the general report from all seven countries (Chaudron et al., 2015)

Table 1. Detailed Description of Participants

ANALYSES

All interviews were transcribed verbatim. For the purpose of this study, only interviews with parents were analyzed. A Thematic Analysis procedure was applied as the analytic method (Braun & Clarke, 2006). The first and second authors conducted the analyses. The six steps of the Thematic Analysis method were used:

- (1) getting familiar with the data through multiple readings of the transcripts in an excel file
- (2) generating initial codes to highlight topics in the data
- (3) grouping the codes into categories and searching for recurring themes
- (4) reviewing the emergent themes
- (5) defining and naming the themes
- (6) producing the report (Braun & Clarke, 2006)

To increase the validity of the findings and to strengthen the inter-coder triangulation of results, an audit was completed. The third author validated the themes developed by the first and second authors.

RESULTS

The parents of 7-8-year-old children face the necessity of using mediation strategies for technology usage. We describe three themes (see Table 2) related to the mediation strategies of parents: (1) Mediation strategies of technology usage; (2) Time and place management of mediation strategies; and (3) Child as a co-creator of mediation strategies

Table 2. Mediation Strategies of Parents of 7-8-Year-Old Children

MEDIATION STRATEGIES OF TECHNOLOGY USAGE

Families in our sample reported mediation strategies for general technology usage and mediation strategies in the context of specific technology opportunities and risks. Two subthemes were identified:

(A) the mediation of technology opportunities, and (B) the future mediation of technology risks. Mediation strategies for general technology usage are related more to general rules and beliefs than to specific risks and opportunities. The parents' mediation strategies for young children are often linked to the belief that children are too young and they do not do inappropriate things with technologies, such as communicating with strangers or finding inappropriate content. As one family (C5) reveals:

Father: "For now they are visiting just appropriate sites, for now they are not going elsewhere, but we will see how it will be in the future. (...) such as they could find websites that are not for them where is..."

Mother: "...where is some advertisement and she [daughter, 7 years old] will click on it and there will be a porn site or something. (...)

Father: But now it is ok, we are waiting [for what will be in the future].

The majority of the families do not have strict rules for technology usage. Those families usually set rules situationally: "I never really had the intention to set [rules], because sometimes he doesn't even touch it and sometimes he sits there for a bit longer, for example. But it is not really like – well now you have an hour. I never really, I never intend to impose it" (Mother, C10). Technology usage in such families was perceived to be one of many activities. Therefore, they did not have any special rules. Nevertheless, general rules were applied. For example, free-time activities (including technologies) were allowed after chores and schoolwork were completed, and children had to request permission to use technologies.

Some of the families had strict rules. These rules related to the time spent with technologies and to the more accurate control of technology usage. Some parents set up rules specifically for technologies that were perceived as something special. For example, in some families technology usage was a form of reward or punishment:

"Anyway, for a reward, and when there is time, that means when... they have a lot of free-time activities, so when we come home, the first thing is to do the homework. When they are finished with the homework and there is time left and there were no problems at school, then there is some kind of reward" (Father, C2).

Mediation strategies for specific opportunities and risks were also identified. Parents reported (a)

co-use – the parent uses technology together with the child; (b) active mediation – the parent explain issues related to technology; (c) supervision – the child uses technologies while a parent is nearby; (d) parent as role model – the parent use technology while the child is observing the parent's activities; (e) restrictive mediation – the parent set up restrictions in the context of technology usage; and (f) trial and error – the parent knowingly lets the child use trial and error while using technology. The next two subthemes describe the content of the parental mediation – the mediation of opportunities and the mediation of risks as perceived by the parents. That means that the parents themselves linked some of their specific mediation activities to the opportunities, such as digital skills or possible risks. We believe it is important to clarify what the goal is for these mediation activities from the parental perspective, especially because parents are very active only in the mediation of opportunities and almost completely inactive in the mediation of risks, as we show below.

Mediation of technology opportunities. Parents from our sample gave extensive examples that provided insight into their mediation of technology opportunities. Technology opportunities perceived by parents for children include free-time activities, practical technology usage, and educational purposes. Parents also mentioned digital skills that children could learn/improve during all of the above-mentioned opportunities. In terms of the mediation strategies of online opportunities, from parent reports we identified the following strategies: co-use, active mediation, supervision, parent as role model, and restrictive mediation, and some parents let their children learn themselves by trial and error.

Digital skills. Trial and error was linked to digital skills. Some parents let their children learn to use technologies themselves, like how to download applications, and use them: "Intuitively. Trial and error, so it is not like it would be targeted... she tries it herself" (Mother, C10). Co-use was also used to manage digital skills. This strategy was initiated by either the children or the parents. Some parents pointed out that their children ask how to continue a game, and they ask for help when they can not read or speak the language. As a father (C8) explained: "They [daughter, 7 years old, and son, 10 years old] could download games on their own, (...) when the game asked for some information they asked what to do and we [father and mother] told them." Co-use initiated by parents was linked to active mediation when parents explain, for example, how to use PC components, like a mouse or a keyboard and how bookmarks, browsers, and some applications work. As a father (C4) pointed out:

"I showed him that he has a bookmark there. Then when he wants to look at something, there it is. And then I saved him tutorials for rubber-band knitting [a popular activity for children in the Czech Republic] into the bookmarks. I told him that he does not need to look for it, he does not need to google it. It is just enough to open it in the bookmark bar. He knows that now."

Parents as role models improves digital skills because it allows children to observe their parents' technology usage. Parents motivate their children to use technologies in the same way as they use them: "Otherwise, he, of course, sees us working, so for example when they are waiting for when a person finishes their work and lets them go on the internet, they see part of the work" (Mother, C3).

Free-time activities. Supervision is usually applied during free-time activities when children are allowed to use technology while a parent is nearby. Co-use is also part of some free-time activities, such as playing games or watching videos. Free-time activities, especially games, are a part of the

restrictive mediation, such as when some parents control games. As a father (C2) reflected: "So we need to choose, select, what is a suitable game for [my son]."

Practical technology usage. Parents also mentioned teaching children how technologies can help them in everyday life. They try to show children the available possibilities, like different programs and websites that could help people connect their online and offline lives, such as when they search the family vacation together. Parents usually use active mediation in combination with co-use while they search for timetables (e.g., so children get to school on their own), vacation destinations (e.g., show pictures of places and the possibilities for how to get there), free-time activities (e.g., websites of different free-time activity clubs), and shop online. For example, a father (C5) described how they look for free-time activities in their family (daughters 5 and 7 years old): "...photos and also the virtual tours are really great... for example, Wikyland [Child Park]. So we just looked, how it looks there, so we looked at the photos – Yeah, we want to go there [the daughters said]."

Education. For educational purposes, parents usually use co-use or supervision to mediate some (school) activities, such as to learn reading, writing, and mathematical skills, as a father (C5) reveals: "When she [daughter, 7 years old] was younger, she learned how to write, she liked it. We opened Word and I told her 'A' and she found and wrote 'A', and then she tried to write also whole words." Parents also mentioned that some games could improve their children's language knowledge and also basic economics skills, like profits and losses in games, or social skills, like fair play, or how to take care of someone. A mother (C9) talked about an educational program on a CD that her son used to learn languages while she supervised the process: "[My son, 8 years old] learns Czech language and English. He had this CD, there are some assignments and when he fills them in he goes to the next level and he travels around the world."

Future mediation of technology risks. Parents reported knowledge about technology risks, such as internet overuse, game addiction, meeting unknown people online (i.e., stranger danger, pedophiles), cyberbullying, data misuse, and inappropriate content. Nevertheless, every parent in our sample perceived those risks as not yet present and the use of mediation strategies unnecessary for young children. As a mother (C5) reported

"Now we really cannot do anything, because like my husband says, they are not at the stage when they would have some need for social networking sites, so there is no point in telling them. Now we tell them not to sit in a car with a stranger after school. We don't jumble their minds with the internet."

This do-nothing strategy could also be linked to the belief that mediation strategies will only be needed when something happens: "I deal with things when they come. Like, I don't worry about something that is not an issue. I try not to forbid something that has not yet happened" (Mother, C1). So far, parents wait and do not pay attention to this potential problem. For every parent in our sample, technology risks for their children in the future were connected to social networking sites (SNS). Two parents revealed that they do not want their children to know that SNS exists. They try to avoid the sites as long as possible, and they would rather lie about their SNS use than explain it. Other parents linked the start of technology risks with the development of reading and social skills, and the necessity to increase technology usage because of schoolwork.

Parents expect to deal with those risks in the future when the children start to visit SNS and develop

an online social life. For example, a father (C8) shared his fear of cyberbullying:

“We are probably afraid of contacts with different people on social sites, but we are afraid maybe more of bullying or cyberbullying than of contacts with older people with the inclination to pedophilia. Not that, I don’t think so. I think that our children are cautious enough.”

Another father (C2) shared his struggles about the mediation of danger from contact with strangers. Once he tried to talk about it with his 8-year-old son, but he did not know how and he found it difficult to use appropriate language and not scare him; therefore, he had not yet done it:

“Here you have a person, a small child, second grade, so how to tell him this fact about these people that abuse children or they pretend to be someone else... And at the same time it is probably difficult to do it in a way the child can understand, that things like this happen, and that it can be unpleasant, but at the same time not to scare them with something that it is dreadful.”

Parents differ about the strategies for how to mediate those risks in the future. Some parents do not yet know how they will manage it. Others would like to use mediation strategies that they already know from the offline world, and apply them to the online environment, i.e. the mediation of meeting strangers in the offline world applies similarly in the online one. Some parents also rely on school and the schools’ technology risk-mediation programs. However, every parent agreed that the mediation of technology risks will be necessary in the future.

TIME AND PLACE MANAGEMENT OF MEDIATION STRATEGIES

Time and place management of mediation strategies are important parts of the mediation process of technology usage. Parents reported that they distinguish between free time and working time. Mediation can be different on weekends, during holidays and days off, and during school days. As a father (C5) expressed: “During holidays, there is more freedom but during the school year... when the older daughter comes home from school, first she has to do the homework and only after that she can play.” The time of day also made a difference in the mediation process. Some families set up rituals related to the daytime and nighttime. For example, watching fairy tales before bedtime or using technologies while the parent was walking the dog in the morning.

There are also changes for exceptional occasions, like traveling, a doctor visit, an illness, or bad weather. As a mother (C10) remarked: “These mobile phones, during travelling when there are long periods of waiting, then there (we use them).” Exceptions may also be made for visits by friends and a family member, like grandparents who may apply different mediation strategies than the parents. Another special occasion is when the parents need time for their own work and they required the children to be engaged and to entertain themselves. Technologies are perceived as helpful in such occasional situations. As a mother (C10) reflected: “At home, when I need to do something quickly and I need to somehow, like, put her away. When I say it bluntly, it really is for putting her away.” Additionally, special occasions are also related to situations when children are alone, such as when they go to school or to a free-time activity. During such situations parents perceived smartphones as a communication and a monitoring tool to stay in touch with their children. This motivation is pivotal for some parents: “That is why I bought him the mobile phone, so I could control him when he would sometimes go with a friend and now I could just call him to check and know where he is” (Mother, C6). Nevertheless, when children have their own smartphones they also have the opportunity to use them without parental supervision.

Consequently, these occasions usually lead to a more liberal mediation strategy, where children are not adequately controlled, or no mediation strategy. Parents let their children use technologies by themselves, sometimes without supervision, during exceptional occasions like an illness or while parents are working or doing household chores. As a mother pointed out (C9): "I can use the P to let them watch something so they would not be scared while I go out for a walk with the dog."

We can conclude that situational factors in the mediation process are strong. Parental mediation strategies are co-constructed by parents and their children and are changing according to the specific family situation. The mediation of technology is not a stable parental behavior, but it is always developing and changing in context, according to time, place, and the children's characteristics and behavior.

CHILD AS A CO-CREATOR OF MEDIATION STRATEGIES

The parents' perceptions of their children's approaches to technologies seem to be important aspects of the mediation strategies. We identified three relevant subthemes of this category: (A) technologies as a natural part of the child's environment, (B) the child's interactions with the parents, and (C) the parent's perceptions of their child's reaction to technology usage.

Technologies as a natural part of the child's environment. The parents in our sample reported that children behave naturally and spontaneously with respect to technologies, and that technologies are a natural part of their everyday lives. They naturally learn quickly by observation and imitation. They quickly develop digital skills and use technologies on their own. For instance, a father (C2) said: "The children, they perceive it differently from the grownups, naturally right. When I show them something, they take it completely naturally and they are not learning, they just see it and that is how they do it." Such an approach encourages parents to perceive technologies as an important part of the everyday lives of their children. Parents think that children are learning naturally from observing other people. They believe that these abilities will help them in the future to use technologies properly.

The child's interactions with the parents. Parents appreciated that their children communicated with them about their technology usage. This subtheme is linked to some mediation strategies, namely co-use initiated by children and parent as role model. Parents reported that their children were able to ask for help when they struggled while using technology, and they asked for permission to use technology. As a father (C4) reported: "Every time there is some kind of problem or when he needs help with something, he comes to me. He just comes to me and asks." Parents as role models reported that their children also liked to observe their technology usage to learn new things. Consequently, parents reported that their children shared their curiosity and had a tendency to ask questions about several topics connected to the technologies. These strategies soothe parents. Parents trust their children and rely on their ability to ask for help.

The parent's perceptions of their child's reaction to technology usage. Two approaches were identified within the third subtheme:

(a) technology usage is perceived by parents as one of many activities, and (b) technology usage is perceived by parents as the preferred activity of the child.

Technology usage is perceived by parents as one of many activities. Some parents reported their children's technology usage in the context of many other activities, such as sports, games with

friends, outdoor activities, and hobbies. Parents also talked about their children's tendency to follow rules and make compromises. Some children are, according to their parents, able to stop using technologies by themselves or when asked to. Parents also perceived that some children spend an acceptable amount of time suitable amount of time with technologies, and they like also other offline activities as well. Technologies are "just" another option of many activities. As a mother (C9) put it: "I was surprised, my daughter [6 years old] is not envious that her brother [8 years old] already has a mobile phone. She is active herself. She is drawing, playing with dolls...she had more activities than technologies." Some parents reported that they have a tendency to set less rules or no specific rules at all. For example, children spend an acceptable amount of time on technologies by themselves, so the parents do not need to set time restrictions. Some parents believed their children behave responsibly. As a father (C5) reported:

"During the school year, the older daughter is so responsible that she deleted the games where you have to take care of animals. That means, she uninstalled them... and when the holidays come she will install them again so she will have time for them."

Technology usage is perceived by parents as the preferred activity. In comparison to previous category, other parents have different experiences with children. These parents perceived their children to be unable to stop the activity themselves or even when asked to. Sometimes they talked about potential tendencies to addiction or they reported that their children were fascinated by technologies. That means that their children would like to use technology any time when it is possible: "I have a feeling with [my son] that he is more inclined to habits... when he plays these games it can be on any device, he has trouble detaching from it, and he can spend endless time with it" (Father, C2). For these children, parents reported the tendency to set more rules and control more media usage. Some parents remarked that they talked with their children and explained things to them, such as the difference between fiction and reality.

The parents of three families reported having one child who was fascinated by the technologies and another who balanced technology usage with other activities. These parents distinguished those two preferences and had the tendency to compare their children. They are able to mediate each child in a different way according to that child's habits with technology preference. As the mother (C3) pointed out:

"As far as computers are concerned, a tendency of almost addiction appeared with [my older son – 7 years old]. Like, from early ages he was fascinated. And, for example, the younger son [3 years old] does not have it at all. There I don't have the need to look at it as closely, because when he, for example, watches or does something on the computer for a while, then he comes to me and says that he had enough."

DISCUSSION

Our study contributes to the current stage of knowledge of the parental mediation of technology risks with in-depth qualitative insight and focus on the situational factors in families with children aged 7-8. Our findings indicate that the parental mediation of digital media is a dynamic process that is co-constructed by the parents and the children in the context of the actual situation.

In the next three sections, we discuss our findings concerning the mediation strategies of online opportunities and risks, the time and place management of mediation strategies as a factor related to parental mediation, and the child as a co-creator of mediation strategies

MEDIATION STRATEGIES OF TECHNOLOGY USAGE

Our results suggest that parents use various kinds of mediation strategies, such as co-use, active mediation, supervision, parent as role model, restrictive mediation, and trial and error. Similar types of parental mediations have already been identified by previous research (Nikken & Jansz, 2014; Zaman et al., 2016). In our investigation, we enrich current knowledge by linking these mediation strategies to specific online opportunities and risks. We believe this distinction between the different goals of the mediation strategies is important because our results have revealed that parents in our sample mostly mediate the digital opportunities and do almost no mediation of the online risks for young children. Our analyses demonstrate only the perspectives of parents, such as the parents saying that the “trial and error” mediation is linked to opportunities because “children are learning on their own”. However, it is clear that such an approach of parents might be problematic because children who learn on their own are also endangered by several online risks (Nikken & Jansz, 2014; Smahel, Wright, & Cernikova, 2014), but parents did not acknowledge this problem with self-learning in our research. In the virtual environment, the border between online opportunities and risks is more blurred than it is reported by the parents in our study, who mainly described the mediation of online opportunities. Future research may reflect the possible consequences of this “trial and error” approach, such as the relation to possible online risks that children could experience while learning on their own.

The mediation of technology opportunities was mostly connected to “content opportunities” where parents let children learn new things and let them improve their digital skills. Digital skills are mediated by different approaches, such as co-use, active mediation, and parent as role model. Contact opportunities that were identified in the previous research on older children were not directly present in our results. Some parents used games or programs in the educational context, which could improve some aspects of their children’s social skills, such as fair play. Parents also did not mention any conduct opportunities for their children. This could be linked to the characteristics of their children’s activities. Children in our sample do not participate in SNS, blogs, or online games. Parents also did not mention these applications as possible opportunities in the future.

Concerning the mediation of online risks for young children, it seems that parents in our sample underestimated the possible online risks. The parents were mostly afraid of the “contact risk”, such as the possibility that their children could communicate with strangers online, like within social networking sites. Therefore, it seems that parents from our sample were mostly afraid of the future, which is in line with the study carried out in Singapore on the population of families with children aged 7 to 12 (Shin, 2015). But previous research has also indicated that young children (under 8 years old) are sometimes exposed to interactions with online strangers within online games (Brito & Dias, 2016). Parents in our sample were not aware of this problem and they planned to mediate online risks in the future when their young children start to communicate more online. Future research should investigate this issue on larger samples and in more cross-cultural contexts.

Further, within our sample none of the parents spoke about the “content risk”, such as advertising, violent content, sexual content, or idealized thin or muscular images that can be displayed to children on the internet (Staksrud & Livingstone, 2009). For instance, media exposure of the ideal physique could be linked with some eating disorders symptomatology, mostly among users at risk for developing an eating disorder (Hausenblas et al., 2013). It seems that parents in our sample

underestimate this kind of risk. In the previous research, about 10% of parents reported that their children under 5 years old had made in-app purchases by accident and that children had been exposed to content that made them feel uncomfortable (Marsh et al., 2015). This theme requires further research that should involve more methods, such as recording the screen devices of children. It is evident that some parents do not know about inappropriate content and further research should probably directly investigate the online behavior of children.

The parents in our sample also did not speak about the possible “conduct risk” where the child becomes an actor within possibly risky scenarios, such as creating aggressive content, and harassing or bullying others (Staksrud & Livingstone, 2009). However, Marsh (2010) reported these kinds of behaviors within the virtual world among 5-8-year-old children, such as throwing virtual snowballs at avatars, excluding avatars from parties, and name-calling. It seems that parents are not aware that their children aged 7 and 8 might engage in this type of possibly risky behavior. In our investigation, parents reported almost no mediation strategies related to online risks, but they reported many strategies for enriching their children’s opportunities, such as digital skills. The enrichment of digital skills might lead to better resilience against online risks. Vandoninck and d’Haenens (2014) reported that technical instrumental actions, such as deleting, unfriending, or blocking certain people, might lead to successful preventive strategies against online risks.

Time and Place Management of Mediation Strategie Time and place was described by parents as a very important factor for the mediation itself. This result is in line with the research of Zaman et al. (2016), who also indicated the importance of considering contextual factors, like when, where, and under which external conditions children are allowed to use the media. Several studies have shown that parents use rules to mediate their children’s usage (i.e., Livingstone & Helsper, 2008). Our study indicates that rules are not strict in some families, and that the rules are set more situationally in relation to the context, such as where and when the children use the technology and also what the needs of the parents are. Therefore, some parents are not able to report specific rules of technology usage that are more contextual and they rely on general rules that are valid for both offline and online life, such as when children finish their homework they can play their dolls or the tablet.

Our results indicate that parental mediation strategies change according to the family situation. They are not a stable, easily measurable behavior; rather, they emerge over and over again according to time, place, and the parents’ and children’s characteristics and behavior. Up-to-date research has mostly measured the socio-demographic factors of parents and children that impact parental mediation, such as gender, age, education, digital skills (i.e., Livingstone, Ólafsson, et al., 2017; Nikken & Schols, 2015). We suggest that future research should involve the context of the situation more, such as the time and place of the application of the mediation strategies, because there is nothing like stable general mediation. Therefore, we recommend that future surveys should not only ask about general parental mediation but also connect the mediation to a concrete situation and context. Future research should also reflect the role of the parents’ perceptions of their children’s behavior, such as their ability to ask for help. When parents, for example, believe that their children will ask them for help if a problem occurs, they apply fewer mediation strategies than if they believe their children will not ask for help. These situational factors, such as the time and place management of mediation strategies, also play a role in the possible underestimation of online risks because, in certain situations, such as travelling and when parents need time for themselves, parents apply fewer mediation strategies or they do not use mediation strategies at all.

CHILD AS A CO-CREATOR OF MEDIATION STRATEGIES

According to Mesch (2009), the research of parental mediation was based on the premise that technologies can affect children's attitudes and behaviors. These technological effects can be influenced by parental activities to a certain extent. Nevertheless, our research indicated that parents are also influenced by their child's behavior, which then affected their mediation strategies. In our perception, parental mediation is more a process of the interactions between children and parents that co-constructs the mediation strategies of the parents. The reported parental perceptions of children as the co-creators of the mediation strategies is in line with the new sociology of childhood (Christensen & James, 2008), which presents the child as an adequate socialization agent and not just the recipient of parental care. Although our research is from the parental perspective, the parents acknowledge the role of their children in the mediation process. This result also supports the study of Livingstone, Ólafsson, et al. (2017), which indicates that the parental mediation of technology usage is interconnected with the parents' perception of their child's digital skills. When parents perceive a child as a competent internet user they support their activities, such as allowing them to use the technology for a longer time and without constant supervision. On the other hand, parents applied more restrictive strategies for less digitally skilled children which may further limit their possibilities for increasing digital skills. Future research should also reflect this position and should be focused on the different aspects of the child's behavior and the various factors that impact the parental mediation.

LIMITATIONS AND FUTURE RESEARCH

Our investigation was carried out within only 10 families in the Czech Republic and the generalization of the results is very limited. We endeavored to make the sample various and we included families in different configurations (see Table 1). The nature of the sample allowed us an in-depth exploration of the families where children have regular access to technologies. Unfortunately, we do not know how it works in families with no regular access to technologies. We also did not have a family with young children whose social networking sites in our sample. It may be that families with such young children use different mediation strategies because some parents said that they will use different strategies in the future when their children meet people online, such as within social networking sites. It is also possible that the parental mediation strategies of young children's technology usage varies across countries and cultures. We recommend future quantitative and comparative research to validate such hypotheses. Our investigation was also focused only on the perspectives of parents, which is a substantial limitation. It might be that children would bring different perspectives to the investigation.

Implication

Our research indicates that parental mediation is a dynamic process that is co-constructed by the parents and the child in the context of the actual situation. This could indicate that it might be more effective to give education concerning digital skills to both parents and children together, such as in families and/or through online courses, because such education would affect both of the actors within the mediation process. It is also important to recognize that there is typically not one parental mediation strategy, but the strategies vary according to different situations. The "optimal mediation" could vary at different places (such as at home, on vacation, while travelling, or with grandparents) and at different times (during weekdays, during weekends, or during holidays). The future education should be aware of these different contexts and this knowledge could also be applied to educational programs for children, parents (Cook, 2016) and teachers (Karaseva, Siibak, Pruulmann-Vengerfeldt, 2015). For example, it could be recommended that parents should

think more about the mediation of situations where they have less control over their children's technology usage, such as when the child is with grandparents or at summer camps. Parents should speak with other caregivers about their mediation strategies to balance the approaches of both sides, or at least to know the mediation strategy of the other side.

It seems from our investigation that parents prefer to not speak with their young children about online risks. Parents should be informed about the possible online risks for their children, such as the content or contact risks within online games. It might also be important to inform parents that they can help children to avoid risks by teaching their children digital skills.

EMERGING AREAS MCQS

1. Coronary artery disease (CAD) can be determined by this test

- (a) Cardiac catheterization
- (b) Electrocardiogram
- (c) Treadmill stress test
- (d) all of these

Answer: (d)

2. The modifiable risk factor associated with coronary artery disease is

- (a) Age
- (b) Obesity
- (c) Heredity
- (d) Gender

Answer: (b)

3. This is one of the symptoms of Coronary artery disease

- (a) Sleep problems
- (b) Headache
- (c) Diarrhoea
- (d) Pain or discomfort in the chest, lower jaw or arms

Answer: (d)

4. If a stent is not used in a few cases who have coronary angioplasty done, the artery tends to narrow down or get blocked again in 6 months. This is more likely to happen if:

- (a) one smokes
- (b) one has unstable angina before the procedure
- (c) one has diabetes
- (d) all of these

Answer: (d)

5. Coronary angioplasty, part of CAD's treatment involves:

- (a) A new part of artery replaces the blocked section
- (b) to expand artery, medication is used

(c) inflation of a tiny balloon inside an artery

(d) None of these

Answer: (c)

6. Doctors place a stent inside the artery during angioplasty. A stent is a

(a) A new fragment of the artery

(b) A wire mesh tube

(c) A cotton tube

(d) A slow-release medicine capsule

Answer: (b)

7. The _____ branches into Circumflex artery and left anterior descending artery

(a) Left main coronary artery

(b) right marginal artery

(c) Posterior descending artery

(d) None of these

Answer: (a)

8. One of these is not a symptom of acute coronary syndrome

(a) ST Segment elevation myocardial infarction

(b) Non ST segment elevation myocardial infarction

(c) unstable angina

(d) No episodes of dyspnea

Answer: (d)

9. Ischemia is

(a) restriction of blood supply to tissues

(b) Overflow of blood to tissues

(c) Inadequate deoxygenated blood carrying veins

(d) the medical term for shortness of breath

Answer: (a)

10. This is the role of the coronary artery

(a) to carry blood away from the heart muscles

(b) to supply blood to heart muscles

(c) to supply blood to all parts of the body

(d) none of these

Answer: (b)

11. person who incites or abets the commission of a crime and is present actually or constructively is considered to be a(n):

a. accessory before the fact

b. principal in the first degree

c. accessory after the fact

d. principal in the second degree

Answer: (d)

12. Which of the following is true in regard to conspiracy?

a. Conspiracy permits criminal prosecution for the behavior of others as well as for one's own acts

b. Conspiracy is a very important tool for prosecutors

c. Conspiracy may be distinguished from attempt in that attempt requires an act or preparation, whereas the agreement may be sufficient to constitute the act requirement in conspiracy

d. All of these are true

Answer: (d)

13. Which of the following is true of forfeitures?

a. RICO is the only federal statute that permits forfeitures

b. RICO is used frequently as a basis for civil cases because of the potentially high penalties

c. Individuals who lose property through forfeiture laws are always charged with crimes

d. All of these are true

Answer: (b)

14. Which of the following is an example of an inchoate crime?

a. attempt

b. murder

c. rape

d. forgery

Answer: (a)

15. Which of the following is true of solicitation?

a. The incitement may be directed at a crowd, not just a particular individual

b. Solicitation requires a purpose to promote or facilitate the commission of a crime

c. In some states renouncing the solicitation is permitted as a defense to solicitation

d. All of these are true

Answer: (d)

16. _____ crimes are important not only because they are threatening in and of themselves, but also because they may lead to other crimes.

a. Strict liability

b. Conspiracy

c. Inchoate

d. Petty

Answer: (c)

17. Enticing another person to commit a crime is known as:

a. conspiracy

b. solicitation

- c. aiding and abetting
- d. vicarious liability

Answer: (b)

18. A(n) ___ crime is defined as an act involving two basic elements: a step toward the commission of a crime and a specific intent to commit that crime.

- a. conspiracy
- b. inchoate
- c. strict liability
- d. attempt

Answer: (d)

19. To ___ is to assist or facilitate the commission of a crime.

- a. aid and abet
- b. conspire
- c. attempt
- d. coerce

Answer: (a)

20. Which of the following is a defense in an attempt case?

- a. impossibility
- b. renunciation
- c. incompleteness
- d. degree of seriousness

Answer: (a)

21. Some state legislatures have enacted statutes criminalizing the knowing exposure of another to:

- a. syphilis
- b. herpes
- c. HIV or AIDS
- d. All of these are included in the statutes

Answer: (c)

22. _____ means agreeing with another to join together for the purpose of committing an unlawful act or agreeing to use unlawful means to commit an act that would otherwise be lawful.

- a. Attempt
- b. Conspiracy
- c. Aid and abet
- d. Coercion

Answer: (b)

23. _____ was intended by Congress to reach serious cases—major violators who engage in a pattern of racketeering activity.

- a. The Wharton rule

- b.** Forfeiture
 - c.** The Pinkerton rule
 - d.** RICO
- Answer: (d)

24. ___ means association in a wrongful act.

- a.** Negligence
- b.** Mens rea
- c.** Complicity
- d.** Tort

Answer: (c)

25. Under the common law a(n) _____ was the person who committed the crime.

- a.** accessory
- b.** principal
- c.** accomplice
- d.** co-conspirator

Answer: (b)

26. In recent years the U.S. Department of Justice has indicted ___ who, they allege, have engaged in aiding and abetting or conspiring with their clients.

- a.** attorneys
- b.** doctors
- c.** psychologists
- d.** accountants

Answer: (a)

27. The ___ rule is a limitation on parties to the crime of conspiracy.

- a.** accomplice
- b.** principal
- c.** facilitation
- d.** Wharton

Answer: (d)

28. Which of the following does RICO prohibit?

- a.** conducting or participating in an enterprise's affairs through a pattern of racketeering activity
- b.** possession of marijuana
- c.** prostitution
- d.** treason

Answer: (a)

29. The ___ holds that a co-conspirator may be held accountable for the acts of fellow conspirators even though the requirements of criminal culpability for the acts of accomplices are not met.

- a.** Pinkerton rule
- b.** Wharton rule

- c. husband-and-wife rule
- d. two-or-more rule

Answer: (a)

30. _____ is the taking by the government of money, personal items, or assets that were secured from criminal acts.

- a. Racketeering
- b. Confiscation
- c. Arbitration
- d. Forfeiture

Answer: (d)

31. Which of the following laws have been attacked as permitting police to exercise too much discretion, leading to discrimination against racial and ethnic minorities and the homeless?

- a. Fighting words
- b. Vagrancy
- c. Public intoxication
- d. Unlawful assembly

Answer: (b)

32. Which crime has been accepted as inevitable, even essential, and in some societies esteemed?

- a. Fornication
- b. Seduction
- c. Lewdness
- d. Prostitution

Answer: (d)

33. Under common law, _____ refers to the meeting of three or more persons to disturb the public peace, with the intention of participating in a forcible and violent execution of an unlawful enterprise or of a lawful enterprise in an unauthorized manner.

- a. Rout
- b. Riot
- c. Unlawful assembly
- d. Public disturbance

Answer: (c)

34. Which of the following is *not* true regarding child pornography?

- a. In 2002, the U.S. Supreme Court held that virtual child pornography—that which is created by computer simulations—may be owned or sold without violating federal statutes
- b. Congress and many states have enacted statutes aimed solely at child pornography
- c. All Judges support increased sentences for those in possession of child pornography
- d. The federal statute concerning child pornography provides for forfeiture of any property or proceeds obtained, used, or produced as a result of the crime committed

Answer: (c)

35. Which of the following crimes has been declared unconstitutional in many jurisdictions?

- a. Disorderly conduct
- b. Vagrancy
- c. Disturbing the peace
- d. Minor is possession

Answer: (b)

36. _____ is a willfully committed act that disturbs the public tranquility or order and for which there is no legal justification.

- a. Pandering
- b. Riot
- c. Breach of the peace
- d. Disorderly conduct

Answer: (c)

36. Which of the following crimes has been declared unconstitutional in many jurisdictions?

- a. Disorderly conduct
- b. Vagrancy
- c. Disturbing the peace
- d. Minor is possession

Answer: (b)

37. _____ refers to the act by a man who uses solicitation, persuasion, promises, bribes, or other methods to entice a woman to have unlawful sexual intercourse with him.

- a. Pandering
- b. Fornication
- c. Lewdness
- d. Seduction

Answer: (d)

38. Which of the following involves a minor offense, such as drunkenness or fighting?

- a. Pandering
- b. Disorderly conduct
- c. Vagrancy
- d. Loitering

answer: (b)

39. Another word for pandering is:

- a. Pimping
- b. Bribery
- c. Prostitution
- d. Embezzlement

Answer: (a)

40. _____ is consensual sexual intercourse between a married person

- a. Fighting words
- b. Vagrancy
- c. Adultery
- d. Fornication

Answer: (c)

41. Which of the following is not an alcohol and drug related offense discussed in the textbook?

- a. Drug abuse
- b. Public intoxication
- c. Driving Under the Influence
- d. Minor in possession

Answer: (a)

42. Under common law, unlawful assembly was considered a _____.

- a. Felony
- b. Violation
- c. Misdemeanor
- d. Violent crime

Answer: (c)

43. Historically, offenses against and someone other than his or _____ encompasses acts her spouse.

- a. Public decency
- b. Public order
- c. Public morality
- d. Society

Answer: (a)

44. Which of the following was created by Congress in an effort to protect children from pornography on the Internet in libraries?

- a. Virtual Child Pornography Protection Act
- b. Kid's Data Act
- c. Child Online Protection Act
- d. Communications Privacy Act

Answer: (c)

45. Which of the following is one of the conditions that must be met for information to be considered obscene?

- a. The information must be witnessed by a reasonable size audience
- b. The information must be deemed obscene by a reasonable person
- c. The work, taken as a whole, lacks serious literary, artistic, political, or scientific value
- d. There is a significant interest in sex that would offend a reasonable person

Answer: (b)

46. The textbook defines how many types of adultery?

- a. 1
- b. 2
- c. 3
- d. 4

Answer: (a)

47. Some modern statutes use which term rather than the term vagrancy?

- a. Loitering
- b. Pandering
- c. Panhandling
- d. Trafficking

Answer: (a)

48. In 2015, surveys indicated that homelessness in the Los Angeles area of California had jumped during the previous two years.

- a. 8%
- b. 12%
- c. 16%
- d. 20%

Answer: (b)

49. Which of the following is not one of the terms mentioned in the text that have been used to describe a variety of behaviors that some people find offensive to the extent that the criminal law is invoked to try to curb them?

- a. Lewd
- b. Lascivious
- c. Lecherous
- d. Sexual

Answer: (d)

50. Which circuit is called as regenerative repeaters?

- a) Analog circuits
- b) Digital circuits
- c) Amplifiers
- d) A/D converters

Answer: b

Explanation: The main advantage of digital communication is that the signals can be reproduced easily. Thus digital circuits are called as regenerative repeaters.

51. What are the advantages of digital circuits?

- a) Less noise
- b) Less interference
- c) More flexible
- d) All of the mentioned

Answer: d

Explanation: Digital circuits are less subject to noise, distortion and interference as it works on digital pulses and also the pulses can be regenerated.

52. How many different combinations can be made from a nbit value?

- a) $2^{(n+1)}$
- b) $2^{(n)}$
- c) $2^{(n)+1}$
- d) None of the mentioned

Answer: b

Explanation: $2^{(n)}$ different combinations can be made from nbit value. For example, from 2 bit value 2^2 different combinations- 00,01,10,11 can be made.

53. How many bytes does a gigabyte have?

- a) 1 million bytes
- b) 10 million bytes
- c) 1 billion bytes
- d) 10 billion bytes

Answer: c

Explanation: One gigabyte has 1 billion bytes.

54. What is the ASCII value of space?

- a) 32
- b) 48
- c) 96
- d) 65

Answer: a

Explanation: The ASCII value of space is 32 and ASCII value of 0 is 48.

55. Which block or device does the data compression?

- a) Channel encoder
- b) Source encoder
- c) Modulator
- d) None of the mentioned

Answer: b

Explanation: Source encoder converts the digital or analog signal to a sequence of binary digits. This process is called as source encoding or compression.

56. What is the code rate?

- a) k/n
- b) n/k
- c) All of the mentioned
- d) None of the mentioned

Answer: a

Explanation: Here n is the total bits of sequence and k bits are mapped. Amount of redundancy introduced is given by n/k and its reciprocal is the code rate.

57. Pulse shaping is done by which block or system?

- a) Encoder
- b) Baseband modulator
- c) Pulse code modulator
- d) Demodulator

Answer: c

Explanation: Pulse code modulator does filtering process to build pulses that occupy more than one bit time.

58. Equalizer is used for?

- a) Filtering
- b) Diminish distortion
- c) All of the mentioned
- d) None of the mentioned

Answer: c

Explanation: Equalizer is used as a filtering option and also diminishes or reduces the distortion.

59. Source coding block is used for?

- a) Compressing
- b) Digitizing
- c) A/D conversion
- d) All of the mentioned

Answer: d

Explanation: Source encoding does all these processes—compression, digitizing the signal and performs analog to digital conversion.

60. Which measurement considers phase as an important parameter?

- a) Coherent
- b) Non-coherent
- c) All of the mentioned
- d) None of the mentioned

Answer: a

Explanation: Coherent measurement considers phase as an important parameter.

61. The size of the alphabet M in symbol is calculated as?

- a) $2^{(k+1)}$
- b) 2^k
- c) $2^{(k-1)}$
- d) $1+2^k$

Answer: b

Explanation: The size of the alphabet is calculated using 2^k where k is the number of bits in the symbol.

62. Which of the following statements is correct?

- a. Health promotion can refer to any event, process or activity that facilitates the protection or improvement of the health status of individuals, groups, communities or populations.

- D. Kusuma Devi

Answer: B

Explanation: Father of Mahatma Gandhi was Karamchand Uttamchand Gandhi while mother's name was Putlibai Gandhi.

83. Marginalisation means :-

- a. At the centre of thing
- b. Forced to occupy the side
- c. Both (a) & (b)
- d. None of these

Ans : (b)

84. In social environment, Marginalisation is due to :-

- a. Different Language
- b. Different Religion
- c. Minority
- d. All of these

Ans : (d)

86. Explain the reason why groups may be marginalized.

- a. Because of government profit
- b. Less Majority
- c. Both (a) & (b)
- d. All of these

Ans : (c)

87. Who are Adivasi?

- a. Original Inhabitants
- b. tribals
- c. Both (a) & (b)
- d. None of these

Ans : (c)

88. How many percent of India's population is Adivasi?

- a. Around 8%
- b. about 10%
- c. About 4%
- d. about 6%

Ans : (a)

89. Scheduled Tribes is term used for :-

- a. Rich people
- b. Adivasis
- c. People below poverty line
- d. All of these

Ans : (b)

90. Adivasi are involved in the worship of :-

- a. Ancestors
- b. Hinduism
- c. Jesus Christ
- d. temple

Ans : (a)

91. The village spirits are worshipped at :-

- a. home
- b. Town

c. Specific Sacred Groves

d. All of these

Ans : (c)

92. Do Adivasi live close to the forest?

a. No

b. May be

c. Yes

d. Can't say

Ans : (c)

93. Adivasi languages have often been deeply influenced by the formation of :-

a. Mainstream

b. Bengali

c. Sanskrit

d. Santhali

Ans : (a)

94. Adivasis are believed to be :-

a. Exotic

b. Primitive

c. Backward

d. All of these

Ans : (d)

95. Where are all the important metals present in India?

a. Forest

b. Village

c. Home

d. Jungle

Ans : (a)

96. 1835 onwards, Adivasis from Jharkhand & adjoining areas moved in India & the world's like :-

a. Mauritius

b. Caribbean

c. Australia

d. All of these

Ans : (d)

97. Niyamgiri hill is located in Kalahandi district of :-

a. Orissa

b. West Bengal

c. Punjab

d. Kerala

Ans : (a)

98.Niyamgiri is a sacred mountain of :-

- a. Adivasis
- b. Religious people
- c. Both (a) & (b)
- d. None of these

Ans : (a)

99.How many national parks are there in India?

- a. 64
- b. 54
- c. 72
- d. 82

Ans : (b)

100. How many wild life sanctuaries covering 1,09,652 square kilometer :-

- a. 570
- b. 458
- c. 372
- d. 190

Ans : (c)

101. The areas where tribal originally lived and continue to stay in these fields :-

- a. Ancestors
- b. Encroachers
- c. Both (a) & (b)
- d. All of these

Ans : (b)

102. Constitution provides safeguards to religious & _ minorities as a part of fundamental Rights.

- a. Linguistic
- b. Cultural
- c. Both (a) & (b)
- d. None of these

Ans : (c)

103. Minority means :-

- a. Used for the communities that is numerically small in population
- b. Used for the communities that is numerically small in population
- c. More groups
- d. All of these

Ans : (b)

104. Many tribal children are ____.

- a. Balanced
- b. Malnourished
- c. Healthy
- d. Efficient

Ans : (b)

105. Why do we need safeguards?

- a. To protect the state
- b. To protect the society
- c. To protect the rich people
- d. To protect minority community

Ans : (d)

106. Who plays a crucial role in upholding the law enforcing fundamental Rights?

- a. Judiciary
- b. Supreme Court
- c. High Court
- d. All of these

Ans : (b)

107. Every citizen of India can approach the courts if they believe that their fundamental Rights have been :-

- a. Increased
- b. Decreased
- c. Violating
- d. None of these

Ans : (c)

108. How many percent of Muslims are in Indian population?

- a. 13.4%
- b. 61%
- c. 14.7%
- d. 20%

Ans : (a)

109. How many Muslims live in kutcha house according to amenities 1994

- a. 63.6%
- b. 43%
- c. 67%
- d. 87%

Ans : (a)

110. Do Muslims have equal access to basic amenities?

- a. yes

- b.** may be
- c.** No
- d.** Can't not

Ans : (c)

111. According to literacy rate by religion, 2001 how many percent of population is literate?

- a.** 65%
- b.** 100%
- c.** 95%
- d.** 80%

Ans : (a)

112. Which religious group has the lowest literacy rate according to censuses of India 2001?

- a.** Hindus
- b.** Muslims
- c.** Sikh
- d.** English

Ans : (b)

113. High level committee in 2005, was chaired by :-

- a.** Hakkim shekh
- b.** Ram Gopal
- c.** Rajinder Sanchar
- d.** None of these

Ans : (c)

114. Many Muslim women wear?

- a.** Burka
- b.** Skirt
- c.** Payjama
- d.** Cargo

Ans : (a)

115. Marginalisation is linked to :-

- a.** Experiencing disadvantages
- b.** Prejudices
- c.** Powerless
- d.** All of these

Ans : (d)

116. Marginalisation result in having :-

- a.** Low social status
- b.** Not equal education
- c.** Both (a) & (b)
- d.** None of these

Ans : (c)

117. Muslims prefer to send their children to :-

- a. Madarsas
- b. Schools
- c. Colleges
- d. All of these

Ans : (a)

118. Hierarchy means :-

- a. A graded system or arrangement of person or thing
- b. Minor group
- c. Major group
- d. None of these

Ans : (a)

119. Displaced means :-

- a. To stick at one place
- b. to live in forest
- c. Refuse to be forced or compelled to move from their homes
- d. All of these

Ans : (c)

120. Militarised means :-

- a. Presence of Minor Group
- b. Presence of Major group
- c. Presence of Adivasis
- d. presence of armed force

Ans : (d)

121. Malnourishment means :-

- a. Person gets a balance diet
- b. Person gets the extra diet
- c. Person does not get adequate food
- d. None of these

Ans : (c)

122. Which one of the following is the main cause of Marginalisation?

- a. Different dress
- b. Different films
- c. Different Languages
- d. All of these

Ans : (c)

123. Marginalised groups are viewed with hostility.

- a. respect
- b. truth
- c. Fear
- d. All of these

Ans : (c)

124. Give another name of Adivasis

- a. Respective truth
- b. Tribals
- c. Educated person
- d. None of these

Ans : (b)

125. Is Adivasis having their own language?

- a. No
- b. Can't say
- c. May be
- d. Yes

Ans : (d)

126. Which one of the following metal is found in forest?

- a. Sugar
- b. Sweet
- c. Iron
- d. Tea

Ans : (c)

127. Literacy rate among tribal are every_

- a. High
- b. Low
- c. In between
- d. Supreme

Ans : (c)

128. _____ are needed to protect minor Communities.

- a. Safeguards
- b. Legal
- c. Laws
- d. None of these

Ans : (b)

129. How many percent of Muslims are in India's population?

- a. 1.34%

- b. 22.3%
- c. 15.1%
- d. 20.0%

Ans : (a)

130. _____are the importantpart of the women's movement in India?

- a. Religious Women
- b. Common people
- c. Muslim women
- d. None of these

Ans : (c)

131. Marginalisation results in :-

- a. Low social status
- b. not equal access of Eduation
- c. Both (a) & (b)
- d. None of these

Ans : (c)

132. How many percent of Muslimchildren in the 6 - 14 year of age group have never been enrolled inschools & dropped out?

- a. 70%
- b. 30%
- c. 25%
- d. 56%

Ans : (c)

133. In Muslim community, there is alink between economic &_____marginalisation.

- a. Political
- b. western
- c. Socio reform
- d. Social

Ans : (d)

134. Richard Shwederdefines 'cultural collisions' as:

- A. when cultural artifacts arecombined
- B. situations where different culturalgroups come into contact
- C. urban planning that takes intoaccount ethnic heritage
- D. when individuals from differentethnic heritages disagree

Answer: B

135. Which of the following IS NOT trueabout female genital surgery?

- A. procedures may involve mild orsevere modifications to the genitalregion
- B. this practice connects to culturalidentity
- C. worldwide this practice is mostprevalent in Australia

D. one cultural reason for the practice is cultural standards of beauty

Answer: C

136. Richard Shweder argues there is a double standard with respect to female genital surgery. Which statement best supports his argument?

A. the practice exists in part because of cultural norms and values

B. the procedure is acceptable for a Western woman who elects the procedure but barbaric for an African woman who desires the procedure

Answer: D

140. Which of the following is an example of prejudice?

A. only girls should play with dolls

B. I would not hire any person under the age of 30 for this position

C. I like Portuguese food

D. I don't like old folks

Answer: D

141. Which of the following IS NOT a component of attitudes?

A. cognitive

B. affective

C. personal

D. behavioral

Answer: C

142. A stereotype is:

- A.** a belief assigned to an entire group
- B.** present at birth
- C.** our actions towards entire groups
- D.** a perceived threat due to cultural differences in beliefs

Answer: A

143. Which of the following IS NOT a function of stereotypes?

- A.** they help us describe in-groups
- B.** they help us describe out-groups
- C.** they help us validate our in-groups and undervalue out-groups
- D.** connect to how we think about people and social groups

Answer: A

144. Which of the following is an example of a stereotype?

- A.** a perceived threat due to contact with an out-group member
- B.** anxiety due to contact with a stranger
- C.** only women make good nurses
- D.** your negative treatment of an out-group member

Answer: C

145. Discrimination is:

- A.** a belief assigned to an entire group
- B.** present at birth
- C.** our actions towards entire groups
- D.** a perceived threat due to cultural differences in beliefs

Answer: C

146. Discrimination differs from prejudice and stereotypes because discrimination:

- A.** involves our actions and the way we treat others because of their group membership
- B.** is a learned attitude
- C.** is a belief system present at birth
- D.** never has negative or damaging consequences

Answer: A

147. One important difference between discrimination, prejudice, and stereotypes is that discrimination:

- A.** involves our beliefs about others because of their group membership
- B.** is a learned attitude
- C.** is a belief system present at birth
- D.** has an emotional component

Answer: D

148. Which of the following is an example of discrimination?

- A. Younger workers are not loyal to their companies
- B. I would never want to work for a woman.
- C. Asian children are high achievers
- D. I hate customer service representatives who aren't helpful

Answer: D

149. In their work on stereotypes, Cuddy, Norton, and Fiske found:

- A. most participants viewed the elderly both positively and negatively

- C. one explanation for participant responses is social media
- D. no ageism emerged in their study

Answer: A

150. Inter-group anxiety refers to:

- A. unfavorable perceptions we hold about out-group individuals
- B. threats we experience due to our experiences
- C. anxiety from real or anticipated contact with an out-group individual
- D. perceived threats due to cultural differences in beliefs and practices

Answer: C

151. Negative stereotypes are:

- A. unfavorable perceptions we hold about out-group individuals
- B. threats we experience due to our experiences
- C. anxiety from real or anticipated contact with an out-group individual
- D. perceived threats due to cultural differences in beliefs and practices

Answer: A

152. Realistic threats are:

- A. unfavorable perceptions we hold about out-group individuals
- B. threats we experience due to actual experiences with our group members
- C. anxiety from real or anticipated contact with an out-group individual
- D. perceived threats due to cultural differences in beliefs and practices

Answer: B

153. Symbolic threats are:

- A. unfavorable perceptions we hold about out-group individuals
- B. threats we experience due to our experiences
- C. anxiety from real or anticipated contact with an out-group individual
- D. perceived threats due to cultural differences in beliefs and practices

Answer: D

154. In their study with Dutch workers, Curseu and colleagues found:

- A.** symbolic threats were more influential in determining ethnic prejudice toward immigrants
- B.** realistic threats were more influential in determining ethnic prejudice toward immigrants
- C.** negative stereotypes were more influential in determining ethnic prejudice toward immigrants
- D.** inter-group anxiety was more influential in determining ethnic prejudice toward immigrants

Answer: C

155. In their study with Dutch workers, Curseu and colleagues found that:

- A.** repeated positive interactions with immigrants reduced all threats and negative stereotypes
- B.** repeated positive interactions with immigrants reduced negative stereotypes
- C.** repeated positive interactions with immigrants reduced all threats
- D.** repeated positive interactions had no impact on Dutch worker and immigrant relationships

Answer: A

156. The Stereotype Content Model is useful for studies on:

- A.** symbolic threats
- B.** inter-group anxiety
- C.** realistic threats
- D.** stereotypes

Answer: D

157. The Stereotype Content Model uses two traits to study stereotypes. They are:

- A.** warmth and competence
- B.** warmth and nurturance
- C.** warmth and power
- D.** status and power

Answer: A

158. You are interested in studying stereotypes. Which of the following relates to the dimension warmth in the Stereotype Content Model?

- A.** a group's ability to work cooperatively
- B.** social status
- C.** power
- D.** positive attitudes

Answer: A

159. Glick and colleagues studied college students worldwide regarding their perceptions of the US and its citizens after the 9/11 attack. They found:

- A.** US citizens were competent, arrogant, and cold
- B.** the US government was more arrogant than its citizens
- C.** the US government showed more concern for cooperating with other nations

- D. modernization

Answer: D

162. The origins of light skin preference in the US connect to which of the following?

- A. slavery
- B. the Civil Rights Act
- C. interethnic romantic unions
- D. social media

Answer: A

163. Implicit bias is:

- A. an unintentional and unconscious bias towards light-skinned individuals
- B. a learned attitude
- C. a stereotype
- D. a bias on the basis of social status

Answer: A

164. In a study that explored cultural mismatch between jurors and defendants, the authors found that European American jurors were more likely to render a guilty verdict when the defendant was dark-skinned. This is an example of:

- A. a stereotype
- B. implicit bias
- C. a learned attitude
- D. discrimination

Answer: B

165. What is one possible explanation for skin color bias in Mexico?

- A. slavery
- B. a person's occupation
- C. Spanish colonization
- D. implicit bias

Answer: C

166. Xenophobia is:

- A. an irrational fear of heights
- B. an irrational fear of water
- C. an irrational fear of the unfamiliar
- D. an irrational fear of snakes

Answer: C

167. One explanation for the hostility some people feel towards immigrants is:

- A. implicit bias
- B. prejudice
- C. stereotype
- D. xenophobia

Answer: D

168. Yakushko suggests that hostility towards immigrants is due to all the following EXCEPT:

- A. xenophobia
- B. ethnocentrism
- C. economic struggles
- D. implicit bias

Answer: D

169. Out-group entitativity describes:

- A. how outsiders perceive a group's strength to act together to achieve shared goals
- B. negative perceptions of an out-group

- a. Systems
- b. Vedas
- c. Ithihasas
- d. Puranas

Answer: B

228. The word 'Veda' originated from the word

- a. Vayu
- b. Vyasa
- c. Vid
- d. Vip

Answer: C

229. Vedas are also called as

- a. Smriti
- b. Chinda
- c. Sruthi
- d. Pravrittis

Answer: C

230. Which among the following is not a Veda

- a. Rig
- b. Sama
- c. Yajur
- d. Sankhya

Answer: D

231. There are -----Vedas

- a. 2
- b. 3
- c. 4
- d. 5

Answer: C

232. The word 'Rik' means

- a. Verse
- b. Song
- c. Prose
- d. None of the above

Answer: A

233. The word 'yajur' means

- a. Verseb Prose.
- c. Song
- d. Grammar

Answer: B

234. The word 'Sama' means

- a. Verse

- b Prose.
 - c. Song
 - d. Grammer
- Answer: C

235. Veda consists of----- parts

- a. 10
- b. 12
- c. 4
- d. 6

Answer: C

236. The part which consists of hymns is called

- a. Mantra
- b. Brahmana
- c. Aranyaka
- d. Upanishad

Answer: A

237. The part which consists of directions for performing sacrifices is called

- a. Mantra
- b. Brahmana
- c. Aranyaka
- d. Upanishad

Answer: B

238. The part which consists of mystic interpretation of Brahmana is called

- a. Mantra
- b. Brahmana
- c. Aranyaka
- d. Upanishad

Answer: C

239. The end portion of Veda is called

- a. Mantra
- b. Brahmana
- c. Aranyaka
- d. Upanishad

Answer: D

240. Which one of the following is not a Vedanga

- a. Vyakarana
- b. Jyothisha
- c. Jathaka
- d. Niruktha

Answer: C

241. The religion which believe in many Gods is called

- a. Polytheism
- b. Henotheism
- c. Monotheism
- d. Monism

Answer: D

242. The religion which believe in one God at a particular period is called

- a. Polytheism
- b. Henotheism
- c. Monotheism
- d. Monism

Answer: B

243. The religion which believe in one God is called

- a. Polytheism
- b. Henotheism
- c. Monotheism
- d. Monism

Answer: C

244. The religion which believe in one Ultimate Reality is called

- a. Polytheism
- b. Henotheism
- c. Monotheism
- d. Monism

Answer: D

245. The word 'Theism' means

- a. Belief in Caste
- b. Belief in Creed
- c. Belief in Race
- d. Belief in God

Answer: D

246. Qualified Monism mentioned about

- a. Personalistic view of Brahman
- b. Impersonalistic view of Brahman
- c. Both
- d. None of the above

Answer: A

247. Para Brahman is

- a. Saguna Brahman

- b. Nirguna Brahman
- c. Both None

Answer: B

248. Apara Brahman is

- a. Saguna Brahman
- b. Nirguna Brahman
- c. Both None

Answer: A

249. Upanishads are also called

- a. Vedanga
- b. Vedanta
- c. Vedabhashya
- d. Vedasadana

Answer: B

250. Upanishad teaches

- a. Realism
- b. Idealistic Monism
- c. Monotheism
- d. Pragmatism

Answer: B

251. The word Brahman came from the word

- a. Brhanthala
- b. Brihaspati
- c. Brh
- d. Brj

Answer: C

252. According to Acosmic view

- a. Brahman alone is real
- b. The world alone is real
- c. Brahman & World are real
- d. Brahman & World are unreal

Answer: A

253. According to Cosmic view

- a. Brahman alone is real
- b. The world alone is real
- c. Brahman & World are real
- d. Brahman & World are unreal

Answer: D

254. The power of Illusion is called

- a. Brahman
- b. Maya
- c. Atman
- d. Sandhya

Answer: B

255. Who among the following is the proponent of Advaita Vedanta

- a. Sri Krishna
- b. Kanada
- c. Sri Sankaracharya
- d. Ramanuja

Answer: C

256. Who among the following is the proponent of Visisht Advaita

- a. Gautama
- b. Kanada
- c. Sri Sankaracharya
- d. Ramanuja

Answer: C

257. Individual soul is called

- a. Jivatman
- b. Paramatman
- c. Manas
- d. Indriya

Answer: A

258. Which among the following is not a Kosa

- a. Annamaya Kosa
- b. Pranamaya Kosa
- c. Santhoshamaya Kosa
- d. Manomaya Kosa

Answer: C

259. Annamaya Kosa is called

- a. Bodily Sheath
- b. Vital Sheath
- c. Mental Sheath
- d. Intellectual Sheath

Answer: A

260. Pranamaya Kosa is called

- a. Bodly Sheath
- b. Vital Sheath
- c. Mental Sheath
- d. Intellectual Sheath

Answer: B

261. Manomaya Kosa is called

- a. Bodly Sheath
- b. Vital Sheath
- c. Mental Sheath
- d. Intellectual Sheath

Answer: C

262. Vijnanamaya Kosa is called

- a. Bodly Sheath
- b. Vital Sheath
- c. Mental Sheath
- d. Intellectual Sheath

Answer: D

263. Anandamaya Kosa is called

- a. Bodly Sheath
- b. Vital Sheath
- c. Sheath of Bliss
- d. Intellectual Sheath

Answer: C

264. First chapter of Bhagavad Gita is

- a. Samkhya Yoga
- b. Arjuna vishada Yoga
- c. Dhyana Yoga
- d. Karma Yoga

Answer: B

265. Which chapter is called Viswarupa Darsana Yoga

- a. One
- b. Thirteen
- c. Eighteen
- d. Eleven

Answer: C

266. Performing one's duties in accordance with his position in the society is called

- a. Nityakarma
- b. Kamyakarma

- c. Swadharna
- d. Anyadharna

Answer: C

267. Performing one's duties without any selfish motive is called

- a. Karma phala
- b. Nishkama karma
- c. Karma samskara
- d. Naimittika karma

Answer: B

268. 'Path of action in inaction' is the contribution of

- a. Upanishads
- b. Samkhya yoga
- c. Buddhism
- d. Bhagavad Gita

Answer: B

269. Path of action towards selfrealization is called

- a. Karma marga
- b. Jnana marga
- c. Bhakti marga
- d. Raja marga

Answer: A

270. Path of wisdom towards selfrealization is called

- a. Karma marga
- b. Jnana marga
- c. Bhakti marga
- d. Raja marga

Answer: B

271. Path of devotion towards selfrealization is called

- a. Karma marga
- b. Jnana marga
- c. Bhakti marga
- d. Raja marga

Answer: C

272. Bhagavad Gita provides a synthesis of

- a. Jnana & Bhakti
- b. Jnana & karma
- c. Karma, bhakti & Jnana
- d. None of the above

Answer: C

273. Purification of mind through Nishkama karma is called

- a. Prana sudhi
- b. Chitta sudhi
- c. Tapas
- d. Dhyana

Answer: B

274. 'Yoga karmasu kausalam' is the ideology of

- a. Advaita Vedanta
- b. Visishta Advaita
- c. Bhagavad Gita
- d. Ramayana

Answer: C

275. The person with steady mind is called

- a. Sthitaprajna
- b. Prajna sree
- c. Vanaprastha
- d. Grahatha

Answer: A

276. Yogi satisfied with the thoughts of

- a. Self
- b. Body
- c. Sense organ
- d. Mind

Answer: A

277. The way towards self realization according to Bhagavad Gita is

- a. Escape from sorrow
- b. Escape from household duties
- c. Nishkama karma
- d. Swadyaya

Answer: C

278. According to Bhagavad Gita 'Preservation of world of humanity' means

- a. Sthitha prajna
- b. Environmental ethics
- c. Mukti marga
- d. Loka samgraha

Answer: D

279. Concept of 'lokasamgraha' aims at

- a. Welfare of humanity
- b. protection of Environment
- c. Presevation of Biosphere
- d. Preservation of Nature

Answer: A

280. Social dimension of Bhakti is called

- a. Asrama
- b. Varna
- c. Lokasamgraha
- d. Sthithaprajna

Answer: C

281. Systems which rejected the authority of Vedas are called

- a. Orthodox systems
- b Heterodox system
- c. Theism
- d. Atheism

Answer: B

282. Systems which accepted the authority of Vedas are called

- a. Orthodox systems
- b Heterodox system
- c. Theism
- d. Atheism

Answer: A

283. Orthodox systems are otherwise known as

- a. Astika darsana
- b. Nastika Darsana
- c. Theism
- d. Atheism

Answer: A

284. Heterodox systems are otherwise known as

- a. Astika darsana
- b. Nastika Darsana
- c. Theism
- d. Atheism

Answer: B

285. Which among the following is not a Heterodox system

- a. Charvaka materialism
- b. Jainism

- c. Buddhism
- d. Purva mimamsa

Answer: D

286 Which among the following is not a Heterodox system

- a. Charvaka materialism
- b. Advaita Vedanta
- c. Buddhism
- d. Jainism

Answer: B

287. Which among the following is not a Heterodox system

- a. Charvaka materialism
- b. Jainism
- c. Nyaya Vaisesika
- d. Buddhism

Answer: C

288. Which among the following is not a Heterodox system

- a. Samkhya yoga
- b. Jainism
- c. Buddhism
- d. Charvaka materialism

Answer: A

289. Which one of the following is a Heterodox system

- a. Nyaya
- b. Buddhism
- c. Samkhya
- d. Vaisesika

Answer: A

290. Which one of the following is a Heterodox system

- a. Jainism
- b. Yoga
- c. Purva Mimamsa
- d. Vaisesika

Answer: A

291. Which one of the following is a Heterodox system

- a. Advaita Vedanta
- b. Nyaya
- c. Charvaka Materialism
- d. Vaisesika

Answer: C

292. Which one of the following is an Orthodox system

- a. Nyaya
- b. Jainism
- c. Buddhism
- d. Lokayata

Answer: A

293. Which among the following is not an Orthodox system

- a. Nyaya
- b. Vaisesika
- c. Samkhya
- d. Buddhism

Answer: D

294. Which among the following is not an Orthodox system

- a. Charvaka Materialism
- b. Uttara Mimamsa
- c. Purva Mimamsa.
- d. Yoga

Answer: A

295. Uttara Mimamsa is otherwise known as

- a. Purva Mimamsa
- b. Mimamsa Sutra
- c. Advaita Vedanta
- d. Upanishad

Answer: C

296. Charvaka Materialism is otherwise known as

- a. Advaita Vedanta
- b. Lokayata
- c. Lokasamgraha
- d. Visishta Advaita

Answer: B

297. Which one of the following elements is not accepted by Charvaka materialism

- a. Earth
- b. Air
- c. water
- d. Ether

Answer: D

298. How many pramanas are accepted by Charvaka materialism

- a. One
- b. Three
- c. Four
- d. Six

Answer: A

299. Name the Pramana accepted by Lokayata

- a. Inference
- b. Comparison
- c. Perception
- d. All the above

Answer: C

300. Which among the following is accepted by Charvaka materialism

- a. God
- b. Matter
- c. Soul
- d. Rebirth

Answer: B

301. Last chapter of Bhagavad Gita is called

- a. Mokshasamnyasa Yoga
- b. Samnyasa Yoga
- c. Bhakthi Yoga
- d. Vibhuti Yoga

Answer: A

302. Which among the following are Parama Purusharthas according to Indian Philosophy

- a. Dharma & Moksha
- b. Artha & Kama
- c. Both a & b
- d. None of the above

Answer: C

303. Purusharthas accepted by Charvaka materialism

- a. Artha & Kama
- b. Dharma & Moksha
- c. Dharma and Kama
- d. Artha & Moksha

Answer: A

304. Which one among the following is called 'Indian Hedonism'

- a. Buddhism
- b. Charvaka Materialism

- c. Jainism
- d. Nyaya

Answer: B

305. Who among the following is the Author of 'Sarva Darsana Samgraha'

- a. Gautama Buddha
- b. Pathanjali
- c. Jaimini
- d. Brihaspati

Answer: D

306. Who among the following is the founder of Buddhism

- a. Rishabha Deva
- b. Vardhmana Mahavira
- c. Gautama Buddha
- d. Brihaspati

Answer: C

307. Which one among the following is a Buddhist sect

- a. Digambara
- b. Mahayana
- c. Swethambara
- d. Avadhuta

Answer: B

308. Buddhists scripture is known as

- a. Nigama
- b. Pitika
- c. Agama
- d. Karika

Answer: B

309. Which one among the following is not a Pitika

- a. Vishesha
- b. Sutta
- c. Vinaya
- d. Abhidamma

Answer: A

310. Central teaching of Buddha consist of Truths

- a. Three
- b. Two
- c. Five
- d. Four

Answer: D

311. Which one among the following is not a Noble Truth of Buddha

- a. Dukha Marga
- b. Sarvam Dukham
- c. Dukha Nirodha
- d. Dukha Karana

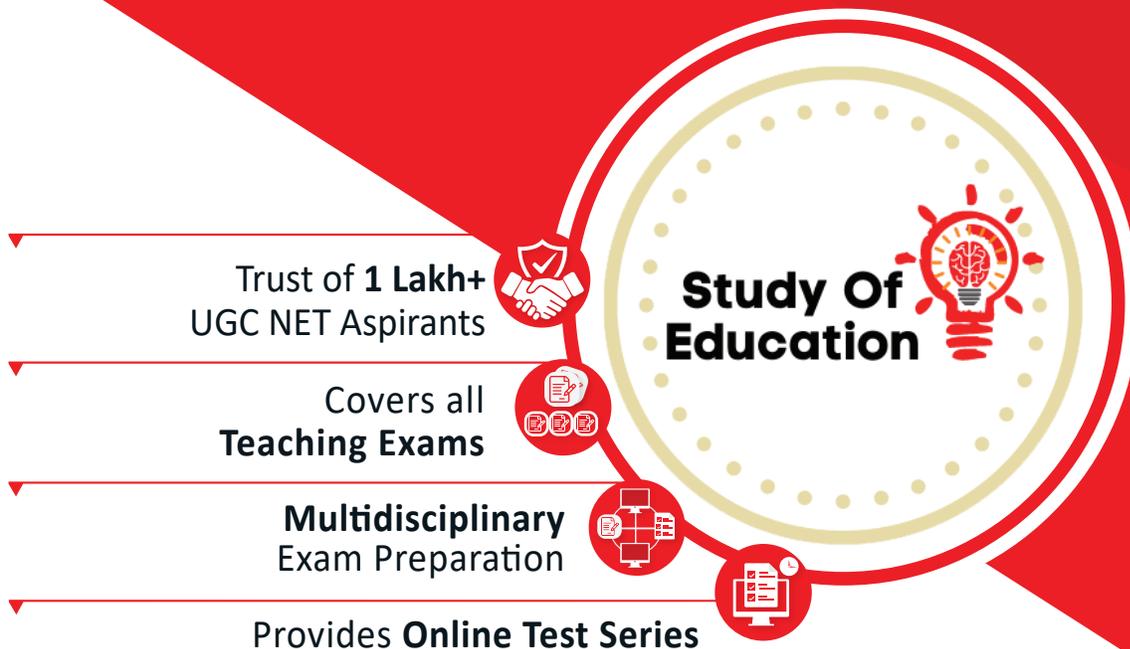

Answer: A

UGC NET

Psychology

A COMPLETE PREPARATION FOR UGC NET PSYCHOLOGY

We holds a team of learned educators, practitioners, and subject matter experts that puts in effort to handcraft every product for our aspirants to excel in their exams. With a dynamic approach towards education, our experts are driven towards making your learning a fascinating experience from the length and expansiveness of the nation. It is with their aptitude, direction, and a sharp eye for particularities for the competitive exams that the content in each Online test Series addresses the issues of the aspirant. Evidently. Our Books give a remarkable impact to any aspirant's preparation.
