Research Methodology and Statistics

RESEARCH METHODOLOGY AND STATISTICS

What is Research: Meaning, Purpose, and Dimensions, Research problems, Variables and Operational Definitions, Hypothesis, Sampling, Ethics in conducting and reporting research?

Research: Meaning, Purpose, and Dimensions, Research problems, Variables and Operational Definitions, Hypothesis, Sampling, Ethics in conducting and reporting research

The Research Meaning of Psychology

Psychologists try to answer these questions, develop the principles to explain them, and use those principles to solve various problems. The range of application of psychology is very wide. A cognitive psychologist may like to know the causes of forgetting. An organisational psychologist may try to find out nature of resistance among the employees to introduction of new performance appraisal system. A health psychologist may like to examine the relationship between smoking behaviour and coronary heart disease.

While evaluating major areas of psychological researches, a psychologist uses the principles and practices of scientific methods. This unit attempts to acquaint you with nature and relevance of psychological research. This is followed by the process of psychological research within the context of discovery and context of justification as well as distinctive goal of psychological researches.

OBJECTIVES

After reading this unit, you will be able to: Describe the research process in terms of how to conduct sound research and

- λ how to evaluate critically the research of others; Understand why people behave as they do;
- λ Discuss how to maintain objectivity and minimize the research bias in psychology
- λ research; Tell others the role of theory, hypothesis and paradigm in psychological research;
- λ Discuss the primary objectives and goals of psychological research;
- λ Identify some of the problems one encounters in trying to do reliable and valid

NATURE OF PSYCHOLOGICAL RESEARCH

Importance and relevance of psychological research is well recognised almost in every sphere of human life. Notable progress has been reported in the field of organisational behaviour, applied aspects of human being, medical sciences and education, through application of psychological research findings. Empirical and theoretical researches in psychology are taking place in various fields, such as learning, motivation, perception, concept learning and memory and so on.

In the quest of psychological facts, laws and theories, psychologists have found research studies very helpful in gauging human and animal behaviour. Psychological research attempts to understand why people and animals behave as they do. Psychologists usually define behaviour as overt activities, such as eating, recalling stories, and so on. What about covert psychological processes, such as thinking and feeling? Although thoughts and feelings are not directly observable, they influence such aspects of behaviour as reaction time and blood pressure, which are often used to measure these covert processes.

Practical gains of psychological research are many, yet include discoveries such as improved methods of treating psychologically disordered people, better designs of vehicles to make them easier and safe to use, and new ways of enhancing the performance and happiness of workers. Before we examine what researchers have found in the major areas of psychology, we need to

identify the ways psychologists gather data about behaviour and mental processes.

You may be a daily consumer of mass media reports on research findings. Some of these are valuable, some are worthless, and others are confusing and misleading. You will become a wiser consumer of research-based conclusions as you develop your understanding of how psychological research is conducted and why the scientific view of knowledge dictates such methods. Let us turn now how psychologists know what they know.

Recall that psychology is the scientific study of behaviour and mental functioning of individuals. It is scientific because it uses the principles and practices of the scientific method.

ROLE OF THEORIES, HYPOTHESES AND PARADIGMS IN PSYCHOLOGICAL RESEARCH

Psychological research focuses on four sets of concerns:

- i) the stimulus events that cause a particular response to start, stop, or change in quality of quantity;
 - ii) the structure of behaviour that links certain actions in predictable, orderly ways to other actions;
 - iii) the relationships between internal psychological processes or psychological mechanisms and observable behaviour patterns; and
 - iv) the consequences that behaviour has on the individual's social and physical environment.
- Researchers begin with the assumption of determinism, the idea that all events (physical, mental and behavioural) result from specific causal factors.

Researchers also assume that behaviour and mental processes follow set patterns of relationships that can be discovered and revealed through research. Psychological theories, in general, attempt to understand how brain, mind, behaviour, and environment function and how they may be related.

Any particular theory focuses on a more specific aspect of this broad conception, using a body of interrelated principles to explain or predict some psychological phenomenon. The value of a theory is often measured in terms of the new ideas, or hypotheses, that can be derived from it and tested.

A hypothesis is a tentative and testable explanation of the relationship between two or more events or variables. A variable is any factor that changes, or varies, in size or quality. To illustrate this mood may be a variable, since people's moods may vary from one situation to another. Test performance is another variable, since a person's score may vary from one test to the next.

A hypothesis is a testable explanation of the relationship between variables, it is a tentative proposition based on observations, or it could be a hunch about how ideas go together. An instructor, for example, may have a hypothesis about how varying teaching techniques will cause changes in students' test scores. Thus, instructor may have formed this hypothesis by observing students; idea about better teaching techniques is also generated from research in educational psychology.

RESEARCH BIASES

One of the challenges, while doing research is to remain objective and free from biases. Most of your ideas and beliefs are probably linked with certain bias because they are influenced by your opinions or values. A variety of biases have been found to distort people's impressions of collected data. External influences such as one's culture or the media can influence people to accept a particular world view.

Personal bias distorts estimating or evaluating processes as a result of personal beliefs, attributes, or past experiences. Observer bias operates when one's biases act as "filters" through which some events are noticed or seen as meaningful while others are not. It must be kept in mind that researchers themselves were raised in certain cultures and societies. They also might have been exposed to certain gender role expectations. These background factors can all affect the way that researchers observe and interpret events in their lives.

Expectancy bias can affect observations of behaviour by triggering reactions to the events being observed. Researchers sometimes expect to find specific outcomes, and being only human, they may see what they expect to see rather than remain objective.

Unfortunately, if one is not alert to the possibility of expectancy bias, it may seem as though the observed events are being "discovered" instead of created by the observer's expectations.

PURPOSE AND DIMENSIONS OF PSYCHOLOGY

GOALS AND OBJECTIVES OF PSYCHOLOGICAL RESEARCH

Every science has goals. In physics, the goals are concerned with learning how the physical world works. In astronomy, the goals are to chart the universe and understand both how it came to be and what it is becoming.

The goals of psychologist conducting basic research are to describe, explain, and predict and control behaviour. The applied psychologist has a fifth goal also, that is application of psychological techniques and principles to improve the quality of human life.

Most applied psychologist are able to conduct their own basic research, scientifically studying particular problem in order to solve them. The process of accomplishing one goal and moving on to the next is ideally a natural, flowing, experience, energized, by the psychologist's interest in the question being studied.

The first step in understanding anything is to give it a name. Description involves observing a behaviour and noting everything about it, as for example, what is happening, where it happens, to whom it happens, and under what circumstances it happens.

EXPLANATION:

To find out why the girl is not behaving properly, the teacher would most likely ask the school counselor to administer some tests. Her parents might be asked to take her to a pediatrician to make sure that there is no physical illness, such as an allergy. They might also take her to a psychologist to be assessed. In other words, the teacher and others are looking for an explanation for the young girl's behaviour. Finding explanation for behaviour is a very important step in the process of forming theories of behaviour. A theory is a general explanation of a set of observations or facts.

The goal of description provides the observations, and the goal of explanation helps to build the theory. If all the tests seem to indicate that the young girl has a learning problem, such as dyslexia (an inability to read at expected levels for a particular age and degree of intelligence), the next step would be trying to predict what is likely to happen if the situation stays the same.

PREDICTION:

When Will it Happen Again? Determining what will happen in the future is a prediction. In the example, the psychologist or counselor would predict (based on previous research into similar situations), that this little girl will probably continue to do poorly in her schoolwork and may never be able to reach her full learning potential.

Clearly, something needs to be done to change this prediction, and that is the point of the last of the four goals of psychology: changing or modifying behaviour.

CONTROL :

How can it be Changed ? Control, or the modification of some behaviour, has been somewhat controversial in the past. Some people hear the word control and think it is brainwashing, but that is not the focus of this goal. The goal is to change a behaviour from an undesirable one (such as failing in school) to a desirable one (such as academic success).

Such efforts also include attempts at improving the quality of life. In the example of the young girl, there are certain learning strategies that can be used to help a child (or an adult) who has dyslexia . She can be helped to improve her reading skills.(Aylward etal,2003;Shaywitz,1996). The psychologist and educators would work together to find a training strategy that works best for this particular girl.

APPLICATION

Improving the quality of life Psychological research are often conducted to solve various problems faced by the society at different levels such as individual, organisation, or community.

Psychological applications to solve problems in diverse settings, such as in a classroom in a school, or in an industry, or in a hospital, or even in a military establishment, demand professional help.

Applications in the health sector are remarkable. Because of these efforts quality of life becomes a major concern for psychologists. Not all psychological investigations will try to meet all five of these goals. In some cases, the main focus might be on description and prediction, as it would be for a personality theorist who wants to know what people are like (description) and what they might do in certain situation (prediction).

Some psychologists are interested in both description and explanation, as is the case with experimental psychologists who design research to find explanations for observed (described) behaviour. Therapists, of course, would be more interested in control, although the other four goals would be important in getting to that goal.

DIMENSIONS OF PSYCHOLOGICAL WELL-BEING

The six dimensions reflected within psychological well-being are as follows:

1. SELF-ACCEPTANCE

This dimension speaks of the acceptance of every aspect of an individual and of one's own past, just as it happened. This means without falling into a pit of impotence for wanting to modify or intervene in what happened.

Think about whether you accept your body, your emotions and your thoughts. If you do, you'll have a

more positive view of yourself. Instead, if you have low self-esteem and struggle to accept who you are, it's possible that due to this dissatisfaction, **you'll feel so overwhelmed that you don't even know where to begin changing those aspects you actually can intervene in.**

2. CONTROL OVER YOUR SURROUNDINGS

This dimension refers to the ability to deal with a difficult environment, having the ability to adapt to adverse circumstances.

If you have a high perception of your **control** over your surroundings, you'll feel capable of influencing your environment and managing complicated situations. Instead, if you have low control over your surroundings, according to the psychological well-being questionnaire, you'll have greater difficulty overcoming the adversities which arise in your day-to-day life.

3. POSITIVE RELATIONSHIPS WITH OTHERS

This dimension measures the ability people have to interact with others in an open and sincere way.

If you're capable of having satisfactory relationships with others, you will promote bonds which will provide you with better emotional quality. **This implies having a greater capacity of empathy and openness towards people.** If you have a lower score on this scale, it's possible you struggle to interact with others. You might have difficulties opening up and trusting others, as well as difficulties maintaining your relationships.

4. AUTONOMY

This dimension evaluates the independence of people in different aspects of their lives. The sensation of being able to choose and make their own decisions, of maintaining a personal criteria and personal and **emotional** independence despite others not being in agreement.

A high degree of autonomy implies that you're able to deploy a greater force of resistance against social pressure and your own impulses. **If, instead, you have a low degree of autonomy, you might be letting other people's opinions guide you.** You also might pay attention to what others say or think about you and might let yourself be led by social pressure within your social circle.

5. PERSONAL GROWTH

This dimension measures the ability people have of learning from themselves, being open to new experiences and challenges.

If you promote your personal growth, it's possible you feel that you're on a continuous journey of learning. You might feel that you have the ability to learn from what you receive and know that you have the resources needed to improve. **If this whole personal growth thing is not your style, you might feel stuck, bored and demotivated.** You might not really want to develop new lessons and new growth behaviors. Or, you might simply feel incapable of it.

6. LIFE PURPOSE

This measures the need people have of finding a purpose that will give meaning to their lives. People need to set clear and acceptable **goals** for themselves. These need to be realistic objectives. If have a high score in this dimension, it means that you feel your life has meaning. You give meaning to your past, present and future. **If, instead, you score poorly in this dimension, you don't have a**

clear purpose. It's possible you feel that your life lacks direction or you might even feel disoriented and lost.

7. SOCIAL SUPPORT: THE BEST PILLAR OF OUR WELL-BEING

Social support is a protective factor against various diseases. It's very important how our social relationships are and also how we perceive them to be.

- **People who are emotionally intelligent are more optimistic, have higher self-esteem and have a greater capacity for empathy.** This contributes to the improvement of our psychological well-being. People who know how to identify their emotions feel more satisfied with themselves. Therefore, they feel a greater sense of overall well-being. **Find your passion** It might be at work, since that's where you spend many hours of your day. And it's best if you spend them doing something that motivates you. But you can also find something you like in a hobby which makes you feel fulfilled. For example, music, a sport or craftsmanship.
- **DON'T TRY TO CHANGE YOURSELF**
Accept yourself in the dimensions you cannot change. Trying to change yourself is going to generate unease and rejection. You will improve your well-being if you give yourself and your own nature a chance. This way, all of the positive things you find will serve to improve your self-esteem, because you will acknowledge it as your own. The same thing will happen with the negative things you find.
- **SURROUND YOURSELF WITH PEOPLE WHO HAVE A GOOD ENERGY**
Positive relationships, being with people you like and who fulfill you is an **important factor** which directly influences your physical and emotional well-being. **Toxic people will reduce your psychological well-being and add stress to your life.**

RESEARCH PROBLEMS IN PSYCHOLOGY RESEARCH PROBLEMS IN PSYCHOLOGY

Your thesis in Psychology should **ask and answer a specific question**, rather than broadly discuss a large topic area. Furthermore, your research problem should **suggest one or more subsequent questions** to your readers.

The statement of the research problem should be **precise** and **concise**. It should be coherent enough that you can readily discuss it with family or friends - and that they will understand it.

It is recommended that you go over the four key parts (**Research Question, Hypothesis, Evidence, Conclusions & Broader Implications**) in an outline **before** you start to write your proposal.

- You may find it easier to write the Research Problem last, after you have already reviewed the literature in the Background of the Problem section, and fleshed out your Research Method
- **THIS MAY HELP YOU TO FOCUS YOUR RESEARCH PROBLEM AND KEEP IT CONCISE**

Nature and Meaning

A scientific inquiry starts when a researcher has already collected some information/ knowledge and that knowledge indicates that there is something we do not know. It may be that we simply do not have enough information to answer a question, or it may be that the knowledge that we have is in such state of distorted form that it cannot be adequately related to the question. Here a problem arises.

The formulation of a problem is especially important, as it guides us in our inquiry. According to

Townsend (1953) 'a problem is a question proposed for solution'. According to Kerlinger (1964) 'A problem is interrogative sentence of statement that asks: What relation exists between two or more variables'. According to McGuigan (1964) 'A solvable problem is one that poses a question that can be answered with the use of man's normal capacities'.

CHARACTERISTICS OF A SCIENTIFIC PROBLEM

After analysing above written definitions of a problem statement, it can be said there are certain characteristics of a problem statement:

1. A problem statement is written clearly and unambiguously, usually in question form.
2. A problem expresses the relationship between two or more than two variables. This kind of problem permits the investigator to manipulate two or more than two variables to examine the effects upon the other variables. For example: Do teacher reinforcement cause improvement in student performance? In this example, one variable is teacher reinforcement and the other variable is student performance. It illustrates the problem found in a scientific study because the problem statement explores the effect of teacher's reinforcements on student performance. The conditions for a problem statement are:

The problem should be testable by empirical methods

- λ A problem statement should be solvable
- .λ The data of a scientific problem should be quantitative
- .λ The variable relating to the problem should be clear and definite

WAYS IN WHICH A PROBLEM IS MANIFESTED

A problem is said to exist when we know enough that there is something we do not know really. There are atleast three ways in which a problem is said to be manifested: Gap in knowledge: A problem is manifested when there is a noticeable gap or absence of information. Suppose a community or group intends to provide psychotherapeutic services, two questions arise, viz.,

- (i) What kind of psychotherapy they should offer and
- (ii) Which one of the different forms of therapeutic methods is most effective for a given type of mental disease. In this example, there exists a noticeable gap in the knowledge, and hence the collection of necessary data and their explanation are needed for filling the gap in knowledge. Contradictory results:

When several investigations done in the same field are not consistent and therefore, at times, contradictory, a problem is to find out a new answer and settle the controversy. Explaining a Fact: Another way in which we become aware of a problem is when we are in possession of a 'fact', and we ask ourselves, "Why is this so?" When the facts in any field are found in terms of unexplained information, a problem is said to exist.

THE IMPORTANCE OF FORMULATING A RESEARCH PROBLEM

The formulation of a research problem is the first and most important step of the research process. It is like the identification of a destination before undertaking a journey. As in the absence of a destination, it is impossible to identify the shortest route, so also in the absence of a clear research problem, a clear and economical plan is impossible. A research problem is like the foundation of a

building.

The type and design of the building is dependent upon the foundation. If the foundation is well designed and strong you can expect the building to be also strong and well designed. In the case of research, the research problem serves as the foundation of a research study. If it is well formulated, you can expect a good study to follow.

VARIABLES USED IN PSYCHOLOGY RESEARCH

Meaning of Variable

A variable, as the name implies, is something which varies. This is the simplest and the broadest way of defining a variable. Webster says that a variable is “a thing that is changeable” or “a quantity that may have a number of different values.” True, a variable is something that has at least two values, however, it is also important that the values of the variable be observable.

Thus, if what is being studied is a variable, it has more than one value and each value can be observed. For example, the outcome of throwing a die is a variable. That variable has six possible values (each side of the die has from one to six dots on it), each of which can be observed. In psychology, the variables of interest are often behaviours or the causes of behaviours. Many psychologists have adopted a theoretical viewpoint or model called the S-O-R model to explain all behaviour.

A variable is something that can be changed or varied, such as a characteristic or value. Variables are generally used in psychology experiments to determine if changes to one thing result in changes to another.

Variables play a critical role in the psychological research process. By systematically varying some variables and measuring the effects on other variables, researchers can determine if changes to one thing result in changes in something else.

The Dependent and Independent Variables In a psychology experiment:¹

- The **independent variable** is the variable that is controlled and manipulated by the experimenter. For example, in an experiment on the impact of sleep deprivation on test performance, sleep deprivation would be the independent variable.
- The **dependent variable** is the variable that is measured by the experimenter. In our previous example, the scores on the test performance measure would be the dependent variable.

EXTRANEOUS AND CONFOUNDING VARIABLES

It is important to note that the independent and dependent variables are not the only variables present in many experiments. In some cases, extraneous variables may also play a role. This type of variable is one that may have an impact on the relationship between the independent and dependent variables.

For example, in our previous description of an experiment on the effects of sleep deprivation on test performance, other factors such as age, gender, and academic background may have an impact on the results. In such cases, the experimenter will note the values of these extraneous variables so this impact on the results can be controlled for.

THERE ARE TWO BASIC TYPES OF EXTRANEOUS VARIABLES:

1. **Participant Variables:** These extraneous variables are related to individual characteristics of each participant that may impact how he or she responds. These factors can include background differences, mood, anxiety, intelligence, awareness and other characteristics that are unique to each person.
2. **Situational Variables:** These extraneous variables are related to things in the environment that may impact how each participant responds. For example, if a participant is taking a test in a chilly room, the temperature would be considered an extraneous variable. Some participants may not be affected by the cold, but others might be distracted or annoyed by the temperature of the room.

OTHER EXTRANEOUS VARIABLES INCLUDE THE FOLLOWING:

- **Demand characteristics:** Clues in the environment that suggest how a participant should behave
- **Experimenter effects:** When a researcher unintentionally suggests clues for how a participant should behave

In many cases, extraneous variables are controlled for by the experimenter. In the case of participant variables, the experiment might select participants that are the same in background and temperament to ensure that these factors do not interfere with the results. Confounding Variables
If a variable cannot be controlled for, it becomes what is known as a **confounding variable**. This type of variable can have an impact on the dependent variable, which can make it difficult to determine if the results are due to the influence of the independent variable, the confounding variable or an interaction of the two.

OPERATIONALLY DEFINING A VARIABLE PSYCHOLOGY

Before conducting a psychology experiment, it is essential to create firm operational definitions for both the independent variable and dependent variable. An operational definition describes how the variables are measured and defined in the study.¹

For example, in our imaginary experiment on the effects of sleep deprivation on test performance, we would need to create very specific operational definitions for our two variables. If our hypothesis is "Students who are sleep deprived will score significantly lower on a test," then we would have a few different concepts to define. First, what do we mean by students? In our example, let's define students as participants enrolled in an introductory university-level psychology course.

Next, we need to operationally define the sleep deprivation variable. In our example, let's say that sleep deprivation refers to those participants who have had less than five hours of sleep the night before the test. Finally, we need to create an operational definition for the test variable. For this example, the test variable will be defined as a student's score on a chapter exam in the introductory psychology course.

Students often report problems with identifying the independent and dependent variables in an experiment. While the task can become more difficult as the complexity of an experiment increases, there are a few questions you can ask when trying to identify a variable.

What is the experimenter manipulating? The things that change, either naturally or through direct manipulation from the experimenter, are generally the independent variables. What is being measured? The dependent variable is the one that the experimenter is measuring.

Every good psychology study contains an operational definition for the variables in the research. An operational definition allows the researchers to describe in a specific way what they mean when they use a certain term. Generally, operational definitions are concrete and measurable. Defining variables in this way allows other people to see if the research has validity. Validity here refers to if the researchers are actually measuring what they intended to measure.

Example One:

A researcher wants to measure if age is related to addiction. Perhaps their hypothesis is: the incidence of addiction will increase with age. Here we have two variables, age and addiction. In order to make the research as clear as possible, the researcher must define how they will measure these variables. Essentially, how do we measure someone's age and how to we measure addiction?

Variable One: Age might seem straightforward. You might be wondering why we need to define age if we all know what age is. However, one researcher might decide to measure age in months in order to get someone's precise age, while another researcher might just choose to measure age in years. In order to understand the results of the study, we will need to know how this researcher operationalized age. For the sake of this example lets say that age is defined as how old someone is in years.

Variable Two: The variable of addiction is slightly more complicated than age. In order to operationalize it the researcher has to decide exactly how they want to measure addiction. They might narrow down their definition and say that addiction is defined as going through withdrawal when the person stops using a substance. Or the researchers might decide that the definition of addiction is: if someone currently meets the DSM-5 diagnostic criteria for any substance use disorder. For the sake of this example, let's say that the researcher chose the latter.

Final Definition: In this research study age is defined as participant's age measured in years and the incidence of addiction is defined as whether or not the participant currently meets the DSM-5 diagnostic criteria for any substance use disorder.

Need Operational Definitions

There are a number of reasons why researchers need to have operational definitions including:

- Validity
- Replicability
- Generalizability
- Dissemination

The first reason was mentioned earlier in the post when reading research others should be able to assess the validity of the research. That is, did the researchers measure what they intended to measure? If we don't know how researchers measured something it is very hard to know if the study had validity.

The next reason it is important to have an operational definition is for the sake of replicability Research should be designed so that if someone else wanted to replicate it they could. By replicating research and getting the same findings we validate the findings. It is impossible to recreate a study if we are unsure about how they defined or measured the variables.

Another reason we need operational definitions is so that we can understand how generalizable the findings are. In research, we want to know that the findings are true not just for a small sample of people. We hope to get findings that generalize to the whole population. If we do not have operational definitions it is hard to generalize the findings because we don't know who they generalize to.

Finally, operational definitions are important for the dissemination of information. When a study is done it is generally published in a peer-reviewed journal and might be read by other psychologists, students, or journalists. Researchers want people to read their research and apply their findings. If the person reading the article doesn't know what they are talking about because a variable is not clear it will be hard to them to actually apply this new knowledge.

HYPOTHESIS OF PSYCHOLOGY

In conducting research, the second important consideration after the formulation of a research problem is the construction of hypothesis. As you know any scientific inquiry starts with the statement of a solvable problem, when the problem has been stated, a tentative solution in the form of testable proposition is offered by the researcher.

The testable proposition and potential answer are termed a hypothesis Therefore a hypothesis is nothing but a suggested, testable and proposed answer to a problem. By stating a specific hypothesis, the researcher narrows the focus of the data collection effort and is able to design a data collection procedure which is aimed at testing the plausibility of the hypothesis as a possible statement of the relationship between the terms of the research problem.

Definition of Hypothesis Several experts have defined hypothesis more or less in the same way. According to Kerlinger (1973), a hypothesis is a conjectural statement of the relation between two or more variables. According to Mcquigan (1970) hypothesis is a testable statement having the potential relationship between two or more variables. In other words, the hypothesis in one way is advanced as a potential solution to problem.

On the basis of these definitions two criteria for good hypothesis and hypothesis statement can be suggested: i) Hypotheses are statements about the relation between variables. ii) Hypotheses carry clear implication for testing the stated relations. These criteria mean that hypothesis contains two or more variables which are measurable or potentially measurable and hypothesis exhibits either a general or specific relationship between the variables.

CHARACTERISTICS OF A HYPOTHESIS

There are a number of considerations one should keep in mind when constructing a hypothesis, as they are important for valid verification. Hypothesis should be simple, specific and conceptually clear.

There is no place of ambiguity in the construction of a hypothesis it should be 'unidimensional i.e. it should test only one relationship at a time. For example; the average scores in maths subjects of the male students in the class is higher than the female students. Suicides rates very inversely with the social cohesion (Black & Champion 1976).

- A Hypothesis thus should be capable of verification: methods and techniques must be available for data collection. A hypothesis should be operationisable. This means that it can be expressed in terms that can be measured. If it cannot be measured and tested and, hence, no

conclusions can be drawn.

- A Hypothesis should be related to the existing body of knowledge. A hypothesis has equal chances of confirmation and rejection.
- A hypothesis should be parsimonious. (economical)
- A hypothesis should be method oriented. In the construction of hypotheses the student must observe the above mentioned rules.

Forming acceptable hypotheses is not difficult if the problem giving rise to the hypotheses has been carefully stated and defined. The form of a hypothesis can be a declarative statement containing a suggested answers to the problem, and which obeys the formal conditions of hypothesis. Following are two examples of problems and their respective hypothesis. Problem

1: Does practice with the preferred hand improve the proficiency of the nonpreferred hand in the mirror drawing experiment ? Hypothesis: Practice with the preferred hand significantly improves the proficiency of the nonpreferred hand in the mirror drawing experiment. Problem

2: Are male rats more active than the same strain of female rats during a 6- day period spent in an activity cage ? Hypothesis: Male rats are not significantly more active than the same strain of female rats during a 6-day period spent in an activity cage.

Functions of Hypothesis A hypothesis serves the following functions:

- i) The formulation of a hypothesis provides a study with focus.
- ii) It tells you what specific aspects of a research problem to investigate
- iii) It tells what data to collect and what not to collect
- iv) The construction of a hypothesis enhances objectivity in a study. The process of testing a hypothesis goes through 3 phases as given below (Kumar, 2002 : Research methodology))

Phase I: Formulate your hunch or assumption Phase II: Collect the required data Phase III: Analyse data to draw conclusion about the hunch – true or false. A hypothesis may enable you to add to the formulation of theory. It enables you to specifically conclude what is true or what is false.

Let's consider a hypothesis that many teachers might subscribe to: that students work better on Monday morning than they do on a Friday afternoon (IV=Day, DV=Standard of work).

Now, if we decide to study this by giving the same group of students a lesson on a Monday morning and on a Friday afternoon and then measuring their immediate recall on the material covered in each session we would end up with the following:

- The **alternative hypothesis** states that students will recall significantly more information on a Monday morning than on a Friday afternoon.
- The **null hypothesis** states that there will be no significant difference in the amount recalled on a Monday morning compared to a Friday afternoon. Any difference will be due to chance or confounding factors.

SAMPLING OF PSYCHOLOGY

- Sampling is the process of selecting a representative group from the population under study.
- The target population is the total group of individuals from which the sample might be drawn.
- A sample is the group of people who take part in the investigation. The people who take part are referred to as "participants".

- Generalisability refers to the extent to which we can apply the findings of our research to the target population we are interested in.

THE PURPOSE OF SAMPLING

In psychological research we are interested in learning about large groups of people who all have something in common. We call the group that we are interested in studying our 'target population'. In some types of research the target population might be as broad as all humans, but in other types of research the target population might be a smaller group such as teenagers, pre-school children or people who misuse drugs.

It is more or less impossible to study every single person in a target population so psychologists select a sample or sub-group of the population that is likely to be representative of the target population we are interested in.

This is important because we want to generalize from the sample to target population. The more representative the sample, the more confident the researcher can be that the results can be generalized to the target population.

One of the problems that can occur when selecting a sample from a target population is sampling bias. Sampling bias refers to situations where the sample does not reflect the characteristics of the target population.

Many psychology studies have a biased sample because they have used an opportunity sample that comprises university students as their participants (e.g. Asch).

OK, so you've thought up this brilliant psychological study and designed it perfectly. But who are you going to try it out on and how will you select your participants?

There are various sampling methods. The one chosen will depend on a number of factors (such as time, money etc.).

Random Sampling

Random sampling is a type of probability sampling where everyone in the entire target population has an **equal chance** of being selected.

This is similar to the national lottery. If the "population" is everyone who has bought a lottery ticket, then each person has an equal chance of winning the lottery (assuming they all have one ticket each).

Random samples require a way of naming or numbering the target population and then using some type of raffle method to choose those to make up the sample. Random samples are the best method of selecting your sample from the population of interest.

The **advantages** are that your sample should represent the target population and eliminate sampling bias, but the **disadvantage** is that it is very difficult to achieve (i.e. time, effort and money).

OPPORTUNITY SAMPLING

Uses people from target population available at the time and willing to take part. It is based on **convenience**.

An opportunity sample is obtained by asking members of the population of interest if they would take part in your research. An example would be selecting a sample of students from those coming out of the library.

ETHICS IN CONDUCTING AND REPORTING RESEARCH OF PSYCHOLOGY

Ethics refers to the correct rules of conduct necessary when carrying out research. We have a moral responsibility to protect research participants from harm.

However important the issue under investigation psychologists need to remember that they have a duty to respect the rights and dignity of research participants. This means that they must abide by certain moral principles and rules of conduct.

In Britain, ethical guidelines for research are published by the British Psychological Society and in America by the American Psychological Association. The purpose of these codes of conduct is to protect research participants, the reputation of psychology, and psychologists themselves.

ETHICAL ISSUES IN PSYCHOLOGY

1. Informed Consent
2. Debrief
3. Protection of Participants
4. Deception
5. Confidentiality
6. Withdrawal

Moral issues rarely yield a simple, unambiguous, right or wrong answer. It is therefore often a matter of judgment whether the research is justified or not. For example, it might be that a study causes psychological or physical discomfort to participants, maybe they suffer pain or perhaps even come to serious harm.

On the other hand, the investigation could lead to discoveries that benefit the participants themselves or even have the potential to increase the sum of human happiness. Rosenthal and Rosnow (1984) also talk about the potential costs of failing to carry out certain research. Who is to weigh up these costs and benefits? Who is to judge whether the ends justify the means?

Finally, if you are ever in doubt as to whether research is ethical or not it is worthwhile remembering that if there is a conflict of interest between the participants and the researcher it is the interests of the subjects that should take priority.

Studies must now undergo an extensive review by an institutional review board (US) or ethics committee (UK) before they are implemented. All UK research requires ethical approval by one or more of the following:

- (a) Department Ethics Committee (DEC): for most routine research.
- (b) Institutional Ethics Committee (IEC): for non routine research.
- (c) External Ethics Committee (EEC): for research that is externally regulated (e.g. NHS research).

Committees review proposals assess if the potential benefits of the research are justifiable in the

light of the possible risk of physical or psychological harm. These committees may request researchers make changes to the study's design or procedure, or in extreme cases deny approval of the study altogether.

The British Psychological Society (BPS) and American Psychological Association (APA) have both issued a code of ethics in psychology that provides guidelines for the conduct of research. Some of the more important ethical issues are as follows:

INFORMED CONSENT

Whenever possible investigators should obtain the consent of participants. In practice, this means it is not sufficient to simply get potential participants to say "Yes". They also need to know what it is that they are agreeing to. In other words, the psychologist should, so far as is practicable explain what is involved in advance and obtain the informed consent of participants.

Before the study begins the researcher must outline to the participants what the research is about, and then ask their consent (i.e. permission) to take part. An adult (18ys +) capable of giving permission to participate in a study can provide consent. Parents/legal guardians of minors can also provide consent to allow their children to participate in a study.

However, it is not always possible to gain informed consent. Where it is impossible for the researcher to ask the actual participants, a similar group of people can be asked how they would feel about taking part. If they think it would be OK then it can be assumed that the real participants will also find it acceptable.

In order that consent be 'informed', consent forms may need to be accompanied by an information sheet for participants setting out information about the proposed study (in lay terms) along with details about the investigators and how they can be contacted.

PARTICIPANTS MUST BE GIVEN INFORMATION RELATING TO:

- A statement that participation is voluntary and that refusal to participate will not result in any consequences or any loss of benefits that the person is otherwise entitled to receive.
- Purpose of the research.
- All foreseeable risks and discomforts to the participant (if there are any). These include not only physical injury but also possible psychological.
- Procedures involved in the research.
- Benefits of the research to society and possibly to the individual human subject.
- Length of time the subject is expected to participate.
- Person to contact for answers to questions or in the event of injury or emergency.
- Subjects' right to confidentiality and the right to withdraw from the study at any time without any consequences.

DEBRIEF

After the research is over the participant should be able to discuss the procedure and the findings with the psychologist. They must be given a general idea of what the researcher was investigating and why, and their part in the research should be explained.

Participants must be told if they have been deceived and given reasons why. They must be asked if they have any questions and those questions should be answered honestly and as fully as possible. Debriefing should take place as soon as possible and be as full as possible; experimenters should take reasonable steps to ensure that participants understand debriefing.

“The purpose of debriefing is to remove any misconceptions and anxieties that the participants have about the research and to leave them with a sense of dignity, knowledge, and a perception of time not wasted” (Harris, 1998).

The aim of the debriefing is not just to provide information, but to help the participant leave the experimental situation in a similar frame of mind as when he/she entered it (Aronson, 1988).

PROTECTION OF PARTICIPANTS

Researchers must ensure that those taking part in research will not be caused distress. They must be protected from physical and mental harm. This means you must not embarrass, frighten, offend or harm participants.

Normally, the risk of harm must be no greater than in ordinary life, i.e. participants should not be exposed to risks greater than or additional to those encountered in their normal lifestyles. The researcher must also ensure that if vulnerable groups are to be used (elderly, disabled, children, etc.), they must receive special care. For example, if studying children, make sure their participation is brief as they get tired easily and have a limited attention span.

WHAT IS PARADIGMS OF RESEARCH: QUANTITATIVE, QUALITATIVE, MIXED METHODS APPROACH METHODS OF RESEARCH: OBSERVATION, SURVEY [INTERVIEW, QUESTIONNAIRES], EXPERIMENTAL, QUASI- EXPERIMENTAL, FIELD STUDIES, CROSS-CULTURAL STUDIES, PHENOMENOLOGY, GROUNDED THEORY, FOCUS GROUPS, NARRATIVES, CASE STUDIES, ETHNOGRAPHY?

PARADIGMS OF RESEARCH: QUANTITATIVE, QUALITATIVE, MIXED METHODS APPROACH METHODS OF RESEARCH: OBSERVATION, SURVEY [INTERVIEW, QUESTIONNAIRES], EXPERIMENTAL, QUASI-EXPERIMENTAL, FIELD STUDIES, CROSS-CULTURAL STUDIES, PHENOMENOLOGY, GROUNDED THEORY, FOCUS GROUPS, NARRATIVES, CASE STUDIES, ETHNOGRAPHY

The Paradigms of research: Quantitative, Qualitative, Mixed methods approach

METHODS OF RESEARCH:

The aim of this paper is to discuss the philosophical tenets of the major research frameworks which postgraduate students in educational research work with but which they are often confused about. Such a clarification is important inasmuch as it determines not only the research methodology which will be followed but also the choice of the appropriate research methods and the procedure used for the analysis of the collected data. The various research schemes and their corresponding philosophical background will be discussed and concrete examples will be provided to help research students better understand the issues at stake.

These definitions of educational research point at some important issues: First and foremost, the

research procedure must answer the canons of 'science' then, the information provided must be reliable, and finally, what is being investigated should be of interest to educators who may carry out their research within or outside the educational institution. Also implicit in these definitions is the fact that educational research must use the same methods as those used in natural sciences in order to come up with answers aimed at improving teaching and learning as well as identifying the conditions for testing and verifying this knowledge and the conditions under which it should occur. It is thus of paramount importance for research students to grasp the fundamentals of these issues since they determine the choices they have to make at all stages of their research which invariably include the following: the choice of a research framework, the selection of the appropriate research tools for the collection of the data, the procedure(s) to be followed for their analysis, and ultimately, the nature of the conclusions they will have to draw. They must be aware that all existing research frameworks reflect shifts in scientific thought which can be traced back to the debate among leading Greek philosophers as to how new knowledge is acquired.

These philosophers challenged earlier explanations based on theological tenets and argued that a better and more systematic understanding of the world could be obtained either through our senses as the empiricist school claimed, or through logical reasoning as the rationalist school believed. Subsequent shifts in scientific thought, as we shall see, will lead to new perceptions as to how knowledge can be derived from, leading thus to new research paradigms.

Justify the choice of a particular framework or paradigm. The latter is defined by Chalmers (1982:11) as being "made up of the general theoretical assumptions and laws, and techniques for their application that the members of a particular scientific community adopt", and by Willis (2007:8) as "a comprehensive belief system, world view, or framework that guides research and practice in a field" Such understanding will hopefully help them make the appropriate choices about :

- (1) Their research question(s) or hypothesis
 - (2) the type of the research instruments to be used,
 - (3) the steps involved in the collection of the data, and ultimately
 - (4) the procedure used for the analysis and discussion of the collected data
- We shall briefly explain how these shifts in scientific thought have occurred and how they have led to the major shifts in research paradigms and then, we shall show how these shifts had an impact on research methods and methodologies.

It will be reminded that the term 'method' is used to refer to the research instruments used to collect and analyse data, e.g. a questionnaire, interview, checklist, data analysis software etc.

RESEARCH PHILOSOPHY: HISTORICAL

Background The type of research methodology the researcher chooses is determined by the research philosophy which the researcher adheres to and this choice will determine the research objective(s) and the research instruments developed and used as well as the quest for the solution to the problem he is investigating. So far, Empiricism and Rationalism have been the most prevailing research philosophies.

These can be traced back to the debate we mentioned earlier between the Empiricists who were inductivists and the Rationalists who were deductivists. These two opposing views will follow different ways in explaining how knowledge is acquired: either through inductive reasoning as the

Empiricists believed or by reasoning as the Rationalists maintained. Therefore, the Inductive/Deductive distinction can be considered as the first major paradigm in science.

The Inductive reasoning (or bottom-up process) starts from specific observations and moves towards a general conclusion or theory. For example, I observe that all the elephants I have seen (repeated observations) have a trunk, therefore I conclude that ALL existing elephants, even those I have not seen, HAVE a trunk (conclusion, or generalisation). Whereas deductive reasoning (also known as top-down process) proceeds differently. The starting point is a general statement (called the first premise, or theory) followed by a more specific statement inferred from this (the second premise, or the observed phenomenon) and, through logical reasoning, reaches a specific conclusion. As an illustration, I know that all planets orbit around the sun (first premise), a new planet is discovered (second premise), therefore I can conclude that this planet also orbits the sun.

This debate was revisited after the Renaissance and witnessed a heated dispute between the Rationalists represented by the French philosopher René Descartes (1596–1650) who argued that Reason was the only mode through which one could arrive at truth and assumed thus, that knowledge could only be acquired if the appropriate reasoning procedure was used, and the Empiricists represented by the British philosophers John Locke (1632–1704) and David Hume (1711–1776) who argued that experience was the basis for acquiring all new knowledge.

It was Locke who put forward the well known formula that each person is born as a blank slate upon which the environment writes. For these philosophers our knowledge derives from our senses (sight, hearing, touch, smell, and taste) which then imprint ideas in our brain which are further worked upon through cognitive processes. However, it must be stressed that both trends were primarily concerned with natural sciences since at that time social sciences had no place as they were considered as being subjective and thus, not treated as real sciences.

RESEARCH PARADIGMS AND TYPES OF STUDIES

We shall now turn to discussing the implications that each paradigm has for the design of the various types of research studies in educational research. This is summarised in Figure 2 below, while Figure 3 lists the criteria to be used for identifying the various types of research, and Figure 4 lists all the research instruments which can be used in all three paradigms and for ensuring triangulation.

QUANTITATIVE RESEARCH STUDIES

There are two types of quantitative studies: either experimental or non experimental 3.1.1 Experimental studies Experimental studies can be either a true experiment, a quasi experiment or a single case study.

The latter is very rarely used in educational research because it is concerned with only one subject. However, one must keep in mind that the single-subject study may be seen as a true experiment because it as a long and respected tradition in empirical research particularly in psychology. According to Kazdin (2003:273), single-subject studies “can demonstrate causal relationships and can rule out or make implausible threats to validity with the same elegance of group research”. The single subject design has objectives similar to other experimental designs, in that

1. it looks at the changes in the dependent variable following the manipulation of the independent variable and

2. it tries to identify the causes of the differences brought about by the variations in the conditions of the study. As far as the other two types are concerned, what differentiates a true experiment from a quasi experiment study is the fact that in the former, the researcher can manipulate the variables under stringent and controlled conditions to study the effect or the impact of one variable (the independent, also called predictor one) on the other variable (the dependent, or outcome variable) to make statements of causality.

This type of research has weaker validity and poor reliability because the researcher cannot establish cause-and-effect relationships and cannot manipulate the predictor variables. Here are some examples for each type of research:

(i) True experimental :

- The effect of small classes on instruction
- The use of intensive mentoring to help beginning teachers develop balanced instruction

(ii) Quasi Experiment

- Are lectures given in the morning memorized better than when given in the afternoon?
- Do teachers' teaching styles play a role in students' motivation for learning?

Non experimental studies These are research studies in which there is no manipulation of the independent variable by the experimenter either for ethical reasons (for example the impact of smoking on health) or because of their abstract nature (for example age, gender , ethnicity opinions etc.). Non experimental research covers a wide variety of studies, such as

- descriptive,
 - causal-comparative,
 - correlational,
 - ex post facto research, and
 - surveys
- Descriptive research, as the name suggests, helps the researcher to collect data about conditions, situations, and events that occur in the present. For example:
 - a) Attitudes of parents toward introducing school outings on Sundays.
 - b) How do university teachers spend their time?
 - c) How do parents feel about a four day school schedule?
 - Causal-comparative research aims investigates the relation between the variables under study in order to identify possible causal relationships between them. For example :
 - a) Effect of birth order on academic achievement
 - b) The effect of having a working mother on school achievements
 - c) The effect of age on achievements in learning a foreign language
 - Correlational research is concerned with establishing possible but not necessarily present relationships between variables. Examples of correlational studies:
 - a) Do male students perform better than female in scientific subjects?
 - b) The relationship between parents' socio-economic status and their children's school achievements
 - c) The relationship between stress and achievement
 - Ex post facto research: Ex-post facto literally means "from what is done afterwards". It focuses first on the effect, then tries to determine possible causes and questions will remain about the effect following the cause, or vice versa. In this type of research, the researcher cannot control the

variables; his role is limited to reporting the outcome of an action or what is happening.

QUALITATIVE RESEARCH STUDIES

A means for exploring and understanding the meaning individuals or groups ascribe to a social or human problem.

The process of research involves emerging questions and procedures. Data typically collected in the participant's setting. data analysis inductively building from particulars to general themes. and the researcher making interpretations of the meaning of the data.

This type of research relies primarily on collecting qualitative data (i.e., non-numerical or categorical data such as words and pictures etc.), and can be either interactive or non interactive (i.e. whether the researcher is personally.

INTERACTIVE

In educational research there is very little room for a personal involvement or immersion of the researcher with the participants of the study, as his role is mostly that of an observer. However, there may be instances where such research can be carried out. The first of these is phenomenology which is the descriptive study of how individuals experience a phenomenon. In this type of research the researcher aims at understanding how individuals' lives are organised and structured. For example:

- a) What are students' attitudes towards an uncaring teacher?
- b) What are teachers' attitudes and beliefs towards teaching?

The second major approach to qualitative research is ethnography (i.e., the discovery and description of the culture of a group of people). Because it is deeply rooted in anthropology the concept of culture is of central importance in this type of research. In the case of educational research one can study the culture in a classroom. Examples of these would be :

- a) How do learners react to cultural differences in foreign language classes?
- b) How do teachers deal with cultural conflicts in their classes?

NON INTERACTIVE

Non interactive qualitative studies are mainly concerned with historical analysis or content analysis. In historical analysis the researcher aims at establishing descriptions, and coming up, whenever possible, with explanations, of what has occurred. For example, a study can document

(i) the changes in the assessment procedures in EFL classes over the past ten years, or
(ii) the developments in the testing procedures of English in the Baccalaureate over the past twenty years. In content analysis the researcher analyzes written documents or other communication media (e.g., photographs, movies, advertisements) in a given topic in order to identify the information and symbols they contain . The researcher identifies a body of material to analyze (e.g., school textbooks, television programs, newspaper articles etc) and then posits a system for recording specific aspects of its content. Content analysis is a nonreactive method because the researcher didn't know about the content beforehand.

For example a researcher might be interested in investigating how school violence is reported in the media or how women are represented in school textbooks.

MIXED METHODS RESEARCH

This research paradigm is used extensively in educational research for its many merits. Thus, in

mixed methods researchers use both types of data because these combined provide the best understanding of a research problem. It has been defined variously by many researchers. For Janice Morse it is a plan for a scientifically rigorous research process comprised of a qualitative or quantitative core component that directs the theoretical drive, with qualitative or quantitative supplementary components. These components of the research fit together to enhance description, understanding and can either be conducted simultaneously or sequentially

CONCLUSION

Research is the acquisition of knowledge in a systematic and organised way. However, the routes leading to the discovery of this new knowledge varies according to the philosophical tenets to which the researcher adheres. This is why the research paradigms which determine the existing research methodologies cannot be fully grasped without a thorough understanding of the epistemological issues which underpin each of them . The inductive- deductive debate which will grow into the quantitative-qualitative methodologies is the direct result of evolving beliefs as to what constitutes the most efficient and most reliable way of carrying the research.

It is true however, that the nature of the data, either natural or social and psychological will direct the researcher to a great extent towards one or another methodology. The frontier between the two is becoming blurred and justifies the resort to a methodology which uses the strengths of the of the two major paradigms, i.e. a mixed method approach. As far as educational research is concerned the choice of one or another methodology depends very much on the nature of the variables being investigated and the more the researcher is aware of the philosophical tenets of the methodology he intends to use the easier the choice of the appropriate research process will be.

QUALITATIVE INQUIRY IN THE HISTORY OF PSYCHOLOGY

The great irony of qualitative inquiry in psychology is that, despite and in part due to its ubiquity, little history has been written. As our knowledge moves further into the past, it becomes murkier even though qualitative research has been practiced long before and continually since the establishment of psychology as an independent science. Studying historical roots is especially difficult because qualitative inquiry is performed in all fields and predates the current organization of knowledge by means of the various sciences, humanities, arts and professions. Moreover, an interdisciplinary cross fertilization of qualitative methods continues to flourish wildly today.

The historian, in the face of qualitative inquiry in psychology, must be awe struck. Such awe can inspire creative scholarship about the history of qualitative inquiry, and there is no better time than the present, which is more hospitable than ever before to such efforts. One of the aims of this article is to begin to address the question of what qualitative research is--what it looks like in psychology, by recognizing past instances of such practices that have not previously been identified as such.

Understanding these modes of inquiry will be greatly enhanced if we develop our sensitivities and bring this work out of the shadows, from the bottom up, with deliberately open naiveté. A second aim is to provide a rough sketch of a history of qualitative inquiry in psychology that differentiates phases from the founding of psychology to the present.

This sketch highlights landmark events as an invitation to appreciate such moments and identify others rather than to bring any closure to what is historically important. Finally, several examples of psychology conducted before the term "qualitative research" entered our vocabulary are presented

in order to illustrate the potential of historical exploration of the hidden treasures of this field. Now that these practices have finally become a thematic object of scientific interest, such reconnaissance work will inform and benefit present and future generations of psychologists, better positioning them to understand and use all available means of inquiry.

It is misleading to speak of “the” history of qualitative inquiry in light of the diversity and complexity of the field, which is virtually coextensive with psychology itself. The genealogy of qualitative research is not well represented by a tree with roots denoting precursors, a single trunk depicting a great inventor/pioneer, and many large and smaller branches extending in directions signifying the progress of followers to their most recently budding contributions. Rather, qualitative methods in psychology are better represented as an expansive forest with many trees of various ages and distances from each other, some growing symbiotically, some competing for sunlight and others ascending in isolation as they rise from subterranean root systems that intermingle in an invisible community from common and different kinds of nourishing soil.

Qualitative inquiry is ubiquitous because of its fundamental necessity and place in the enterprise of science. Scientific knowledge is inconceivable without some rational determination of what its subject matter is, and answers to the ‘what’ question require some manner of qualitative inquiry. Hypothesis testing and measurement, for instance, cannot proceed except on the basis of some conceptualization of what the hypothesis is about, what is to be observed and measured. The logic and practice of empirical science requires evidence, and the determination of its relevance and validity requires qualitative knowledge and judgment.

The equation of science with hypothesis testing has led to an emphasis on measurement issues and statistical reasoning, with little attention to inductive, interpretive, and other rational means of defining constructs, even though it is a crucial and indispensable part of all scientific research.

Qualitative inquiry and knowledge can range from being highly implicit and taken for granted, even free wheeling and unsystematic, to being rigorously established and accounted for with specially designed and critically evaluated research procedures. Qualitative reasoning and practices have not long been a part of our discipline’s formal methodology, and even today there is limited if any presentation of them in the education and training of research psychologists. The present examination focuses primarily on the self-conscious and deliberate scientific practice of qualitative research.

QUALITATIVE RESEARCH PRACTICE WITHOUT METHODOLOGY

Qualitative inquiry can certainly be traced back to ancient times, for instance in the work of Aristotle. The qualitative tradition of naturalism was developed and applied in psychology by Darwin (1871 & 1872), in his classic comparative investigations of emotions and moral sense. The tradition of case history, as a means of establishing general knowledge, had long been employed in medicine when Freud used it in his research on psychopathology (Freud & Breuer, 1895). Although the official founding of psychology in 1879 is marked by the first psychological laboratory, Wundt’s experimental work was only a part of the psychology he conceived and practiced. Recent historians (Danziger, 1983, 2003) inform us that Wundt viewed his 10 volume *Völkerpsychologie* (1900-1920, & 1916) translated as “social psychology,” “folk psychology,” or “cultural psychology”), involving qualitative research on language, expressive movement, imagination, art, mythology, religion, and morality, as equally important to laboratory research in the science of psychology. Psychologists of

no less stature than Sigmund and Anna Freud, Carl Jung, William James, E.B. Titchener, Max Wertheimer and the Gestalt school, Kurt Lewin, John Watson, Wilhelm Stern, Jean Piaget, Lev Vygotsky, Frederick Bartlett, John Dollard, Abraham Maslow, Lawrence Kohlberg, Carol Gilligan, Leon Festinger, Stanley Schacter, Philip Zimbardo, and David Rosenhan have also contributed ground breaking, well known research in psychology without their qualitative methods receiving much attention even to this date.

It is significant that the two psychologists who were awarded Nobel Prizes (in Economics)--Herbert Simon and Daniel Kahneman, both won their distinction by carrying out inquiries on thinking and problem solving by developing mathematical models based on verbal description and a qualitative analysis of everyday problem solving (Ericcson & Simon, 1993 & Kahneman, 2003). There can be little question that qualitative inquiry has played a very important part in the history of psychology. The Call for Qualitative Methodology In 1940, the Social Science Research Council, charged with improving the quality of research in the social sciences, enlisted the Committee on Appraisal of Research, chaired by Edmund Day, to appraise research on psychological and social life focusing on "the subjective factor" by using "human documents" as source materials.

The Committee asked Gordon Allport to investigate the use in psychology of "any self revealing record that intentionally or unintentionally yields information about the structure, dynamics, or functioning of the author's mental life" (Allport, 1942, p. xii). Allport's survey and evaluation, published in a 1942 monograph, addressed such questions as the nature of this first person materials (e.g., autobiographies, questionnaires, verbatim recordings such as interviews, diaries/journals, letters, and expressive/artistic productions); the history of the employment of such documents; attempts to establish the reliability and validity of procedures; how investigators accounted for their methods; the kind(s) of analyses used; the employment of induction, illustration and hypotheses; how inferences were generalized; and the biases or frames of reference of investigators. Allport estimated that although two or three hundred psychological authors had employed personal documents, no more than a dozen had given thought to the method they had employed, and there were very few critical studies of these methods.

THE DEVELOPMENT OF QUALITATIVE METHODOLOGIES

Qualitative research continued in psychology unabated, but Allport's monograph did not result in a widespread recognition of the value of these methods for more than a generation. In the next decade and through the 1960s, qualitative research was practiced and even developed, but the vast majority of researchers who continued to use these methods did so without accounting systematically for their procedures or asserting their scientific value. As mentioned above, one noteworthy example of such innovative studies is Kohlberg's 1954 dissertation. The details of his method were not reported in his subsequent publications and became available only when the actual dissertation was published in 1994, when qualitative research was becoming a common concern of psychologists. Only recently has this work begun to receive methodological attention (Wertz et al, 2011).

Other good examples of the continuing innovation and development of qualitative inquiry are Maslow's studies of the self-actualized personality (1954, 1968), which Maslow initially hesitated to publish because he himself viewed his method as of purely personal interest and insufficiently scientific. After Maslow submitted the self-actualization study for publication because he viewed the findings as important, the manuscript was rejected for publication by leading psychological journals.

A persistent Maslow delivered his very methodologically interesting study of self actualization as his presidential address to APA in 1958 and bitterly refused any further submission his work for publication in psychology's top tier journals. He viewed his methods as being of sufficient scientific value to continue and extend them in his fruitful investigation of peak experiences (1959), for which he gathered participants' descriptions of their best experiences, and disseminated his very influential research on self actualization and peak experiences in his books.

METHODS OF RESEARCH: OBSERVATION, SURVEY [INTERVIEW, QUESTIONNAIRES]

Primary Research: Definitions and Overview How research is defined varies widely from field to field, and as you progress through your college career, your coursework will teach you much more about what it means to be a researcher within your field.* For example, engineers, who focus on applying scientific knowledge to develop designs, processes, and objects, conduct research using simulations, mathematical models, and a variety of tests to see how well their designs work. Sociologists conduct research using surveys, interviews, observations, and statistical analysis to better understand people, societies, and cultures.

Graphic designers conduct research through locating images for reference for their artwork and engaging in background research on clients and companies to best serve their needs. Historians conduct research by examining archival materials— newspapers, journals, letters, and other surviving texts—and through conducting oral history interviews.

Rather, individuals conducting research are producing the articles and reports found in a library database or in a book. Primary research, the focus of this essay, is research that is collected firsthand rather than found in a book, database, or journal. Primary research is often based on principles of the scientific method, a theory of investigation first developed by John Stuart Mill in the nineteenth century in his book *Philosophy of the Scientific Method*.

Although the application of the scientific method varies from field to field, the general principles of the scientific method allow researchers to learn more about the world and observable phenomena. Using the scientific method, researchers develop research questions or hypotheses and collect data on events, objects, or people that is measurable, observable, and replicable. The ultimate goal in conducting primary research is to learn about something new that can be confirmed by others and to eliminate our own biases in the process.

ESSAY OVERVIEW AND STUDENT

Examples The essay begins by providing an overview of ethical considerations when conducting primary research, and then covers the stages that you will go through in your primary research: planning, collecting, analyzing, and writing. After the four stages comes an introduction to three common ways of conducting primary research in first year writing classes:

- Observations. Observing and measuring the world around you, including observations of people and other measurable events.
- Interviews. Asking participants questions in a one-on-one or small group setting.
- Surveys. Asking participants about their opinions and behaviors through a short questionnaire.

In addition, we will be examining two student projects that used substantial portions of primary

research: Derek Laan, a nutrition major at Purdue University, wanted to learn more about student eating habits on campus. His primary research included observations of the campus food courts, student behavior while in the food courts, and a survey of students' daily food intake. His secondary research included looking at national student eating trends on college campuses, information from the United States Food and Drug Administration, and books on healthy eating. Jared Schwab, an agricultural and biological engineering major at Purdue, was interested in learning more about how writing and communication took place in his field. His primary research included interviewing a professional engineer and a student who was a senior majoring in engineering. His secondary research included examining journals, books, professional organizations, and writing guides within the field of engineering.

ETHICS OF PRIMARY RESEARCH

Both projects listed above included primary research on human participants; therefore, Derek and Jared both had to consider research ethics throughout their primary research process. As Earl Babbie writes in *The Practice of Social Research*, throughout the early and middle parts of the twentieth century researchers took advantage of participants and treated them unethically.

During World War II, Nazi doctors performed heinous experiments on prisoners without their consent, while in the U.S., a number of medical and psychological experiments on caused patients undue mental and physical trauma and, in some cases, death. Because of these and other similar events, many nations have established ethical laws and guidelines for researchers who work with human participants. In the United States, the guidelines for the ethical treatment of human research participants are described in *The Belmont Report*, released in 1979. Today, universities have Institutional Review Boards (or IRBs) that oversee research. Students conducting research as part of a class may not need permission from the university's IRB, although they still need to ensure that they follow ethical guidelines in research. The following provides a brief overview of ethical considerations:

VOLUNTARY PARTICIPATION

The Belmont Report suggests that, in most cases, you need to get permission from people before you involve them in any primary research you are conducting. If you are doing a survey or interview, your participants must first agree to fill out your survey or to be interviewed. Consent for observations can be more complicated, and is discussed later in the essay.

CONFIDENTIALITY AND ANONYMITY

Your participants may reveal embarrassing or potentially damaging information such as racist comments or unconventional behavior. In these cases, you should keep your participants' identities anonymous when writing your results. An easy way to do this is to create a "pseudonym" (or false name) for them so that their identity is protected.

RESEARCHER BIAS

There is little point in collecting data and learning about something if you already think you know the answer! Bias might be present in the way you ask questions, the way you take notes, or the conclusions you draw from the data you collect.

PLANNING YOUR PRIMARY RESEARCH PROJECT

The primary research process is quite similar to the writing process, and you can draw upon your

knowledge of the writing process to understand the steps involved in a primary research project. Just like in the writing process, a successful primary research project begins with careful planning and background research. This section first describes how to create a research timeline to help plan your research. It then walks you through the planning stages by examining when primary research is useful or appropriate for your first year composition course, narrowing down a topic, and developing research questions.

THE RESEARCH TIMELINE

When you begin to conduct any kind of primary research, creating a timeline will help keep you on task. Because students conducting primary research usually focus on the collection of data itself, they often overlook the equally important areas of planning (invention), analyzing data, and writing. To help manage your time, you should create a research timeline, such as the sample timeline presented here.

WHEN PRIMARY RESEARCH IS USEFUL OR APPROPRIATE IN

Evaluating Scientific Research:

Separating Fact from Fiction, Fred Leavitt explains that primary research is useful for questions that can be answered through asking others and direct observation. For first year writing courses, primary research is particularly useful when you want to learn about a problem that does not have a wealth of published information.

This may be because the problem is a recent event or it is something not commonly studied. For example, if you are writing a paper on a new political issue, such as changes in tax laws or healthcare, you might not be able to find a wealth of peer-reviewed research because the issue is only several weeks old. You may find it necessary to collect some of your own data on the issue to supplement what you found at the library.

Primary research is also useful when you are studying a local problem or learning how a larger issue plays out at the local level. Although you might be able to find information on national statistics for healthy eating, whether or not those statistics are representative of your college campus is something that you can learn through primary research.

DEVELOPING RESEARCH

Questions or Hypotheses As John Stuart Mill describes, primary research can use both inductive and deductive approaches, and the type approach is usually based on the field of inquiry.

Some fields use deductive reasoning, where researchers start with a hypothesis or general conclusion and then collect specific data to support or refute their hypothesis.

Other fields use inductive reasoning, where researchers start with a question and collect information that eventually leads to a conclusion. Once you have spent some time reviewing the secondary research on your topic, you are ready to write a primary research question or hypothesis. A research question or hypothesis should be something that is specific, narrow, and discoverable through primary research methods. Just like a thesis statement for a paper, if your research question or hypothesis is too broad, your research will be unfocused and your data will be difficult to analyze and write about. Here is a set of sample research questions:

OBSERVATIONS

Observations have led to some of the most important scientific discoveries in human history. Charles Darwin used observations of the animal and marine life at the Galapagos Islands to help him formulate his theory of evolution that he describes in *On the Origin of Species*. Today, social scientists, natural scientists, engineers, computer scientists, educational researchers, and many others use observations as a primary research method. Observations can be conducted on nearly any subject matter, and the kinds of observations you will do depend on your research question. You might observe traffic or parking patterns on campus to get a sense of what improvements could be made. You might observe clouds, plants, or other natural phenomena. If you choose to observe people, you will have several additional considerations including the manner in which you will observe them and gain their consent. If you are observing people, you can choose between two common ways to observe: participant observation and unobtrusive observation. Participant observation is a common method within ethnographic research in sociology and anthropology. In this kind of observation, a researcher may interact with participants and become part of their community.

Margaret Mead, a famous anthropologist, spent extended periods of time living in, and interacting with, communities that she studied. Conversely, in unobtrusive observation, you do not interact with participants but rather simply record their behavior. Although in most circumstances people must volunteer to be participants in research, in some cases it is acceptable to not let participants know you are observing them. In places that people perceive as public, such as a campus food court or a shopping mall, people do not expect privacy, and so it is generally acceptable to observe without participant consent. In places that people perceive as private, which can include a church,

ELIMINATING BIAS IN YOUR OBSERVATION NOTES

The ethical concern of being unbiased is important in recording your observations. You need to be aware of the difference between an observation (recording exactly what you see) and an interpretation (making assumptions and judgments about what you see). When you observe, you should focus first on only the events that are directly observable. Consider the following two example entries in an observation log:

1. The student sitting in the dining hall enjoys his greasy, oilsoaked pizza. He is clearly oblivious of the calorie content and damage it may do to his body.
2. The student sits in the dining hall. As he eats his piece of pizza, which drips oil, he says to a friend, "This pizza is good."

SURVEYS AND INTERVIEWS:

Question Creation Sometimes it is very difficult for a researcher to gain all of the necessary information through observations alone. Along with his observations of the dining halls, Derek wanted to know what students ate in a typical day, and so he used a survey to have them keep track of their eating habits.

Likewise, Jared wanted to learn about writing and communication in engineering and decided to draw upon expert knowledge by asking experienced individuals within the field. Interviews and surveys are two ways that you can gather information about people's beliefs or behaviors. With these methods, the information you collect is not first-hand (like an observation) but rather "self-reported" data, or data collected in an indirect manner.

William Shadish, Thomas Cook, and Donald Campbell argued that people are inherently biased about how they see the world and may report their own actions in a more favorable way than they may actually behave. Despite the issues in self-reported data, surveys and interviews are an excellent way to gather data for your primary research project.

Survey or Interview? How do you choose between conducting a survey or an interview? It depends on what kind of information you are looking for.

You should use surveys if you want to learn about a general trend in people's opinions, experiences, and behavior. Surveys are particularly useful to find small amounts of information from a wider selection of people in the hopes of making a general claim. Interviews are best used when you want to learn detailed information from a few specific people. Interviews are also particularly useful if you want to interview experts about their opinions, as Jared did. In sum, use interviews to gain details from a few people, and surveys to learn general patterns from many people.

WRITING GOOD QUESTIONS

One of the greatest challenges in conducting surveys and interviews is writing good questions. As a researcher, you are always trying to eliminate bias, and the questions you ask need to be unbiased and clear. Here are some suggestions on writing good questions:

ASK ABOUT ONE THING AT A TIME

A poorly written question can contain multiple questions, which can confuse participants or lead them to answer only part of the question you are asking. This is called a "double-barreled question" in journalism. The following questions are taken from Jared's research: Poor question: What kinds of problems are being faced in the field today and where do you see the search for solutions to these problems going?

Revised question #1 : What kinds of problems are being faced in the field today?

Revised question #2: Where do you see the search for solutions to these problems going?

UNDERSTAND WHEN TO USE OPEN AND CLOSED QUESTIONS

Closed questions, or questions that have yes/no or other limited responses, should be used in surveys. However, avoid these kinds of questions in interviews because they discourage the interviewee from going into depth.

The question sample above, "Do you believe the economy currently is in a crisis?" could be answered with a simple yes or no, which could keep a participant from talking more about the issue. The "why or why not?" portion of the question asks the participant to elaborate. On a survey, the question "Do you believe the economy currently is in a crisis?"

is a useful question because you can easily count the number of yes and no answers and make a general claim about participant responses.

INTERVIEWS

Interviews, or question and answer sessions with one or more people, are an excellent way to learn in-depth information from a person for your primary research project. This section presents information on how to conduct a successful interview, including choosing the right person, ways of interviewing, recording your interview, interview locations, and transcribing your interview.

Choosing the Right Person One of the keys to a successful interview is choosing the right person to interview. Think about whom you would like to interview and whom you might know. Do not be afraid to ask people you do not know for interviews. When asking, simply tell them what the interview will be about, what the interview is for, and how much time it will take. Jared used his Purdue University connection to locate both of the individuals that he ended up interviewing—an advanced Purdue student and a Purdue alum working in an Engineering firm.

FACE-TO-FACE AND VIRTUAL INTERVIEWS

When interviewing, you have a choice of conducting a traditional, face-to-face interview or an interview using technology over the Internet. Face-to-face interviews have the strength that you can ask follow-up questions and use non-verbal communication to your advantage. Individuals are able to say much more in a face-to-face interview than in an email, so you will get more information from a face-to-face interview. However, the Internet provides a host of new possibilities when it comes to interviewing people at a distance. You may choose to do an email interview, where you send questions and ask the person to respond.

You may also choose to use a video or audio conferencing program to talk with the person virtually. If you are choosing any Internet-based option, make sure you have a way of recording the interview. You may also use a chat or instant messaging program to interview your participant—the benefit of this is that you can ask follow-up questions during the interview and the interview is already transcribed for you. Because one of his interviewees lived several hours away, Jared chose to interview the Purdue student face-to-face and the Purdue alum via email.

Transcribing Your Interview Once your interview is over, you will need to transcribe your interview to prepare it for analysis. The term transcribing means creating a written record that is exactly what was said—i.e. typing up your interviews. If you have conducted an email or chat interview, you already have a transcription and can move on to your analysis stage.

ANALYZING AND WRITING ABOUT PRIMARY

Research Once you collect primary research data, you will need to analyze what you have found so that you can write about it. The purpose of analyzing your data is to look at what you collected (survey responses, interview answers to questions, observations) and to create a cohesive, systematic interpretation to help answer your research question or examine the validity of your hypothesis. When you are analyzing and presenting your findings, remember to work to eliminate bias by being truthful and as accurate as possible about what you found, even if it differs from what you expected to find. You should see your data as sources of information, just like sources you find in the library, and you should work to represent them accurately. The following are suggestions for analyzing different types of data.

OBSERVATIONS

If you've counted anything you were observing, you can simply add up what you counted and report the results. If you've collected descriptions using a double-entry notebook, you might work to write thick descriptions of what you observed into your writing. This could include descriptions of the scene, behaviors you observed, and your overall conclusions about events. Be sure that your readers are clear on what were your actual observations versus your thoughts or interpretations of those observations.

INTERVIEWS

If you've interviewed one or two people, then you can use your summary, paraphrasing, and quotation skills to help you accurately describe what was said in the interview. Just like in secondary research when working with sources, you should introduce your interviewees and choose clear and relevant quotes from the interviews to use in your writing. An easy way to find the important information in an interview is to print out your transcription and take a highlighter and mark the important parts that you might use in your paper. If you have conducted a large number of interviews, it will be helpful for you to create a spreadsheet of responses to each question and compare the responses, choosing representative answers for each area you want to describe.

SURVEYS

Surveys can contain quantitative (numerical) and qualitative (written answers/descriptions) data. Quantitative data can be analyzed using a spreadsheet program like Microsoft Excel to calculate the mean (average) answer or to calculate the percentage of people who responded in a certain way. You can display this information in a chart or a graph and also describe it in writing in your paper. If you have qualitative responses, you might choose to group them into categories and/or you may choose to quote several representative responses.

Experimental

Experimental psychology can be defined as the scientific and empirical approach to the study of the mind. The experimental approach means that tests are administered to participants, with both control and experimental conditions.

This means that a group of participants are exposed to a stimulus (or stimuli), and their behavior in response is recorded. This behavior is compared to some kind of control condition, which could be either a neutral stimulus, the absence of a stimulus, or against a control group.

Experimental psychology is concerned with testing theories of human thoughts, feelings, actions, and beyond – any aspect of being human that involves the mind. This is a broad category that features many branches within it (e.g. behavioral psychology, cognitive psychology). Below, we will go through a brief history of experimental psychology, the aspects that characterize it, and outline research that has gone on to shape this field.

A Brief History of Experimental Psychology

As with anything, and perhaps particularly with scientific ideas, it's difficult to pinpoint the exact moment in which a thought or approach was conceived. One of the best candidates with which to credit the emergence of experimental psychology with is Gustav Fechner who came to prominence in the 1830's. After completing his Ph.D in biology at the University of Leipzig [1], and continuing his work as a professor, he made a significant breakthrough in the conception of mental states.

As Schultz and Schultz recount [2]: "An increase in the intensity of a stimulus, Fechner argued, does not produce a one-to-one increase in the intensity of the sensation ... For example, adding the sound of one bell to that of an already ringing bell produces a greater increase in sensation than adding one bell to 10 others already ringing. Therefore, the effects of stimulus intensities are not absolute but are relative to the amount of sensation that already exists."

The next scientist to advance the field of experimental psychology was influenced directly by reading Fechner's book "Elements of Psychophysics". Hermann Ebbinghaus, also a German scientist, carried out the first properly formalized research into memory and forgetting, by using long lists of (mostly) nonsense syllables (such as: "VAW", "TEL", "BOC") and recording how long it took for people to forget them.

Experiments using this list, concerning learning and memory, would take up much of Ebbinghaus' career, and help cement experimental psychology as a science. There are many other scientists' whose contributions helped pave the way for the direction, approach, and success of experimental psychology (Hermann von Helmholtz, Ernst Weber, and Mary Whiton Calkins, to name just a few), yet their work is beyond the scope of this post.

Defining any scientific field is in itself no exact science – there are inevitably aspects that will be missed. However, experimental psychology features at least three central components that define it: empiricism, falsifiability, and determinism. These features are central to experimental psychology but also many other fields within science.

Empiricism refers to the collection of data that can support or refute a theory. In opposition to purely theoretical reasoning, empiricism is concerned with observations that can be tested. It is based on the notion that all knowledge stems from sensory experience – that observations can be perceived and data surrounding them can be collected to form experiments.

Falsifiability is a foundational aspect of all contemporary scientific work. Karl Popper, a 20th century philosopher, formalized this concept – that for any theory to be scientific there must be a way to falsify it.

CLASSIC STUDIES IN EXPERIMENTAL PSYCHOLOGY

Little Albert

One of the most notorious studies within experimental psychology was also one of the foundational pieces of research for behaviorism. Popularly known as the study of "Little Albert", this experiment, carried out in 1920, focused on whether a baby could be made to fear a stimulus through conditioning (conditioning refers to the association of a response to a stimulus) [3].

The psychologist, John B. Watson, devised an experiment in which a baby was exposed to an unconditioned stimulus (in this case, a white rat) at the same time as a fear-inducing stimulus (the loud, sudden sound of a hammer hitting a metal bar). The repetition of this loud noise paired with the appearance of the white rat eventually led to the white rat becoming a conditioned stimulus – inducing the fear response even without the sound of the hammer.

ASCH'S CONFORMITY EXPERIMENT

Three decades following Watson's infamous experiment, beliefs were studied rather than behavior. Research carried out by Solomon Asch in 1951 showed how group pressure could make people say what they didn't believe.

The goal was to examine how social pressures "induce individuals to resist or to yield to group pressures when the latter are perceived to be contrary to fact" [6]. Participant's were introduced to a group of seven people in which, unbeknownst to them, all other individuals were actors hired by

Asch. The task was introduced as a perceptual test, in which the length of lines was to be compared.

THE FUTURE OF EXPERIMENTAL PSYCHOLOGY

The majority of this article has been concerned with what experimental psychology is, where it comes from, and what it has achieved so far. An inevitable follow-up question to this is – where is it going?

While predictions are difficult to make, there are at least indications. The best place to look is to experts in the field. Schultz and Schultz refer to modern psychology “as the science of behavior and mental processes instead of only behavior, a science seeking to explain overt behavior and its relationship to mental processes.” [2].

The Association for Psychological Science (APS) asked for forecasts from several prominent psychology researchers (original article available here), and received some of the following responses.

QUASI-EXPERIMENTAL RESEARCH

The prefix quasi means “resembling.” Thus quasi-experimental research is research that resembles experimental research but is not true experimental research. Although the independent variable is manipulated, participants are not randomly assigned to conditions or orders of conditions (Cook & Campbell, 1979). Because the independent variable is manipulated before the dependent variable is measured, quasi-experimental research eliminates the directionality problem. But because participants are not randomly assigned—making it likely that there are other differences between conditions—quasi-experimental research does not eliminate the problem of confounding variables. In terms of internal validity, therefore, quasi-experiments are generally somewhere between correlational studies and true experiments.

Quasi-experiments are most likely to be conducted in field settings in which random assignment is difficult or impossible. They are often conducted to evaluate the effectiveness of a treatment—perhaps a type of psychotherapy or an educational intervention. There are many different kinds of quasi-experiments, but we will discuss just a few of the most common ones here.

NONEQUIVALENT GROUPS DESIGN

Recall that when participants in a between-subjects experiment are randomly assigned to conditions, the resulting groups are likely to be quite similar. In fact, researchers consider them to be equivalent. When participants are not randomly assigned to conditions, however, the resulting groups are likely to be dissimilar in some ways. For this reason, researchers consider them to be nonequivalent.

Imagine, for example, a researcher who wants to evaluate a new method of teaching fractions to third graders. One way would be to conduct a study with a treatment group consisting of one class of third-grade students and a control group consisting of another class of third-grade students.

This design would be a nonequivalent groups design because the students are not randomly assigned to classes by the researcher, which means there could be important differences between them. For example, the parents of higher achieving or more motivated students might have been more likely to request that their children be assigned to Ms. Williams’s class. Or the principal might have assigned the “troublemakers” to Mr. Jones’s class because he is a stronger disciplinarian. Of

course, the teachers' styles, and even the classroom environments, might be very different and might cause different levels of achievement or motivation among the students. If at the end of the study there was a difference in the two classes' knowledge of fractions, it might have been caused by the difference between the teaching methods—but it might have been caused by any of these confounding variables.

Of course, researchers using a nonequivalent groups design can take steps to ensure that their groups are as similar as possible. In the present example, the researcher could try to select two classes at the same school, where the students in the two classes have similar scores on a standardized math test and the teachers are the same sex, are close in age, and have similar teaching styles. Taking such steps would increase the internal validity of the study because it would eliminate some of the most important confounding variables. But without true random assignment of the students to conditions, there remains the possibility of other important confounding variables that the researcher was not able to control.

If the average posttest score is better than the average pretest score, then it makes sense to conclude that the treatment might be responsible for the improvement. Unfortunately, one often cannot conclude this with a high degree of certainty because there may be other explanations for why the posttest scores are better. One category of alternative explanations goes under the name of **history**. Other things might have happened between the pretest and the posttest. Perhaps an antidrug program aired on television and many of the students watched it, or perhaps a celebrity died of a drug overdose and many of the students heard about it. Another category of alternative explanations goes under the name of **maturation**. Participants might have changed between the pretest and the posttest in ways that they were going to anyway because they are growing and learning. If it were a yearlong program, participants might become less impulsive or better reasoners and this might be responsible for the change.

Natural Experiment

Natural experiments are conducted in the everyday (i.e. real life) environment of the participants, but here the experimenter has no control over the independent variable as it occurs naturally in real life. For example, Hodges and Tizard's attachment research (1989) compared the long term development of children who have been adopted, fostered or returned to their mothers with a control group of children who had spent all their lives in their biological families.

- **Strength:** behavior in a natural experiment is more likely to reflect real life because of its natural setting, i.e. very high ecological validity.
- **Strength:** There is less likelihood of demand characteristics affecting the results, as participants may not know they are being studied.
- **Strength:** Can be used in situations in which it would be ethically unacceptable to manipulate the independent variable, e.g. researching stress.
- **Limitation:** They may be more expensive and time consuming than lab experiments.
- **Limitation:** There is no control over extraneous variables that might bias the results. This makes it difficult for another researcher to replicate the study in exactly the same way.

FIELD STUDY

A field study is a general method for collecting data about users, user needs, and product

requirements that involves observation and interviewing. Data are collected about task flows, inefficiencies, and the organizational and physical environments of users.

Investigators in field studies observe users as they work, taking notes on particular activities and often asking questions of the users. Observation may be either direct, where the investigator is actually present during the task, or indirect, where the task is viewed by some other means like a video recorder set up in an office. The method is useful early in product development to gather user requirements. It is also useful for studying currently executed tasks and processes.

THE FOCUS OF CROSS-CULTURAL PSYCHOLOGY

Cross-cultural psychology is a branch of psychology that looks at how cultural factors influence human behavior. While many aspects of human thought and behavior are universal, cultural differences can lead to often surprising differences in how people think, feel, and act.

Some cultures, for example, might stress individualism and the importance of personal autonomy. Other cultures, however, may place a higher value on collectivism and cooperation among members of the group. Such differences can play a powerful role in many aspects of life.

Cross-cultural psychology is also emerging as an increasingly important topic as researchers strive to understand both the differences and similarities among people of various cultures throughout the world. The International Association of Cross- Cultural Psychology (IACCP) was established in 1972, and this branch of psychology has continued to grow and develop since that time.¹ Today, increasing numbers of psychologists investigate how behavior differs among various cultures throughout the world.

WHY CROSS-CULTURAL PSYCHOLOGY IS IMPORTANT

After prioritizing European and North American research for many years, Western researchers began to question whether many of the observations and ideas that were once believed to be universal might apply to cultures outside of these areas. Could their findings and assumptions about human psychology be biased based on the sample from which their observations were drawn?

Cross-cultural psychologists work to rectify many of the biases that may exist in the current research² and determine if the phenomena that appear in European and North American cultures also appear in other parts of the world.

For example, consider how something such as social cognition might vary from an individualist culture such as the United States versus a collectivist culture such as China. Do people in China rely on the same social cues as people in the U.S. do? What cultural differences might influence how people perceive each other? These are just some of the questions that a cross-cultural psychologist might explore.

Many cross-cultural psychologists choose to focus on one of two approaches:

- **The etic approach** studies culture through an "outsider" perspective, applying one "universal" set of concepts and measurements to all cultures.
- **The emic approach** studies culture using an "insider" perspective, analyzing concepts within the specific context of the observed culture.

Some cross-cultural psychologists take a combined emic-etic approach. Meanwhile, some cross-cultural psychologists also study something known as ethnocentrism.

Ethnocentrism refers to a tendency to use your own culture as the standard by which to judge and evaluate other cultures.⁶ In other words, taking an ethnocentric point of view means using your understanding of your own culture to gauge what is "normal." This can lead to biases and a tendency to view cultural differences as abnormal or in a negative light. It can also make it difficult to see how your own cultural background influences your behaviors.

Psychologists are also concerned with how ethnocentrism can influence the research process. For example, a study might be criticized for having an ethnocentric bias.

Major Topics in Cross-Cultural Psychology

- Emotions
- Language acquisition
- Child development
- Personality
- Social behavior
- Family and social relationships

CROSS-CULTURAL PSYCHOLOGY DIFFERS FROM OTHER BRANCHES OF PSYCHOLOGY

- Many other branches of psychology focus on how parents, friends, and other people impact human behavior, but most do not take into account the powerful impact that culture may have on individual human actions.
- Cross-cultural psychology, on the other hand, is focused on studying human behavior in a way that takes the effects of culture into account.
- According to Walter J. Lonner, writing for *Eye on Psi Chi*, cross-cultural psychology can be thought of as a type of research methodology rather than an entirely separate field within psychology.

Phenomenology

Phenomenology is commonly understood in either of two ways: as a disciplinary field in philosophy, or as a movement in the history of philosophy.

The discipline of phenomenology may be defined initially as the study of structures of experience, or consciousness. Literally, phenomenology is the study of "phenomena": appearances of things, or things as they appear in our experience, or the ways we experience things, thus the meanings things have in our experience. Phenomenology studies conscious experience as experienced from the subjective or first person point of view. This field of philosophy is then to be distinguished from, and related to, the other main fields of philosophy: ontology (the study of being or what is), epistemology (the study of knowledge), logic (the study of valid reasoning), ethics (the study of right and wrong action), etc.

The historical movement of phenomenology is the philosophical tradition launched in the first half of the 20th century by Edmund Husserl, Martin Heidegger, Maurice Merleau-Ponty, Jean-Paul Sartre, et al. In that movement, the discipline of phenomenology was prized as the proper foundation of all philosophy—as opposed, say, to ethics or metaphysics or epistemology. The methods and

characterization of the discipline were widely debated by Husserl and his successors, and these debates continue to the present day. (The definition of phenomenology offered above will thus be debatable, for example, by Heideggerians, but it remains the starting point in characterizing the discipline.)

In recent philosophy of mind, the term “phenomenology” is often restricted to the characterization of sensory qualities of seeing, hearing, etc.: what it is like to have sensations of various kinds. However, our experience is normally much richer in content than mere sensation. Accordingly, in the phenomenological tradition, phenomenology is given a much wider range, addressing the meaning things have in our experience, notably, the significance of objects, events, tools, the flow of time, the self, and others, as these things arise and are experienced in our “life-world”.

Phenomenology as a discipline has been central to the tradition of continental European philosophy throughout the 20th century, while philosophy of mind has evolved in the Austro-Anglo-American tradition of analytic philosophy that developed throughout the 20th century. Yet the fundamental character of our mental activity is pursued in overlapping ways within these two traditions. Accordingly, the perspective on phenomenology drawn in this article will accommodate both traditions. The main concern here will be to characterize the discipline of phenomenology, in a contemporary purview, while also highlighting the historical tradition that brought the discipline into its own.

THE DISCIPLINE OF PHENOMENOLOGY

The discipline of phenomenology is defined by its domain of study, its methods, and its main results. Phenomenology studies structures of conscious experience as experienced from the first-person point of view, along with relevant conditions of experience. The central structure of an experience is its intentionality, the way it is directed through its content or meaning toward a certain object in the world.

We all experience various types of experience including perception, imagination, thought, emotion, desire, volition, and action. Thus, the domain of phenomenology is the range of experiences including these types (among others). Experience includes not only relatively passive experience as in vision or hearing, but also active experience as in walking or hammering a nail or kicking a ball. (The range will be specific to each species of being that enjoys consciousness; our focus is on our own, human, experience. Not all conscious beings will, or will be able to, practice phenomenology, as we do.)

Conscious experiences have a unique feature: we experience them, we live through them or perform them. Other things in the world we may observe and engage. But we do not experience them, in the sense of living through or performing them. This experiential or first- person feature—that of being experienced—is an essential part of the nature or structure of conscious experience: as we say, “I see / think / desire / do ...” This feature is both a phenomenological and an ontological feature of each experience: it is part of what it is for the experience to be experienced (phenomenological) and part of what it is for the experience to be (ontological).

FROM PHENOMENA TO PHENOMENOLOGY

The Oxford English Dictionary presents the following definition: “Phenomenology. a. The science of phenomena as distinct from being (ontology). b. That division of any science which describes and classifies its phenomena. From the Greek *phainomenon*, appearance.” In philosophy, the term is used in the first sense, amid debates of theory and methodology. In physics and philosophy of

science, the term is used in the second sense, albeit only occasionally.

In its root meaning, then, phenomenology is the study of phenomena: literally, appearances as opposed to reality. This ancient distinction launched philosophy as we emerged from Plato's cave. Yet the discipline of phenomenology did not blossom until the 20th century and remains poorly understood in many circles of contemporary philosophy. What is that discipline? How did philosophy move from a root concept of phenomena to the discipline of phenomenology?

Originally, in the 18th century, "phenomenology" meant the theory of appearances fundamental to empirical knowledge, especially sensory appearances. The Latin term "Phenomenologia" was introduced by Christoph Friedrich Oetinger in 1736. Subsequently, the German term "Phänomenologia" was used by Johann Heinrich Lambert, a follower of Christian Wolff. Immanuel Kant used the term occasionally in various writings, as did Johann Gottlieb Fichte. In 1807, G. W. F. Hegel wrote a book titled *Phänomenologie des Geistes* (usually translated as *Phenomenology of Spirit*). By 1889 Franz Brentano used the term to characterize what he called "descriptive psychology". From there Edmund Husserl took up the term for his new science of consciousness, and the rest is history.

THE HISTORY AND VARIETIES OF PHENOMENOLOGY

Phenomenology came into its own with Husserl, much as epistemology came into its own with Descartes, and ontology or metaphysics came into its own with Aristotle on the heels of Plato. Yet phenomenology has been practiced, with or without the name, for many centuries. When Hindu and Buddhist philosophers reflected on states of consciousness achieved in a variety of meditative states, they were practicing phenomenology. When Descartes, Hume, and Kant characterized states of perception, thought, and imagination, they were practicing phenomenology. When Brentano classified varieties of mental phenomena (defined by the directedness of consciousness), he was practicing phenomenology.

When William James appraised kinds of mental activity in the stream of consciousness (including their embodiment and their dependence on habit), he too was practicing phenomenology. And when recent analytic philosophers of mind have addressed issues of consciousness and intentionality, they have often been practicing phenomenology. Still, the discipline of phenomenology, its roots tracing back through the centuries, came to full flower in Husserl.

Husserl's work was followed by a flurry of phenomenological writing in the first half of the 20th century. The diversity of traditional phenomenology is apparent in the *Encyclopedia of Phenomenology* (Kluwer Academic Publishers, 1997, Dordrecht and Boston), which features separate articles on some seven types of phenomenology.

1. Transcendental constitutive phenomenology studies how objects are constituted in pure or transcendental consciousness, setting aside questions of any relation to the natural world around us.
2. Naturalistic constitutive phenomenology studies how consciousness constitutes or takes things in the world of nature, assuming with the natural attitude that consciousness is part of nature.
3. Existential phenomenology studies concrete human existence, including our experience of free choice or action in concrete situations.
4. Generative historicist phenomenology studies how meaning, as found in our experience, is generated in historical processes of collective experience over time.

5. Genetic phenomenology studies the genesis of meanings of things within one's own stream of experience.
6. Hermeneutical phenomenology studies interpretive structures of experience, how we understand and engage things around us in our human world, including ourselves and others.
7. Realistic phenomenology studies the structure of consciousness and intentionality, assuming it occurs in a real world that is largely external to consciousness and not somehow brought into being by consciousness.

Phenomenology and Ontology, Epistemology, Logic, Ethics

The discipline of phenomenology forms one basic field in philosophy among others. How is phenomenology distinguished from, and related to, other fields in philosophy?

Traditionally, philosophy includes at least four core fields or disciplines: ontology, epistemology, ethics, logic. Suppose phenomenology joins that list. Consider then these elementary definitions of field:

- Ontology is the study of beings or their being—what is.
- Epistemology is the study of knowledge—how we know.
- Logic is the study of valid reasoning—how to reason.
- Ethics is the study of right and wrong—how we should act.
- Phenomenology is the study of our experience—how we experience.

The domains of study in these five fields are clearly different, and they seem to call for different methods of study.

Philosophers have sometimes argued that one of these fields is “first philosophy”, the most fundamental discipline, on which all philosophy or all knowledge or wisdom rests. Historically (it may be argued), Socrates and Plato put ethics first, then Aristotle put metaphysics or ontology first, then Descartes put epistemology first, then Russell put logic first, and then Husserl (in his later transcendental phase) put phenomenology first.

Consider epistemology. As we saw, phenomenology helps to define the phenomena on which knowledge claims rest, according to modern epistemology. On the other hand, phenomenology itself claims to achieve knowledge about the nature of consciousness, a distinctive kind of first-person knowledge, through a form of intuition.

Consider logic. As we saw, logical theory of meaning led Husserl into the theory of intentionality, the heart of phenomenology. On one account, phenomenology explicates the intentional or semantic force of ideal meanings, and propositional meanings are central to logical theory. But logical structure is expressed in language, either ordinary language or symbolic languages like those of predicate logic or mathematics or computer systems. It remains an important issue of debate where and whether language shapes specific forms of experience (thought, perception, emotion) and their content or meaning. So there is an important (if disputed) relation between phenomenology and logico-linguistic theory, especially philosophical logic and philosophy of language (as opposed to mathematical logic per se).

Consider ontology. Phenomenology studies (among other things) the nature of consciousness, which is a central issue in metaphysics or ontology, and one that leads into the traditional mind-body problem. Husserlian methodology would bracket the question of the existence of the surrounding

world, thereby separating phenomenology from the ontology of the world. Yet Husserl's phenomenology presupposes theory about species and individuals (universals and particulars), relations of part and whole, and ideal meanings—all parts of ontology.

Now consider ethics. Phenomenology might play a role in ethics by offering analyses of the structure of will, valuing, happiness, and care for others (in empathy and sympathy). Historically, though, ethics has been on the horizon of phenomenology. Husserl largely avoided ethics in his major works, though he featured the role of practical concerns in the structure of the life-world or of Geist (spirit, or culture, as in *Zeitgeist*), and he once delivered a course of lectures giving ethics (like logic) a basic place in philosophy, indicating the importance of the phenomenology of sympathy in grounding ethics. In *Being and Time* Heidegger claimed not to pursue ethics while discussing phenomena ranging from care, conscience, and guilt to “fallenness” and “authenticity” (all phenomena with theological echoes). In *Being and Nothingness* Sartre analyzed with subtlety the logical problem of “bad faith”, yet he developed an ontology of value as produced by willing in good faith (which sounds like a revised Kantian foundation for morality). Beauvoir sketched an existentialist ethics, and Sartre left unpublished notebooks on ethics. However, an explicitly phenomenological approach to ethics emerged in the works of Emmanuel Levinas, a Lithuanian phenomenologist who heard Husserl and Heidegger in Freiburg before moving to Paris. In *Totality and Infinity* (1961), modifying themes drawn from Husserl and Heidegger, Levinas focused on the significance of the “face” of the other, explicitly developing grounds for ethics in this range of phenomenology, writing an impression

PHENOMENOLOGY AND PHILOSOPHY OF MIND

It ought to be obvious that phenomenology has a lot to say in the area called philosophy of mind. Yet the traditions of phenomenology and analytic philosophy of mind have not been closely joined, despite overlapping areas of interest. So it is appropriate to close this survey of phenomenology by addressing philosophy of mind, one of the most vigorously debated areas in recent philosophy.

The tradition of analytic philosophy began, early in the 20th century, with analyses of language, notably in the works of Gottlob Frege, Bertrand Russell, and Ludwig Wittgenstein. Then in *The Concept of Mind* (1949) Gilbert Ryle developed a series of analyses of language about different mental states, including sensation, belief, and will. Though Ryle is commonly deemed a philosopher of ordinary language, Ryle himself said *The Concept of Mind* could be called phenomenology.

In effect, Ryle analyzed our phenomenological understanding of mental states as reflected in ordinary language about the mind. From this linguistic phenomenology Ryle argued that Cartesian mind-body dualism involves a category mistake (the logic or grammar of mental verbs—“believe”, “see”, etc.—does not mean that we ascribe belief, sensation, etc., to “the ghost in the machine”). With Ryle's rejection of mind-body dualism, the mind-body problem was re-awakened: what is the ontology of mind vis-à-vis body, and how are mind and body related?

René Descartes, in his epoch-making *Meditations on First Philosophy* (1641), had argued that minds and bodies are two distinct kinds of being or substance with two distinct kinds of attributes or modes: bodies are characterized by spatiotemporal physical properties, while minds are characterized by properties of thinking (including seeing, feeling, etc.).

Centuries later, phenomenology would find, with Brentano and Husserl, that mental acts are characterized by consciousness and intentionality, while natural science would find that physical

systems are characterized by mass and force, ultimately by gravitational, electromagnetic, and quantum fields. Where do we find consciousness and intentionality in the quantum-electromagnetic-gravitational field that, by hypothesis, orders everything in the natural world in which we humans and our minds exist? That is the mind-body problem today. In short, phenomenology by any other name lies at the heart of the contemporary mind-body problem.

GROUNDED THEORY OF PSYCHOLOGY

Grounded theory is a well-known methodology employed in many research studies. Qualitative and quantitative data generation techniques can be used in a grounded theory study. Grounded theory sets out to discover or construct theory from data, systematically obtained and analysed using comparative analysis. While grounded theory is inherently flexible, it is a complex methodology. Thus, novice researchers strive to understand the discourse and the practical application of grounded theory concepts and processes.

Glaser and Strauss are recognised as the founders of grounded theory. Strauss was conversant in symbolic interactionism and Glaser in descriptive statistics.⁸⁻¹⁰ Glaser and Strauss originally worked together in a study examining the experience of terminally ill patients who had differing knowledge of their health status. Some of these suspected they were dying and tried to confirm or disconfirm their suspicions. Others tried to understand by interpreting treatment by care providers and family members. Glaser and Strauss examined how the patients dealt with the knowledge they were dying and the reactions of healthcare staff caring for these patients. Throughout this collaboration, Glaser and Strauss questioned the appropriateness of using a scientific method of verification for this study. During this investigation, they developed the constant comparative method, a key element of grounded theory, while generating a theory of dying first described in *Awareness of Dying* (1965). The constant comparative method is deemed an original way of organising and analysing qualitative data.

Glaser and Strauss subsequently went on to write *The Discovery of Grounded Theory: Strategy for Qualitative Research* (1967). This seminal work explained how theory could be generated from data inductively. This process challenged the traditional method of testing or refining theory through deductive testing. Grounded theory provided an outlook that questioned the view of the time that quantitative methodology is the only valid, unbiased way to determine truths about the world. Glaser and Strauss challenged the belief that qualitative research lacked rigour and detailed the method of comparative analysis that enables the generation of theory. After publishing *The Discovery of Grounded Theory*, Strauss and Glaser went on to write independently, expressing divergent viewpoints in the application of grounded theory methods.

OBJECTIVE:

The aim of this article is to provide a contemporary research framework suitable to inform a grounded theory study.

RESULT:

This article provides an overview of grounded theory illustrated through a graphic representation of the processes and methods employed in conducting research using this methodology. The framework is presented as a diagrammatic representation of a research design and acts as a visual guide for the novice grounded theory researcher.

DISCUSSION:

As grounded theory is not a linear process, the framework illustrates the interplay between the essential grounded theory methods and iterative and comparative actions involved. Each of the essential methods and processes that underpin grounded theory are defined in this article.

CONCLUSION:

Rather than an engagement in philosophical discussion or a debate of the different genres that can be used in grounded theory, this article illustrates how a framework for a research study design can be used to guide and inform the novice nurse researcher undertaking a study using grounded theory. Research findings and recommendations can contribute to policy or knowledge development, service provision and can reform thinking to initiate change in the substantive area of inquiry.

Keywords: Framework, grounded theory, grounded theory methods, novice researcher, study design

FOCUS GROUPS OF PSYCHOLOGY

Focus group discussion requires a team consisting of a skilled facilitator and an assistant (Burrows & Kendall, 1997; Krueger, 1994). The facilitator is central to the discussion not only by managing existing relationships but also by creating a relaxed and comfortable environment for unfamiliar participants. Similarly, the assistant's role includes observing non-verbal interactions and the impact of the group dynamics, and documenting the general content of the discussion, thereby supplementing the data (Kitzinger, 1994, 1995). Non-verbal data rely on the behaviour and actions of respondent's pre-focus group discussion, during and post-focus group discussion. Non-verbal data provide "thicker" descriptions and interpretations compared to the sole use of verbal data (Fonteyn, Vettese, Lancaster, & Bauer-Wu, 2008). Gordon (1980) outlines four non-verbal communication data sources based on participants' behaviour reflected by body displacements and postures (kinesics); use of interpersonal space to communicate attitudes (proxemics); temporal speech markers such as gaps, silences, and hesitations (chronemics); and variations in volume, pitch and quality of voice (paralinguistic).

TYPES OF FOCUS GROUP DISCUSSION

Five types of focus group discussion have been identified in the literature, and a further two are emerging with the growth in access and variety of online platforms.

SINGLE FOCUS GROUP

The key feature of a single focus group is the interactive discussion of a topic by a collection of all participants and a team of facilitators as one group in one place. This is the most common and classical type of focus group discussion (Morgan, 1996). It has been widely used by both researchers and practitioners across different disciplines (e.g. Lunt & Livingstone, 1996; Morgan, 1996; Wilkinson, 1998).

TWO-WAY FOCUS GROUP

This format involves using two groups where one group actively discusses a topic, whereas the other observes the first group (Morgan, 1996; Morgan et al., 1998). Usually, this type of focus group is conducted behind a one-way glass. The observing group and the moderator can observe and note the interactions and discussion of the first group without being seen. Hearing what the other group thinks (or by observing their interactions) often leads the second group to different conclusions than those it may have reached otherwise (Morgan, 1988). Dual moderator focus group 3.3 Involves two moderators working together, each performing a different role within the same

focus group (Krueger & Casey, 2000). The division of roles ensures a smooth progression of the session and ensures that all topics are covered..

DUELLING MODERATOR FOCUS GROUP

This involves two moderators who purposefully take opposing sides on an issue or topic under investigation (Krueger & Casey, 2000). Proponents believe that the introduction of contrary views to the discussion by the moderators is critical to achieving more in- depth disclosure of data and information (Kamberelis & Dimitriadis, 2005).

RESPONDENT MODERATOR FOCUS GROUP

In this type of focus group discussion, researchers recruit some of the participants to take up a temporary role of moderators (Kamberelis & Dimitriadis, 2005). Having one of the participants lead the discussion is thought to impact on the dynamics of the group by influencing participants' answers, thereby increasing the chances of varied and more honest responses.

MINI FOCUS GROUP

Researchers are usually faced with a situation where there is a small potential pool of participants and are difficult to reach, yet the research design requires that the topic must be discussed in a group. Under these circumstances, researchers can only convene a small group of between two and five participants (Kamberelis & Dimitriadis, 2005). Such groups are usually made up of individuals with high level of expertise (Hague, 2002).

ONLINE FOCUS GROUPS

Online focus groups are not a different type of focus group discussion per se but one borne out of the introduction of the Internet as an adaptation of traditional methods. It is applied within the online environment, using conference calling, chat rooms or other online means (Kamberelis & Dimitriadis, 2005). Online focus groups boast an aura of dynamism, modernity and competitiveness that transcends classic problems with face-to-face focus group discussion (Edmunds, 1999). However, these discussion platforms are only accessible to participants with access to the Internet and are prone to technical problems such as poor or loss of connectivity and failure to capture non-verbal data (Dubrovsky, Kiesler, & Sethna, 1991).

MATERIALS AND METHODS

Our primary aim was to understand how focus group discussion has been used as a methodological tool in conservation in the last 20 years. Using a stepwise, structured approach, we reviewed the literature on the use of this method in biodiversity, ecology and conservation research. We used a combination of "Focus Group Discussion*" AND "conserv*," OR "ecology," OR "biodivers*," where "*" denotes a wild card to search for alternative word endings, in a search query within the Scopus database from 1996 to 2016 (accessed on 20th April 2016). A subsequent search using the term "Focus Group" with the other terms was run on 21st April 2017 in the same database. The search returned 438 peer reviewed articles excluding reviews. We screened the titles and abstracts to identify only those relevant to conservation, biodiversity and ecology. Studies which had focused primarily on soil or water conservation and did not have a direct bearing on biodiversity conservation were discarded. This resulted in 196 peer- reviewed papers. We retrieved all the relevant papers and scanned the full text to check if they specifically used focus group discussion as a method to answer a research question. All studies where the technique was merely mentioned in the introduction or conclusion section were eliminated. We developed a protocol (Appendix S1, Supporting Information)

for extracting data from the final list of studies.

INTRODUCING NARRATIVE PSYCHOLOGY

It may seem obvious to turn towards psychology in order to throw light on these complex questions regarding self and identity. After all, most people are drawn towards the study of psychology because they are interested in the 'human condition', what makes us human, our loves, passions, hates and desires. But most of us find ourselves only a few months into a psychology degree when we realise that we are dealing with very little of this. Instead, you are enmeshed in statistics, principles of learning, cognition, abstract theories and theoretical models, all of which bear very little resemblance to anything you were originally interested in studying. Somewhat ironically, a great deal of contemporary psychology, supposedly an area devoted to the study of human beings, has become a totally 'lifeless' discipline. So where do we look, in the discipline of psychology, if we want to examine these questions of self and identity? In *Introducing Narrative Psychology*, I suggested four main areas of psychology which address these issues. These included:

- i) experimentally based social psychology;
- ii) humanistic psychology;
- iii) psychoanalytic/ psychodynamic psychology; and
- iv) social constructivist approaches. Highlighting the limitations associated with each of these four areas, I opened the way for a new narrative psychology approach which, although influenced by these approaches (especially humanistic and social constructivist), had the potential to avoid the pitfalls endemic within them.

NARRATIVE AS AN 'ORGANISING PRINCIPLE' FOR HUMAN LIFE

But it is not just the fact that people tell stories in making sense of themselves and others. A narrative psychological approach goes far deeper than that. For, central to this approach, is the development of a phenomenological understanding of the unique 'order of meaning' constitutive of human consciousness (see Crossley, 2000a; Polkinghorne, 1988). One of the main features of this 'order of meaning' is the experience of time and temporality. An understanding of temporality associated with the human realm of meaning is entirely different to that encountered in the natural sciences.

This is because the human realm of meaning it is not related to a 'thing' or a 'substance' but to an 'activity' (Polkinghorne, 1988: 4). Everything experienced by human beings is made meaningful, understood and interpreted in relation to the primary dimension of 'activity' which incorporates both 'time' and 'sequence'. In order to define and interpret 'what' exactly has happened on any particular occasion, the sequence of events is of extreme importance. Hence, a valid portrayal of the experience of selfhood necessitates an understanding of the inextricable connection between temporality and identity.

HUMAN EXPERIENCE AND NARRATIVE STRUCTURE

Carr (1986) argues that the reality of human experience can be characterised as one which has a narrative or story-telling character (ibid, p.18). What would it be, he asks, to experience life as a 'mere' or 'pure' sequence of isolated events, one thing after another? In order to illustrate his thesis Carr draws upon phenomenological approaches such as Husserl's theory of time consciousness which depicts the way in which humans ordinarily experience time. He basically makes a distinction between three levels of human experience: passive experience, active experience and experience of self/life. At each of these levels, human experience can be characterised by a complex temporal

structure akin to the configuration of the storied form (see also Bruner, 1990; 1991). In the following exploration of human time consciousness, we will look at each of these experiential levels in turn.

Human Life Narratively Configured? In characterising psychological life through the concept of narrative, however, are we not overplaying the significance played by the storied form in human experience? At the level of 'personal' experience, some researchers have argued that although human experience may bear some resemblance to the story, the idea that it takes on a narrative structure is mistaken. The core of this argument is that the coherent temporal unity lying at the heart of stories (the connection between beginning, middle and end) is something that is not at all intrinsic to real human events, real selves and real life. As literary theorist Frank Kermode argues, such 'narrative properties cannot be ascribed to the real' (cited in Wood, 1991: 160). The historian Louis Mink argues a similar point: 'Stories are not lived but told ... Life has no beginnings, middles and ends...Narrative qualities are transferred from art to life' (cited in Wood, 1991: 161).

Narrative Incoherence and the Breach of Trauma One good example of disruptive traumatising experiences is that of chronic or serious illness. In recent years numerous studies of chronic illness have illustrated the potentially devastating impact they can have on a person's life. This has been characterised as an 'ontological assault' in which some of the most basic, underlying existential assumptions that people hold about themselves and the world are thrown into disarray (Crossley, 2000b; Janoff Bulman, 1992; Kleinman, 1988; Taylor, S., 1989).

ADAPTING TO TRAUMA: STORIES AND NARRATIVE COHERENCE

Research into the experience of chronic and serious illness illustrates the way in which our routine, 'lived' sense of time and identity is one of implicit connection and coherence. This sense is severely disrupted in the face of trauma and it is in such contexts that stories become important as a way of rebuilding a sense of connection and coherence. As the recent proliferation of autobiographies (especially in relation to diseases such as cancer and HIV/AIDS) and self-help groups suggests, for people suffering the trauma of illness, storytelling takes on a 'renewed urgency' (Mathieson and Stam, 1995: 284). Of course, such a narrative understanding bears a strong affinity with Freud's work, which equated mental ill health with an 'incoherent story' and narrative breakdown. From this perspective, psychotherapy constituted an exercise in 'story repair' and, as Spence (1982) argued: Freud made us aware of the persuasive power of a coherent narrative - in particular of the ways in which an aptly chosen reconstruction can fill the gap between two apparently unrelated events, and in the process, make sense out of nonsense. There seems no doubt but that a well constructed story possesses a kind of narrative truth that is real and immediate and carries an important significance for the process of therapeutic change.

CONCLUSION

This paper has aimed to introduce some of the main themes underpinning a narrative approach towards psychology. Drawing on some of dominant theories in this area, it has argued that human life carries within it a narrative structure to the extent that the the individual, at the level of tacit, phenomenological experience, is constantly projecting backwards and forwards in a manner that maintains a sense of coherence, unity, meaningfulness and identity. From this perspective, the characterisation of human experience as one of constant flux, variability and incoherence, as manifest in many discursive and postmodern approaches, fails to take sufficient account of the essential unity and integrity of everyday lived experience. In accordance with this theoretical perspective, it has been argued that the experience of traumatic events such as serious illness are

instrumental in facilitating an appreciation of the way in which human life is routinely narratively configured.

This is because the experience of traumatising often serves to fundamentally disrupt the routine and orderly sense of existence, throwing into radical doubt our taken-for-granted assumptions about time, identity, meaning, and life itself. When this happens, it is possible to examine the way in which narratives become important in another sense. This is in terms of the way in which they are used to restore a sense of order and connection, and thus to re-establish a semblance of meaning in the life of the individual. Accordingly, narratives of illness are useful because they help to reveal structures or meanings that typically remain implicit or unrecognised, thus potentiating a transformation of life and elevation to another level.

CASE STUDIES IN PSYCHOLOGY

Case studies are in-depth investigations of a single person, group, event or community. Typically, data are gathered from a variety of sources and by using several different methods (e.g. observations & interviews).

The case study research method originated in clinical medicine (the case history, i.e. the patient's personal history). In psychology, case studies are often confined to the study of a particular individual.

The information is mainly biographical and relates to events in the individual's past (i.e. retrospective), as well as to significant events which are currently occurring in his or her everyday life.

The case study is not itself a research method, but researchers select methods of data collection and analysis that will generate material suitable for case studies. Case studies are widely used in psychology and amongst the best known were the ones carried out by Sigmund Freud, including Anna O and Little Hans.

Freud (1909a, 1909b) conducted very detailed investigations into the private lives of his patients in an attempt to both understand and help them overcome their illnesses. Even today case histories are one of the main methods of investigation in abnormal psychology and psychiatry. This makes it clear that the case study is a method that should only be used by a psychologist, therapist or psychiatrist, i.e. someone with a professional qualification.

There is an ethical issue of competence. Only someone qualified to diagnose and treat a person can conduct a formal case study relating to atypical (i.e. abnormal) behavior or atypical development. The procedure used in a case study means that the researcher provides a description of the behavior. This comes from interviews and other sources, such as observation.

The client also reports detail of events from his or her point of view. The researcher then writes up the information from both sources above as the case study, and interprets the information.

Strengths of Case Studies

- Provides detailed (rich qualitative) information.
- Provides insight for further research.
- Permitting investigation of otherwise impractical (or unethical) situations.

Case studies allow a researcher to investigate a topic in far more detail than might be possible if they were trying to deal with a large number of research participants (nomothetic approach) with the aim of 'averaging'.

Because of their in-depth, multi-sided approach case studies often shed light on aspects of human thinking and behavior that would be unethical or impractical to study in other ways.

Research which only looks into the measurable aspects of human behavior is not likely to give us insights into the subjective dimension to experience which is so important to psychoanalytic and humanistic psychologists.

Case studies are often used in exploratory research. They can help us generate new ideas (that might be tested by other methods). They are an important way of illustrating theories and can help show how different aspects of a person's life are related to each other.

The method is therefore important for psychologists who adopt a holistic point of view (i.e. humanistic psychologists).

Limitations of Case Studies

- Lacking scientific rigour and providing little basis for generalization of results to the wider population.
- Researchers' own subjective feeling may influence the case study (researcher bias).
- Difficult to replicate.
- Time-consuming and expensive.
- The volume of data, together with the time restrictions in place, impacted on the depth of analysis that was possible within the available resources.

Because a case study deals with only one person/event/group we can never be sure if the case study investigated is representative of the wider body of "similar" instances. This means the the conclusions drawn from a particular case may not be transferable to other settings. Because case studies are based on the analysis of qualitative (i.e. descriptive) data a lot depends on the interpretation the psychologist places on the information she has acquired. This means that there is a lot of scope for observer bias and it could be that the subjective opinions of the psychologist intrude in the assessment of what the data means.

For example, Freud has been criticized for producing case studies in which the information was sometimes distorted to fit the particular theories about behavior).

This is also true of Money's interpretation of the Bruce/Brenda case study (Diamond, 1997) when he ignored evidence that went against his theory.

ETHNOGRAPHY

Ethnography, descriptive study of a particular human society or the process of making such a study. Contemporary ethnography is based almost entirely on fieldwork and requires the complete immersion of the anthropologist in the culture and everyday life of the people who are the subject of his study.

There has been some confusion regarding the terms ethnography and ethnology. The latter, a term

more widely used in Europe, encompasses the analytical and comparative study of cultures in general, which in American usage is the academic field known as cultural anthropology (in British usage, social anthropology). Increasingly, however, the distinction between the two is coming to be seen as existing more in theory than in fact. Ethnography, by virtue of its intersubjective nature, is necessarily comparative. Given that the anthropologist in the field necessarily retains certain cultural biases, his observations and descriptions must, to a certain degree, be comparative. Thus the formulating of generalizations about culture and the drawing of comparisons inevitably become components of ethnography.

The description of other ways of life is an activity with roots in ancient times. Herodotus, the Greek traveler and historian of the 5th century BC, wrote of some 50 different peoples he encountered or heard of, remarking on their laws, social customs, religion, and appearance. Beginning with the age of exploration and continuing into the early 20th century, detailed accounts of non-European peoples were rendered by European traders, missionaries, and, later, colonial administrators. The reliability of such accounts varies considerably, as the Europeans often misunderstood what they saw or had a vested interest in portraying their subjects less than objectively.

Modern anthropologists usually identify the establishment of ethnography as a professional field with the pioneering work of both the Polish-born British anthropologist Bronisław Malinowski in the Trobriand Islands of Melanesia (c. 1915) and the American anthropologist Margaret Mead, whose first fieldwork was in Samoa (1925). Ethnographic fieldwork has since become a sort of rite of passage into the profession of cultural anthropology. Many ethnographers reside in the field for a year or more, learning the local language or dialect and, to the greatest extent possible, participating in everyday life while at the same time maintaining an observer's objective detachment. This method, called participant-observation, while necessary and useful for gaining a thorough understanding of a foreign culture, is in practice quite difficult. Just as the anthropologist brings to the situation certain inherent, if unconscious, cultural biases, so also is he influenced by the subject of his study. While there are cases of ethnographers who felt alienated or even repelled by the culture they entered, many—perhaps most—have come to identify closely with “their people,” a factor that affects their objectivity. In addition to the technique of participant-observation, the contemporary ethnographer usually selects and cultivates close relationships with individuals, known as informants, who can provide specific information on ritual, kinship, or other significant aspects of cultural life. In this process also the anthropologist risks the danger of biased viewpoints, as those who most willingly act as informants frequently are individuals who are marginal to the group and who, for ulterior motives (e.g., alienation from the group or a desire to be singled out as special by the foreigner), may provide other than objective explanations of cultural and social phenomena. A final hazard inherent in ethnographic fieldwork is the ever-present possibility of cultural change produced by or resulting from the ethnographer's presence in the group.

Contemporary ethnographies usually adhere to a community, rather than individual, focus and concentrate on the description of current circumstances rather than historical events. Traditionally, commonalities among members of the group have been emphasized, though recent ethnography has begun to reflect an interest in the importance of variation within cultural systems. Ethnographic studies are no longer restricted to small primitive societies but may also focus on such social units as urban ghettos. The tools of the ethnographer have changed radically since Malinowski's time. While detailed notes are still a mainstay of fieldwork, ethnographers have taken full advantage of technological developments such as motion pictures and tape recorders to augment their written

accounts.

Ethnomusicology, field of scholarship that encompasses the study of all world musics from various perspectives. It is defined either as the comparative study of musical systems and cultures or as the anthropological study of music. Although the field had antecedents in the 18th and early 19th centuries, it began to gather energy with the development of recording techniques in the late 19th century.

It was known as comparative musicology until about 1950, when the term ethnomusicology was introduced simultaneously by the Dutch scholar of Indonesian music Jaap Kunst and by several American scholars, including Richard Waterman and Alan Merriam. In the period after 1950, ethnomusicology burgeoned at academic institutions. Several societies and periodicals were founded, the most notable being the Society for Ethnomusicology, which publishes the journal *Ethnomusicology*. Some ethnomusicologists consider their field to be associated with musicology, while others see the field as related more closely to anthropology.

Among the general characteristics of the field are dependence on field research, which may include the direct study of music performance, and interest in all types of music produced in a society, including folk, art, and popular genres. Among the field's abiding concerns are whether outsiders can validly study another culture's music and what the researcher's obligations are to his informants, teachers, and consultants in colonial and postcolonial contexts. Over time, ethnomusicologists have gradually abandoned the detailed analytical study of music and increased

their focus on the anthropological study of music as a domain of culture. With this shift in emphasis has come greater concern with the study of popular musics as expressions of the relationships between dominant and minority cultures; of music as a reflection of political, social-ethnic, and economic movements; and of music in the context of the cultural meanings of gender. See also anthropology: Ethnomusicology.

What is Statistics in Psychology: Measures of Central Tendency and Dispersion. Normal Probability Curve. Parametric [t-test] and Non-parametric tests [Sign Test, Wilcoxon Signed rank test, Mann-Whitney test, Kruskal-Wallis test, Friedman]. Power analysis. Effect size

STATISTICS IN PSYCHOLOGY: MEASURES OF CENTRAL TENDENCY AND DISPERSION. NORMAL PROBABILITY CURVE. PARAMETRIC [T-TEST] AND NON-PARAMETRIC TESTS [SIGN TEST, WILCOXON SIGNED RANK TEST, MANN-WHITNEY TEST, KRUSKAL-WALLIS TEST, FRIEDMAN]. POWER ANALYSIS. EFFECT SIZE

Statistics in Psychology: Measures of Central Tendency and Dispersion.

The following points highlight the three types of measures of central tendency. The types are: 1. Mean 2. Median 3. Mode

TYPE # 1. MEAN:

It is also known as arithmetic mean. It is the ordinary average in Arithmetic.

ACCORDING TO GARRETT, "THE ARITHMETIC MEAN, OR MORE SIMPLY THE MEAN, IS

THE SUM OF THE SEPARATE SCORES OR MEASURES DIVIDED BY THEIR NUMBER.”

Calculation of the Mean when Data are Ungrouped:

In ungrouped data, mean is the sum of separate scores or measures divided by their number. If a man earns Rs. 5, Rs. 6 Rs. 4, Rs. 9 on four successive days his mean of daily wage (Rs. 6) is obtained by dividing the sum of his daily earnings by the number of days he has worked. The formula for the mean (M) of a series of ungrouped measures is: $M = \frac{\sum X}{N}$ (arithmetic mean calculated from ungrouped data).

Where \sum means the “sum of,”

X stands for a score of other measure,

N is the number of measures in the series.

CALCULATION OF THE MEAN WHEN DATA ARE GROUPED:

When data or measures have been grouped into a frequency distribution, the mean may be calculated by a simple formula:

F stands for the frequency of each class-interval.

X represents the mid-point in each class-interval. N stands for the total number of frequencies.

THE FOLLOWING EXAMPLE IS GIVEN FOR CALCULATING THE MEAN FROM GROUPED DATA:

In calculating mean we first of all find the mid-point (x) of various class- intervals. After finding x we find the fx. Column fx is found by multiplying the mid-point (x) of each interval by the number of scores (f) on it; the mean (47.4) is then simply the sum of the fx namely, (2607.5) divided by N (55). This is known as long method of finding the mean.

SHORT METHOD OF FINDING THE MEAN:

The long method of finding the mean gives accurate results but often requires the handling of large numbers and entails tedious calculation. Because of this, short method or the “assumed mean” method has been devised for computing the mean.

ACCORDING TO THIS METHOD WE SHALL FIND THE MEAN AS FOLLOWS:

Mean = AM + Ci

AM stands for the assumed mean or guessed mean, C stands for correction in terms of class-interval, i stands for the length of class-intervals. Ci stands for $\frac{fx'}{N} \times i$

NOW, WE SHALL CALCULATE THE MEAN BY SHORT METHOD FROM THE FOLLOWING DATA:

The various steps in calculating the mean by the short method may be explained below:

1. In the first column, write the class-intervals.
2. After writing class-intervals, find the mid-points.
3. Then write the frequency.
4. Assume a mean as near the centre of the distribution as possible and preferably on the interval containing the largest frequency.
5. After assuming the mean, find its deviation in terms of class- interval from the assumed mean in units of interval.
6. Multiply each deviation (x') by its appropriate f, the f opposite to it.

7. Find the algebraic sum of the plus and minus of x' and divide the sum by N , number of cases. This gives C , the correction in units of class interval.
8. Multiply C by the interval length (i) to get C_i , the score correction.
9. Add C_i algebraically to the AM. This will give the true mean.

ADVANTAGES OF THE MEAN:

1. It utilises all the items in a group.
2. It is widely understood and easy to calculate.
3. It can be known even when number of items and their aggregate values are known, but details of the different items are not available.
4. It is always definite,
5. It is capable of further algebraic treatment.
6. It is less subject to chance variation. Hence it is more stable measure of central tendency.

LIMITATIONS OF THE MEAN:

1. It may not be an actual item in a series.
2. It cannot be computed by merely observing the series, unless the series, is very simple.
3. It is essential to know the actual values of all the items before computing the arithmetic mean, but in the case of median and mode the items on the extreme may be ignored without understanding the values of these measurements.

THERE ARE MORE IMPORTANT THINGS:

Questioning American Psychology's Commitment to Personal Happiness and Self-esteem While I hope I am still too young to write a retrospective of my career, I find myself reflecting on recurring themes in both my professional career as a practicing and teaching psychologist and my personal life. I hope that the reader will indulge a certain personal focus and use of the personal "I" pronoun even though this is a voice not used much in academic psychology.

My focus in this article is on the commitment in American psychology to the ideal of personal happiness and Self-esteem. While for most Americans these aims seem self-evident, I have grown increasingly uncomfortable with and skeptical of these mostly unquestioned assumptions in my field. I hope that what I have to say can influence the reader both professionally and personally in their pursuit of academic goals and the right kind of life. I will focus on three primary assumptions made by modern American psychology: first, that human beings should or ought to be happy; second, that we should seek to be free of suffering; and third, that humans beings should (and deserve to) feel good about themselves.

HEALTHY PEOPLE SUFFER

Much of modern psychotherapy sets the goal for a healthy individual to be free of suffering. Measures of mental health are almost always organized as "symptom checklists" which add up negative symptoms (like feelings of unhappiness or anxiety) to give you a score reflecting the "amount" of suffering you are experiencing. In other words, each symptom of suffering is counted against your mental health. This is universal enough that it must seem to most psychologists to be self-evident that suffering is bad and a sign of poor mental health.

I myself helped create one of these measures and also worked in a clinic that used such a checklist to track the progress of psychotherapy. I was certainly committed to ending the suffering of my

clients and believed that problems needed to be fixed so that a person would be free of suffering and problems.

FEELING GOOD ABOUT ONESELF

is to Encourage Illusory Thinking Perhaps the most provocative of my professional disagreements has to do with the way that we should think of ourselves. American psychology has long had an obsession with positive Self-esteem and working to help psychotherapy patients “feel good about themselves.” This kind of positive self-image is encouraged regardless of the kind of lifestyle or decisions the person is making in their lives. People are encouraged to think positively of themselves even if they are failing miserably in their relationships, career, and personal lives. One of my colleagues worked at a mental hospital where they treated youth who were convicted of violent sexual assault. Even these youth were taught to love themselves more, disregarding or separating themselves from their horrific behavior. I believe that this focus in psychology is counter-productive and I have a feeling that most of us know that it is ultimately wrong. I will explain.

This article throws light upon the fifteen main principles of normal probability curve. Some of the properties are: 1. The normal curve is symmetrical 2. The normal curve is unimodal 3. Mean, median and mode coincide 4. The maximum ordinate occurs at the centre 5. The normal curve is asymptotic to the X-axis 6. The height of the curve declines symmetrically and Others.

1. THE NORMAL CURVE IS SYMMETRICAL:

The Normal Probability Curve (N.P.C.) is symmetrical about the ordinate of the central point of the curve. It implies that the size, shape and slope of the curve on one side of the curve is identical to that of the other.

That is, the normal curve has a bilateral symmetry. If the figure is to be folded along its vertical axis, the two halves would coincide. In other words the left and right values to the middle central point are mirror images.

2. THE NORMAL CURVE IS UNIMODAL:

Since there is only one point in the curve which has maximum frequency, the normal probability curve is unimodal, i.e. it has only one mode.

PARAMETRIC [T-TEST] AND NON-PARAMETRIC TESTS [SIGN TEST PSYCHOLOGY PARAMETRIC and NON-PARAMETRIC TESTS

In the literal meaning of the terms, a parametric statistical test is one that makes assumptions about the parameters (defining properties) of the population distribution(s) from which one's data are drawn, while a non-parametric test is one that makes no such assumptions.

PARAMETRIC TESTS:

Parametric tests normally involve data expressed in absolute numbers or values rather than ranks; an example is the Student's t- test. The parametric statistical test operates under certain conditions. Since these conditions are not ordinarily tested, they are assumed to hold valid. The meaningfulness of the results of a parametric test depends on the validity of the assumption. Proper interpretation of parametric test based on normal distribution also assumes that the scene being analysed results from measurement in at least an interval scale. Let us try to understand the term population.

Population refers to the entire group of people which a researcher intends to understand in regard to a phenomenon. The study is generally conducted on a sample of the said population and the obtained results are then applied to the larger population from which the sample was selected.

Tests like t , z , and F are called parametrical statistical tests. T-tests: A T-test is used to determine if the scores of two groups differ on a single variable. A t-test is designed to test for the differences in mean scores. For instance, you could use t-test to determine whether writing ability differs among students in two classrooms. It may be mentioned here that the parametric tests, namely, t-test and F-test, are considered to be quite robust and are appropriate even when some assumptions are not met.

ASSUMPTIONS OF PARAMETRIC STATISTICS

Parametric tests like, 't and f' tests may be used for analysing the data which satisfy the following conditions :

- The population from which the sample have been drawn should be normally distributed. Normal Distributions refer to Frequency distribution following a normal curve, which is infinite at both the ends.
- The variables involved must have been measured interval or ratio scale. Variable and its types: characteristic that can have different values.
- Types of Variables Dependent Variable: Variable considered to be an effect; usually a measured variable. Independent Variable: Variable considered being a cause. The observation must be independent.
- The inclusion or exclusion of any case in the sample should not unduly affect the results of study.
- These populations must have the same variance or, in special cases, must have a known ratio of variance. This we call homoscedasticity.
- The samples have equal or nearly equal variances. This condition is known as equality or homogeneity of variances and is particularly important to determine when the samples are small. The observations are independent.
- The selection of one case in the sample is not dependent upon the selection of any other case.
- Most of the statistical tests we perform are based on a set of assumptions. When these assumptions are violated the results of the analysis can be misleading or completely erroneous.

NORMALITY:

Data have a normal distribution (or at least is symmetric)♣ Homogeneity of variances: Data from multiple groups have the same variance♣ Linearity: Data have a linear relationship♣ Independence: Data are independent♣ We explore in detail what it means for data to be normally distributed in Normal Distribution, but in general it means that the graph of the data has the shape of a bell curve. Such data is symmetric around its mean and has kurtosis equal to zero.

In Testing for Normality and Symmetry we provide tests to determine whether data meet this assumption. Some tests (e.g. ANOVA) require that the groups of data being studied have the same variance. In Homogeneity of Variances we provide some tests for determining whether groups of data have the same variance. Some tests (e.g. Regression) require that there be a linear correlation between the dependent and independent variables. Generally linearity can be tested graphically using scatter diagrams or via other techniques explored in Correlation, Regression and Multiple Regression.

INTRODUCTION:

The t-test is a basic test that is limited to two groups. For multiple groups, you would have

- to compare each pair of groups. For example with three groups there would be three tests (AB, AC, BC) whilst with seven groups there would be need of 21 tests.

The basic principle is to test the null hypothesis that means of the two groups are equal

THE T-TEST ASSUMES:

A normal distribution (parametric data)- Underlying variances are equal (if not, use welch's test)- It is used when there is random assignment and only two sets of measurement to compare.- There are two main types of t-test: Independent – measures – t- test: when samples are not matched.

- Match – pair – t-test: when samples appear in pairs (eg. before and after)
- A single – sample t-test compares a sample against a known figure. For example when measures- of a manufactured item are compared against the required standard.

APPLICATIONS:

To compare the mean of a sample with population mean. (Simple t-test)

- To compare the mean of one sample with the independent sample. (Independent Sample ttest)
- To compare between the values (readings) of one sample but in two occasions.

(Paired· sample t-test) Independent Samples t-Test (or 2-Sample t- Test) The independent samples t-test is probably the single most widely used test in statistics. It is used to compare differences between separate groups. In Psychology, these groups are often composed by randomly assigning research participants to conditions.

However, this test can also be used to explore differences in naturally occurring groups. For example, we may be interested in differences of emotional intelligence between males and females. Any differences between groups can be explored with the independent t-test, as long as the tested members of each group are reasonably representative of the population.

NON-PARAMETRIC STATISTICS

The term non-parametric was first used by Wolfowitz, 1942. To understand the idea of nonparametric statistics it is required to have a basic understanding of parametric statistics which we have already discussed.

A parametric test requires a sample to be normally distributed. A nonparametric test does not rely on parametric assumptions like normality. Nonparametric test create flexible demands of the data. To make standard parametric legitimate, some provisions need to fulfilled, especially for minor sample sizes. For example, the requirement of the one sample t-test is that the observation must be made from ordinarily distributed population. In case, the provision is defined, then the resultants may not be credible. However, in case of Wilcoxon Signed rank test to illustrate valid inference, normality is not required. We can assume that the sampling distribution is normal even if we are not sure that the distribution of the variable in the population is normal, as long as our sample is large enough, (for example, 100 or more observations). However, if our selected sample is too large, then those tests can only be utilized if we are assured that the variable is disseminated normally. The applications of tests that are based on the normality assumptions are restricted by the deficiency of accurate measurement. For example, a study measures Grade Point Average (GPA) in place of

percentage Marks. This measurement scale does not measure the exact distance between the marks of two students. GPA allows us only to rank the students from “good” to “poor” students. This measurement is called the ordinal scale. Statistical techniques such as Analysis of Variance, t-test etc. assume that the data are measured either on interval or ratio scale. In such situations where data is measured on nominal or ordinal scale nonparametric tests are more useful. Thus, nonparametric tests are used when either: Sample is not normally distributed

- Sample size is small
- The variables are measured on nominal or ordinal scale.

There is at least one nonparametric equivalent for each parametric general type of test. Broadly, these tests fall into the following categories: Test of differences between groups (independent samples

- Test of differences (dependent samples)
- Test of relationships between variables.
- The concepts and procedure to undertake Run Test, Chi-Square Test, Wilcoxon Signed Rank Test, Mann-Whitney Test and Kruskal- Wallis Test are discussed here under: Run Test: Run Test is used to examine the randomness of data. Many statistical procedures require data to be randomly selected.

Statistics is an Independent branch and its use is highly prevalent in all the fields of knowledge. Many methods and techniques are used in statistics. These have been grouped under parametric and non-parametric statistics. Statistical tests which are not based on a normal distribution of data or on any other assumption are also known as distribution-free tests and the data are generally ranked or grouped. Examples include the chi-square test and Spearman’s rank correlation coefficient. The first meaning of non-parametric covers techniques that do not rely on data belonging to any particular distribution. These include, among others:

1. Distribution free methods: This means that there are no assumptions that the data have been drawn from a normally distributed population. This consists of non-parametric statistical models, inference and statistical tests.
2. Non-parametric statistics: In this the statistics is based on the ranks of observations and do not depend on any distribution of the population.
3. No assumption of a structure of a model: In non-parametric statistics, the techniques do not assume that the structure of a model is fixed. In this, the individual variables are typically assumed to belong to parametric distributions, and assumptions about the types of connections among variables are also made. These techniques include, among others:
 - a) Non-parametric regression
 - b) Non-parametric hierarchical Bayesian models.

In non-parametric regression, the structure of the relationship is treated nonparametrically. In regard to the Bayesian models, these are based on the Dirichlet process, which allows the number of latent variables to grow as necessary to fit the data. In this the individual variables however follow parametric distributions and even the process controlling the rate of growth of latent variables follows a parametric distribution.

ASSUMPTIONS OF PARAMETRIC STATISTICS

Parametric tests like, 't and f' tests may be used for analysing the data which satisfy the following conditions :

- The population from which the sample have been drawn should be normally distributed. Normal Distributions refer to Frequency distribution following a normal curve, which is infinite at both the ends.
- The variables involved must have been measured interval or ratio scale. Variable and its types:
- characteristic that can have different values. Types of Variables Dependent Variable: Variable considered to be an effect; usually a measured variable. Independent Variable: Variable considered being a cause.
- The observation must be independent.
- The inclusion or exclusion of any case in the sample should not unduly affect the results of study.
- These populations must have the same variance or, in special cases, must have a known ratio of variance.
- This we call homosedasticity.
- The samples have equal or nearly equal variances.
- This condition is known as equality or homogeneity of variances and is particularly important to determine when the samples are small. The observations are independent.
- The selection of one case in the sample is not dependent upon the selection of any other case.

ASSUMPTIONS OF NON-PARAMETRIC STATISTICS

We face many situations where we can not meet the assumptions and conditions and thus cannot use parametric statistical procedures. In such situation we are bound to apply non-parametric statistics.

If our sample is in the form of nominal or ordinal scale and the distribution of sample is not normally distributed, and also the sample size is very small, it is always advisable to make use of the non-parametric tests for comparing samples and to make inferences or test the significance or trust worthiness of the computed statistics.

In other words, the use of non-parametric tests is recommended in the following situations: Where sample size is quite small. If the size of the sample is as small as $N=5$ or $N=6$, the only alternative is to make use of non-parametric tests.

When assumption like normality of the distribution of scores in the population are doubtful, we use non-parametric tests.

When the measurement of data is available either in the form of ordinal or nominal scales or when the data can be expressed in the form of ranks or in the shape of + signs or – signs and classification like “good-bad”, etc., we use non-parametric statistics.

ADVANTAGES OF NON-PARAMETRIC STATISTICS

If the sample size is very small, there may be no alternative except to use a nonparametric statistical test. Non-parametric tests typically make fewer assumptions about the data and may be relevant to a particular situation.

The hypothesis tested by the non-parametric test may be more appropriate for research investigation. Non-parametric statistical tests are available to analyse data which are inherently in

ranks as well as data whose seemingly numerical scores have the strength of ranks. For example, in studying a variable such as anxiety, we may be able to state that subject A is more anxious than subject B without knowing at all exactly how much more anxious A is. Thus if the data are inherently in ranks, or even if they can be categorised only as plus or minus (more or less, better or worse), they can be treated by non-parametric methods.

Non-parametric methods are available to treat data which are simply classificatory and categorical, i.e., are measured in nominal scale. Samples made up of observations from several different populations at times cannot be handled by Parametric tests.

Non-parametric statistical tests typically are much easier to learn and to apply than are parametric tests. In addition, their interpretation often is more direct than the interpretation of parametric tests.

DISADVANTAGES OF NON-PARAMETRIC STATISTICAL TESTS

If all the assumptions of a parametric statistical model are in fact met in the data and the research hypothesis could be tested with a parametric test, then non-parametric statistical tests are wasteful. The degree of wastefulness is expressed by the power-efficiency of the non-parametric test. It will be remembered that, if a non-parametric statistical test has power efficiency of say, 90 percent, this means that when all conditions of parametric statistical test are satisfied the appropriate parametric test would be just as effective with a sample which is 10 percent smaller than that used in non-parametric analysis. Another objection to non-parametric statistical test has to do with convenience. Tables necessary to implement non-parametric tests are scattered widely and appear in different formats (The same is true of many parametric tests too).

WILCOXON SIGNED RANK TEST

Wilcoxon signed-ranks test

a nonparametric statistical procedure used to determine whether a single sample is derived from a population in which the median equals a specified value. The data are values obtained using a ratio scale, each is subtracted from the hypothesized value of the population median, and the difference scores are then ranked. The test takes into account the direction of the differences and gives more weight to large differences than to small differences.

The Wilcoxon test, which can refer to either the Rank Sum test or the Signed Rank test version, is a nonparametric statistical test that compares two paired groups. The tests essentially calculate the difference between sets of pairs and analyzes these differences to establish if they are statistically significantly different from one another.

KEY TAKEAWAYS

- The Wilcoxon test is a nonparametric statistical test that compares two paired groups, and comes in two versions the Rank Sum test or the Signed Rank test.
- The goal of the test is to determine if two or more sets of pairs are different from one another in a statistically significant manner.
- Both versions of the model assume that the pairs in the data come from dependent populations, i.e. following the same person or share price through time or place.

The Basics of the Wilcoxon Test

The Rank Sum and Signed Rank tests were both proposed by American statistician Frank Wilcoxon

in a groundbreaking research paper published in 1945. The tests laid the foundation for hypothesis testing of nonparametric statistics, which are used for population data that can be ranked but do not have numerical values, such as customer satisfaction or music reviews. Nonparametric distributions do not have parameters and cannot be defined by an equation as parametric distributions can.

The types of questions that the Wilcoxon Test can help us answer include things like:

- Are test scores different from 5th grade to 5th grade for the same students?
- Does a particular drug have an effect on health when tested on the same individuals?

These models assume that the data comes from two matched, or dependent, populations, following the same person or stock through time or place. The data is also assumed to be continuous as opposed to discrete. Because it is a non-parametric test it does not require a particular probability distribution of the dependent variable in the analysis.

Versions of the Wilcoxon Test

- The Wilcoxon Rank Sum test can be used to test the null hypothesis that two populations have the same continuous distribution. The base assumptions necessary to employ this method of testing is that the data are from the same population and are paired, the data can be measured on at least an interval scale, and the data were chosen randomly and independently.
- The Wilcoxon Signed Rank test assumes that there is information in the magnitudes and signs of the differences between paired observations. As the nonparametric equivalent of the paired student's t-test, the Signed Rank can be used as an alternative to the t-test when the population data does not follow a normal distribution.

Calculating a Wilcoxon Test Statistic

The steps for arriving at a Wilcoxon Signed-Ranks Test Statistic, W , are as follows:

For each item in a sample of n items, obtain a difference score D_i between two measurements (i.e., subtract one from the other).

1. Neglect then positive or negative signs and obtain a set of n absolute differences $|D_i|$.
2. Omit difference scores of zero, giving you a set of n' non-zero absolute difference scores, where $n' \leq n$. Thus, n' becomes the actual sample size.
3. Then, assign ranks R_i from 1 to n to each of the $|D_i|$ such that the smallest absolute difference score gets rank 1 and the largest gets rank n . If two or more $|D_i|$ are equal, they are each assigned the average rank of the ranks they would have been assigned individually had ties in the data not occurred.
4. Now reassign the symbol “+” or “-” to each of the n ranks R_i , depending on whether D_i was originally positive or negative.
5. The Wilcoxon test statistic W is subsequently obtained as the sum of the positive ranks.

In practice, this test is easily performed using statistical analysis software or a spreadsheet. The **Wilcoxon signed rank test** (also called the Wilcoxon signed rank sum test) is a non-parametric test. When the word “non- parametric” is used in stats, it doesn’t quite mean that you know nothing about the population. It usually means that you know the population data does not have a normal distribution. The Wilcoxon signed rank test should be used if the differences between pairs of data are non-normally distributed.

Two slightly different versions of the test exist:

- The **Wilcoxon signed rank test** compares your sample median against a hypothetical median.
- The **Wilcoxon matched-pairs signed rank test** computes the difference between each set of matched pairs, then follows the same procedure as the signed rank test to compare the sample against some median.

The term “Wilcoxon” is often used for either test. This usually isn’t confusing, as it should be obvious if the data is matched, or not matched.

The null hypothesis for this test is that the medians of two samples are equal. It is generally used:

MANN-WHITNEY TEST

It is generally recognized that psychological studies often involve small samples. For example, researchers in clinical psychology often have to deal with small samples that generally include less than 15 participants (Kazdin 2003; Shapiro & Shapiro, 1983; Kraemer, 1981; Kazdin, 1986). Although the researchers aim at collecting large normally distributed samples, they rarely have the appropriate amount of resources (time and money) to recruit a sufficient number of participants. It is thus useful, particularly in psychology, to consider tests that have few constraints and allow experimenters to test their hypotheses on small and poorly distributed samples.

A lot of studies do not provide very good tests for their hypotheses because their samples have too few participants (for a review of the reviews, see Sedlmeier & Gigerenzer, 1989). Even though small samples can be methodologically questionable (e.g. generalization is difficult); they can be useful to infer conclusions on the population if the adequate statistical test is applied.

THE MANN-WHITNEY

Hypotheses of the Test The Mann-Whitney U test null hypothesis (H_0) stipulates that the two groups come from the same population. In other terms, it stipulates that the two independent groups are homogeneous and have the same distribution. The two variables corresponding to the two groups, represented by two continuous cumulative distributions, are then called stochastically equal.

In this case, the null hypothesis is rejected for values of the test statistic falling into either tail of its sampling distribution (see Figure 1 for a visual illustration). On the other hand, if a one-sided or one-tailed test is required, the alternative hypothesis suggests that the variable of one group is stochastically larger than the other group, according to the test direction (positive or negative). Here, the null hypothesis is rejected only for values of the test statistic falling into one specified tail of its sampling distribution (see Figure 1 for a visual illustration).

In more specific terms, let one imagine two independent groups that have to be compared. Each group contains a number n of observations. The Mann-Whitney test is based on the comparison of each observation from the first group with each observation from the second group. According to this, the data must be sorted in ascending order. The data from each group are then individually compared together. The highest number of possible paired comparisons is thus: $(n_x n_y)$, where n_x is the number of observations in the first group and n_y the number of observations in the second. If the two groups come from the same population, as stipulated by the null hypothesis, each datum of the first group will have an equal chance of being larger or smaller than each datum of the second group,

that is to say a probability p of one half ($1/2$). In technical terms, Assumptions of the Test In order to verify the hypotheses, the sample must meet certain conditions. These conditions can be easily respected. They are of three types:

- a) The two investigated groups must be randomly drawn from the target population.
- b) implies the absence of measurement and sampling errors (Robert et al., 1988). Note that an error of these last types can be involved but must remain small.
- c) Each measurement or observation must correspond to a different participant. In statistical terms, there is independence within groups and mutual independence between groups.
- d) The data measurement scale is of ordinal or continuous type. The observations values are then of ordinal, relative or absolute scale type.

COMPUTING THE MANN-WHITHNEY

U test using SPSS First of all, one needs to enter the data in SPSS, not forgetting the golden rule which stipulates that each participant's observation must occupy a line. The numbers of the groups are generally 1 and 2, except whenever it is more practical to use other numbers. Following the entry of the data, open a new syntax window and enter the following syntax.

DISCUSSION

Like any statistical test, the Mann-Whitney U has forces and weaknesses. In terms of forces, like any non-parametric test, the Mann-Whitney U does not depend on assumptions on the distribution (i.e. one does not need to postulate the data distribution of the target population).

One can also use it when the conditions of normality neither are met nor realisable by transformations. Moreover, one can use it when his sample is small and the data are semi-quantitative or at least ordinal. In short, few constraints apply to this test.

The Mann-Whitney U test is also one of the most powerful non-parametric tests (Landers, 1981), where the statistical power corresponds to the probability of rejecting a false null hypothesis. This test has thus good probabilities of providing statistically significant results when the alternative hypothesis applies to the measured reality.

Even if it is used on average-size samples (between 10 and 20 observations) or with data that satisfy the constraints of the t-test, the Mann-Whitney has approximately 95% of the Student's t-test statistical power (Landers). By comparison with the t-test, the Mann-Whitney U is less at risk to give a wrongfully significant result when there is presence of one or two extreme values in the sample under investigation (Siegel and Castellan, 1988).

the distributions of these populations do not meet the criteria of normality (Zimmerman, 1985). On the other hand, very little statistical power is lost if the Mann-Whitney U test is used instead of the t-test and this, under statistically controlled conditions (Gibbons and Chakraborti, 1991). In addition, the Mann-Whitney U test is, in exceptional circumstances, more powerful than the t-test. Indeed, it is more powerful in the detection of a difference on the extent of the possible differences between populations' averages than the t-test when a small manpower is associated with a small variance (Zimmerman, 1987). On the other hand, when the sample size is similar or when the smallest manpower has the greatest variance, the t-test is more powerful on all the extent of the possible

differences (Zimmerman). Lastly, the Monte Carlo methods showed that the Mann-Whitney U test can give wrongfully significant results, that is to say the erroneous acceptance of the alternative hypothesis (Robert & Casella, 2004). This type of results is at risk to be obtained whenever one's samples are drawn from two populations with a same average but with different variances.

In this type of situations, it is largely more reliable to use the t-test which gives a possibility for the samples to come from distributions with different variances. The alpha (α) error or of type I is to reject H_0 whereas this one is true. This error is thus amplified when Mann-Whitney U is applied in a situation of heteroscedasticity or distinct variances. In addition, some solutions exist to this major problem (see Kasuya, 2001).

KRUSKAL WALLIS ANOVA TEST IN PSYCHOLOGY

The Kruskal-Wallis test is a nonparametric (distribution free) test, and is used when the assumptions of one-way ANOVA are not met. Both the Kruskal-Wallis test and one-way ANOVA assess for significant differences on a continuous dependent variable by a categorical independent variable (with two or more groups). In the ANOVA, we assume that the dependent variable is normally distributed and there is approximately equal variance on the scores across groups. However, when using the Kruskal-Wallis Test, we do not have to make any of these assumptions. Therefore, the Kruskal-Wallis test can be used for both continuous and ordinal-level dependent variables. However, like most non-parametric tests, the Kruskal-Wallis Test is not as powerful as the ANOVA.

Null hypothesis: Null hypothesis assumes that the samples (groups) are from identical populations.

Alternative hypothesis: Alternative hypothesis assumes that at least one of the samples (groups) comes from a different population than the others.

EXAMPLE QUESTIONS ANSWERED:

How do test scores differ between the different grade levels in elementary school? Do job satisfaction scores differ by race?

The distribution of the Kruskal-Wallis test statistic approximates a chi-square distribution, with $k-1$ degrees of freedom, if the number of observations in each group is 5 or more. If the calculated value of the Kruskal-Wallis test is less than the critical chi-square value, then the null hypothesis cannot be rejected. If the calculated value of Kruskal-Wallis test is greater than the critical chi-square value, then we can reject the null hypothesis and say that at least one of the samples comes from a different population.

The Kruskal Wallis test is the non parametric alternative to the One Way ANOVA. Non parametric means that the test doesn't assume your data comes from a particular distribution. The H test is used when the assumptions for ANOVA aren't met (like the assumption of normality). It is sometimes called the one-way ANOVA on ranks, as the ranks of the data values are used in the test rather than the actual data points.

The test determines whether the medians of two or more groups are different. Like most statistical tests, you calculate a test statistic and compare it to a distribution cut-off point. The test statistic used in this test is called the **H statistic**. The hypotheses for the test are:

- H_0 : population medians are equal.
- H_1 : population medians are not equal.

The Kruskal Wallis test will tell you if there is a significant difference between groups. However, it won't tell you which groups are different. For that, you'll need to run a Post Hoc test.

Examples

1. You want to find out how test anxiety affects actual test scores. The independent variable "test anxiety" has three levels: no anxiety, low-medium anxiety and high anxiety. The dependent variable is the exam score, rated from 0 to 100%.
2. You want to find out how socioeconomic status affects attitude towards sales tax increases. Your independent variable is "socioeconomic status" with three levels: working class, middle class and wealthy. The dependent variable is measured on a 5-point Likert scale from strongly agree to strongly disagree.

KRUSKAL-WALLIS H TEST

The Kruskal-Wallis test is considered a nonparametric analogue to the parametric one-way ANOVA presented in Chapter 10. Just as the one-way ANOVA is an extension of the two independent groups t-test, the Kruskal-Wallis test is an extension of the Mann-Whitney U test.

The Kruskal-Wallis test handles k-independent groups of samples. Like the Mann-Whitney U test, this test uses ranks. The null and alternative hypotheses are stated verbally. For example:

ho: The diet plans A, B and C are equally effective. h1: At least one of the following is true: A is different from B, A is different from C or B is different from C.

The test statistic for the Kruskal-Wallis H test is obtained through the following steps:

- Rank all the data disregarding group membership, where a rank of "1" is given to the highest score. For observations that are tied (having the same value), compute the average rank and assign this average to each of the tied observations.
- Add up the ranks for each group, designated as $r(i)$, where i is the group number..

FRIEDMAN]. POWER ANALYSIS. EFFECT SIZE IN PSYCHOLOGY

The reporting of accurate and appropriate conclusions is an essential aspect of scientific research, and failure in this endeavor can threaten the progress of cumulative knowledge. This is highlighted by the current reproducibility crisis, and this crisis disproportionately affects fields that use behavioral research methods, as in much lighting research. A sample of general and topic-specific lighting research papers was reviewed for information about sample sizes and statistical reporting. This highlighted that lighting research is generally underpowered and, given median sample sizes, is unlikely to be able to reveal small effects. Lighting research most commonly uses parametric statistical tests, but assessment of test assumptions is rarely carried out.

This risks the inappropriate use of statistical tests, potentially leading to type I and type II errors. Lighting research papers also rarely report measures of effect size, and this can hamper cumulative science and power analyses required to determine appropriate sample sizes for future research studies. Addressing the issues raised in this article related to sample sizes, statistical test assumptions, and reporting of effect sizes can improve the evidential value of lighting research.

At the heart of publication bias and the reproducibility crisis is the occurrence of type I errors (false-positive findings) and type II errors (false-negative findings). We use statistical methods in science in an attempt to avoid making claims that in reality may be a type I or type II error. Null hypothesis statistical testing (Hubbard and Ryan 2000) produces a P-value that represents the probability of

obtaining the result (or something more extreme) assuming that there was no real effect or difference between the groups or measures being tested (the “null” hypothesis).

The P-value does not explicitly refer to the probability of the null hypothesis being true, but it does provide a “measure of the strength of evidence against H_0 (the null hypothesis)” (Dorey 2010, p. 2297). Abelson (1995) referred to “discrediting the null hypothesis” (p. 10) based on the P-value from a statistical test. A smaller P-value provides stronger evidence against the null hypothesis.

By convention, in the field of lighting research and most other scientific disciplines, we use a threshold of $P < 0.05$ to indicate a significant or “real” effect, based on proposals by Fisher (1925). However, Fisher himself recognized that this threshold was arbitrary and debate is ongoing about its use. The reproducibility crisis has led some researchers to suggest that a stricter threshold of 0.005 should be used (Benjamin et al. 2017), to reduce the number of type I errors reported in the scientific literature.

ASSESSMENT OF NORMALITY

Confirming whether the data collected within a study sufficiently meets the assumption of a normal distribution should be seen as an informed judgment based on a series of diagnostic checks, rather than a definitive black and white decision. Note also that in regression analyses, it is the residuals (errors between the predicted and actual values) that are required to be normally distributed, not the actual variable values themselves. Normality of residuals may also be adequate for between-subjects ANOVAs and independent t-tests (Williams et al. 2013).

Three types of checks should be carried out to perform a comprehensive assessment of normality: (1) visual inspection of graphical representations of the data; (2) assessment of descriptive statistics; and (3) statistical tests of deviation from a normal distribution. These methods are illustrated using two sets of simulated data, representing normal and nonnormal distributions. The normally distributed data have been generated using the “rnorm” function within the R software package (Version 3.4.0, R Core Team 2017), with the parameters of sample size = 100, mean = 5, standard deviation = 1.5. The nonnormal data are based on a positively skewed exGaussian distribution. This type of distribution is frequently found in reaction time data (Palmer et al. 2011), and reaction times are commonly used as a response measure in lighting research (e.g., Cengiz et al. 2015; Fotios et al. 2017; He et al. 1997).

REPORTING OF EFFECT SIZES

When conducting research, we are generally interested in discovering whether our variables of interest have some effect on what we are studying. This effect may relate to a difference between groups; for example, hazard detection rates under different lighting conditions. Alternatively, it may relate to associations between variables; for example, whether outdoor illuminance levels are associated with perceived safety. If applied appropriately (see Section 3), null hypothesis statistical testing and the P-value produced can provide evidence toward an effect being present (or at least that no effect, the null hypothesis, is implausible). As well as knowing whether an effect may be present, we are also interested in how big this effect is—do our variables have a big influence on what we are measuring or only a trivial influence? A range of methods is available to calculate the size of an effect, some of which are listed in Table 4. Measures of effect size often produce a standardized value that allows comparison between studies using different metrics and a consistent

“language” of effect magnitudes. Further information about effect sizes and their calculation is available elsewhere (e.g., Cohen 1988, 1992; Lakens 2013; Sullivan and Feinn 2012).

The size of any effect revealed within a study is a valuable piece of information when results are reported, for three reasons (Lakens 2013). First it provides information about the magnitude of the effect found, allowing its practical importance to be considered. This information cannot be adequately gleaned from only a P-value (Durlak 2009). Second, it can be incorporated into meta-analyses that combine the findings from multiple studies to provide holistic evidence and more definitive conclusions about a research question or area. Third, it can be used in the design of future related research to estimate required samples sizes, through a priori power analyses, as discussed above. However, despite the evidential and scientific value of reporting effect sizes, this is rarely done in lighting research. The review of recent lighting research papers and papers related to spatial brightness (Section 2) showed that only 24% of the 50 studies included in the review reported effect sizes of some kind, with the majority of effect size measures being R^2 values from a linear regression.

SAMPLE SIZE AND POWER

As discussed in previous sections, key goals of any research study are to discover whether an effect exists (which requires appropriate application of statistical tests; see Section 3) and the magnitude of any effect (which requires the calculation and reporting of a measure of effect size; see Section 4).

The sample size used has implications for both of these objectives. Sample size is an essential determinant of the size of the effect that study will be able to reveal. It also contributes to determining the power of the study—the probability that a significant effect will be revealed through statistical testing when a true effect does really exist (i.e., the probability of avoiding a type II error). Increasing the sample size increases the power of a study, thus making it more able to detect an effect of a smaller size, reducing the likelihood that the null hypothesis will be incorrectly accepted.

CONCLUSIONS

Publication bias and the reproducibility crisis are issues that pose a significant risk to the evidential value of research within a number of fields but particularly within lighting research. At the heart of these issues lies the risk of making type I or type II errors. The statistical methods employed in research are designed to reduce these errors, and their role in determining the presence and importance of any effect is critical to the veracity of published research. This article reviewed a sample of general and topic-specific lighting research papers. The review highlighted the relatively small samples used in behavioral lighting research and the lack of power this introduces. The sample sizes used in most lighting studies may only be capable of revealing medium to large effects.

It is important to consider whether an effect of a certain size is of practical significance. Depending on the specific research area and question being investigated, a small effect size may be insufficiently interesting or noteworthy to warrant investigation, and researchers may only be interested in discovering effects equal to or greater than a certain magnitude. With limited research funding and resources available, the size of an effect that is worth detecting is an important consideration when determining the sample size of a study. Whatever size of effect is judged to be sufficiently large to be of interest, it remains important to justify the sample size used. However, the justification of sample sizes, based on anticipated or targeted effect sizes, was virtually nonexistent

within the papers reviewed here.

One possible reason for this absence of sample size justification is that the practice of reporting effect sizes in lighting research papers is not commonplace and therefore it may be difficult to estimate anticipated effect sizes with any confidence. Only 24% of reviewed papers reported any kind of effect size measure. The American Psychological Association Task Force on Statistical Inference (Wilkinson 1999) states that: "... reporting and interpreting effect sizes in the context of previously reported effects is essential to good research" (p. 599). Increased reporting of effect sizes should be encouraged within lighting research, as should detailed, accurate, and appropriate statistical analysis and reporting. This can help reduce the promotion of unsupported findings within lighting research literature.

CORRELATIONAL ANALYSIS: CORRELATION [PRODUCT MOMENT]

Are stock prices related to the price of gold? Is unemployment related to inflation? Is the amount of money spent on research and development related to a company's net worth? Correlation can answer these questions, and there is no statistical technique more useful or more abused than correlation. Correlation is a statistical method that determines the degree of relationship between two different variables. It is also known as a "bivariate" statistic, with bi- meaning two and variate indicating variable or variance.

The two variables are usually a pair of scores for a person or object. The relationship between any two variables can vary from strong to weak or none. When a relationship is strong, this means that knowing a person's or object's score on one variable helps to predict their score on the second variable.

In other words, if a person has a high score of variable A (compared to all the other peoples' scores on A, then they are likely to have a high score on variable B (compared to the other peoples' scores on B). The latter would be considered a strong positive correlation.

A correlation coefficient that is close to $r = 0.00$ (note that the typical correlation coefficient is reported to two decimal places) means knowing a person's score on one variable tells you nothing about their score on the other variable. For example, there might be a zero correlation between the number of letters in a person's last name and the number of miles they drive per day. If you know the number of letters in a last name, it tells you nothing about how many miles they drive per day. There is no relationship between the two variables; therefore, there is a zero correlation. It is also important to note that there are no hard rules about labeling the size of a correlation coefficient. Statisticians generally do not get excited about a correlation until it is greater than $r = 0.30$ or less than $r = -0.30$.

The correlational statistical technique usually accompanies correlational designs. In a correlational design, the experimenter typically has little or no control over the variables to be studied. The variables may be statistically analyzed long after they were initially produced or measured. Such data is called archival. The experimenter no longer has any experimental power to control the gathering of the data.

The data has already been gathered, and the experimenter now has only statistical power in his or her control. Cronbach (1967), an American statistician, stated well the difference between the

experimental and correlational techniques, "... the experimentalist [is] an expert puppeteer, able to keep untangled the strands to half- a-dozen independent variables. The correlational psychologist is a mere observer of a play where Nature pulls a thousand strings."

CORRELATION: USE AND ABUSE

The crux of the nature and the problem with correlation is that, just because two variables are correlated, it does not mean that one variable caused the other. We mentioned earlier of a governor who wanted to supply every parent of a newborn child in his state with a classical CD or tape in order to boost the child's IQ.

The governor supported his decision by citing studies, which have shown a positive relationship between listening to classical music and intelligence. In fact, the controversy has grown to the point where it is referred to as the Mozart Effect. The governor is making at least two false assumptions. First, he is assuming a causal relationship between classical music and intelligence, that is, classical music causes intelligence to rise. However, the technique of correlation does not allow the implication of causation.

A WARNING:

Correlation Does Not Imply Causation A major caution must be reiterated. Correlation does not imply causation. Because there is a strong positive or strong negative correlation between two variables, this does not mean that one variable is caused by the other variable. As noted previously, many statisticians claim that a strong correlation never implies a cause-effect relationship between two variables.

Yet, there are daily published abuses of the correlational design and statistical technique, not only in newspapers but major scientific journals! A sampling of these misinterpretations follows:

1. Marijuana use and heroin use are positively correlated. Some drug opponents note that heroin use is frequently correlated with marijuana use. Therefore, they reason that stopping marijuana use will stop the use of heroin. Clear-thinking statisticians note that even
 2. a higher correlation is obtained between the drinking of milk in childhood and later adult heroin use. Thus, it is just as absurd to think that if early milk use is banned, subsequent heroin use will be curbed, as it is to suppose that banning marijuana will stop heroin abuse.
 3. Milk use is positively correlated to cancer rates. While this is not a popular finding within the milk industry, there is a moderately positive correlation with drinking milk and getting cancer (Paulos, 1990). Could drinking milk cause cancer? Probably not. However, milk consumption is greater in wealthier countries. In wealthier countries people live longer. Greater longevity means people live long enough to eventually get some type of cancer. Thus, milk and cancer are correlated but drinking milk does not cause cancer (nor does getting cancer cause one to drink more milk).
 4. Weekly church attendance is negatively correlated with drug abuse. A recent study demonstrated that adolescents who attended church weekly were much less likely to abuse illegal drugs or alcohol. Does weekly church attendance cause a decrease in drug abuse? If the Federal Government passed a law for mandatory church attendance, would there be a decrease in drug abuse? Probably not, and there might even be an increase in drug abuse. This study is another example of the abuse of the interpretation of the correlational design and statistical analysis.
4. Lead Levels are positively correlated to antisocial behavior.

A 1996 correlational study (Needleman et al.) examined the relationship of lead levels in the bones of 301 children and found that higher levels of lead were associated with higher rates of antisocial

behavior. "This is the first rigorous study to demonstrate a significant association between lead and antisocial behavior," said one environmental health professor about the study. While the studies authors may have been very excited, the study is still correlational in design and analysis, thus, implications of causation should have been avoided. Perhaps antisocial children have a unique metabolic chemistry such that their bodies do not metabolize lead like normal children. Perhaps lead is not a cause of antisocial behavior but the result of being antisocial.

Therefore, the reduction of lead exposure in early childhood may not reduce antisocial behavior at all. Also, note that there was a statistically "significant" relationship. As you will learn later in this chapter, with large samples (like 301 children in this study) even very weak relationships can be statistically significant with correlational techniques.

Correlation is a statistical technique that can show whether and how strongly pairs of variables are related. For example, height and weight are related; taller people tend to be heavier than shorter people.

The relationship isn't perfect. People of the same height vary in weight, and you can easily think of two people you know where the shorter one is heavier than the taller one. Nonetheless, the average weight of people 5'5" is less than the average weight of people 5'6", and their average weight is less than that of people 5'7", etc. Correlation can tell you just how much of the variation in peoples' weights is related to their heights.

Although this correlation is fairly obvious your data may contain unsuspected correlations. You may also suspect there are correlations, but don't know which are the strongest. An intelligent correlation analysis can lead to a greater understanding of your data.

TECHNIQUES IN DETERMINING CORRELATION

There are several different correlation techniques. The Survey System's optional **Statistics Module** includes the most common type, called the Pearson or product-moment correlation. The module also includes a variation on this type called partial correlation. The latter is useful when you want to look at the relationship between two variables while removing the effect of one or two other variables.

Like all statistical techniques, correlation is only appropriate for certain kinds of data. **Correlation works for quantifiable data** in which numbers are meaningful, usually quantities of some sort. It cannot be used for purely categorical data, such as gender, brands purchased, or favorite color.

RATING SCALES

Rating scales are a controversial middle case. The numbers in rating scales have meaning, but that meaning isn't very precise. They are not like quantities. With a quantity (such as dollars), the difference between 1 and 2 is exactly the same as between 2 and 3. With a rating scale, that isn't really the case. You can be sure that your respondents think a rating of 2 is between a rating of 1 and a rating of 3, but you cannot be sure they think it is exactly halfway between. This is especially true if you labeled the mid-points of your scale (you cannot assume "good" is exactly half way between "excellent" and "fair").

Most statisticians say you cannot use correlations with rating scales, because the mathematics of the technique assume the differences between numbers are exactly equal. Nevertheless, many

survey researchers do use correlations with rating scales, because the results usually reflect the real world. Our own position is that you can use correlations with rating scales, but you should do so with care. When working with quantities, correlations provide precise measurements. When working with rating scales, correlations provide general indications.

CORRELATION COEFFICIENT

The main result of a correlation is called the **correlation coefficient** (or "r"). It ranges from -1.0 to +1.0. The closer r is to +1 or -1, the more closely the two variables are related.

If r is close to 0, it means there is no relationship between the variables. If r is positive, it means that as one variable gets larger the other gets larger. If r is negative it means that as one gets larger, the other gets smaller (often called an "inverse" correlation).

While correlation coefficients are normally reported as $r =$ (a value between -1 and +1), squaring them makes them easier to understand. The square of the coefficient (or r square) is equal to the percent of the variation in one variable that is related to the variation in the other. After squaring r, ignore the decimal point. An r of .5 means 25% of the variation is related (.5 squared = .25). An r value of .7 means 49% of the variance is related (.7 squared = .49).

A correlation report can also show a second result of each test - statistical significance. In this case, the significance level will tell you how likely it is that the correlations reported may be due to chance in the form of random sampling error. If you are working with small sample sizes, choose a report format that includes the significance level. This format also reports the sample size.

A key thing to remember when working with correlations is never to assume a correlation means that a change in one variable causes a change in another. Sales of personal computers and athletic shoes have both risen strongly over the years and there is a high correlation between them, but you cannot assume that buying computers causes people to buy athletic shoes (or vice versa).

The second caveat is that the Pearson correlation technique works best with linear relationships: as one variable gets larger, the other gets larger (or smaller) in direct proportion. It does not work well with curvilinear relationships (in which the relationship does not follow a straight line). An example of a **curvilinear relationship** is age and health care. They are related, but the relationship doesn't follow a straight line. Young children and older people both tend to use much more health care than teenagers or young adults. Multiple regression (also included in the **Statistics Module**) can be used to examine curvilinear relationships, but it is beyond the scope of this article.

CORRELATIONAL ANALYSIS: CORRELATION [PRODUCT MOMENT OF PSYCHOLOGY]

An outlier (in correlation analysis) is a data point that does not fit the general trend of your data, but would appear to be a wayward (extreme) value and not what you would expect compared to the rest of your data points. You can detect outliers in a similar way to how you detect a linear relationship, by simply plotting the two variables against each other on a graph and visually inspecting the graph for wayward (extreme) points. You can then either remove or manipulate that particular point as long as you can justify why you did so (there are far more robust methods for detecting outliers in regression analysis). Alternatively, if you cannot justify removing the data point(s), you can run a nonparametric test such as Spearman's rank-order correlation or Kendall's Tau Correlation instead, which are much less sensitive to outliers. This might be your best approach if you cannot justify

removing the outlier. The diagram below indicates what a potential outlier might look like: Outliers can have a very large effect on the line of best fit and the Pearson correlation coefficient, which can lead to very different conclusions regarding your data. This point is most easily illustrated by studying scatterplots of a linear relationship with an outlier included and after its removal, with respect to both the line of best fit and the correlation coefficient. This is illustrated in the diagram below:

The present hypothesis can be stated more specifically as - "The scores of School Environment (SE) test & the scores of Reading Comprehension (RC) test of the students will show the positive correlation" On the basis of researches done on the effect of SE & RC in English, it has been evident that better the schools and their academic climate with better facilities, the better the scholastic achievement in the students.

The related findings have already been shown in the previous chapter. On the basis of these research evidences, the present directional hypothesis has been framed. With the view to putting this hypothesis to test, Pearson's Product Moment correlation (r) between the scores of SE & the scores of RC in English of the students have been computed.

RESULTS OF DIFFERENTIAL STUDIES

The hypotheses hereafter are pertaining to see the differences of the means of the variables and the interactional effects on the dependent variables of the varied independent variables. Before analysing and testing these hypotheses it was desirable to see the variability of the values found for the dependent variable from the sample taken. To apply ANOVA for the (2x2x2) factorial design the data were tested for homogeneity of the variance by employing Kolmogorov-Smirnov Test of Goodness of Fit for the homogeneity of variance.

As per the above table the value of 'D' is less than 0.438 which shows the significance limit at .05 level. This clearly shows that the value of 'D' does not show significance which indicate that there existed homogeneity of variance ensuring the application of ANOVA and other differential hypotheses.

READING COMPREHENSION IN ENGLISH IN

* n in . HYPOTESIS: DH 6 There is no significant difference in Reading Comprehension in English in Boys & Girls." Stated in other words - "No significant difference exists in the scores of Reading comprehension in English in boys and girls." With the view to test the tenability of the hypothesis, the scores of boys & girls separately in Reading Comprehension in English are analysed on the basis of the 'means' and 't-values.'

On the strength of the above results, we reject our hypothesis OH* and conclude that there exists a significance difference in Reading Comprehension in English in favour of girls.

"Relatively, School Environment would show the maximum main effect and Anxiety would show the minimum main effect on Reading Comprehension in English whereas Socio-Economic Status would fall in between these two main effects."

INTERPRETATION AND DISCUSSION

Results obtained in the present chapter shows the significant association of the independent variables viz., Anxiety, Socio- Economic Status and School Environment with the Reading

Comprehension in English of the students of class XI, taken as a dependent variable in the study. From the three independent variables, taken under the present study, the two variables SES & SE belong to the social variables whereas the Anxiety comes under the psychological variables. Thus, the independent variables cover the socio-psychological variables. The association of all these independent variables on the dependent variable noticed different variations in the findings which needs different and separate interpretations.

INFLUENCE OF PSYCHOLOGICAL VARIABLE ON READING COMPREHENSION IN ENGLISH

Influence of Anxiety on Reading Comprehension in English The results obtained on IH7 indicate that the Anxiety emerged as the potent source variable interacting with Reading Comprehension in English among the students of class XI. The Anxiety indicates a negative correlation with Reading Comprehension in English (CHi) though the correlation is not significant. These facts could be discussed on the strength of the association of the socio- psychological activities with the members and resources of the schools.

RANK-ORDER CORRELATION USING

The Spearman rank-order correlation coefficient (Spearman's correlation, for short) is a nonparametric measure of the strength and direction of association that exists between two variables measured on at least an ordinal scale. It is denoted by the symbol r_s (or the Greek letter ρ , pronounced rho). The test is used for either ordinal variables or for continuous data that has failed the assumptions necessary for conducting the Pearson's product- moment correlation. For example, you could use a Spearman's correlation to understand whether there is an association between exam performance and time spent revising; whether there is an association between depression and length of unemployment; and so forth. If you would like some more background information about this test, which does not include instructions for SPSS Statistics, see our more general statistical guide: Spearman's rank-order correlation. Possible alternative tests to Spearman's correlation are Kendall's tau-b or Goodman and Kruskal's gamma.

This "quick start" guide shows you how to carry out a Spearman's correlation using SPSS Statistics. We show you the main procedure to carry out a Spearman's correlation in the Procedure section. First, we introduce you to the assumptions that you must consider when carrying out a Spearman's correlation.

ASSUMPTIONS

When you choose to analyse your data using Spearman's correlation, part of the process involves checking to make sure that the data you want to analyse can actually be analysed using a Spearman's correlation. You need to do this because it is only appropriate to use a Spearman's correlation if your data "passes" three assumptions that are required for Spearman's correlation to give you a valid result. In practice, checking for these three assumptions just adds a little bit more time to your analysis, requiring you to click of few more buttons in SPSS Statistics when performing your analysis, as well as think a little bit more about your data, but it is not a difficult task. These three assumptions are:

1. **Assumption #1:** Your two variables should be measured on an **ordinal, interval** or **ratio scale**.
Examples of **ordinal**
2. **variables** include Likert scales (e.g., a 7-point scale from "strongly agree" through to "strongly

disagree"), amongst other ways of ranking categories (e.g., a 3-point scale explaining how much a customer liked a product, ranging from "Not very much", to "It is OK", to "Yes, a lot"). Examples of **interval/ratio variables** include revision time (measured in hours), intelligence (measured using IQ score), exam performance (measured from 0 to 100), weight (measured in kg), and so forth. You can learn more about ordinal, interval and ratio variables in our article: Types of Variable.

3. **Assumption #2:** Your two variables represent **paired observations**. For example, imagine that you were interested in the relationship between daily cigarette consumption and amount of exercise performed each week. A single paired observation reflects the score on each variable for a single participant (e.g., the daily cigarette consumption of "Participant 1" and the amount of exercise performed each week by "Participant 1"). With 30 participants in the study, this means that there would be 30 paired observations.
4. **Assumption #3:** There is a **monotonic relationship** between the two variables. A monotonic relationship exists when either the variables increase in value together, or as one variable value increases, the other variable value decreases. Whilst there are a number of ways to check whether a monotonic relationship exists between your two variables, we suggest creating a scatterplot using SPSS Statistics, where you can plot one variable against the other, and then visually inspect the scatterplot to check for monotonicity. Your scatterplot may look something like one of the following:

Example

A teacher is interested in whether those who do better at English also do better in maths. To test whether this is the case, the teacher records the scores of her 10 students in their end-of-year examinations for both English and maths. Therefore, one variable records the English scores and the second variable records the maths scores for the 10 pupils.

PARTIAL CORRELATION PSYCHOLOGY

Partial correlation is the measure of association between two variables, while controlling or adjusting the effect of one or more additional variables. Partial correlations can be used in many cases that assess for relationship, like whether or not the sale value of a particular commodity is related to the expenditure on advertising when the effect of price is controlled.

ASSUMPTIONS

Useful in only small models like the models which involve three or four variables. Used in only those models which assume a linear relationship. The data is supposed to be interval in nature.

The residual variables or unmeasured variables are not correlated with any of the variables in the model, except for the one for which these residuals have occurred.

Partial correlation **measures the strength of a relationship between two variables, while controlling for the effect of one or more other variables**. For example, you might want to see if there is a correlation between amount of food eaten and blood pressure, while controlling for weight or amount of exercise. It's possible to control for multiple variables (called control variables or covariates). However, more than one or two is usually not recommended because the more control variables, the less reliable your test.

SEMI-PARTIAL CORRELATION

Semi-partial correlation is almost the same as partial. In fact, many authors use the two terms to mean the same thing. However, others do make the following subtle distinction:

With semi-partial correlation, **the third variable holds constant for either X or Y but not both**; with partial, the third variable holds constant for both X and Y.

For example, the semi partial correlation statistic can tell us the particular part of variance, that a particular independent variable explains. It explains how one specific independent variable affects the dependent variable, while other variables are controlled for to prevent them getting in the way. To find it, calculate the correlation between the dependent variable and the residual of the prediction of one independent variable by the others.

Example

Suppose we use a set of data (from a 2002 paper from Abdi et al.) which lists three variables over six children. Each child was tested for memory span (Y) and speech rate (X_2), and their age was also noted. A correlation statistic was desired which predicts Y (memory span) from X_1 and X_2 (age and speech rate).

Normally, in a situation where X_1 and X_2 were independent random variables, we'd find out how important each variable was by computing a squared coefficient of correlation between X_1 and X_2 and the dependent variable Y. We would know that these squared coefficients of correlation were equal to the square multiple coefficient of correlation. But in a case like ours, X_1 and X_2 are anything but independent. Speech rate is highly dependent on age, and so using the squared coefficient will count the contributions of each variable several times over.

MULTIPLE CORRELATION PSYCHOLOGY

In statistics, regression analysis is a method for explanation of phenomena and prediction of future events. In the regression analysis, a coefficient of correlation r between random variables X and Y is a quantitative index of association between these two variables. In its squared form, as a coefficient of determination r^2 , indicates the amount of variance in the criterion variable Y that is accounted for by the variation in the predictor variable X. In the multiple regression analysis, the set of predictor variables X_1, X_2, \dots is used to explain variability of the criterion variable Y. A multivariate counterpart of the coefficient of determination r^2 is the coefficient of multiple determination, R^2 . The square root of the coefficient of multiple determination is the coefficient of **multiple correlation**.

CONCEPTUALIZATION OF MULTIPLE CORRELATION

An intuitive approach to the multiple regression analysis is to sum the squared correlations between the predictor variables and the criterion variable to obtain an index of the over-all relationship between the predictor variables and the criterion variable. However, such a sum is often greater than one, suggesting that simple summation of the squared coefficients of correlations is not a correct procedure to employ. In fact, a simple summation of squared coefficients of correlations between the predictor variables and the criterion variable is the correct procedure, but only in the special case when the predictor variables are not correlated. If the predictors are related, their inter-correlations must be removed so that only the unique contributions of each predictor toward explanation of the criterion are included.

FUNDAMENTAL EQUATION OF MULTIPLE REGRESSION ANALYSIS

Initially, a matrix of correlations R is computed for all variables involved in the analysis. This matrix can be conceptualized as a supermatrix, consisting of the vector of cross-correlations between the predictor variables and the criterion variable c , its transpose c' and the matrix of intercorrelations between predictor variables R_{xx} . The fundamental equation of the multiple regression analysis is $R^2 = c' R_{xx}^{-1} c$.

The expression on the left side signifies the coefficient of multiple determination (squared coefficient of multiple correlation). The expressions on the right side are the transposed vector of cross-correlations c' , the matrix of inter-correlations R_{xx} to be inverted (cf., matrix inversion), and the vector of cross-correlations, c . The premultiplication of the vector of cross-correlations by its transpose changes the coefficients of correlation into coefficients of determination. The inverted matrix of the inter-correlations removes the redundant variance from the of inter-correlations of the predictor set of variables. These not-redundant cross-correlations are summed to obtain the multiple coefficient of determination R^2 . The square root of this coefficient is the coefficient of multiple correlation R .

Correlation means association - more precisely it is a measure of the extent to which two variables are related. There are three possible results of a correlational study: a positive correlation, a negative correlation, and no correlation.

A **positive correlation** is a relationship between two variables in which both variables move in the same direction. Therefore, when one variable increases as the other variable increases, or one variable decreases while the other decreases. An example of positive correlation would be height and weight. Taller people tend to be heavier.

A **negative correlation** is a relationship between two variables in which an increase in one variable is associated with a decrease in the other. An example of negative correlation would be height above sea level and temperature. As you climb the mountain (increase in height) it gets colder (decrease in temperature).

A **zero correlation** exists when there is no relationship between two variables. For example there is no relationship between the amount of tea drunk and level of intelligence. Scattergrams
A correlation can be expressed visually. This is done by drawing a scattergram (also known as a scatterplot, scatter graph, scatter chart, or scatter diagram).

A scattergram is a graphical display that shows the relationships or associations between two numerical variables (or co-variables), which are represented as points (or dots) for each pair of score.

A scattergraph indicates the strength and direction of the correlation between the co-variables. When you draw a scattergram it doesn't matter which variable goes on the x-axis and which goes on the y-axis.

Remember, in correlations we are always dealing with paired scores, so the values of the 2 variables taken together will be used to make the diagram. Decide which variable goes on each axis and then simply put a cross at the point where the 2 values coincide.

Some uses of Correlations

PREDICTION

- If there is a relationship between two variables, we can make predictions about one from another.

VALIDITY

- Concurrent validity (correlation between a new measure and an established measure).

RELIABILITY

- Test-retest reliability (are measures consistent).
- Inter-rater reliability (are observers consistent).

THEORY VERIFICATION

- Predictive validity.

CORRELATION COEFFICIENTS: DETERMINING CORRELATION STRENGTH

Instead of drawing a scattergram a correlation can be expressed numerically as a coefficient, ranging from -1 to +1. When working with continuous variables, the correlation coefficient to use is Pearson's r .

The correlation coefficient (r) indicates the extent to which the pairs of numbers for these two variables lie on a straight line. Values over zero indicate a positive correlation, while values under zero indicate a negative correlation.

A correlation of -1 indicates a perfect negative correlation, meaning that as one variable goes up, the other goes down. A correlation of $+1$ indicates a perfect positive correlation, meaning that as one variable goes up, the other goes up.

There is no rule for determining what size of correlation is considered strong, moderate or weak. The interpretation of the coefficient depends on the topic of study.

When studying things that are difficult to measure, we should expect the correlation coefficients to be lower (e.g. above 0.4 to be relatively strong). When we are studying things that are more easier to measure, such as socioeconomic status, we expect higher correlations (e.g. above 0.75 to be relatively strong).

In these kinds of studies, we rarely see correlations above 0.6. For this kind of data, we generally consider correlations above 0.4 to be relatively strong; correlations between 0.2 and 0.4 are moderate, and those below 0.2 are considered weak.

When we are studying things that are more easily countable, we expect higher correlations. For example, with demographic data, we we generally consider correlations above 0.75 to be relatively strong; correlations between 0.45 and 0.75 are moderate, and those below 0.45 are considered weak.

Correlation vs Causation

Causation means that one variable (often called the predictor variable or independent variable) causes the other (often called the outcome variable or dependent variable).

Experiments can be conducted to establish causation. An experiment isolates and manipulates the independent variable to observe its effect on the dependent variable, and controls the environment

in order that extraneous variables may be eliminated.

A correlation between variables, however, does not automatically mean that the change in one variable is the cause of the change in the values of the other variable. A correlation only shows if there is a relationship between variables.

Correlation does not always prove causation as a third variable may be involved. For example, being a patient in hospital is correlated with dying, but this does not mean that one event causes the other, as another third variable might be involved (such as diet, level of exercise).

Strengths of Correlations

1. Correlation allows the researcher to investigate naturally occurring variables that maybe unethical or impractical to test experimentally. For example, it would be unethical to conduct an experiment on whether smoking causes lung cancer.
2. Correlation allows the researcher to clearly and easily see if there is a relationship between variables. This can then be displayed in a graphical form

LIMITATIONS OF CORRELATIONS

1. Correlation is not and cannot be taken to imply causation. Even if there is a very strong association between two variables we cannot assume that one causes the other.

For example suppose we found a positive correlation between watching violence on T.V. and violent behavior in adolescence. It could be that the cause of both these is a third (extraneous) variable - say for example, growing up in a violent home - and that both the watching of T.V. and the violent behavior are the outcome of this.

2. Correlation does not allow us to go beyond the data that is given. For example suppose it was found that there was an association between time spent on homework (1/2 hour to 3 hours) and number of G.C.S.E. passes (1 to 6). It would not be legitimate to infer from this that spending 6 hours on homework would be likely to generate 12 G.C.S.E. passes.

SPECIAL CORRELATION METHODS: BISERIAL, POINT BISERIAL, TETRACHORIC, PHI COEFFICIENT

This procedure calculates estimates, confidence intervals, and hypothesis tests for both the point-biserial and the biserial correlations. The point-biserial correlation is a special case of the product-moment correlation in which one variable is continuous and the other variable is binary (dichotomous).

The categories of the binary variable do not have a natural ordering. For example, the binary variable gender does not have a natural ordering. That is, it does not matter whether the males are coded as a zero or a one. Such variables are often referred to as nominal binary variables.

It is assumed that the continuous data within each group created by the binary variable are normally distributed with equal variances and possibly different means. The biserial correlation has a different interpretation which is may be explained with an example. Suppose you have a set of bivariate data from the bivariate normal distribution.

The two variables have a correlation sometimes called the product- moment correlation coefficient.

Now suppose one of the variables is dichotomized by creating a binary variable that is zero if the original variable is less than a certain variable and one otherwise.

The biserial correlation is an estimate of the original product-moment correlation constructed from the point-biserial correlation. For example, you may want to calculate the correlation between IQ and the score on a certain test, but the only measurement available with whether the test was passed or failed. You could then use the biserial correlation to estimate the more meaningful product-moment correlation.

POINT-BISERIAL CORRELATION

Suppose you want to find the correlation between a continuous random variable Y and a binary random variable X which takes the values zero and one. Assume that n paired observations (Y_k, X_k) , k are available. If the common product-moment correlation r is calculated from these data, the resulting correlation is called the point-biserial correlation.

BISERIAL CORRELATION

Suppose you want to find the correlation between a pair of bivariate normal random variables when one has been dichotomized. Sheskin (2011) states that the biserial correlation can be calculated from the point-biserial.

ONE OR MORE CONTINUOUS VARIABLES AND A BINARY VARIABLE

The continuous data is in one variable (column) and the binary group identification is in another variable. Each row contains the values for one subject. If multiple continuous variables are selected, a separate analysis is made for each. If the binary variable has more than two levels (unique values), a separate analysis is made for each pair.

POINT-BISERIAL AND BISERIAL CORRELATIONS

This report shows the point-biserial correlation and associated confidence interval and hypothesis test on the first row. It shows the biserial correlation and associated confidence interval and hypothesis test on the second row.

TYPE

The type of correlation coefficient shown on this row. Note that, although the names point-biserial and biserial sound similar, these are two different correlations that come from different models.

CORRELATION

The computed values of the point-biserial correlation and biserial correlation. Note that since the assignment of the zero and one to the two binary variable categories is arbitrary, the sign of the point-biserial correlation can be ignored. This is not true of the biserial correlation.

Note that the point-biserial correlation demands that the variances are equal but is robust to mild non-normality. On the other hand, the biserial correlation is robust to unequal variances, but demands that the data are normal. This report presents the usual descriptive statistics. This report displays a brief summary of a linear regression of Y on X .

RANK ORDER CORRELATIONS

We have learned about Pearson's correlation in earlier unit. The Pearson's correlation is calculated

on continuous variables. Pearson's correlation is not advised under two circumstances: one, when the data are in the form of ranks and two, when the assumptions of Pearson's correlation are not followed by the data. In this condition, the application of Pearson's correlations is doubtful.

Under such circumstances, rank-order correlations constitute one of the important options. The ordinal scale data is called as rank-order data. Now let us look at these two aspects, rank-order and assumption of Pearson's correlations, in greater detail.

Rank-Order Data When the data is in rank-order format, then the correlation that can be computed is called as rank order correlations. The rank-order data present the ranks of the individuals or subjects. The observations are already in the rank order or the rank order is assigned to them. Marks obtained in the unit test will constitute a continuous data. But if only the merit list of the students is displayed then the data is called as rank order data. If the data is in terms of ranks, then Pearson's correlation need not be done. Spearman's rho constitutes a good option.

ASSUMPTIONS UNDERLYING PEARSON'S CORRELATION NOT SATISFIED

The statistical significance testing of the Pearson's correlation requires some assumptions about the distributional properties of the variables. We have already delineated these assumptions in the earlier unit. When the assumptions are not followed by the data, then employing the Pearson's correlation is problematic. It should be noted that small violations of the assumptions does not influence the distributional properties and associated probability judgments. Hence it is called as a robust statistics. However, when the assumptions are seriously violated, then application of Pearson's correlation should no longer be considered as a choice. Under such circumstances, Rank order correlations should be preferred over Pearson's correlation.

It needs to be noted that rank-order correlations are applicable under the circumstances when the relationship between two variables is not linear but still it is a monotonic relationship. The monotonic relationship is one where values in the data are consistently increasing and never decreasing or consistently decreasing and never increasing. Hence, monotonic relationship implies that as X increases Y consistently increase or as X increases Y consistently decrease. In such cases, rank-order is a better option than Pearson's correlation coefficient. However, some caution should be observed while doing so.

A careful scrutiny of Figure 1 below indicates that, in reality, it is a power function. So actually a relationship between X and Y is not linear but curvilinear power function. So, indeed, curve-fitting is a best approach for such data than using the rank order correlation. The rank-order can be used with this data since the curvilinear relationship shown in figure 1 is also a monotonic relationship. It must be kept in mind that all curvilinear relationships would not be monotonic relationships.

THE PHI-COEFFICIENT, THE TETRACHORIC CORRELATION COEFFICIENT, AND THE PEARSON-YULE DEBATE

The phi-coefficient and the tetrachoric correlation coefficient are two measures of association for dichotomous variables. The association between variables is of fundamental interest in most scientific disciplines, and dichotomous variables occur in a wide range of applications.

Consequently, measures of association for dichotomous variables are useful in many situations. For example in medicine, many phenomena can only be reliably measured in terms of dichotomous

variables. Another example is psychology, where many conditions only can be reliably measured in terms of, for instance, diagnosed or not diagnosed. Data is often presented in the form of 2×2 contingency tables.

A historically prominent example is Pearson's smallpox recovery data, see Table 1, studying possible association between vaccination against, and recovery from, smallpox infection. Another interesting data set is Pearson's diphtheria recovery data, Table 2, studying possible association between antitoxin serum treatment and recovery from diphtheria. Measures of association for dichotomous variables is an area that has been studied from the very infancy of modern statistics. One of the first scholars to treat the subject was Karl Pearson, one of the fathers of modern statistics.

probabilities of the contingency table. The tetrachoric correlation coefficient is then defined as that parameter, which, of course, corresponds to the linear correlation of the bivariate normal distribution. According to Pearson's colleague Burton H. Camp (1933), Pearson considered the tetrachoric correlation coefficient as being one of his most important contributions to the theory of statistics, right besides his system of continuous curves, the chi-square test and his contributions to small sample statistics. However, the tetrachoric correlation coefficient suffered in popularity because of the difficulty in its computation.

While the tetrachoric correlation coefficient is the linear correlation of a so-called underlying bivariate normal distribution, the phi-coefficient is the linear correlation of an underlying bivariate discrete distribution. This measure of association was independently proposed by Boas (1909), Pearson (1900), Yule (1912), and possibly others. The question of whether the underlying bivariate distribution should be considered continuous or discrete is at the core of the so-called Pearson-Yule debate. In the historical context of the Pearson-Yule debate, though, it is important to understand that no one at the time looked upon these two measures of association as the linear correlations of different underlying distributions, the framework in which both were presented in the preceding paragraph. On the contrary, according to Yule (1912) the tetrachoric correlation coefficient is founded upon ideas entirely different from those of which the phi-coefficient is founded upon.

The sentiment is echoed by Pearson & Heron (1913), which even claims that the phi-coefficient is not based on a reasoned theory, while at the same time arguing for the soundness of the tetrachoric correlation coefficient. In fact, the point of view that both measures of association are the linear correlations of underlying distributions is one of the contributions of the present article.

THE PEARSON-YULE DEBATE

George Udny Yule, a former student of Pearson, favored the approach of an inherently discrete underlying distribution. Yule (1912) is a comprehensive review of the area of measures of association for dichotomous variables, as well as a response to Heron (1911), and contains blunt criticism of Pearson's tetrachoric correlation coefficient.

This standpoint Professor Pearson's assumptions are quite inapplicable, and do not lead to the true correlation between the attributes. But this is not, apparently, the standpoint taken by Professor Pearson himself.

THE PHI-COEFFICIENT

The phi-coefficient is the linear correlation between postulated underlying discrete univariate

distributions of X and Y . Formally, let T_X and T_Y be two mappings such that $T_X(X(\Omega))$ and $T_Y(Y(\Omega))$ are both subsets of R . For example, T_X could be $a + b1_{\{\text{pos.}\}}$, for some real constants a and b , 1 being the indicator function. Furthermore, denote $T_X(\text{pos.}) = \alpha$, $T_X(\text{neg.}) = \beta$, $T_Y(\text{pos.}) = \gamma$ and $T_Y(\text{neg.}) = \delta$. The technical conditions $\alpha = \beta$, $\gamma = \delta$ and $\text{sign}(\alpha - \beta) = \text{sign}(\gamma - \delta)$ are also needed. The phi-coefficient is then defined as the linear correlation of T_X and T_Y , i.e. $\rho_{\phi} = \text{Corr}(T_X, T_Y)$.

COROLLARY 2.

Except for its sign, the phi-coefficient does not depend on the choice of mappings T_X and T_Y . An implication of Corollary 2 is that proliferation of phi-coefficients is avoided, and the amount of subjectivism inserted into the phi-coefficient construction is limited. Also, the phi-coefficient can be considered scale and origin free. The only assumption needed is that it is possible to, without loss (or distortion) of information, map the values of X and Y into R . The assumption is formalized as follows. Assumption A1. The values of the dichotomous variables can without loss of information be mapped into the real ordered field, R .

One possible interpretation of Assumption A1 is that the dichotomous variables X and Y are inherently discrete and that both values of X and Y , respectively, represent the same thing but of different magnitudes. Note that Assumption A1 implies an order relation between the values of X and Y , respectively, i.e. that the variables are ordinal. Assumption A1 is not appropriate if a dichotomous variable is strictly nominal, e.g. if the values are Male and Female, Cross and Self-Fertilization, or Treatment A and Treatment B. Pearson & Heron (1913) call these cases Mendelian.

THE TETRACHORIC CORRELATION

coefficient. The tetrachoric correlation coefficient is the linear correlation between postulated underlying normal distributions of X and Y . The 2×2 contingency table is thought of as a double dichotomy of a bivariate normal distribution. One can visualize the bell-shaped bivariate normal density function standing atop the contingency table. Since the dichotomous variables are both scale and origin free, and the family of normal distributions is closed under linear transformations, the normal distribution can without loss of generality be set to standard normal.

Changing the parameter value of the bivariate standard normal distribution will change the shape of the bell-shaped bivariate normal density function, and hence the probability masses over the four rectangles that results from the double dichotomization.

The parameter value of the bivariate standard normal distribution equals, of course, the linear correlation of the postulated joint normal distribution. Since the contingency table is fully determined by the marginal probabilities and one joint probability, it suffices to choose parameter value such that, under given marginal probabilities, one joint probability equals the corresponding volume. Conventionally, that joint probability is chosen to be the probability p_a , corresponding to positive values of both dichotomous variables. Since a volume of a normal distribution cannot be expressed in closed form, computing the tetrachoric correlation coefficient amounts to solving an integral equation.

There are several theories why Pearson (1900) for the purpose of the above definition chose the parametric family of bivariate normal distributions. At the time, the normal distribution was prevalent, and according to Pearson & Heron (1913) there were no other bivariate distributions that

up until the time had been discussed effectively. Furthermore, Pearson (1900) was primarily interested in applications in the fields of evolution and natural selection, which is evident from the article's title, and such variables were generally assumed to be normally distributed.

Pearson's friend and mentor Francis Galton even had a philosophical argument why all variables in nature ought to be normally distributed. Also, the parameter of the parametric family of bivariate normal distributions happens to be a measure of association, and this in combination with other nice properties makes the choice of the bivariate normal distribution most convenient. Ekström (2009) has generalized the definition so that a large class of parametric families of bivariate distributions can be assumed.

In particular, Assumption A2 implies that the values of the dichotomous variables have an ordering, i.e. that the variables are ordinal. In many of the examples of Pearson (1900), the dichotomous variables are actual dichotomizations of continuous variables such as the stature of fathers and sons.

In practice, however, such variables are most often measured with greater precision than two categories, and for dichotomous variables which cannot be measured with greater precision it is in general not easy to make an assertion about the distribution of a postulated underlying continuous variable. If a tetrachoric correlation coefficient exists and is unique for every contingency table, then the tetrachoric correlation coefficient is said to be well defined. The following theorem is of theoretical and practical importance, and has not been found in the literature.

REGRESSION: SIMPLE LINEAR REGRESSION PSYCHOLOGY

Like correlation, regression also allows you to investigate the relationship between variables. But while correlation is just used to describe this relationship, regression allows you to take things one step further; from description to prediction. Regression allows you to model the relationship between variables, which enables you to make predictions about what one variable will do based on another. Or more specifically, it enables you to predict the value of one variable based on the value of another. The variable you want to predict is called the outcome variable (or DV)

- The variable you will base your prediction on is called the predictor variable
- (or IV) For this tutorial, we will use an example based on a fictional study investigating the people's recovery following brain damage. After a brain injury, plasticity enables different regions of the brain to compensate for the regions that have been affected; taking over some of the functions that the damaged regions were initially responsible for. However, the extent to which this occurs is dependent on a number of factors. For example, we know that people are much more likely to recover cognitive function if they experience the brain injury when they are young (all other things being equal, such as the severity of the injury, brain location and so on). So, if we know that brain injury recovery might be related to age, can we predict the degree of brain function someone might expect to recover, based on the age they experienced the injury? This is what we will explore in this tutorial. As with ANOVA, there are different types of regression. But this tutorial will focus on regression in its simplest form: simple linear regression. For simple linear regression, you only have two variables that you are interested in: the predictor (IV) and outcome (DV) variable. In this example our two variables are:

Age – the predictor variable: Proportion of brain function recovered

the outcome variable: Imagine we carried out a study that measured how much brain function

patients recovered following an accident. We could then input it into SPSS (along with their age) as follows:

The final box is the Coefficients table. While the ANOVA table tells us whether the model is a significant predictor of the outcome variable overall, this table tells us how the individual predictor variables contribute to the model.

This table is most useful in situations where multiple variables have been included as predictors – which is not the case in this example. In this example, given that we only have one predictor variable in our model (Age); and that we know the model is significant, we would expect this table to tell us that Age is a significant predictor of brain function recovery score.

When writing up your results there are certain statistics that you need to report. First, you need to state the proportion of variance that can be explained by your model. This is represented by the statistic R^2 and is a number between 0 and 1. It can either be reported in this format (e.g. $R^2 = .872$) or it can be multiplied by 100 to represent the percentage of variance your model explains (e.g. 87.2%). Second, you need to report whether or not your model was a significant predictor of the outcome variable using the results of the ANOVA. Finally, you need to include information about your predictor variables.

In this case (as there is only one) you need to include your β_1 value and the significance of its contribution to the model. While this isn't so important for simple linear regression, when you have multiple predictors you would need to present this information for each variable you have. You might also want to include your final model here. So, in this case we might say something like: A simple linear regression was carried out to test if age significantly predicted brain function recovery .

EXAMPLE OF SIMPLE LINEAR REGRESSION

The table below shows some data from the early days of the Italian clothing company Benetton. Each row in the table shows Benetton's sales for a year and the amount spent on advertising that year. In this case, our outcome of interest is sales—it is what we want to predict.

If we use advertising as the predictor variable, linear regression estimates that **Sales = 168 + 23**

Advertising.

That is, if advertising expenditure is increased by one million Euro, then sales will be expected to increase by 23 million Euros, and if there was no advertising we would expect sales of 168 million Euros.

EXAMPLE OF MULTIPLE LINEAR REGRESSION

Linear regression with a single predictor variable is known as simple regression. In real-world applications, there is typically more than one predictor variable. Such regressions are called multiple regression. For more information, check out this post on why you should not use multiple linear regression for Key Driver Analysis with example data for multiple linear regression examples.

Returning to the Benetton example, we can include **year** variable in the regression, which gives the result that **Sales = 323 + 14 Advertising + 47 Year**.

CHECKING THE QUALITY OF REGRESSION MODELS

Estimating a regression is a relatively simple thing. The hard bit of using regression is avoiding using a regression that is wrong. Below are standard regression diagnostics for the earlier regression. The column labelled **Estimate** shows the values used in the equations before. These estimates are also known as the coefficients and parameters. The **Standard** quantifies the uncertainty of the estimates.

MULTIPLE REGRESSION OF PSYCHOLOGY

Multiple regression generally explains the relationship between multiple independent or predictor variables and one dependent or criterion variable. A dependent variable is modeled as a function of several independent variables with corresponding coefficients, along with the constant term. Multiple regression requires two or more predictor variables, and this is why it is called multiple regression.

The multiple regression equation explained above takes the following form:

$y = b_1x_1 + b_2x_2 + \dots + b_nx_n + c$. Here, b_i 's ($i=1,2,\dots,n$) are the regression coefficients, which represent the value at which the criterion variable changes when the predictor variable changes.

As an example, let's say that the test score of a student in an exam will be dependent on various factors like his focus while attending the class, his intake of food before the exam and the amount of sleep he gets before the exam. Using this test one can estimate the appropriate relationship among these factors.

Multiple regression in SPSS is done by selecting "analyze" from the menu. Then, from analyze, select "regression," and from regression select "linear."

ASSUMPTIONS:

1. There should be proper specification of the model in multiple regression. This means that only relevant variables must be included in the model and the model should be reliable.
2. Linearity must be assumed; the model should be linear in nature.
3. Normality must be assumed in multiple regression. This means that in multiple regression, variables must have normal distribution.
4. Homoscedasticity must be assumed; the variance is constant across all levels of the predicted variable.

There are certain terminologies that help in understanding multiple regression. These terminologies are as follows:

1. **The beta value** is used in measuring how effectively the predictor variable influences the criterion variable, it is measured in terms of standard deviation.
2. **R**, is the measure of association between the observed value and the predicted value of the criterion variable. R Square, or R^2 , is the square of the measure of association which indicates the percent of overlap between the predictor variables and the criterion variable. Adjusted R^2 is an estimate of the R^2 if you used this model with a new data set.

The regression model was conceptualized in the late nineteenth century by Sir Francis Galton, who was studying how characteristics are inherited from one generation to the next (e.g., Stanton, 2001; Stigler, 1997). Galton's goal was to model and predict the characteristics of offspring based on the

characteristics of their parents.

The term 'regression' came from the observation that extreme values (or outliers) in one generation produced offspring that were closer to the mean in the next generation; hence, 'regression to the mean' occurred (the original terminology used was regression to 'mediocrity'). Galton also recognized that previous generations (older than the parents) could influence the characteristics of the offspring as well, and this led him to conceptualize the multiple-regression model.

The residuals provide a measure of the goodness or accuracy of the model's predictions, as smaller (larger) residuals indicate more accurate (inaccurate) predictions. The residuals, ϵ_i , are sometimes labeled 'errors', but we find this terminology potentially misleading since it connotes that (some of) the variables are subject to measurement error.

In fact, the statistical model assumes implicitly that all measurements are perfectly reliable, and the residuals are due to sampling variance, reflecting the fact that the relationships between Y and the various Xs are probabilistic in nature (e.g., in Galton's studies, not all boys born to fathers who are 180 cm tall, and mothers who are 164 cm tall, have the same height). The more complex structural equation models (SEM) combine the statistical MR model with measurement models that incorporate the imperfection of the measurement procedures for all the variables involved.

These models are beyond the scope of this chapter, but are covered in Part V (e.g., Chapter 21) of this book. This chapter covers the wide variety of MR applications in behavioral research. Specifically, we will discuss the measurement, sampling and statistical assumptions of the model, estimation of its parameters, interrelation of its various results, and evaluation of its fit. We illustrate the key results with several numerical examples.

Applications of the multiple-regression model The regression model can be used in one of two general ways, referred to by some (e.g., Pedhazur, 1997) as explanation and prediction. The distinction between these approaches is akin to the distinction between confirmatory and exploratory analyses. The explanatory/confirmatory use of the model seeks to confirm (or refute) certain theoretical expectations and predictions derived from a particular model (typically developed independently of the data at hand).

The ultimate goal is to understand the specific process by which the criterion of interest is produced by the (theoretically determined) predictors. The explanatory regression model is used to confirm the predictions of the theory in the context of a properly formulated model, by using standard statistical tools. It can verify that those predictors that are specified by theory are, indeed, significant and others, which are considered irrelevant by the theory, are not. Similarly, it could test whether the predictor that is postulated by the theory to be the most important in predicting Y reproduces by itself the highest amount of variance, produces the most accurate predictions, and so forth. Consider, for example, specific theories related to the process and variables that determine an individual's IQ. Some theories may stress the hereditary nature of IQ and others may highlight the environmental components.

Thus, they would have different predictions about the significance and/or relative importance of various predictors in the model. An explanatory application of the model would estimate the model's parameters (e.g., regression coefficients), proceed to test the significance of the relevant predictors,

and/or compare the quality and accuracy of the predictions of the various theories.

The predictive/exploratory analysis can be also guided, at least in part, by theory but it is more open ended and flexible and, in particular, relies on the data to direct the analysis. Such an analysis seeks to identify the set of predictors that predicts best the outcome, regardless of whether the model is the 'correct' explanatory mechanism by which the outcome is produced. Of course, it is reassuring if the model makes sense theoretically, but this is not a must. For example, to predict IQ one would start with a large set of predictors that are theoretically viable and include the predictors that optimally predict the observed values of IQ in the regression model.

Thus, the decision in this case is data driven and more exploratory in nature than the explanatory approach. While the model selected using a prediction approach should yield highly accurate predictions, the components of the model are not considered to be any more 'correct' than those for other potential predictors that would yield the same prediction accuracy.

To borrow an example from Pedhazur (1997), if one is trying to predict the weather, a purely predictive approach is concerned with the accuracy of the prediction regardless of whether the predictors are the true scientific 'causes' of the observed-weather conditions. The explanatory approach, on the other hand, would require a model that can also provide a scientific explanation of how the predictors produce the observed-weather conditions. Therefore, while the predictive approach may provide accurate predictions of the outcome, the explanatory approach also provides true knowledge about the processes that underlie and actually produce the outcome. THE VARIOUS FORMS OF THE MODEL Measurement level Typically, all the variables (the response and predictors) are assumed to be quantitative in nature; that is, measured on scales that have well defined and meaningful units (interval or higher).

This assumption justifies the typical interpretation of the regression coefficients as conditional slopes – the expected change in the value of the response variable per unit change of the target predictor, conditional on holding the values of the other ($p - 1$) predictors fixed. This assumption is also critical for one of the key properties of the MR model. MR is a compensatory model in the sense that the same response value can be predicted by multiple combinations of the predictors. In particular, high values on some predictors can compensate for low values on others.

DERIVATIVE PREDICTORS

Typically, the p predictors are measured independently from each other by distinct instruments (various scales, different tests, multiple raters, etc.). In some cases, researchers supplement these predictors by additional measures that are derived by specific transformations and/or combinations of the measured variables. For example, polynomial-regression models include successive powers (quadratic, cubic, quartic, etc.) of some of the original predictors, and are designed to capture nonlinear trends in the relationship between the response and the relevant predictors. Interactive-regression models include variables that are derived by multiplying two, or more, of the measured variables (or some simple transformations of these variables) in an attempt to capture the joint (i.e., above and beyond the additive) effects of the target variables. Computationally, these models do not require any special treatment as one can treat the product X_1X_2 or the quadratic term X_2^2 as additional variables, but we mention several subtle interpretational issues.

SAMPLING DESIGNS

The classical regression model assumes that the values of the predictors are 'fixed'; that is, chosen by various design considerations (including, possibly, plain convenience) rather than sampled randomly. Random samples (of equal, or unequal, size) of the response variable are then obtained for each relevant combination of the p predictors.

Thus, the data consist of a (possibly large) collection of distributions of Y , conditional on particular predetermined combinations of X_1, \dots

X_p . The X 's (predictors) are not random variables, and their distributions in the sample are not necessarily expected to match their underlying distributions in the population. Thus, no distributional assumptions are made about the predictors. The unknown parameters to be estimated in the model are the p regression coefficients and the variance of the residuals. Alternatively, in the 'random' design the researcher randomly samples cases from the population of interest, where a 'case' consists of a vector of all p predictors and the response variable.

The former is a fixed design and the latter is a random one. In both cases one would have the same variables and, subject to minor subtle differences, be able to address the same questions (e.g., Sampson, 1974). In general, the results of a fixed design can be generalized only to the values of X included in the study while the results of a random design can be generalized to the entire population of X values that is represented (by a random sample of values) in the study.

FACTOR ANALYSIS: ASSUMPTIONS, METHODS, ROTATION AND INTERPRETATION OF PSYCHOLOGY

Factor Analysis

Factor analysis is a technique that is used to reduce a large number of variables into fewer numbers of factors. This technique extracts maximum common variance from all variables and puts them into a common score. As an index of all variables, we can use this score for further analysis. Factor analysis is part of general linear model (GLM) and this method also assumes several assumptions: there is linear relationship, there is no multicollinearity, it includes relevant variables into analysis, and there is true correlation between variables and factors. Several methods are available, but principal component analysis is used most commonly.

TYPES OF FACTORING:

There are different types of methods used to extract the factor from the data set:

1. **Principal component analysis:** This is the most common method used by researchers. PCA starts extracting the maximum variance and puts them into the first factor. After that, it removes that variance explained by the first factors and then starts extracting maximum variance for the second factor. This process goes to the last factor.
2. **Common factor analysis:** The second most preferred method by researchers, it extracts the common variance and puts them into factors. This method does not include the unique variance of all variables. This method is used in SEM.
3. **Image factoring:** This method is based on correlation matrix. OLS Regression method is used to predict the factor in image factoring.
4. **Maximum likelihood method:** This method also works on correlation metric but it uses maximum likelihood method to factor.

6. **Other methods of factor analysis:** Alfa factoring outweighs least squares. Weight square is another regression based method which is used for factoring.

FACTOR LOADING:

Factor loading is basically the correlation coefficient for the variable and factor. Factor loading shows the variance explained by the variable on that particular factor. In the SEM approach, as a rule of thumb, 0.7 or higher factor loading represents that the factor extracts sufficient variance from that variable. **Eigenvalues:** Eigenvalues is also called characteristic roots. Eigenvalues shows variance explained by that particular factor out of the total variance. From the commonality column, we can know how much variance is explained by the first factor out of the total variance. For example, if our first factor explains 68% variance out of the total, this means that 32% variance will be explained by the other factor.

Factor score: The factor score is also called the component score. This score is of all row and columns, which can be used as an index of all variables and can be used for further analysis. We can standardize this score by multiplying a common term. With this factor score, whatever analysis we will do, we will assume that all variables will behave as factor scores and will move.

Criteria for determining the number of factors: According to the Kaiser Criterion, Eigenvalues is a good criteria for determining a factor. If Eigenvalues is greater than one, we should consider that a factor and if Eigenvalues is less than one, then we should not consider that a factor. According to the variance extraction rule, it should be more than 0.7. If variance is less than 0.7, then we should not consider that a factor.

Rotation method: Rotation method makes it more reliable to understand the output. Eigenvalues do not affect the rotation method, but the rotation method affects the Eigenvalues or percentage of variance extracted. There are a number of rotation methods available: (1) No rotation method, (2) Varimax rotation method, (3) Quartimax rotation method, (4) Direct oblimin rotation method, and (5) Promax rotation method. Each of these can be easily selected in SPSS, and we can compare our variance explained by those particular methods.

ASSUMPTIONS:

1. **No outlier:** Assume that there are no outliers in data.
2. **Adequate sample size:** The case must be greater than the factor.
3. **No perfect multicollinearity:** Factor analysis is an interdependency technique. There should not be perfect multicollinearity between the variables.
4. **Homoscedasticity:** Since factor analysis is a linear function of measured variables, it does not require homoscedasticity between the variables.
5. **Linearity:** Factor analysis is also based on linearity assumption. Non-linear variables can also be used. After transfer, however, it changes into linear variable.
6. **Interval Data:** Interval data are assumed.

KEY CONCEPTS AND TERMS:

Exploratory factor analysis: Assumes that any indicator or variable may be associated with any factor. This is the most common factor analysis used by researchers and it is not based on any prior theory.

Confirmatory factor analysis (CFA): Used to determine the factor and factor loading of measured variables, and to confirm what is expected on the basis or pre-established theory. CFA assumes that each factor is associated with a specified subset of measured variables. It commonly uses two approaches:

1. **The traditional method:** Traditional factor method is based on principal factor analysis method rather than common factor analysis. Traditional method allows the researcher to know more about insight factor loading.
2. **The SEM approach:** CFA is an alternative approach of factor analysis which can be done in SEM. In SEM, we will remove all straight arrows from the latent variable, and add only that arrow which has to observe the variable representing the covariance between every pair of latents. We will also leave the straight arrows error free and disturbance terms to their respective variables. If standardized error term in SEM is less than the absolute value two, then it is assumed good for that factor, and if it is more than two, it means that there is still some unexplained variance which can be explained by factor. Chi-square and a number of other goodness-of-fit indexes are used to test how well the model fits.

EXPERIMENTAL DESIGNS: ANOVA [ONE-WAY, FACTORIAL], RANDOMIZED BLOCK DESIGNS,

Design of experiment means how to design an experiment in the sense that how the observations or measurements should be obtained to answer a query in a valid, efficient and economical way. The designing of the experiment and the analysis of obtained data are inseparable. If the experiment is designed properly keeping in mind the question, then the data generated is valid and proper analysis of data provides the valid statistical inferences. If the experiment is not well designed, the validity of the statistical inferences is questionable and may be invalid. It is important to understand first the basic terminologies used in the experimental design.

EXPERIMENTAL UNIT:

For conducting an experiment, the experimental material is divided into smaller parts and each part is referred to as an experimental unit. The experimental unit is randomly assigned to treatment is the experimental unit. The phrase “randomly assigned” is very important in this definition.

EXPERIMENT:

A way of getting an answer to a question which the experimenter wants to know.

Treatment Different objects or procedures which are to be compared in an experiment are called treatments.

SAMPLING UNIT:

The object that is measured in an experiment is called the sampling unit. This may be different from the experimental unit.

FACTOR:

A factor is a variable defining a categorization. A factor can be fixed or random in nature. A factor is termed as a fixed factor if all the levels of interest are included in the experiment.

A factor is termed as a random factor if all the levels of interest are not included in the experiment and those that are can be considered to be randomly chosen from all the levels of interest.

Design of experiment: One of the main objectives of designing an experiment is how to verify the hypothesis in an efficient and economical way. In the context of the null hypothesis of equality of several means of normal populations having the same variances, the analysis of variance technique can be used. Note that such techniques are based on certain statistical assumptions.

If these assumptions are violated, the outcome of the test of a hypothesis then may also be faulty and the analysis of data may be meaningless. So the main question is how to obtain the data such that the assumptions are met and the data is readily available for the application of tools like analysis of variance. The designing of such a mechanism to obtain such data is achieved by the design of the experiment.

After obtaining the sufficient experimental unit, the treatments are allocated to the experimental units in a random fashion. Design of experiment provides a method by which the treatments are placed at random on the experimental units in such a way that the responses are estimated with the utmost precision possible.

An **ANOVA** test is a way to find out if survey or experiment results are significant. In other words, they help you to figure out if you need to reject the null hypothesis or accept the alternate hypothesis. Basically, **you're testing groups to see if there's a difference between them**. Examples of when you might want to test different groups:

- A group of psychiatric patients are trying three different therapies: counseling, medication and biofeedback. You want to see if one therapy is better than the others.
- A manufacturer has two different processes to make light bulbs. They want to know if one process is better than the other.
- Students from different colleges take the same exam. You want to see if one college outperforms the other.

What Does "One-Way" or "Two-Way Mean?"

One-way or **two-way** refers to the number of independent variables (IVs) in your Analysis of Variance test.

- One-way has one independent variable (with 2 levels). For example: brand of cereal,
- Two-way has two independent variables (it can have multiple levels). For example: brand of cereal, calories.

What are "Groups" or "Levels"?

Groups or levels are different groups within the same independent variable. In the above example, your levels for "brand of cereal" might be Lucky Charms, Raisin Bran, Cornflakes – a total of three levels. Your levels for "Calories" might be: sweetened, unsweetened a total of two levels.

Let's say you are studying if an alcoholic support group and individual counseling combined is the most effective treatment for lowering alcohol consumption. You might split the study participants into three groups or levels:

- Medication only,
- Medication and counseling,
- Counseling only.

Your dependent variable would be the number of alcoholic beverages consumed per day.

If your groups or levels have a hierarchical structure (each level has unique subgroups), then use a nested ANOVA for the analysis. What Does “Replication” Mean?

It’s whether you are replicating (i.e. duplicating) your test(s) with multiple groups. With a two way ANOVA with replication , you have two groups and individuals within that group are doing more than one thing (i.e. two groups of students from two colleges taking two tests). If you only have one group taking two tests, you would use **without replication**.

TYPES OF TESTS.

There are two main types: one-way and two-way. Two-way tests can be with or without replication.

- One-way ANOVA between groups: used when you want to test **two groups** to see if there’s a difference between them.
- Two way ANOVA without replication: used when you have **one group** and you’re **double-testing** that same group. For example, you’re testing one set of individuals before and after they take a medication to see if it works or not.
- Two way ANOVA with replication: **Two groups**, and the members of those groups are **doing more than one thing**. For example, two groups of patients from different hospitals trying two different therapies.

ONE WAY ANOVA

A one way ANOVA is used to compare two means from two independent (unrelated) groups using the F-distribution. The null hypothesis for the test is that the two means are equal. Therefore, a significant result means that the two means are unequal. Examples of when to use a one way ANOVA

Situation 1: You have a group of individuals randomly split into smaller groups and completing different tasks. For example, you might be studying the effects of tea on weight loss and form three groups: green tea, black tea, and no tea. **Situation 2:** Similar to situation 1, but in this case the individuals are split into groups based on an attribute they possess. For example, you might be studying leg strength of people according to weight. You could split participants into weight categories (obese, overweight and normal) and measure their leg strength on a weight machine.

LIMITATIONS OF THE ONE WAY ANOVA

A one way ANOVA will tell you that at least two groups were different from each other. But **it won’t tell you which groups were different**. If your test returns a significant f-statistic, you may need to run an ad hoc test (like the Least Significant Difference test) to tell you exactly which groups had a difference in means.

TWO WAY ANOVA

A Two Way ANOVA is an extension of the One Way ANOVA. With a One Way, you have one independent variable affecting a dependent variable. With a Two Way ANOVA, there are two independents. Use a two way ANOVA when you have one measurement variable (i.e. a quantitative variable) and two nominal variables. In other words, if your experiment has a quantitative outcome and you have two categorical explanatory variables, a two way ANOVA is appropriate.

For example, you might want to find out if there is an interaction between income and gender for anxiety level at job interviews. The anxiety level is the outcome, or the variable that can be measured. Gender and Income are the two categorical variables. These categorical variables are also the

independent variables, which are called **factors** in a Two Way ANOVA.

The factors can be split into levels. In the above example, income level could be split into three levels: low, middle and high income. Gender could be split into three levels: male, female, and transgender. Treatment groups are all possible combinations of the factors. In this example there would be $3 \times 3 = 9$ treatment groups.

MAIN EFFECT AND INTERACTION EFFECT

The results from a Two Way ANOVA will calculate a main effect and an interaction effect. The main effect is similar to a One Way ANOVA: each factor's effect is considered separately.

With the interaction effect, all factors are considered at the same time. Interaction effects between factors are easier to test if there is more than one observation in each cell. For the above example, multiple stress scores could be entered into cells. If you do enter multiple observations into cells, the number in each cell must be equal.

Two null hypotheses are tested if you are placing one observation in each cell. For this example, those hypotheses would be: H01: All the income groups have equal mean stress. H02: All the gender groups have equal mean stress. For multiple observations in cells, you would also be testing a third hypothesis: H03:

The factors are independent or the interaction effect does not exist. An F-statistic is computed for each hypothesis you are testing.

ASSUMPTIONS FOR TWO WAY ANOVA

- The population must be close to a normal distribution.
- Samples must be independent.
- Population variances must be equal.
- Groups must have equal sample sizes.

MANOVA

MANOVA is just an ANOVA with several dependent variables. It's similar to many other tests and experiments in that it's purpose is to find out if the response variable (i.e. your dependent variable) is changed by manipulating the independent variable. The test helps to answer many research questions, including:

- Do changes to the independent variables have statistically significant effects on dependent variables?
- What are the interactions among dependent variables?
- What are the interactions among independent variables?

MANOVA EXAMPLE

Suppose you wanted to find out if a difference in textbooks affected students' scores in math and science. Improvements in math and science means that there are two dependent variables, so a MANOVA is appropriate. An ANOVA will give you a single (univariate) f-value while a MANOVA will give you a multivariate F value. MANOVA tests the multiple dependent variables by creating new, artificial, dependent variables that maximize group differences. These new dependent variables are linear combinations of the measured dependent variables.

INTERPRETING THE MANOVA

results If the multivariate F value indicates the test is statistically significant, this means that something is significant. In the above example, you would not know if math scores have improved, science scores have improved (or both). Once you have a significant result, you would then have to look at each individual component (the univariate F tests) to see which dependent variable(s) contributed to the statistically significant result. Advantages

1. MANOVA enables you to test multiple dependent variables.
2. MANOVA can protect against Type I errors. Disadvantages

1. MANOVA is many times more complicated than ANOVA, making it a challenge to see which independent variables are affecting dependent variables.
2. One degree of freedom is lost with the addition of each new variable.
3. The dependent variables should be uncorrelated as much as possible. If they are correlated, the loss in degrees of freedom means that there isn't much advantages in including more than one dependent variable on the test.

FACTORIAL ANOVA

A factorial ANOVA is an Analysis of Variance test with more than one independent variable, or "factor". It can also refer to more than one Level of Independent Variable. For example, an experiment with a treatment group and a control group has one factor (the treatment) but two levels (the treatment and the control).

The terms "two-way" and "three-way" refer to the number of factors or the number of levels in your test. Four-way ANOVA and above are rarely used because the results of the test are complex and difficult to interpret.

- A two-way ANOVA has two factors (independent variables) and one dependent variable. For example, time spent studying and prior knowledge are factors that affect how well you do on a test.
 - A three-way ANOVA has three factors (independent variables) and one dependent variable. For example, time spent studying, prior knowledge, and hours of sleep are factors that affect how well you do on a test
- Factorial ANOVA is an efficient way of conducting a test.

Instead of performing a series of experiments where you test one independent variable against one dependent variable, you can test all independent variables at the same time.

Variability In a one-way ANOVA, variability is due to the differences between groups and the differences within groups. In factorial ANOVA, each level and factor are paired up with each other ("crossed").

This helps you to see what interactions are going on between the levels and factors. If there is an interaction then the differences in one factor depend on the differences in another.

Let's say you were running a two-way ANOVA to test male/female performance on a final exam. The subjects had either had 4, 6, or 8 hours of sleep.

- IV1: SEX (Male/Female)

- IV2: SLEEP (4/6/8) • DV: Final Exam Score A two-way factorial ANOVA would help you answer the following questions:
 - Is sex a main effect? In other words, do men and women differ significantly on their exam performance?
 - Is sleep a main effect? In other words, do people who have had 4,6, or 8 hours of sleep differ significantly in their performance?
 - Is there a significant interaction between factors? In other words, how do hours of sleep and sex interact with regards to exam performance?
 - Can any differences in sex and exam performance be found in the different levels of sleep? Assumptions of Factorial ANOVA
- Normality: the dependent variable is normally distributed.
- Independence: Observations and groups are independent from each other.
- Equality of Variance: the population variances are equal across factors/levels.

COMPLETE AND INCOMPLETE BLOCK DESIGNS:

In most of the experiments, the available experimental units are grouped into blocks having more or less identical characteristics to remove the blocking effect from the experimental error. Such design is termed as block designs. The number of experimental units in a block is called the block size. If size of block = number of treatments and each treatment in each block is randomly allocated, then it is a full replication and the design is called a complete block design. In case, the number of treatments is so large that a full replication in each block makes it too heterogeneous with respect to the characteristic under study, then smaller but homogeneous blocks can be used. In such a case, the blocks do not contain a full replicate of the treatments. Experimental designs with blocks containing an incomplete replication of the treatments are called incomplete block designs.

COMPLETELY RANDOMIZED DESIGN (CRD)

The CRD is the simplest design. Suppose there are v treatments to be compared. All experimental units are considered the same and no division or grouping among them exist.

In CRD, the v treatments are allocated randomly to the whole set of experimental units, without

- making any effort to group the experimental units in any way for more homogeneity. Design is entirely flexible in the sense that any number of treatments or replications may be used. The number of replications for different treatments need not be equal and may vary from treatment to treatment.
- treatment depending on the knowledge (if any) on the variability of the observations on individual treatments as well as on the accuracy required for the estimate of individual treatment effect.

EXAMPLE:

Suppose there are 4 treatments and 20 experimental units, then – the treatment 1 is replicated, say 3 times and is given to 3 experimental units, - the treatment 2 is replicated, say 5 times and is given to 5 experimental units, - the treatment 3 is replicated, say 6 times and is given to 6 experimental units and – finally, the treatment 4 is replicated $[20-(6+5+3)]=6$ times and is given to the remaining 6 experimental units.

RANDOMIZED BLOCK DESIGN

If a large number of treatments are to be compared, then a large number of experimental units are required. This will increase the variation among the responses and CRD may not be appropriate to use. In such a case when the experimental material is not homogeneous and there are v treatments to be compared, then it may be possible to group the experimental material into blocks of sizes v units.

- Blocks are constructed such that the experimental units within a block are relatively homogeneous
- and resemble to each other more closely than the units in the different blocks. If there are b such blocks, we say that the blocks are at b levels. Similarly, if there are v treatments,
- we say that the treatments are at v levels. The responses from the b levels of blocks and v levels of treatments can be arranged in a two-way layout. The observed data set is arranged as follows:

LAYOUT:

A two-way layout is called a randomized block design (RBD) or a randomized complete block design (RCB) if, within each block, the v treatments are randomly assigned to v experimental units such that each of the $v!$ ways of assigning the treatments to the units has the same probability of being adopted in the experiment and the assignment in different blocks are statistically independent.

RANDOMIZATION:

- Number the v treatments $1, 2, \dots, v$. - Number the units in each block as $1, 2, \dots, v$. - Randomly allocate the v treatments to v experimental units in each block.

REPLICATION

Since each treatment is appearing in each block, so every treatment will appear in all the blocks. So each treatment can be considered as if replicated the number of times as the number of blocks. Thus in RBD, the number of blocks and the number of replications are same.

LOCAL CONTROL LOCAL CONTROL IS ADOPTED IN RBD IN THE FOLLOWING WAY: -

First form the homogeneous blocks of the experimental units. - Then allocate each treatment randomly in each block. The error variance now will be smaller because of homogeneous blocks and some variance will be parted away from the error variance due to the difference among the blocks. Example: Suppose there are 7 treatments denoted as T_1, T_2, \dots, T_7 , corresponding to 7 levels of a factor to be included in 4 blocks.

LATIN SQUARE DESIGN

The treatments in the RBD are randomly assigned to b blocks such that each treatment must occur in each block rather than assigning them at random over the entire set of experimental units as in the CRD.

There are only two factors – block and treatment effects – which are taken into account and the total number of experimental units needed for complete replication are bv where b and v are the numbers of blocks and treatments respectively.

If there are three factors and suppose there are b , v and k levels of each factor, then the total number of experimental units needed for a complete replication are bvk .

This increases the cost of experimentation and the required number of experimental units over RBD. In Latin square design (LSD), the experimental material is divided into rows and columns, each having the same number of experimental units which is equal to the number of treatments.

The treatments are allocated to the rows and the columns such that each treatment occurs once and only once in each row and in each column. In order to allocate the treatment to the experimental units in rows and columns, we take help from

LATIN SQUARES

Latin Square: A Latin square of order p is an arrangement of p symbols in $2 p$ cells arranged in p rows and p columns such that each symbol occurs once and only once in each row and in each column. For example, to write a Latin square of order 4, choose four symbols – A, B, C and D.

These letters are Latin letters which are used as symbols. Write them in a way such that each of the letters out of A, B, C and D occurs once and only once in each row and each column. For example, as This is a Latin square. We consider first the following example to illustrate how a Latin square is used to allocate the treatments and in getting the response.

EXAMPLE:

Suppose different brands of petrol are to be compared with respect to the mileage per liter achieved in motor cars. Important factors responsible for the variation in mileage are - the difference between individual cars. - the difference in the driving habits of drivers. We have three factors – cars, drivers and petrol brands. Suppose we have – 4 types of cars denoted as 1, 2, 3, 4. - 4 drivers that are represented by a, b, c, d. – 4 brands of petrol are indicated as A, B, C, D. the number of experiments. We choose only Now the complete replication will require 4 4 4 64 experiments. To choose such 16 experiments, we take the help of the Latin square. Suppose we choose the following Latin square:

Write them in rows and columns and choose rows for drivers, columns for cars and letter for petrol brands. Thus 16 observations are recorded as per this plan of treatment combination (as shown in the next figure) and further analysis is carried out. Since such design is based on Latin square, so it is called as a Latin square design.

The LSD is an incomplete three-way layout in which each of the three factors, viz, rows, columns and treatments, is at v levels each and observations only on $2 v$ of the $3 v$ possible treatment combinations are taken. Each treatment combination contains one level of each factor. The analysis of data in an LSD is conditional in the sense it depends on which Latin square is used for allocating the treatments. If the Latin square changes, the conclusions may also change.

STANDARD FORM OF LATIN SQUARE

A Latin square is in the standard form if the symbols in the first row and first columns are in the natural order (Natural order means the order of alphabets like A, B, C, D,...). Given a Latin square, it is possible to rearrange the columns so that the first row and first column remain in a natural order.

Orthogonal Latin squares If two Latin squares of the same order but with different symbols are such that when they are superimposed on each other, every ordered pair of symbols (different) occurs exactly once in the Latin square, then they are called orthogonal.

Mutually orthogonal Latin square A set of Latin squares of the same order is called a set of mutually orthogonal Latin square (or a hyper Graeco-Latin square) if every pair in the set is orthogonal. The total number of mutually orthogonal Latin squares of order p is at most $(p - 1)$.

Analysis of LSD (one observation per cell) In designing an LSD of order p , choose one Latin square at random from the set of all possible Latin squares of order p . Select a standard Latin square from the set of all standard Latin squares with equal probability.

- Randomize all the rows and columns as follows:
- Choose a random number, less than p , say $1/n$ and then 2nd row is the $1/n$ th row. - Choose another random number less than p , say $2/n$ and then 3rd row is the $2/n$ th row and so on. - Then do the same for the column. For Latin squares of the order less than 5, fix the first row and then randomize rows and then
- randomize columns. In Latin squares of order 5 or more, need not to fix even the first row. Just randomize all rows and columns.

MEASURES DESIGN PSYCHOLOGY

An independent measures design is a research method in which multiple experimental groups are used and participants are only in one group. Each participant is only in one condition of the independent variable during the experiment.

An example would be a drug trial for a new pharmaceutical. To test the effect on the disorder and discover any side effects an independent measures design could be used. The researchers use two different conditions: group A who receives the drug and group B who receives a placebo (a fake pill). The participants would be randomly assigned to one of the two groups- for it to be an independent measures design each participant would either be in group A or B, not both. Advantages of independent measures design include less time/money involved than a within subjects design and increased external validity because more participants are used. A disadvantage is that individual differences in participants can sometimes lead to differences in the groups' results. This can lead to false conclusions that the different conditions caused results when it was really just individual differences between the participants. Random sampling can help with this problem.

This should be done by random allocation, which ensures that each participant has an equal chance of being assigned to one group or the other.

Independent measures involve using two separate groups of participants; one in each condition. For example:

- **Con:** More people are needed than with the repeated measures design (i.e., more time consuming).
- **Pro:** Avoids order effects (such as practice or fatigue) as people participate in one condition only. If a person is involved in several conditions, they may become bored, tired and fed up by the time they come to the second condition, or becoming wise to the requirements of the experiment!
- **Con:** Differences between participants in the groups may affect results, for example; variations in age, gender or social background. These differences are known as participant variables (i.e., a type of extraneous variable).
- **Control:** After the participants have been recruited, they should be randomly assigned to their

groups. This should ensure the groups are similar, on average (reducing participant variables).

REPEATED MEASURES:

Repeated Measures design is an experimental design where the same participants take part in each condition of the independent variable. This means that each condition of the experiment includes the same group of participants.

Repeated Measures design is also known as within groups, or within-subjects design.

- **Pro:** As the same participants are used in each condition, participant variables (i.e., individual differences) are reduced.
- **Con:** There may be order effects. Order effects refer to the order of the conditions having an effect on the participants' behavior. Performance in the second condition may be better because the participants know what to do (i.e. practice effect). Or their performance might be worse in the second condition because they are tired (i.e., fatigue effect). This limitation can be controlled using counterbalancing.
- **Pro:** Fewer people are needed as they take part in all conditions (i.e. saves time).
- **Control:** To combat order effects the researcher counter balances the order of the conditions for the participants. Alternating the order in which participants perform in different conditions of an experiment. Counterbalancing
- Suppose we used a repeated measures design in which all of the participants first learned words in 'loud noise' and then learned it in 'no noise.' We would expect the participants to show better learning in 'no noise' simply because of order effects, such as practice. However, a researcher can control for order effects using counterbalancing.
- The sample would split into two groups experimental (A) and control (B). For example, group 1 does 'A' then 'B,' group 2 does 'B' then 'A' this is to eliminate order effects. Although order effects occur for each participant, because they occur equally in both groups, they balance each other out in the results.

COHORT STUDIES

Cohort design is a type of nonexperimental or observational study design. In a cohort study, the participants do not have the outcome of interest to begin with. They are selected based on the exposure status of the individual. They are then followed over time to evaluate for the occurrence of the outcome of interest. Some examples of cohort studies are

- (1) Framingham Cohort study,
- (2) Swiss HIV Cohort study, and
- (3) The Danish Cohort study of psoriasis and depression.

These studies may be prospective, retrospective, or a combination of both of these types. Since at the time of entry into the cohort study, the individuals do not have outcome, the temporality between exposure and outcome is well defined in a cohort design. If the exposure is rare, then a cohort design is an efficient method to study the relation between exposure and outcomes. A retrospective cohort study can be completed fast and is relatively inexpensive compared with a prospective cohort study. Follow-up of the study participants is very important in a cohort study, and losses are an important source of bias in these types of studies. These studies are used to estimate the cumulative incidence and incidence rate. One of the main strengths of a cohort study is the longitudinal nature of the data. Some of the variables in the data will be time-varying and some may be time independent. Thus,

advanced modeling techniques (such as fixed and random effects models) are useful in analysis of these studies.

Cohort studies are important in research design. The term “cohort” is derived from the Latin word “Cohors” – “a group of soldiers.” It is a type of nonexperimental or observational study design. The term “cohort” refers to a group of people who have been included in a study by an event that is based on the definition decided by the researcher. For example, a cohort of people born in Mumbai in the year 1980. This will be called a “birth cohort.” Another example of the cohort will be people who smoke. Some other terms which may be used for these studies are “prospective studies” or “longitudinal studies.”

In a cohort study, the participants do not have the outcome of interest to begin with. They are selected based on the exposure status of the individual. Thus, some of the participants may have the exposure and others do not have the exposure at the time of initiation of the study. They are then followed over time to evaluate for the occurrence of the outcome of interest.

As seen in at baseline, some of the study participants have exposure (defined as exposed) and others do not have the exposure (defined as unexposed). Over the period of follow-up, some of the exposed individuals will develop the outcome and some unexposed individuals will develop the outcome of interest. We will compare the outcomes in these two groups.

FRAMINGHAM COHORT STUDY

This cohort study was initiated in 1948 in Framingham. Framingham, at the time of initiation of the cohort, was an industrial town 21 miles west of Boston with a population of 28,000. This Framingham Heart Study recruited 5209 men and women (30–62- year-old) in the study to assess the factors associated with cardiovascular disease (CVD). The researchers also recruited second generation participants (children of original participants) in 1971 and the third general participants in 2002. This has been one of the landmark cohort studies and has contributed immensely to our knowledge of some of the important risk factors for CVD. The investigators have published 3064 publications using the Framingham Heart Study data.

SWISS HIV COHORT STUDY

This cohort study was initiated in 1988. It was a longitudinal study of HIV-infected individuals to conduct research on HIV pathogenesis, treatment, immunology, and coinfections. They also work on the social aspects of the disease and management of HIV-infected pregnant women. The study started with a recruitment of individuals ≥ 16 years. The cohort was gradually expanded to include the Swiss Mother and Child HIV Cohort Study. The cohort has provided useful information on various aspects of HIV and published 542 manuscripts on these aspects.

THE DANISH COHORT STUDY OF PSORIASIS AND DEPRESSION (JENSEN, 2015)

This is another large cohort study that evaluated the association between psoriasis and onset of depression. The participants in the cohort were enrolled from national registries in Denmark. None of the included participants had psoriasis or depression at baseline. The outcome of interest was the initiation of antidepressants or hospitalization for depression. The authors compared the incidence rates of hospitalization for depression in psoriasis and reference population. The psoriasis group was further classified as mild and moderate psoriasis. The authors found that psoriasis was an independent risk factor for new-onset depression in young people. However, in the elderly, it was

mediated through comorbid conditions.

We have presented examples of some large cohort studies. It will be worthwhile to read the design and conduct of these studies, and it will help the readers understand the practical aspects of conducting and analyzing cohort studies.

TYPES OF COHORT STUDIES PROSPECTIVE COHORT STUDY

In this type of cohort study, all the data are collected prospectively. The investigator defines the population that will be included in the cohort. They then measure the potential exposure of interest. The participants are then classified as exposed or unexposed by the investigator. The investigator then follows these participants. At baseline and during follow-up, the investigator also collects information on other variables that are important for the study (such as confounding variables). The investigator then assesses the outcome of interest in these individuals. Some of these outcomes may only occur once (for example, death), and some may occur multiple times (for example, conditions which may recur in the same individual – diarrhea, wheezing episodes, etc.).

RETROSPECTIVE COHORT STUDY

In this type of cohort study, the data are collected from records. Thus, the outcomes have occurred in the past. Even though the outcomes have occurred in the past, the basic study design is essentially the same. Thus, the investigator starts with the exposure and other variables at baseline and at follow-up and then measures the outcome during the follow-up period.

Sometimes, the direction may not be as well defined as prospective and retrospective. One may analyze retrospective data on a group of people well as collect prospective data from the same individuals.

EXAMPLES OF PROSPECTIVE AND RETROSPECTIVE COHORT STUDIES EXAMPLE 1

Our objective is to estimate the incidence of cardiovascular events in patients with psoriasis. We have decided to conduct a 10-year study. All the individuals who are diagnosed with psoriasis are eligible for being included in this cohort study. However, one has to ensure that none of them have cardiovascular events at baseline. Thus, they should be thoroughly investigated for the presence of these events at baseline before including them in the study. For this, we have to define all the events we are interested in the study (such as angina or myocardial infarction). The criteria for identifying psoriasis and cardiovascular outcomes should be decided before initiating the study. All those who do not have cardiovascular outcomes should be followed at regular intervals (predecided by the researcher and as required for clinical management). This will be a prospective cohort study.

EXAMPLE 2

Our objective is to assess the survival in HIV-infected individuals and the factors associated with survival. We have clinical data from about 430 HIV-infected individuals in the center. The follow-up period ranges from 3 months to 4 years, and we know that 33 individuals have died in this group. We decide to perform the survival analysis in this group of individuals. We prepare a clinical record form and abstract data from these clinical forms. This design will be a retrospective cohort study.

OUTCOMES IN A COHORT STUDY

A cohort study may have different types of outcomes. Some of the outcomes may occur only once.

In the above mentioned retrospective study, if we assess the mortality in these individuals, then the outcome will occur only once. Other outcomes in the cohort study may be measured more than once. For instance, if we assess CD4 counts in the same retrospective study, then the values of CD4 counts may change at every visit. Thus, the outcome will be measured at every visit.

STRENGTHS OF A COHORT STUDY

- **Temporality:** Since at the time of entry into the cohort study, the individuals do not have outcome, the temporality between exposure and outcome is well defined
- A cohort study helps us to study multiple outcomes in the same exposure. For example, if we follow patients of hypercholesterolemia, we can study the incidence of melasma or psoriasis in them. Thus, there is one exposure (hypercholesterolemia) and multiple outcomes (melasma and psoriasis). However, we have to ensure that none of the individuals have any of the outcomes at the baseline
- If the exposure is rare, then a cohort design is an efficient method to study the relation between exposure and outcomes
- It is generally said that a cohort design may not be efficient for rare outcomes (a case-control design is preferred). However, if the rare outcome is common in some exposures, then it may
- be useful to follow a cohort design. For example, melanoma is not a common condition in India. Hence, if we follow individuals to study the incidence of melanoma, then it may not be efficient. However, if we know that, theoretically, a particular chemical may be associated with melanoma, then we should follow a cohort of individuals exposed to this chemical (in occupational settings or otherwise) and study the incidence of melanoma in this group
- In a prospective cohort study, the exposure variable, other variables, and outcomes may be measured more accurately. This is important to maintain uniformity in the measurement of exposures and outcomes. This is also useful for exposures that may require subjective assessment or recall by the patient. For example, dietary history, smoking history, or alcoholic history, etc. This may help in reducing the bias in measurement of exposure
- A retrospective cohort study can be completed fast and is relatively inexpensive compared with a prospective cohort study. However, it also has other strengths of the prospective cohort study.

LIMITATIONS OF A COHORT STUDY

- One major limitation of a prospective cohort design is that it is time consuming and costly. For example, if we have to study the incidence of cardiovascular patients in patients of psoriasis, we may have to follow them up for many years before the outcome occurs
- In a retrospective cohort study, the exposure and the outcome variables are collected before the study has been initiated.
- Thus, the measurements may not be very accurate or according to our requirements. In addition, some of the exposures may have been assessed differently for various members of the cohort
- As discussed earlier, cohort studies may not be very efficient for rare outcomes except in some conditions.

ADDITIONAL POINTS IN COHORT STUDIES

Multiple cohort study

Sometimes, we may be interested to compare the outcomes in two or more groups of individuals. Thus, we may have a multiple cohort study. It is important the exposure, outcome, and other variables should be measured similarly in both the study and the comparison group.

Measurement of exposure and outcome Since the individuals are included in the study based on the exposure status, this has to be well defined and accurate. The outcomes also have to be well defined and measured similarly in all the participants. If you have more than one group in the cohort (as in multiple cohorts or reference population), you should ensure that the follow-up protocols are similar in all the groups.

It is quite possible that individuals participating in a cohort study may not be correctly classified – some exposed individuals may be classified as unexposed and the other way round. If the misclassification of the exposure or the outcome is random or nondifferential, then the two groups will be similar and the estimates from the study will be biased towards the null. Thus, we will underestimate the association between the exposure and the outcome. If, however, the misclassification is differential or nonrandom, then the estimates may be biased toward the null, away from the null, or may be an appropriate estimate.

FOLLOW-UP

Follow-up of the study participants is very important in a cohort study and losses are an important source of bias in these types of studies. Some patients are lost to follow-up in large cohorts; however, if the proportion is very high (>30%), then the validity of the results from this study are doubtful. This loss to follow-up becomes all the more important if it is related to the exposure or outcome of interest. For example, in our prospective study, majority of the patients who were lost to follow-up had severe psoriasis at the baseline, then we will get biased estimates from the study. Thus, managing follow-ups and minimizing losses are an important component of the design of a cohort study.

NESTED CASE-CONTROL STUDY

This is a specific type of study design nested within a cohort study. In this, the investigator will match the controls to the cases within a specific cohort.

The exposure of interest will be assessed in these selected cases and controls. For example, our hypothesis is that there is a biological marker that is present/elevated (to begin with) in individuals who develop cardiovascular events in psoriatic patients.

It is expensive to assess this marker in all patients. Thus, we select all those who develop the outcomes (cases) in our cohort and a sample of individuals who do not develop the outcomes (controls). An important aspect, however, is that we should have stored the biological material that we have collected at baseline, and the biological marker should be assessed in this sample. This procedure maintains the temporal strength of the cohort study.

TIME SERIES

The purpose of the present paper is to present a methodological approach to such research areas as psychotherapy, education, psychophysiology, operant research, etc., where the data consist of dependent observations over time. Existing methodologies are frequently inappropriate to research in these areas; common field methodologies are unable to control irrelevant variables and eliminate rival hypotheses, while traditional parametric laboratory designs relying on control groups are often unsuitable. New data-analysis techniques have made possible the development of a different methodological approach which can be applied in either the laboratory or in natural (field) settings.

This approach is responsive to ecological considerations (Willems, 1965) while permitting satisfactory experimental control. Control is achieved by a network of complementary control strategies, not solely by control-group designs.

INTERRUPTED TIME SERIES DESIGN

A variant of the pretest-posttest design is the **interrupted time-series design**. A time series is a set of measurements taken at intervals over a period of time. For example, a manufacturing company might measure its workers' productivity each week for a year. In an interrupted time series-design, a time series like this one is "interrupted" by a treatment.

In one classic example, the treatment was the reduction of the work shifts in a factory from 10 hours to 8 hours (Cook & Campbell, 1979). Because productivity increased rather quickly after the shortening of the work shifts, and because it remained elevated for many months afterward, the researcher concluded that the shortening of the shifts caused the increase in productivity.

Notice that the interrupted time-series design is like a pretest- posttest design in that it includes measurements of the dependent variable both before and after the treatment. It is unlike the pretest-posttest design, however, in that it includes multiple pretest and posttest measurements.

Figure 8.1 shows data from a hypothetical interrupted time-series study. The dependent variable is the number of student absences per week in a research methods course. The treatment is that the instructor begins publicly taking attendance each day so that students know that the instructor is aware of who is present and who is absent.

The top panel of Figure shows how the data might look if this treatment worked. There is a consistently high number of absences before the treatment, and there is an immediate and sustained drop in absences after the treatment.

The bottom panel of Figure shows how the data might look if this treatment did not work. On average, the number of absences after the treatment is about the same as the number before. This figure also illustrates an advantage of the interrupted time-series design over a simpler pretest-posttest design.

If there had been only one measurement of absences before the treatment at Week 7 and one afterward at Week 8, then it would have looked as though the treatment were responsible for the reduction. The multiple measurements both before and after the treatment suggest that the reduction between Weeks 7 and 8 is nothing more than normal week-to-week variation.

THE USE OF TIME SERIES IN DESIGN

The most persuasive experimental evidence comes from a triangulation of research designs as well as from a triangulation of measurement processes. The following three designs, when used in conjunction, represent such a triangulation:

- (a) the one-group pretest-posttest design;
- (b) the time-series design; and
- (c) the multiple time-series design. These designs need not be applied simultaneously;

THE ONE-GROUP PRETEST-FOLLOWUP DESIGN

This design, although inadequate when used alone, makes a significant and unique contribution to the total design package. It provides an external criterion measure of the outcome of a programmed intervention. Each subject serves as his own control, and the difference between his pre- and posttest scores represents a stringent measure of the degree to which "real life" program goals have been achieved.

For example, the ultimate success of psychotherapy is best evaluated in terms of extratherapeutic behavior change. This design, then, documents the fact of outcome-change without pinpointing the process producing the change.

THE TIME-SERIES DESIGN THIS DESIGN

involves successive observations throughout a programmed intervention and assesses the characteristics of the change process. It is truly the mainstay of the proposed design package because it serves several simultaneous functions. First, it is descriptive. The descriptive function of the time series is particularly important when the intervention extends over a considerable time period. The time series is the only design to furnish a continuous record of fluctuations in the experimental variables over the entire course of the program.

Second, the time-series design functions as an heuristic device. When coupled with a carefully kept historical log of potentially relevant nonexperimental events, the time series is an invaluable source of post hoc hypotheses regarding observed, but unplanned, changes in program variables.

Moreover, where treatment programs require practical administrative decisions, the time series serves as a source of hypotheses regarding the most promising decisions, and later as a feedback source regarding the consequences and effectiveness of such decisions.

Finally, the time series can function as a quasi-experimental design for planned interventions imbedded in the total program when a control group is implausible. depicts a time-series experiment with an extended intervention ; of course, in some cases, the intervention might simply be a discrete event. A time-series analysis must demonstrate that the perturbations of a system are not uncontrolled variations, that is, noise in the system. It is precisely this problem of partitioning noise from "effect" that has discouraged the use of time series in the social sciences.

THE MULTIPLE TIME-SERIES DESIGN

This design is basically a refinement of the simple time series. It is yet a more precise method for investigating specific program hypotheses because it allows the time series of the experimental group to be compared with that of a control group. As a result, it offers a greater measure of control over unwanted sources of rival hypotheses.

THE ANALYSIS OF TIME-SERIES DATA

The data resulting from the best of experimental designs is of little value unless subsequent statistical analyses permit the investigator to test the extent to which obtained differences exceed chance fluctuations. The above design package, with its emphasis on time-series designs, is a realistic possibility only because of recent developments in the field of mathematics. Appropriate analysis techniques have evolved from work in such diverse areas as economics, meteorology, industrial quality control, and psychology. Historically, the time-series design has been neglected

due to the lack of such appropriate analytical techniques. Two statistical methods for solving the problem of time-series analyses are presented below.

MANOVA

Multivariate ANOVA (MANOVA) extends the capabilities of analysis of variance (ANOVA) by assessing multiple dependent variables simultaneously. ANOVA statistically tests the differences between three or more group means. For example, if you have three different teaching methods and you want to evaluate the average scores for these groups, you can use ANOVA. However, ANOVA does have a drawback. It can assess only one dependent variable at a time. This limitation can be an enormous problem in certain circumstances because it can prevent you from detecting effects that actually exist.

MANOVA provides a solution for some studies. This statistical procedure tests multiple dependent variables at the same time. By doing so, MANOVA can offer several advantages over ANOVA.

Multivariate ANOVA (MANOVA) extends the capabilities of analysis of variance (ANOVA) by assessing multiple dependent variables simultaneously. ANOVA statistically tests the differences between three or more group means. For example, if you have three different teaching methods and you want to evaluate the average scores for these groups, you can use ANOVA. However, ANOVA does have a drawback. It can assess only one dependent variable at a time. This limitation can be an enormous problem in certain circumstances because it can prevent you from detecting effects that actually exist.

MANOVA provides a solution for some studies. This statistical procedure tests multiple dependent variables at the same time. By doing so, MANOVA can offer several advantages over ANOVA.

MANOVA ASSESSES THE DATA

Let's see what patterns we can find between the dependent variables and how they are related to teaching method. I'll graph the test and satisfaction scores on the scatterplot and use teaching method as the grouping variable. This multivariate approach represents how MANOVA tests the data. These are the same data, but sometimes how you look at them makes all the difference.

The graph displays a positive correlation between Test scores and Satisfaction. As student satisfaction increases, test scores tend to increase as well. Moreover, for any given satisfaction score, teaching method 3 tends to have higher test scores than methods 1 and 2. In other words, students who are equally satisfied with the course tend to have higher scores with method 3. MANOVA can test this pattern statistically to help ensure that it's not present by chance.

In your preferred statistical software, fit the MANOVA model so that Method is the independent variable and Satisfaction and Test are the dependent variables.

MANOVA Provides Benefits

Use multivariate ANOVA when your dependent variables are correlated. The correlation structure between the dependent variables provides additional information to the model which gives MANOVA the following enhanced capabilities:

- **Greater statistical power:** When the dependent variables are correlated, MANOVA can identify effects that are smaller than those that regular ANOVA can find.
- **Assess patterns between multiple dependent variables:** The factors in the model can affect the relationship between dependent variables instead of influencing a single dependent variable. As

the example in this post shows, ANOVA tests with a single dependent variable can fail completely to detect these patterns.

- **Limits the joint error rate:** When you perform a series of ANOVA tests because you have multiple dependent variables, the joint probability of rejecting a true null hypothesis increases with each additional test. Instead, if you perform one MANOVA test, the error rate equals the significance level.

(1) reading, (2) mathematics, and (3) moral reasoning skills. Using MANOVA the psychologist could examine how the two groups differ on a linear combination of the three measures. Perhaps the Catholic school children score higher on moral reasoning skills relative to reading and math when compared to the public school children? Perhaps the Catholic school children score higher on both moral reasoning skills and math relative to reading when compared to the public school children? These potential outcomes, or questions, are multivariate in nature because they treat the quantitative measures simultaneously and recognize their potential inter-relatedness. The goal of conducting a MANOVA is thus to determine how quantitative variables can be combined to maximally discriminate between distinct groups of people, places, or things.

As will be discussed below this goal also includes determining the theoretical or practical meaning of the derived linear combination or combinations of variables.

CONDUCTING THE MANOVA

Returning to the Big Five trait example, let us decide to pursue a truly multivariate approach. In other words, let us commit to examining the linear combinations of personality traits that might differentiate between the European American (EA), Asian American (AA), and Asian International (AI) students. Assuming that no a priori model for combining the Big Five traits is available, these six steps will consequently be followed:

APPLIED MULTIVARIATE RESEARCH

1. Conduct an omnibus test of differences among the three groups on linear combinations of the five personality traits.
2. Examine the linear combinations of personality traits embodied in the discriminant functions.
3. Simplify and interpret the strongest linear combination.
4. Test the simplified linear combination (multivariate composite) for statistical significance.
5. Conduct follow-up tests of group differences on the simplified multivariate composite.
6. Summarize results in APA style. If an existing model for combining the traits were available, a priori, then an abbreviated approach, which will be discussed near the end of this paper, would be undertaken.

Step 1: Conducting the Omnibus MANOVA. The omnibus null hypothesis for this example posits the EA, AA, and AI groups are equal with regard to their population means on any and all linear combinations of the Big Five personality traits.

This hypothesis can be tested using any one of the major computer software packages. In SPSS for Windows the General Linear Model (GLM) procedure can be used or the dated MANOVA routine can be run through the syntax editor.

SINGLE-FACTOR ANCOVA

In this model a single-factor ANOVA model is extended by specifying one or more additional

continuous (quantitative) variables called covariates. The resulting single-factor analysis of covariance (ANCOVA) model explains variation in a dependent variable by combining a categorical (qualitative) independent variable with one or more continuous (quantitative) variables. If a covariate is linearly related to the dependent variable, it will reduce pre-existing variability between subjects. In effect, the variance component in the dependent variable which is due to covariation with the covariate is removed ("partialled out") from the dependent variable. This reduces the variance of the error term in the model, which increases the sensitivity of the ANCOVA as compared to the same model without the covariate (ANOVA model). A higher test sensitivity means that smaller mean differences between groups will become significant as compared to a standard ANOVA model.

Note that ANCOVA has a similar goal as repeated measures ANOVA, namely to remove pre-existing differences between subjects. In repeated measures ANOVA models, this is achieved by measuring the same subjects under various conditions (within- subjects) instead of assigning different subjects to different conditions. From the obtained data, changes of the dependent variable across conditions are only analyzed within each subject completely removing between-subjects variability. In ANCOVA models, the reduction of inter-subject variability depends on the strength of correlation of the covariate with the dependent variable. This consideration implies that ANCOVA models are only useful for designs with between-subjects factors but provide no benefits in pure within-subjects factorial designs.

The obvious difference between ANOVA and ANCOVA is the the letter "C", which stands for 'covariance'. Like ANOVA, "Analysis of Covariance" (ANCOVA) has a single continuous response variable. Unlike ANOVA, ANCOVA compares a response variable by both a factor and a continuous independent variable (e.g. comparing test score by both 'level of education' and 'number of hours spent studying'). The term for the continuous independent variable (IV) used in ANCOVA is "covariate".

ANCOVA is also commonly used to describe analyses with a single response variable, continuous IVs, and no factors. Such an analysis is also known as a regression. In fact, you can get almost identical results in SPSS by conducting this analysis using either the "Analyze > Regression > Linear" dialog menus or the "Analyze > General Linear Model (GLM) > Univariate" dialog menus.

A key (but not only) difference in these methods is that you get slightly different output tables. Also, regression requires that user dummy code factors, while GLM handles dummy coding through the "contrasts" option. The linear regression command in SPSS also allows for variable entry in hierarchical blocks (i.e. stages).

SINGLE SUBJECT DESIGN PSYCHOLOGY

Single subject research design is a type of research methodology characterized by repeated assessment of a particular phenomenon (often a behavior) over time and is generally used to evaluate interventions. Repeated measurement across time differentiates single subject research design from case studies and group designs, as it facilitates the examination of client change in response to an intervention. Although the use of single subject research design has generally been limited to research, it is also appropriate and useful in applied practice.

A wide variety of valid, useful designs exist for the measurement of a single case. These designs are either classified as qualitative or quasi experimental designs as they do not contain the provisions

of random, representative samples or randomization to treatment/intervention. This classification convention also occurs because traditional statistical analyses based classical theorems are not used.

With focus currently on evidenced-based practice/medicine in health care, more exacting measurements of treatment are needed. The purposeful, visible emphasis on process and outcome data provides the participant/client with an ongoing view of the validity of the intervention approach. The evidence-based practice movement can be addressed easily with the low cost (i.e., low expense and time expenditure).

The Scientist Practitioner Model guides clinicians to use data collected in laboratory to guide decisions of treatment implementation. In turn, treatment implementation, according to the Scientist Practitioner Model, influences the direction of research. Research evidence of treatment effectiveness is valued. In single case designs, the systematic monitoring and evaluation positions the participant/client to adopt a problem-solving experiment, conjointly with the practitioner/field researcher on herself/himself. In so doing, the findings are immediate and directly applicable to their situation. In some cases, these approaches promote the generation of alternative interpretations of collected data and quite possibly, causal explanations of behaviors. The clinical practices of establishing support, setting up a conceptual/ethical concept of clients' situation, identification of areas of change/strength/weakness, selection and implementation of treatment, evaluation of change/plan for relapse and follow-up are conducted within the simple case design context.

All single case designs involve training the participant/client in observation practices. This training of the individual to understand what behavior to record, how to record the behavior and when to record the behavior is central to single case design. It is common for the practitioner/field researcher to work with the participant/client in their selection of a behavior to change and thereby, record. This becomes important as this descriptive data will ultimately become the pivotal source of information about the functional relationship between the target behavior for change and those behaviors that precede and follow (i.e., antecedent consequences) as they are typically interdependent. In fact, this circumstance is what is termed the functional assessment. Some representative target behaviors often used in an ABA single case design are: nutrition; hydration – amount of water; weight gain or loss; medication compliance; adherence to treatment; smoking cessation; substance use cessation. Client's values are incorporated in the choice of targets and goal setting procedures. The baseline measurement is followed by the implementation of a change in a target behavior such as the examples listed above. After the implementation period, the participant/client returns to an adlib or no intervention schedule.

The ABA design, like other single case designs, allows the client values to be incorporated into the choice of targets and goal setting procedures. In the AB design, the intervention is followed by a baseline period.

Conclusions

We find that single case designs are powerful measurement tools of behavior. The challenges and need for quantification that occurs in field settings can be uniquely and precisely addressed with single case designs.

MULTIPLE CHOICE QUESTION

1. Who authored the book "methods in Social Research"

- A. Wilkinson**
- B. CR Kothari**
- C. Kerlinger**
- D. Goode and Halt**

Ans:- D

2. "Research is an organized and systematic enquiry" Defined by

- A. Marshall**
- B. P.V. Young**
- C. Emory**
- D. Kerlinger**

Ans:- C

3. Research is a "Scientific undertaking" opined by

- A. Young**
- B. Kerlinger**
- C. Kothari**
- D. Emory**

Ans:- A

4. "A systematic step-by-step Procedure following logical process of reasoning" called

- A. Experiment**
- B. Observation**
- C. Deduction**
- D. Scientific method**

Ans:- D

5. Ethical Neutrality is a feature of

- A. Deduction**
- B. Scientific method**
- C. Observation**
- D. Experience**

Ans:- B

6. Scientific method is committed to

.....

- A. Objectivity**
- B. Ethics**
- C. Proposition**
- D. Neutrality**

Ans:- A

7. "One of the methods of logical reasoning process" is called

- A.** Induction
- B.** Deduction
- C.** Research
- D.** Experiment

Ans:- A

8. An essential Criterion of Scientific study is

- A.** Belief
- B.** Value
- C.** Objectivity
- D.** Subjectivity

Ans:- C

9. "Reasoning from general to particular "is called

- A.** Induction
- B.** deduction
- C.** Observation
- D.** experience

Ans:- B

10. "Deduction and induction are a part of system of reasoning" – stated by

- A.** Caroline
- B.** P.V.Young
- C.** Dewey John
- D.** Emory

Ans:- B

11. " A system of systematically interrelated concepts definitions and propositions that are advanced to explain and predict phenomena" ... is

- A.** Facts
- B.** Values
- C.** Theory
- D.** Generalization

Ans:- C

12. " A system of systematically interrelated concepts, definitions and propositions that are advanced to explain and Predict phenomena" defined by

- A.** Jack Gibbs
- B.** PV Young
- C.** Black

D. Rose Arnold

Ans:- B

13. Theory is “ a set of systematically related propositions specifying casual relationship among variables” is defined by

A. Black James and Champion

B. P.V. Young

C. Emory

D. Gibbes

Ans:- A

14. “Empirically verifiable observation” is

A. Theory

B. Value

C. Fact

D. Statement

Ans:- C

15. Fact is “empirically verifiable observation” --- is defined by

A. Good and Hatt

B. Emory

C. P.V. Young

D. Claver

Ans:- A

16 is “systematically conceptual structure of inter related elements in some

A. schematic form”

B. Concept

C. Variable

D. Model E. Facts

Ans:- C

17. Social Science deals with

A. Objects

B. Human beings

C. Living things

D. Non living things

Ans:- B

18. Science is broadly divided into.....

A. Natural and Social

B. Natural and Physical

- C. Physical and Mental
- D. Social and Physical

Ans:- A

19. Social Science try to explain..... Between human activities and natural laws

- A. governing them
- B. Causal Connection
- C. reason
- D. Interaction
- E. Objectives

Ans:- A

20. Social Science Research Problems

- A. Explain
- B. diagnosis
- C. Recommend
- D. Formulate

Ans:- B

21. Social research aims at.....

- A. Integration
- B. Social Harmony
- C. National Integration
- D. Social Equality

Ans:- A

22. The method by which a sample is chosen

- A. Unit
- B. design
- C. Random
- D. Census

Ans:- B

23. Basing conclusions without any bias and value judgment is

- A. Objectivity
- B. Specificity
- C. Values
- D. Facts

Ans:- A

24. Research is classified on the basis of_____and methods

- A. Purpose

- B. Intent
- C. Methodology
- D. Techniques

Ans:- B

25. Research undertaken for knowledge sake is

- A. Pure Research
- B. Action Research
- C. Pilot study
- D. Survey

Ans:- A

26. Example for fact finding study is

- A. Pure Research
- B. Survey
- C. Action Research
- D. Long term Research

Ans:- B

27. Facts or information's are analyzed and critical evaluation is made in

- A. Survey
- B. Action research
- C. Analytical research
- D. Pilot study

Ans:- C

28. Research conducted to find solution for an immediate problem is

- A. Fundamental Research
- B. Analytical Research
- C. Survey
- D. Action Research

Ans:- D

29. Fundamental Research is otherwise called

- A. Action Research
- B. Survey
- C. Pilot study
- D. Pure Research

Ans:- D

30. Motivation Research is a type of..... research

- A. Quantitative
- B. Qualitative

- C. Pure
- D. Applied

Ans:- B

31. Research related to abstract ideas or concepts is

- A. Empirical research
- B. Conceptual Research
- C. Quantitative research
- D. Qualitative research

Ans:- B

32. A research which follows case study method is called

- A. Clinical or diagnostic
- B. Causal
- C. Analytical
- D. Qualitative

Ans:- A

33. Research conducted in class room atmosphere is called

- A. Field study
- B. Survey
- C. Laboratory Research
- D. Empirical Research

Ans:- C

34. Research through experiment and observation is called

- A. Clinical Research
- B. Experimental Research
- C. Laboratory Research
- D. Empirical Research

Ans:- D

35. Population Census is an example of Research

- A. Survey
- B. Empirical
- C. Clinical
- D. Diagnostic

Ans:- A

36. The author of " The Grammar of Science" is

- A. Ostle
- B. Richard
- C. Karl Pearson

D. Kerlinger

Ans:- C

37. "The Romance of Research" is authored by

A. Redmen and Mory

B. P.V.Young

C. Robert C meir

D. Harold Dazier

Ans:- A

38. is a way to systematically solve the research problem

A. Technique

B. Operations

C. Research methodology

D. Research Process

Ans:- C

39. Good Research is always

A. Slow

B. Fast

C. Narrow

D. Systematic

Ans:- D

40. Good research is

A. Logical

B. Non logical

C. Narrow

D. Systematic

Ans:- A

41. "Criteria of Good Research" is written by

A. Delta Kappan

B. James Harold Fox

C. P.V.Young

D. Karl Popper

Ans:- B

42. Research method is a part of

A. Problem

B. Experiment

C. Research Techniques

D. Research methodology

Ans:- D

43. Identifying causes of a problem and possible solution to a problem is

- A.** Field Study
- B.** diagnosis tic study
- C.** Action study
- D.** Pilot study

Ans:- B

44 helps in social planning

- A.** Social Science Research
- B.** Experience Survey
- C.** Problem formulation
- D.** diagnostic study

Ans:- A

45. “Foundations of Behavioral Research” is written by

- A.** P.V. Young
- B.** Kerlinger
- C.** Emory
- D.** Clover Vernon

Ans:- B

46. Methods and issues in Social Research” is written by

- A.** Black James and Champions
- B.** P.V. Young
- C.** Mortan Kaplan
- D.** William Emory

Ans:- A

47. “Scientific Social Survey and Research” is written by

- A.** Best John
- B.** Emory
- C.** Clover
- D.** P.V. Young

Ans:- D

48. “Doubt is often better than

- A.** Belief
- B.** Value
- C.** Confidence
- D.** Overconfidence

Ans:- D

49. Research help in explaining the with which something operates.

- A.** Velocity
- B.** Momentum
- C.** Frequency
- D.** gravity

Ans:- C

50 is a motivation for research in students

- A.** Research degree
 - B.** Research Academy
 - C.** Research Labs
 - D.** Research Problems
- Ans:- A

51. Which of the following is an example of primary data?

- A.** Book
- B.** Journal
- C.** News Paper
- D.** Census Report

Ans:- C

52. Major drawback to researchers in India is

- A.** Lack of sufficient number of Universities
- B.** Lack of sufficient research guides
- C.** Lack of sufficient Fund
- D.** Lack of scientific training in research

Ans:- D

53. ICSSR stands for

- A.** Indian Council for Survey and Research
- B.** Indian Council for strategic Research
- C.** Indian Council for Social Science Research
- D.** Inter National Council for Social Science Research

Ans:- C

54. UGC Stands for

- A.** University Grants Commission
 - B.** Union Government Commission
 - C.** University Governance Council
 - D.** Union government Council
- Ans:- A

55. JRF is for

- A.** Junior Research Functions

- B.** Junior Research Fellowship
- C.** Junior Fellowship
- D.** None of the above

Ans:- B

56 is the first step of Research process

- A.** Formulation of a problem
- B.** Collection of Data
- C.** Editing and Coding
- D.** Selection of a problem

Ans:- D

57. A problem well put is

- A.** Fully solved
- B.** Not solved
- C.** Cannot be solved
- D.** half- solved

Ans:- D

58 is a source of problem

- A.** Schools and Colleges
- B.** Class Room Lectures
- C.** Play grounds
- D.** Infra structures

Ans:- B

59. A question which requires a solution is

- A.** Observation
- B.** Problem
- C.** Data
- D.** Experiment

Ans:- B

60. Converting a question into a Researchable problem is called

- A.** Solution
- B.** Examination
- C.** Problem formulation
- D.** Problem Solving

Ans:- C

61. While Selecting a problem, problem which is no taken

- A.** Very Common
- B.** Overdone

C. Easy one

D. rare

Ans:- B

62. The first step in formulating a problem is

A. Statement of the problem

B. Gathering of Data

C. Measurement

D. Survey

Ans:- A

63 will help in finding out a problem for research

A. Professor

B. Tutor

C. HOD

D. Guide

Ans:- D

64. Second step in problem formulation is

A. Statement of the problem

B. Understanding the nature of the problem

C. Survey

D. Discussions

Ans:- B

65. Third step in problem formulation is

A. Statement of the problem

B. Understanding the nature of the problem

C. Survey the available literature

D. Discussion

Ans:- C

66. Fourth step in problem formulation is

A. Develop ideas through discussion

B. Survey

C. Statement of problem

D. Enactment

Ans:- A

67. Last step in problem formulation is

A. Survey

B. Discussion

C. Literature survey

D. Re Phrasing the Research problem

Ans:- D

68. In the formulation of the problem we need to give a

- A. Title**
- B. Index**
- C. Bibliography**
- D. Concepts**

Ans:- A

69. Objectives in problem formulation means

- A. Questions to be answered**
- B. methods**
- C. Techniques**
- D. methodology**

Ans:- A

70. The problem selected must have

- A. Speed**
- B. Facts**
- C. Values**
- D. Novelty**

Ans:- D

71. The formulated problem should have

- A. Originality**
- B. Values**
- C. Coherence**
- D. Facts**

Ans:- A

72. The purpose of Social Science Research is

- A. Academic and Non academic**
- B. Cultivation**
- C. Academic**
- D. Utilitarian**

Ans:- B

73. The Academic purpose is to have

- A. Information**
- B. firsthand knowledge**
- C. Knowledge and information**
- D. models**

Ans:- C

74. Social Science Research creates Social

- A.** Alienation
- B.** Cohesion
- C.** mobility
- D.** Integration

Ans:- B

75 is a quality of Good Researcher

- A.** Scientific temper
- B.** Age
- C.** Money
- D.** time

Ans:- A

76. Social Science Research in India aims at a State

- A.** Secular
- B.** Totalitarian
- C.** democratic
- D.** welfare

Ans:- D

77. A _____ is an abstraction formed by generalization from particulars

- A.** Hypothesis
- B.** Variable
- C.** Concept
- D.** facts

Ans:- C

78. Concept is of two types

- A.** Abstract and Coherent
- B.** Concrete and Coherent
- C.** Abstract and concrete
- D.** None of the above

Ans:- C

79. Concepts are of _____ types

- A.** 4
- B.** 6
- C.** 10
- D.** 2

Ans:- D

80. There is a concept by

- A. Observation
- B. formulation
- C. Theory
- D. Postulation

Ans:- D

81. Another concept is by

- A. Formulation
- B. Postulation
- C. Intuition
- D. Observation

Ans:- C

82. Concepts are _____ of Research

- A. guide
- B. tools
- C. methods
- D. Variables

Ans:- B

83. Concepts are

- A. Metaphor
- B. Simile
- C. Symbols
- D. Models

Ans:- C

84. Concepts represent various degree of

- A. Formulation
- B. Calculation
- C. Abstraction
- D. Specification

Ans:- C

85. Concepts which cannot be given operational definitions are
concepts

- A. Verbal
- B. Oral
- C. Hypothetical
- D. Operational

Ans:- C

86. "Concept is in reality a definition in short hand or a class or group of facts" –defined by

- A.** Kerlinger
- B.** P.V. Young
- C.** Aurthur
- D.** Kaplan

Ans:- B

87. Different people hold of the same thing

- A.** Same and different
- B.** Same
- C.** different
- D.** None of the above

Ans:- C

88. Many concepts find their origin from

- A.** Greek
- B.** English
- C.** Latin
- D.** Many languages

Ans:-D

89. A tentative proposition subject to test is

- A.** Variable
- B.** Hypothesis
- C.** Data
- D.** Concept

Ans:- B

90. Analogies are sources of

- A.** Data
- B.** Concept
- C.** Research
- D.** Hypothesis

Ans:- D

91. "A Proposition which can be put to test to determine its validity" Defined by

- A.** Lund berg
- B.** Emory
- C.** Johnson
- D.** Good and Hatt

Ans:- D

92. " A tentative generalization" stated by

- A.** Good and Hatt
- B.** Lund berg
- C.** Emory
- D.** Orwell

Ans:- B

93. Propositions which describe the characteristics areHypothesis

- A.** Descriptive
- B.** Imaginative
- C.** Relational
- D.** Variable

Ans:- A

94. A Hypothesis which develops while planning the research is

- A.** Null Hypothesis
- B.** Working Hypothesis
- C.** Relational Hypothesis
- D.** Descriptive Hypothesis

Ans:- B

95. When a hypothesis is stated negatively it is called

- A.** Relational Hypothesis
- B.** Situational Hypothesis
- C.** Null Hypothesis
- D.** Casual Hypothesis

Ans:- C

96. The first variable is variable

- A.** Abstract
- B.** Dependent
- C.** Independent
- D.** Separate

Ans:- C

97. The second variable is called.....

- A.** Independent
- B.** Dependent
- C.** Separate
- D.** Abstract

Ans:- B

98. Hypothesis which explain relationship between two variables is

- A. Causal
- B. Relational
- C. Descriptive
- D. Tentative

Ans:- B

99. Null means

- A. One
- B. Many
- C. Zero
- D. None of these

Ans:- C

100 . Represent common sense ideas

- A. Statistical Hypothesis
- B. Complex Hypothesis
- C. Common sense Hypothesis
- D. Analytical Hypothesis

Ans:- C

101. Which one of the following is regarded as the very breath of an experiment?

- A. Independent Variable
- B. Dependent Variable
- C. Controlled Variable
- D. Experimental Control
- E. None of the above

Ans:- D

102. When large groups of interconnected facts are considered together in a consistent manner, we get a/an:

- A. Scientific theory
- B. Non-scientific theory
- C. Social theory
- D. Authentic theory
- E. None of the above

Ans:- A

103. Experimental method starts with some problems which have:

- A. No solution for a brief time span
- B. No adequate solution
- C. An immediate solution
- D. No hypothesis
- E. None of the above

Ans:- B

104. When we assign numbers to objects, events or mental phenomena, we obtain a:

- A.** Scale
- B.** Rule
- C.** Test
- D.** Measure
- E.** None of the above

Ans:- A

105. Interval Scales have:

- A.** Equal appearing units
- B.** No equal appearing units
- C.** No statistical value
- D.** No mathematical Design
- E.** None of the above

Ans:- A

106. We find a true zero in a/an:

- A.** Interval Scale
- B.** Ordinal Scale
- C.** Rating Scale
- D.** Ratio Scale
- E.** None of the above

Ans:- D

107. Method of rating or Method of successive categories is otherwise called as:

- A.** Interval Scale
- B.** Method of Introspection
- C.** Method of Observation
- D.** Method of graded dichotomies
- E.** None of the above

Ans:- D

108. The first rating scale was developed by:

- A.** Starch (1910)
- B.** Diggory (1953)
- C.** Ebbinghaus (1885)
- D.** Galton (1883)
- E.** J. B. Watson (1913)

Ans:- D

109. The method of ranking was formerly known as the method of:

- A.** Order of Merit
- B.** Order of Steps
- C.** Sequential Order
- D.** Constant Intervals
- E.** None of the above

Ans:- A

110. The method of 'paired comparison' was introduced by:

- A.** Watson
- B.** Galton
- C.** Cohn
- D.** Weber
- E.** Fechner

Ans:- C

111. While studying colour preferences, the method of 'paired' comparison' was introduced by Cohn in:

- A.** 1148 AD
- B.** 1481 AD
- C.** 1984 AD
- D.** 1894 AD
- E.** 1418 AD

Ans:- D

112. From the following, who is the first scientist to undertake systematic and statistical investigations of individual differences?

- A.** 1. P. Pavlov
- B.** C. E. Spearman
- C.** J. B. Watson
- D.** Francies Galton
- E.** William Mc Dougall

Ans:- D

113. The term "mental tests" was first employed by:

- A.** Spearman
- B.** Binet
- C.** James
- D.** Cattell
- E.** Mc Daugall

Ans:- A

114. According to P. T. Young, a comprehensive study of a social unit be that a person, a group, a social institution, a district or a community is called a:

- A.** Case study
- B.** Cultural study
- C.** Class study
- D.** Group Study
- E.** None of the above

Ans:- A

115. Ex-Post Facto Research is a systematic empirical enquiry in which the scientist does not have direct control of:

- A.** Independent Variables
- B.** Dependent Variables
- C.** Both Independent and Dependent Variables
- D.** Controlled Variables
- E.** None of the above

Ans:- A

116. A laboratory experiment is a research study in which the variance of all the possible influential independent variables not pertinent to the immediate problem of the investigations is kept at a:

- A.** Maximum
- B.** Constant level
- C.** Highest Point
- D.** Minimum
- E.** None of the above

Ans:- D

117. A research study in a realistic situation in which one or more independent variables are manipulated by the experimenter under as carefully controlled conditions as the situation permit is known as:

- A.** A field experiment
- B.** A situational experiment
- C.** A case study
- D.** Observational study
- E.** None of the above

Ans:- A

118. The variables in a field experiment operate more strongly than those used in:

- A.** Case study
- B.** Introspective method
- C.** Laboratory Experiment
- D.** Observational Method
- E.** None of the above

Ans:- C

119. The field experiments have the advantage of investigating more fruitfully the dynamics of interrelationships of:

- A.** Small groups of Variables
- B.** Large groups of Variables
- C.** Both small and large groups of Variables
- D.** Independent Variables
- E.** Dependent Variables

Ans:- A

120. Which type of research is approached through the methods of personal interviews, mailed questionnaires and personal discussions besides indirect oral investigation?

- A.** Case Study
- B.** Field Study
- C.** Survey Research
- D.** Observation
- E.** Experimentation

Ans:- C

121. Which type of research is a product of developmental programming that has been adopted on a very large scale in the recent years more practically particularly after Second World War when most of the Third World Countries emerged on the development scene?

- A.** Case Study
- B.** Survey Research
- C.** Experimentation
- D.** Evaluation Research
- E.** None of the above

Ans:- D

122. A research through launching of a direct action with the objective of obtaining workable solutions to the given problems is known as:

- A.** Action Research
- B.** Survey Research
- C.** Evaluation Research
- D.** Experimentation
- E.** None of the above

Ans:- A

123. A proposition which can be put to determine its validity is called:

- A.** Variable
- B.** Error
- C.** Hypothesis
- D.** Problem
- E.** None of the above

Ans:- C

124. The least noticeable value of a stimulus is called:

- A.** Stimulus Threshold
- B.** Response Threshold
- C.** Hypothesis
- D.** Problem
- E.** None of the above

Ans:- A

125. Which method is regarded as the most preferred method of psychology?

- A.** Observation
- B.** Introspection
- C.** Case Study
- D.** Experimental Method
- E.** Action Research

Ans:- D

126. "I bet this will happen if I do this" design of experimentation otherwise known as:

- A.** Exploratory Experimentation
- B.** Case Study
- C.** Hypothesis Testing
- D.** Survey Research
- E.** None of the above

Ans:- C

127. To ensure that the influence of all relevant variables is the same for all the subjects and does not change during the experimental period is the main objective of:

- A.** Experimental Error
- B.** Experimental Control
- C.** Experimental Variables
- D.** Hypothesis Testing
- E.** None of the above

Ans:- B

128. Field Study method is the method of:

- A.** Laboratory Observation
- B.** Situational Observation
- C.** Naturalistic Observation
- D.** Occasional Observation
- E.** None of the above

Ans:- C

129. In studying the public opinion:

- A.** Field Study method is applied
- B.** Action Research is applied
- C.** Survey Research is applied
- D.** Scaling method is applied
- E.** None of the above

Ans:- A

130. Which scale represents the lowest level of measurement and imparts the least information?

- A.** Nominal Scale
- B.** Ordinal Scale
- C.** Interval Scale
- D.** Ratio Scale
- E.** None of the above

Ans:- A

131. Which Scale has an absolute zero at the point of origin?

- A.** Ordinal Scale
- B.** Interval Scale
- C.** Nominal Scale
- D.** Ratio Scale
- E.** None of the above

Ans:- D

132. The method of selecting a portion of the universe with a view to drawing conclusion about the universe 'in toto' is known as:

- A.** Scaling
- B.** Leveling
- C.** Randomizing
- D.** Sampling
- E.** None of the above

Ans:- D

133. How many samples out of 100 samples drawn from a given population, the researcher wants, should represent the true population estimates is known as:

- A.** The confidence level
- B.** The sampling level
- C.** The situational level
- D.** The experimental level
- E.** None of the above

Ans:- A

134. The most common method of sampling in marketing researches and election polls is:

- A.** Random Sampling
- B.** Stratified Random Sampling
- C.** Quota Sampling
- D.** Proportionate Stratified Sampling
- E.** Cluster Sampling

Ans:- C

135. Itemized rating scales are otherwise known as:

- A.** Numerical Scales
- B.** Rank Order Scales
- C.** Graphic rating Scales
- D.** Comparative Scales
- E.** None of the above

Ans:- A

136. The men of medicine of the ancient as well as the modern tribal groups are masters in the techniques of:

- A.** Suggestion and Hypnosis
- B.** Experimentation
- C.** Introspection
- D.** Field Study
- E.** None of the above

Ans:- A

137. In India, the first psychological laboratory was started in the year 1916 in Calcutta University and the second in 1923 in Mysore University. Both these laboratories are the result of the endeavour of:

- A.** Prof. K. Kautilya
- B.** Prof. B. Sinha
- C.** Prof. B. N. Seal
- D.** Prof. R. N. Rath
- E.** None of the above

Ans:- C

138. In Observation Method, there is a tendency to read one's own thought and feeling into other's mind. This may be otherwise called:

- A.** Projection
- B.** Sublimation
- C.** Identification
- D.** Rationalization
- E.** None of the above

Ans:- A

139. In the field of sensation, psychologists can easily gather valuable information's by the help of:

- A.** Survey Method
- B.** Introspection Method
- C.** Experimentation
- D.** Clinical Method
- E.** None of the above

Ans:- B

140. When a person is becoming angry, if he starts observing and studying his state of mind simultaneously, he will not be able to show his anger. The moment he starts observing his own anger, it may subside. This problem can be partially solved by observing the experience after it is over. This is popularly known as:

- A.** Retrospection
- B.** Introjection
- C.** Projection
- D.** Identification
- E.** None of the above

Ans:- A

141. There are some people in the world who can move objects which are away from them without using any form of physical force. In psychology, this phenomenon is called:

- A.** Psychoanalysis
- B.** Telepathy
- C.** Precognition
- D.** Psychokinesis
- E.** Levitation

Ans:- D

142. The story of the Bible affirms that St. Peter walked on the surface of water. Among the Indian mystics, Padmapada, a disciple of Adi Sankar is reported to have walked across water, his steps being supported by lotus flowers. In psychology, this form of mysterious behaviour is popularly known as:

- A.** Levitation
- B.** Telepathy
- C.** Psychokinesis
- D.** Precognition
- E.** None of the above.

Ans:- A

143. Some people are able to know and predict events long before others can. This process is popularly known as:

- A.** Telepathy
- B.** Precognition

- C. Levitation
- D. Psychokinesis
- E. None of the above

Ans:- B

144. Some people in this world who are able to understand the thought processes of other individuals who are far away and perhaps even influence them without any form of contact. In psychology, this phenomenon is popularly known as:

- A. Telepathy
- B. Precognition
- C. Levitation
- D. Psychokinesis
- E. None of the above

Ans:- A

145. A recent development of "Applied Social Psychology" which is concerned with the application of psychology in solving the problems of particular communities of people like village community, the urban community and the socially backward community etc. is popularly known as:

- A. Community Psychology
- B. Group Psychology
- C. Educational Psychology
- D. Criminal Psychology
- E. None of the above

Ans:- A

146. Non-naturalistic observations on children may be contrived in a:

- A. Society
- B. Group
- C. Laboratory
- D. School
- E. None of the above

Ans:- C

147. Projective test is a:

- A. Non-naturalistic Observation
- B. Naturalistic Observation
- C. Self Observation
- D. Internal Observation
- E. None of the above

Ans:- A

148. The qualitative changes occurring in behavioural characteristics of the child leading towards maturity is otherwise known as:

- A.** Development
- B.** Growth
- C.** Maturation
- D.** Learning
- E.** Intelligence

Ans:- A

149. The earlier concepts of "Child Development" started with the:

- A.** Birth of the Child
- B.** Death of the Child
- C.** Conception
- D.** Phallic Stage
- E.** Second year of the Child

Ans:- A

150. The concept which refers to the consistency of scores obtained by the same persons when re-examined with the same test on different occasions is known as:

- A.** Validity
- B.** Reliability
- C.** Standard Error
- D.** Error Variance
- E.** None of the above

Ans:- B

151. Experimental Analysis enables us to discern lawful relationships between antecedents and consequents involved in:

- A.** Behaviour
- B.** Experience
- C.** Habit
- D.** Attitude
- E.** None of the above

Ans:- A

152. When large groups of interconnected facts are considered together in a consistent manner, we get a:

- A.** Scientific Theory
- B.** Critical Problem
- C.** Combined Result
- D.** Confirmed Fact
- E.** None of the above

Ans:- A

153. Suppose you have a glass of milk and with a measuring glass you continue to add half a c.c.

of plain tea at every step, till your friend reports a change in judgement in the colour of the milk. The quantity of tea added, has just crossed what is just termed as:

- A.** Illusion
- B.** Absolute Threshold
- C.** Colour Blindness
- D.** Just Noticeable Difference
- E.** None of the above

Ans:- B

154. Suppose one Experimenter (E) in psychology firmly believes that Brahmin children are inherently superior to the Harijan children. Naturally he would never think of home environment as an explanation. This is a very obvious example of:

- A.** Experimenter's Bias
- B.** Subject's Bias
- C.** Stimulus Error
- D.** Response Error
- E.** None of the above

Ans:- A

155. Which one of the following approaches tries to analyze human behaviour in terms of stimulus-response units acquired through the process of learning, mainly through instrumental conditioning?

- A.** Cognitive Approach
- B.** Dynamic and Psychoanalytic Approach
- C.** Stimulus-Response-Behaviouristic Approach
- D.** Existential Approach
- E.** Organismic, Wholistic and Self Approach

Ans:- C

156. The approach which has its roots in Gestalt Psychology is popularly known as:

- A.** Wholistic Approach
- B.** Stimulus-Response- Behaviouristic Approach
- C.** Dynamic and Psychoanalytic Approach
- D.** Cognitive Approach
- E.** None of the above

Ans:- D

157. Which approach emphasises the role of instinctual processes and their modification in the course of interaction with the society?

- A.** Dynamic and Psychoanalytic Approach
- B.** Cognitive Approach
- C.** Wholistic Approach
- D.** Stimulus-Response- Behaviouristic Approach
- E.** None of the above

Ans:- A

158. Which approach placed emphasis on human existence—the need to establish a sense of personal identity and to build meaningful links with the world?

- A.** Cognitive Approach
- B.** Dynamic and Psychoanalytic Approach
- C.** Wholistic Approach
- D.** Existential Approach
- E.** None of the above

Ans:- D

159. Existentialism tries to reach modern man, offer him help in terms of clarifying his values, work out a meaningful and purposive existence. Psychologists who shaped this approach were:

- A.** Rollo May, R. D. Laing and Erick Fromm
- B.** G. W. Allport, R. B. Catell and H.J. Eysenk
- C.** Erickson and Sullivan
- D.** Piaget, Bruner and Witkin
- E.** None of the above

Ans:- A

160. The system which still survives very nearly in its rigid forms is:

- A.** Cognitive Approach
- B.** Dynamic and Psychoanalytic Approach
- C.** Wholistic Approach
- D.** Existential Approach
- E.** None of the above

Ans:- B

161. Which approach tells us that under normal conditions the Organism is not a passive recipient of stimuli but an active, seeking and striving entity trying to master the environment and also master itself?

- A.** Organismic, Wholistic and Self Approaches
- B.** Dynamic and Psychoanalytic Approach
- C.** Cognitive Approach
- D.** Existential Approach
- E.** None of the Above

Ans:- A

162. Psychologists are sometimes interested to study consciousness even though they have no method of observing it directly except by using:

- A.** 'Inference' as the only tool
- B.** 'Experimentation' as the only tool
- C.** 'Observation' technique
- D.** 'Introspection' technique

E. None of the above

Ans:- A

163. The term “unconscious motivation” describes the key idea of:

A. Structuralism

B. Functionalism

C. Psychoanalysis

D. Behaviourism

E. None of the above

Ans:- C

164. The psychologists who are especially concerned with increasing the efficiency of learning in school by applying their psychological knowledge about learning and motivation to the curriculum are popularly known as :

A. Experimental Psychologists

B. Clinical Psychologists

C. Physiological Psychologists

D. Educational Psychologists

E. Social Psychologists

Ans:- D

165. In some developed countries like U.S A. and U.K. many psychologists are engaged for diagnosing learning difficulties and trying to remedy them. These psychologists are popularly called:

A. School Psychologists

B. Social Psychologists

C. Experimental Psychologists

D. Industrial Psychologists

E. Organisational Psychologists

Ans:- A

166. Today, private and public organizations also apply psychology to problems of management and employee training, to supervision of personnel, to improving communication within the organization, to counselling employees and to alleviating industrial strife. The applied psychologists who do this work are sometimes called:

A. Personnel Psychologists

B. Organizational Psychologists

C. Experimental Psychologists

D. Social Psychologists

E. None of the above

Ans:- A

167. A person who uses the particular psychotherapeutic techniques which originated with Sigmund Freud and his followers is called:

A. A psychoanalyst

- B.** A psychiatrist
- C.** A child psychologist
- D.** A clinical psychologist
- E.** None of the above

Ans:- A

168. Finding the causes of behaviour from a number of observations is called:

- A.** Inductive reasoning
- B.** Observational technique
- C.** Deductive reasoning
- D.** Introspection
- E.** None of the above

Ans:- A

169. The clinical method is ordinarily used only when people come to psychologists with:

- A.** Social problems
- B.** Personal Problems
- C.** Organizational problems
- D.** Internal problems
- E.** None of the above

Ans:- B

170. The technique of regulating various variables in an experiment is called:

- A.** Independent Variable
- B.** Dependent variable
- C.** Experimental control
- D.** Controlled variable
- E.** None of the above

Ans:- C

171. Psychologists with the Biological perspective try to relate behaviour to functions of:

- A.** Body
- B.** Mind
- C.** Soul
- D.** Unconscious
- E.** Subconscious

Ans:- A

172. A little girl Leny pushed Bapula, her brother, off his tricycle. She learned to behave this way because the behaviour paid off in the past, in other words, she learned to act aggressively in certain situations because she was rewarded for such behaviour in the past. With which perspective, a psychologist can study this type of problem?

- A.** Biological Perspective

- B.** Behavioural Perspective
- C.** Cognitive Perspective
- D.** Social Perspective
- E.** Developmental Perspective

Ans:- B

173. The perspective which is concerned with characteristic changes that occur in people as they mature is known as:

- A.** Developmental Perspective
- B.** Biological Perspective
- C.** Humanistic Perspective
- D.** Psychoanalytic Perspective
- E.** Cognitive Perspective

Ans:- A

174. A person's sense of self is emphasized by:

- A.** Psychoanalytic Perspective
- B.** Biological Perspective
- C.** Developmental Perspective
- D.** Cognitive Perspective
- E.** Humanistic Perspective

Ans:- E

175. A key psychodynamic idea is that when unconscious impulses are unacceptable or when they make us anxious; to reduce anxiety, we use:

- A.** Defense Mechanisms
- B.** Super ego
- C.** Instincts
- D.** Dreams
- E.** Frustration

Ans:- A

176. The distinction between a clinical psychologist and a psychiatrist is that:

- A.** A clinical psychologist normally holds a Ph.D. or M.A. degree or Psy.D. (Doctor in Psychology) and a psychiatrist holds an MD degree
- B.** A clinical psychologist holds a Ph.D. degree in Psychology and a psychiatrist holds both Psy. D. degree and Ph.D. degree
- C.** A clinical psychologist holds a special degree in Psychology and a psychiatrist holds a Ph.D. degree in Psychology
- D.** A clinical psychologist has a special training in psychotherapy and a psychiatrist holds M.A. degree in Psychology
- E.** A clinical psychologist holds an M.A. degree in Psychology and a psychiatrist holds Ph.D. degree in Psychology

Ans:- A

177. The Subject "Psychology" was formally recognised in Germany in the year:

- A. 1789
- B. 1668
- C. 1879
- D. 1897
- E. 1968

Ans:- C

178. To study Abnormal Psychology means, to study mainly the nature of:

- A. Conscious Mind
- B. Unconscious Mind
- C. Subconscious Mind
- D. Normal Mind
- E. Abnormal Mind

Ans:- B

179. Sigmund Freud is regarded as the father of:

- A. Psychoanalysis
- B. Behaviourism
- C. Functionalism
- D. Gestalt Psychology
- E. Stnicturalism

Ans:- A

180. The unit of Sociology is the 'Group', whereas the unit of Psychology is the:

- A. Stimulus
- B. Individual
- C. Animal
- D. Institution
- E. None of the above

Ans:- B

181. The branch of psychology which (teals with the study of animal behaviour is known as:

- A. Social Psychology
- B. Abnormal Psychology
- C. Differential Psychology
- D. Comparative Psychology
- E. None of the alxrve

Ans:- D

182. The father of 'Experimental Psychology' is:

- A. Wilhelm Wundt

- B.** Sigmund Freud
- C.** C.G. Jung
- D.** E. B. Titchener
- E.** William James

Ans:- A

183. For the first time, the word 'Psychology' was used by:

- A.** Rudolf Goeckle
- B.** Sigmund Freud
- C.** William James
- D.** E. B. Titchener
- E.** C.G. Jung

Ans:- A

184. The literal meaning of 'Psychology' is:

- A.** Science of Behaviour
- B.** Science of Soul
- C.** Science of Consciousness
- D.** Science of Mind
- E.** Science of Temperament

Ans:- B

185. Rudolf Goekle used the word 'Psychology' for the first time in:

- A.** 1590 AD
- B.** 1950 AD
- C.** 1095 AD
- D.** 1509 AD
- E.** 1905 AD

Ans:- A

186. Psychology as the 'Science of Mind' was defined by:

- A.** Psychoanalysis
- B.** Behaviourists
- C.** Functionalists
- D.** Ancient Greek Philosophers
- E.** None of the above

Ans:- D

187. Scientific Psychology came into existence during:

- A.** 19th Century
- B.** 20th Century
- C.** 18th Century
- D.** 17th Century

E. 15th Century

Ans:- A

188. E. B. Titchener (1867-1927) defined 'Psychology' as the science of:

A. Soul

B. Mind

C. Experience

D. Conscious Experience

E. Behaviour

Ans:- D

189. J. B. Watson defined 'Psychology' as the science:

A. Soul

B. Behaviour

C. Mind

D. Consciousness

E. Experience

Ans:- B

190. Psychology was defined as the "Science of Behaviour" by:

A. Functionalists

B. Structuralists

C. Gestalt Psychologists

D. Behaviourists

E. None of the above

Ans:- D

191. Who defined 'Psychology' as the scientific study of activities of the organism in relation to its environment?

A. J. B. Watson

B. Sigmund Freud

C. C. G. Jung

D. William James

E. Woodworth

Ans:- E

192. Any systematically organised body of verified knowledge about a certain class of facts and events is known as:

A. Science

B. Experiment

C. Hypothesis

D. Fact

E. Theory

Ans:- A

193. Psychology is:

- A.** A social Science
- B.** A Natural Science
- C.** A Biological Science
- D.** Both Natural and Social Science
- E.** None of the above

Ans:- A

194. Behaviouristic School was established by:

- A.** William James
- B.** W. Kohler
- C.** J.B. Watson
- D.** K. Koffka
- E.** I. P. Pavlov

Ans:- C

195. The most effective method of studying psychology is:

- A.** Experimental Method
- B.** Observation Method
- C.** Introspection Method
- D.** Survey Method
- E.** Clinical Method

Ans:- A

196. Anything which evokes a response in the Organism is called:

- A.** Stimulus
- B.** Thing
- C.** Situation
- D.** Incidence
- E.** None of the above

Ans:- A

197. A systematic study of facts according to a reliable and correct method of study is called a:

- A.** Biological Study
- B.** Social Technique
- C.** Scientific Study
- D.** Methodology
- E.** None of the above

Ans:- C

198. That, which cannot be observed by another person, is called:

- A. Experience
- B. Activity
- C. Action
- D. Exercise
- E. Event

Ans:- A

199. The first psychological laboratory was established in Leipzig by Wilhelm Wundt in the year:

- A. 1789
- B. 1879
- C. 189
- D. 1798
- E. 1897

Ans:- B

200. "S-R" concept was first established by:

- A. J. B. Watson
- B. Wilhelm Wundt
- C. William James
- D. C. G. Jung
- E. I. P. Pavlov

Ans:- A

201. Which of the following is not associated with use of the scientific method in psychological research? [TY2.1]

- A. A commitment to producing knowledge through observation and experiment.
- B. A commitment to basing knowledge exclusively on common sense and opinion.
- C. A commitment to basing knowledge on empirical evidence.
- D. A commitment to discovering truth.
- E. A commitment to ensuring that findings are correctly interpreted.

Answer: B

202. Which of the following contribute to the development of knowledge and theory in psychology? [TY2.2]

- A. Evidence that supports a hypothesis.
- B. Evidence that contradicts a hypothesis.
- C. Evidence that tests a hypothesis.
- D. All of the above.
- E. Answers (a) and (c) only.

Answer: D

203. Which of the following statements is true? [TY2.3]

- A. If a finding is reliable it should be easy to replicate using the same procedures.
- B. If a finding is reliable it will also be valid.

- C. If a finding is reliable it will be important.
- D. If a finding is reliable it must be an example of good scientific practice.
- E. If a finding is reliable it has been correctly interpreted.

Answer: A

204. After reading some research on the topic of students' attitudes to university courses, Mark does a study to find out what students' favourite subject at university is. In this he finds that final-year psychology students prefer studying psychology to any other subject. On this basis he concludes that psychology is the most popular subject. However, Jane argues that this conclusion is wrong as the research actually shows that students prefer the subject they end up studying. What is the basis of her objection to Mark's research? [TY2.7]

- A. The study is invalid.
- B. The study is unreliable.
- C. The study is non-cumulative.
- D. The study is unparsimonious.
- E. None of the above.

Answer: A

205. If an experimental finding is valid, which of the following statements is true?

- A. It should be easy to replicate
- B. It supports a researcher's experimental predictions
- C. It supports a researcher's theory
- D. It occurred for the reason hypothesised by the researcher
- E. It will make a demonstrable contribution to scientific knowledge

Answer: D

206. Which of the following would not be of interest to a behaviourist?

- A. A person's reaction to a flashing light.
- B. Differences in various people's responses to a flashing light.
- C. The cognitive processes associated with reaction to a stimulus.
- D. The impact of a particular stimulus on behaviour.
- E. The different behaviours that arise from exposure to different stimuli.

Answer: A

207. Which of the following is a physiological measure?

- A. A measure of blood flow through a person's brain.
- B. Details of a person's family tree.
- C. A person's response to questions on a survey.
- D. A person's response to questions in an experiment.
- E. The preference a person shows for one stimulus rather than another.

Answer: A

208. Theory A explains phenomenon L, phenomenon M and phenomenon N using principles J and K. Theory B explains phenomenon L, phenomenon M, and phenomenon N using only principle K. Theory C explains phenomenon L and phenomenon N using principles J and K. Which of the

following statements is true?

- A.** Theory A is the most parsimonious.
- B.** Theory B is the most parsimonious.
- C.** Theory C is the most parsimonious.
- D.** Theory A and Theory C are equally and most parsimonious.
- E.** Theory A and Theory B are equally and most parsimonious.

Answer: B

209. "An argument in which the thing to be explained is presented as the explanation (e.g. where memory ability is used to explain memory performance)." What type of argument is this a glossary definition of?

- A.** Conceptual argument
- B.** Convenient argument
- C.** Causal argument
- D.** Circular argument
- E.** Casual argument

Answer: D

210. "The goal of accounting for the maximum number of empirical findings in terms of the smallest number of theoretical principles." This a glossary definition of which principle?

- A.** Maximization.
- B.** Parsimony.
- C.** Reliability.
- D.** Validity.
- E.** External validity.

Answer: B

211. "Formally, a statement about the causal relationship between particular phenomena (i.e. in the form 'A causes B'). This is usually derived from a particular theory and designed to be tested in research." Which construct is this a glossary definition of?

- A.** Prediction.
- B.** Deduction.
- C.** Hypothesis.
- D.** Conventional reasoning.
- E.** Deductive reasoning.

Answer: C

212. "Treating an abstraction as if it were a real concrete thing. In psychology this refers to the process and outcome of treating an empirical finding as if it were the straightforward expression of an underlying psychological process (e.g. seeing performance on intelligence tests as the expression of intelligence)." This a glossary definition of which process?

- A.** Reification.
- B.** Refutation
- C.** Concretization.

- D. False consensus.
- E. Experimental artifice.

Answer: A

213. Which of the following statements is not true? [TY3.1]

- A. Psychological measurement can involve the measurement of phenomena believed to be related to a given psychological state or process.
- B. Psychological measurement can involve the measurement of behaviour believed to result from a given psychological state or process.
- C. Psychological measurement can involve self-reports of behaviour believed to be related to a given psychological state or process.
- D. Psychological measurement can involve the self-reports of a sample drawn from a particular sub-population.
- E. Psychological measurement can involve direct examination of psychological states and processes.

Answer: E

214. A researcher conducts an experiment that tests the hypothesis that 'anxiety has an adverse effect on students' exam performance'. Which of the following statements is true? [TY3.2]

- A. Anxiety is the dependent variable, exam performance is the independent variable.
- B. Anxiety is the dependent variable, students are the independent variable.
- C. Anxiety is the independent variable, students are the dependent variable.
- D. Anxiety is the independent variable, exam performance is the dependent variable.
- E. Students are the dependent variable, exam performance is the independent variable.

Answer: D

215. An experimenter conducts a study in which she wants to look at the effects of altitude on psychological well-being. To do this she randomly allocates people to two groups and takes one group up in a plane to a height of 1000 metres and leaves the other group in the airport terminal as a control group. When the plane is in the air she seeks to establish the psychological well-being of both groups. Which of the following is a potential confound, threatening the internal validity of the study? [TY3.3]

- A. The reliability of the questionnaire that she uses to establish psychological health.
- B. The size of the space in which the participants are confined.
- C. The susceptibility of the experimental group to altitude sickness.
- D. The susceptibility of the control group to altitude sickness.
- E. The age of people in experimental and control groups.

Answer: B

216. What distinguishes the experimental method from the quasi-experimental method? [TY3.4]

- A. The scientific status of the research.
- B. The existence of an independent variable.
- C. The existence of different levels of an independent variable.
- D. The sensitivity of the dependent variable.

E. The random assignment of participants to conditions.

Answer: E

217. Which of the following is not an advantage of the survey/correlational method? [TY3.5]

- A.** It allows researchers to examine a number of different variables at the same time.
- B.** It allows researchers to examine the relationship between variables in natural settings.
- C.** It allows researchers to make predictions based on observed relationships between variables.
- D.** It allows researchers to explain observed relationships between variables.
- E.** It is often more convenient than experimental methods.

Answer: D

218. Which of the following statements is true? [TY3.6]

- A.** Case studies have played no role in the development of psychological theory.
- B.** Case studies have all of the weaknesses and none of the strengths of larger studies.
- C.** Case studies have none of the weaknesses and all of the strengths of larger studies.
- D.** Case studies should only be conducted if every other option has been ruled out.
- E.** None of the above.

Answer: E

219. An experimenter, Tom, conducts an experiment to see whether accuracy of responding and reaction time are affected by consumption of alcohol. To do this, Tom conducts a study in which students at university A react to pairs of symbols by saying 'same' or 'different' after consuming two glasses of water and students at university B react to pairs of symbols by saying 'same' or 'different' after consuming two glasses of wine. Tom predicts that reaction times will be slower and that there will be more errors in the responses of students who have consumed alcohol. Which of the following statements is not true? [TY3.7]

- A.** The university attended by participants is a confound.
- B.** The experiment has two dependent variables.
- C.** Reaction time is the independent variable.
- D.** Tom's ability to draw firm conclusions about the impact of alcohol on reaction time would be improved by assigning participants randomly to experimental conditions.
- E.** This study is actually a quasi- experiment.

Answer: C

220. What is an extraneous variable? [TY3.8]

- A.** A variable that can never be manipulated.
- B.** A variable that can never be controlled.
- C.** A variable that can never be measured.
- D.** A variable that clouds the interpretation of results.
- E.** None of the above.

Answer: D

221. Which of the following statements is true? [TY3.9]

- A.** The appropriateness of any research method is always determined by the research question and

the research environment.

- B.** Good experiments all involve a large number of participants.
- C.** Experiments should be conducted in laboratories in order to improve experimental control.
- D.** Surveys have no place in good psychological research.
- E.** Case studies are usually carried out when researchers are too lazy to find enough participants.

Answer: A

222. A piece of research that is conducted in a natural (non- artificial) setting is called: [TY3.10]

- A.** A case study.
- B.** A field study.
- C.** A quasi-experiment.
- D.** A survey.
- E.** An observational study.

Answer: B

223. “Measures designed to gain insight into particular psychological states or processes that involve recording performance on particular activities or tasks.” What type of measures does this glossary entry describe?

- A.** State measures.
- B.** Behavioural measures.
- C.** Physiological measures.
- D.** Activity measures.
- E.** Performance measures.

Answer: B

224. “An approach to psychology that asserts that human behaviour can be understood in terms of directly observable relationships (in particular, between a stimulus and a response) without having to refer to underlying mental states.” Which approach to psychology is this a glossary definition of?

- A.** Behaviourism.
- B.** Freudianism.
- C.** Cognitivism.
- D.** Radical observationism.
- E.** Marxism.

Answer: A

225. “The complete set of events, people or things that a researcher is interested in and from which any sample is taken.” What does this glossary entry define?

- A.** Total sample.
- B.** Complete sample.
- C.** Reference sample.
- D.** Reference group.
- E.** Population.

Answer: E

226. “Either the process of reaching conclusions about the effect of one variable on another, or the outcome of such a process.” What does this glossary entry define?

- A.** Causal inference.
- B.** Induction.
- C.** Deduction.
- D.** Inductive reasoning.
- E.** Inferential accounting.

Answer: A

227. “The extent to which the effect of an independent variable on a dependent variable has been correctly interpreted.” Which construct is this a glossary definition of?

- A.** Internal inference.
- B.** External inference.
- C.** External validity.
- D.** Holistic deduction.
- E.** Internal validity.

Answer: E

228. What is a manipulation check and what is its purpose? [TY4.1]

- A.** A dependent measure used to check that manipulation of an independent variable has been successful.
- B.** An independent variable used to check that measurement of a dependent variable has been successful.
- C.** A measure used to check that an experiment has an independent variable.
- D.** An independent measure used to check that the operationalization is relevant.
- E.** A dependent measure used to check that an independent variable is sufficiently relevant.

Answer: A

229. Which of the following statements is true? [TY4.2]

- A.** Dependent variables that do not measure the most relevant theoretical variable are pointless.
- B.** A study that employs dependent variables that are sensitive enough to detect variation in the independent variable is a quasi-experiment.
- C.** Unless dependent variables are sufficiently sensitive they will not reveal the effects of manipulating an independent variable.
- D.** Unless dependent variables are sufficiently relevant they will not reveal the effects of manipulating an independent variable.
- E.** None of the above.

Answer: C

230. A team of researchers is interested in conducting an experiment in order to test an important theory. In order to draw appropriate conclusions from any experiment they conduct, which of the following statements is true? [TY4.3]

- A.** The experimental sample must be representative of the population to which they want to

generalize the research on dimensions of age, sex and intelligence.

- B.** The experimental sample must be representative of the population to which they want to generalize the research on all dimensions.
- C.** The experimental sample must be representative of the population to which they want to generalize the research on all dimensions that can be measured in that population.
- D.** The experimental sample must be representative of the population to which they want to generalize the research on all dimensions relevant to the process being studied.
- E.** None of the above.

Answer: D

231. An experimenter conducts a study examining the effects of television violence on children's aggressiveness. To do this she asks 40 schoolboys who display normal levels of aggressiveness to watch one violent video a week for 40 weeks. On a standard measure of aggressiveness, which she administers both before and after each video over the 40-week treatment, she finds that the boys are much more aggressive in the last 10 weeks of the study. Without knowing anything more about this study, which of the following can be ruled out as a threat to the internal validity of any conclusions she may seek to draw? [TY4.4]

- A.** History effects.
- B.** Maturation effects.
- C.** Mortality effects.
- D.** Regression to the mean.
- E.** Testing effects.

Answer: D

232. Which of the following can increase a researcher's ability to generalize findings from a particular piece of research? [TY4.5]

- A.** Cheating.
- B.** Experimenter bias.
- C.** Deception and concealment.
- D.** Participants' sensitivity to demand characteristics.
- E.** The use of unrepresentative samples.

Answer: C

233. A researcher conducts an experiment to investigate the effects of positive mood on memory. Mood is manipulated by giving participants a gift. In the experiment, before they are given a memory test, half of the participants are randomly assigned to a condition in which they are given a box of chocolates, and the other half are given nothing. Which of the following statements is not true? [TY4.6]

- A.** Mood is a between-subjects variable.
- B.** The experiment has two conditions.
- C.** The experiment includes a control condition.
- D.** The independent variable is manipulated within subjects.
- E.** Experimental control eliminates potential threats to the internal validity of the experiment.

Answer: D

234. Which of the following is a researcher's overall objective in using matching? [TY4.7]

- A.** To control for extraneous variables in quasi- experimental designs.
- B.** To increase participants' enjoyment of correlational research.
- C.** To ensure that participants are randomly assigned to conditions.
- D.** To ensure that groups of participants do not differ in age and sex.
- E.** To ensure that groups of participants do not differ in intelligence.

Answer: A

235. Which of the following threats to validity is the most difficult to control by improving experimental design? [TY4.8]

- A.** Maturation effects.
- B.** Cheating by experimenters.
- C.** History effects.
- D.** Sensitivity to demand characteristics.
- E.** Experimenter bias.

Answer: B

236. Some researchers decided to conduct an experiment to investigate the effects of a new psychological therapy on people's self-esteem. To do this they asked all their clients who were currently receiving treatment for low self- esteem to continue using an old therapy but treated all their new clients with the new therapy. A year later they found that clients subjected to the new therapy had much higher self-esteem. Which of the following statements is true? [TY4.9]

- A.** The greater self-esteem of the clients exposed to the new therapy resulted from the superiority of that therapy.
- B.** The greater self-esteem of the clients exposed to the new therapy resulted from the fact that the new clients were more optimistic than those who were previously receiving treatment.
- C.** The greater self-esteem of the clients exposed to the new therapy resulted from the fact that the new clients were less disillusioned with therapy than those who were previously receiving treatment.
- D.** The greater self-esteem of the clients exposed to the new therapy resulted from the fact that the new clients were more intelligent than those who were previously receiving treatment.
- E.** It is impossible to establish the validity of any of the above statements based on the results of this study.

Answer: E

237. An experimenter conducts an experiment to see whether people's reaction time is affected by their consumption of alcohol. To do this, she conducts a study in which students from University A describe symbols as 'red' 'green' or 'blue' before they consume two glasses of wine and students from University B describe symbols as 'red' 'green' or 'blue' after they consume two glasses of wine. She hypothesizes that reaction times will be slower and that there will be more errors in the responses of students who consume alcohol before reacting to the symbols.

Which of the following statements is false?

- A.** It is appropriate to analyse the results using independent sample t-tests

- B.** Type of University is a potential experimental confound
- C.** The experiment has two dependent variables
- D.** The experiment has three independent variables
- E.** The experiment has a between-subjects design.

Answer: D

238. “Both (a) the process of constructing experiments and (b) the resulting structure of those experiments.” What research feature is this a glossary definition of?

- A.** Experimental design.
- B.** Constructive design.
- C.** Experimental structuration.
- D.** Solidification.
- E.** Experimental procedure.

Answer: A

239. “A system for deciding how to arrange objects or events in a progressive series. These are used to assign relative magnitude to psychological and behavioural phenomena (e.g. intelligence or political attitudes).” What is this a glossary definition of?

- A.** A scale.
- B.** A measure.
- C.** A measurement.
- D.** A callibration.
- E.** A test.

Answer: A

240. “The principle that the more relevant a dependent variable is to the issue in which a researcher is interested, the less sensitive it may be to variation in the independent variable.” What is this a glossary definition of?

- A.** Systematic desensitization.
- B.** Random variation.
- C.** Meaurement error.
- D.** Relevance–sensitivity trade- off.
- E.** Inferential uncertainty.

Answer: D

241. “The extent to which a research finding can be generalized to other situations.” What is this a glossary definition of?

- A.** External validity
- B.** Generalization.
- C.** Induction.
- D.** Extendability.
- E.** Empirical applicability.

Answer: A

242. “Systematic change to an independent variable where the same participants are exposed to different levels of that variable by the experimenter.” What procedure is this a glossary definition of?

- A.** Random assignment.
- B.** Within-subjects manipulation.
- C.** Between-subjects manipulation.
- D.** Variable assignment.
- E.** Experimenter manipulation.

Answer: B

243. Surveys are preferred in some areas of psychology for which of the following reasons? [TY5.1]

- A.** They are usually cheaper.
- B.** They allow researchers to infer causal relationships.
- C.** They are more scientific because similar methods are used in astronomy and geology.
- D.** It is often impossible to manipulate the independent variables the researchers are interested in.
- E.** They use randomization to achieve random sampling.

Answer: D

244. A television news programme shows a murder case including video footage of the grieving parents of the victim. The television station then conducts an opinion poll in which it asks viewers to phone in and vote for or against the death penalty for murder. The results of the survey show that 83% of the 20,000 viewers who ring in are in favour of the death penalty. Which of the following statements is true? [TY5.2]

- A.** The results of this study can only be generalized to people who watch news programmes.
- B.** The results of this study can only be generalized to people who own a television.
- C.** The results of this study can only be generalized to people who care about the death penalty.
- D.** The results of this study can only be generalized when we know much more about the sampling method.
- E.** The results of this study can only be generalized if the bias created by showing the grieving parents is eliminated.

Answer: D

245. Which of the following can be a threat to the internal validity of longitudinal studies? [TY5.3]

- A.** Testing effects.
- B.** The IQ of the participants.
- C.** Sample size.
- D.** Maturation effects.
- E.** Both (a) and (d).

Answer: E

246. Which of the following statements is true? [TY5.4]

- A.** Questionnaires should not ask people to provide personal information.
- B.** Questionnaires should aim to obtain as much information from people as possible.

- C.** The order of items in a questionnaire is not particularly important.
- D.** Questionnaires should contain a mixture of open-ended and forced-choice items.
- E.** None of the above.

Answer: E

247. In a survey where the results are obtained from a representative random sample of a population, which of the following is true? [TY5.5]

- A.** The results can be generalized to that population.
- B.** The sample can only be obtained by simple random sampling.
- C.** The sampling procedure is similar to that used in most experimental research.
- D.** Both (a) and (b).
- E.** None of the above.

Answer: A

248. Which of the following statements about convenience sampling is true? [TY5.6]

- A.** It should always be avoided.
- B.** It is appropriate providing the sample size is extremely large.
- C.** It can be used under some circumstances.
- D.** It is a non-probability sampling technique.
- E.** Both (c) and (d).

Answer: E

249. Which of the following is likely to be a problem for non-reactive studies that use non-obtrusive measures? [TY5.7]

- A.** Social desirability effects.
- B.** Defining the probability of maturation for each member of the population.
- C.** Appropriate operationalization of variables.
- D.** Behavioural traces.
- E.** Both (c) and (d).

Answer: C

250. A team of researchers conducts a study in which they ask boys and girls from a local high school to complete a battery of psychological tests that investigate their social skills and levels of sociability. Ten years later they ask boys and girls from the same school to perform the same tests. Which of the following statements is false? [TY5.8]

- A.** The study has a successive cross-sectional design.
- B.** The research is invalid because developmental studies should not include psychological tests.
- C.** Testing effects are eliminated by using a between-subjects design.
- D.** Mortality effects are eliminated by using a between-subjects design.
- E.** Maturation effects are eliminated by using a between-subjects design.

Answer: B

251. Which of the following statements is most correct?

- A.** The use of unobtrusive measures in surveys helps deal with reactivity.
- B.** The use of unobtrusive measures in surveys helps deal with standardization.
- C.** The use of unobtrusive measures in surveys helps deal with social desirability.
- D.** The use of unobtrusive measures in surveys helps deal with reactivity and social desirability.
- E.** The use of unobtrusive measures in surveys helps deal with reactivity, standardization and social desirability.

Answer: D

252. A researcher conducts a research project in which she surveys all the members of her local golf club. This is most likely to be an example of which of the following?

- A.** Purposive sampling.
- B.** Random sampling.
- C.** Simple random sampling.
- D.** Split ballot sampling.
- E.** None of the above.

Answer: A

253. “The extent to which people’s behaviour appears acceptable to other people. If behaviour is affected by people trying to behave in ways that they perceive to be desirable to the researcher then this threatens both the internal and external validity of research.” What construct does this glossary entry define?

- A.** Social desirability.
- B.** Self-presentation.
- C.** Deception.
- D.** Experimenter bias.
- E.** Participant bias.

Answer: A

254. “A listing of all members of the population of interest.” What is this a glossary definition of?

- A.** A sample brochure.
- B.** A population directory.
- C.** A sampling directory.
- D.** A sampling frame.
- E.** A full sample specification.

Answer: D

255. “A preliminary piece of research designed to ‘road-test’ various design elements (e.g. independent variables, dependent variables, details of procedure), in order to establish their viability and utility prior to the investment of time and money in a full study.” What type of study does this glossary entry define?

- A.** A sampling study.
- B.** A replication study.
- C.** A pre-test.

- D. A pilot study.
- E. A viability study.

Answer: D

256. "Studies where the same sample of participants is measured on more than one occasion." What type of study is this a glossary definition of?

- A. Longitudinal surveys
- B. Carry-over surveys
- C. Repeated-measures surveys
- D. Cohort surveys
- E. Population censuses

Answer: A

257. "Questionnaire items where a respondent has to select one response from two or more options." What type of response is this a glossary definition of?

- A. Selective response.
- B. Forced-choice response.
- C. Free response.
- D. Likert-scale response.
- E. Double-barrelled response.

Answer: B

258. A researcher conducts an experiment in which she assigns participants to one of two groups and exposes the two groups to different doses of a particular drug. She then gets the participants to learn a list of 20 words and two days later sees how many they can recall. In the experiment the dependent measure is simply the number of words recalled by each participant. What type of dependent measure is this? [TY6.1]

- A. Nominal.
- B. Ordinal.
- C. Interval.
- D. Ratio.
- E. None of the above.

Answer: D

259. A researcher conducts a study to find out how many times people had visited a doctor in the previous year. Five people participated in the study and the numbers of visits they had made were 2, 5, 7, 4 and 2. Which of the following statements is true? [TY6.2]

- A. The mean number of visits is 2.
- B. The median number of visits is 2.
- C. The median number of visits is 4.
- D. The modal number of visits is 4.
- E. The modal number of visits is 7.

Answer: C

260. Which of the following statements is most likely to be true if the distribution of a variable is severely skewed? [TY6.3]

- A.** The mean will be the best measure of central tendency.
- B.** The median will be as misleading as the mean.
- C.** The mode will no longer be the most common response.
- D.** The median will be the best measure of central tendency.
- E.** The mode will be the best measure of central tendency.

Answer: D

261. If X is a variable, which of the following is not measured in the same units as X ? [TY6.4]

- A.** The mean of X .
- B.** The range of X .
- C.** The standard deviation of X .
- D.** The variance of X .
- E.** The difference between minimum and maximum values of X .

Answer: D

262. If scores on a variable are normally distributed, which of the following statements is false?

- A.** All scores on the variable will have been observed with equal frequency.
- B.** The distribution of scores is symmetrical about the mean.
- C.** Similar distributions are commonly observed in data obtained from psychological research.
- D.** There will be relatively few extreme scores.
- E.** The mean, median and modal scores will be equal.

Answer: A

263. Which of the following is not a measure of central tendency?

- A.** The mean of a distribution.
- B.** The mean squared deviation of some data.
- C.** The modal value of a set of values.
- D.** The median response on a scale.
- E.** An average score.

Answer: B

264. The shaded bars in the histogram below represent the times (rounded to the nearest 10 milliseconds) that 50 people take to react to a loud noise. Which of the following statements is not true?

- A.** The distribution of reaction times is negatively skewed.
- B.** The modal reaction time is 240 ms.
- C.** The median reaction time is greater than 240 ms.
- D.** The mean reaction time will be greater than the modal reaction time.
- E.** The mean is an ambiguous measure of central tendency.

Answer: A

265. 'Root mean squared deviate' could be used as another name for which measure of dispersion?

- A.** Range.
- B.** Skewness
- C.** Variance.
- D.** Standard deviation.
- E.** Squared deviation from the root.

Answer: D

266. A researcher measures a variable whose distribution she observes to be normally distributed. On this basis which of the following statements is most likely to be true?

- A.** The distribution's mean will be greater than its median and mode.
- B.** The distribution's median will be greater than its mean and mode.
- C.** The distribution's mean will be similar to its median and mode.
- D.** The distribution's mean will be less than its median and mode.
- E.** The distribution's mean will be greater than its median but less than its mode.

Answer: C

267. Which of the following is a measure of central tendency?

- A.** The variance in scores obtained on a dependent measure.
- B.** The mean deviation of some data.
- C.** Standard deviation.
- D.** The range of a set of values.
- E.** None of the above.

Answer: E

268. The SPSS output below is from a study in which the scores for the variable "Survey_Point" could vary between 0 and 30. Looking at the distribution of frequencies, which of the following statements is true?

- A.** The distribution of scores is positively skewed.
- B.** The distribution of scores is negatively skewed.
- C.** There is a uniform distribution of scores.
- D.** The data have a bimodal distribution.
- E.** None of the above.

Answer: B

269. The SPSS output below is from a study in which the scores for the variable "Survey_Point" could vary between 0 and 30. Looking at the distribution of frequencies, which of the following statements is true?

- A.** The mean will be higher than the mode.
- B.** The mode will be higher than the mean.
- C.** The mean will be the same as the mode.
- D.** The median will be lower than the mean.
- E.** The median will be higher than the mode.

Answer: B

270. "A variable that can be treated as if there were no breaks or steps between its different levels (e.g., reaction time in milliseconds)." What type of variable is this a glossary definition of?

- A. A logical variable.
- B. A discrete variable.
- C. A scale variable.
- D. A continuous variable.
- E. A measurement variable.

Answer: D

271. "A measure reflecting distinct categories that have different names but the categories are not numerically related to one another." What type of measure is this a glossary definition of?

- A. An ordinal measure.
- B. A nominal measure.
- C. A scale measure.
- D. A desperate measure.
- E. A ratio measure.

Answer: B

272. "The spread of scores across levels of a variable." What is this a glossary definition of?

- A. Distribution.
- B. Range.
- C. Variance.
- D. Covariance.
- E. Standard deviation.

Answer: A

273. "Scores that are very different from the typical value for a distribution. Because they are very different from the central tendency of a distribution they contribute a great deal to the amount of dispersion in the distribution." What does this glossary entry define?

- A. Deviates.
- B. Mean deviates.
- C. Outliers
- D. Non-respondents.
- E. Missing data.

Answer: C

274. Which of the following statements is/are true about the t- distribution? [TY8.1]

- A. Its shape changes with the number of degrees of freedom.
- B. Its expected value is 0.
- C. It can be used to test differences between means providing that the population standard deviation is known.

- D. Both (a) and (b).
- E. All of the above.

Answer: D

275. The mean height of a sample of 100 men in 2014 is 180 cm, with a standard deviation of 10 cm. The mean for the same population in 1914 was 170 cm. Imagine that we want to use the 2014 sample to test whether the height of the population has changed over the intervening 100 years. Which of the following statements is true? [TY8.2]

- A. The number of degrees of freedom for the test in this case is 99.
- B. The t-value is 10.0.
- C. The t-value corresponds to a very small probability that a random process of taking samples of 100 men from a population similar to the 1914 population would produce a sample of 180 cm or taller.
- D. All of the above.
- E. Answers (a) and (b) only.

Answer: D

276. Which of the following is not relevant to a between- subjects t-test? [TY8.3]

- A. The pooled variance estimate.
- B. A difference score D .
- C. An information term.
- D. A sampling distribution of the differences between means.
- E. A probability that a difference of the same size or larger could be obtained by a random process.

Answer: B

277. If an experimenter conducts a t- test to see whether the responses of participants in a control group differ from those of an experimental group, which of the following outcomes will yield the highest t- value? [TY8.4]

- A. If there are 10 participants in each condition and the difference between the mean responses of the control group and the experimental group is 2 and both have standard deviations of 1.
- B. If there are 10 participants in each condition and the difference between the mean responses of the control group and the experimental group is 2 and both have standard deviations of 2.
- C. If there are 20 participants in each condition and the difference between the mean responses of the control group and the experimental group is 1 and both have standard deviations of 1.
- D. If there are 20 participants in each condition and the difference between the mean responses of the control group and the experimental group is 2 and both have standard deviations of 1.
- E. If there are 20 participants in each condition and the difference between the mean responses of the control group and the experimental group is 2 and both have standard deviations of 2.

Answer: D

278. Which of the following must be true of a statistically significant result of a t-test? [TY8.5]

- A. The probability that a difference at least as large as the observed difference could be produced by a particular random process will be less than the alpha level.
- B. The obtained value of t will exceed the alpha level.

- C. The rejection regions must be significantly different from each other.
- D. Both (a) and (c).
- E. Alpha must be set at .05.

Answer: A

279. Researchers conduct a t-test and obtain a p-value of .0012. Which of the following is an appropriate conclusion on the basis of the information provided? [TY8.6]

- A. The result is significant.
- B. The effect size will be large.
- C. Both (a) and (b).
- D. A 99% confidence interval for the differences between the means will include the observed difference.
- E. A 95% confidence interval for the differences between the means will not include the observed difference.

Answer: E

280. Researchers conduct a t-test to compare two groups and find that one of the groups has a much larger standard deviation than the other. Which of the following statements is true? [TY8.7]

- A. The variances are robust.
- B. The assumption of equal variance may have been violated.
- C. The researchers should make sure that their distributions are free of parameters.
- D. The standard deviations are not normal.
- E. Both (b) and (d).

Answer: B

281. If an experimenter were to conduct an experiment in which participants were randomly assigned to either a control condition or an experimental condition, which of the following statements would be true? [TY8.8]

- A. It will be appropriate to analyse results using a between-subjects t-test.
- B. Any statistical analysis will be based on pairs of responses.
- C. If a t-test is performed to analyse the results, it will have $n - 1$ degrees of freedom.
- D. The experiment involves two related samples.
- E. Both (a) and (c).

Answer: A

282. John, a second-year psychology student, is using the hypothesis- testing approach and an alpha level of .05 to examine a difference between two means. He discovers that this difference is associated with a t-value of 3.46. If the critical t- value with $\alpha = .05$ is 2.056 what should he conclude? [TY8.9]

- A. That the difference between the means is statistically significant.
- B. That the alpha level is too high.
- C. That the alpha level is not high enough.
- D. That the experiment did not contain enough participants to draw a strong conclusion.
- E. That no conclusion can be made about the nature of the underlying populations.

Answer: A

283. Which of the following suggests that the assumptions underlying a between-subjects t-test have been violated? [TY8.10]

- A.** Evidence that the dependent variable is normally distributed.
- B.** Evidence that the samples being compared have unequal variances.
- C.** Evidence that the manipulation of the independent variable had no effect.
- D.** Evidence that sampling was random, and that scores were independent.
- E.** None of the above.

Answer: B

284. Which of the following increases the likelihood of a Type II error when conducting a t-test? [TY8.11]

- A.** A high alpha level.
- B.** A large sample size.
- C.** High power.
- D.** Low random error.
- E.** A small difference between means.

Answer: E

285. An experimenter conducts an experiment using a control group containing 8 subjects and an experimental group containing 8 subjects. How many degrees of freedom are there in this experimental design?

- A.** 7
- B.** 8
- C.** 14
- D.** 15
- E.** 16

Answer: C

286. The graph below was generated by SPSS and plots participants' scores on the variable "Survey_Point" which can vary between 0 and 30. Looking at this graph, what might make these data inappropriate to analyse using a t- test

- A.** The assumption of independence is violated.
- B.** The assumption of normality is violated.
- C.** The assumption of equal variance is violated.
- D.** Both (a) and (b).
- E.** Both (b) and (c).

Answer: B

287. "The probability, as revealed by a statistical test, that a random process (involving taking random samples of a particular size from a particular population) could produce some outcome." What is this a glossary definition of?

- A.** Random error

- B. Sampling error
- C. The random value
- D. The p-value
- E. The q-value

Answer: D

288. “An outcome where the probability that an effect at least as large as that observed could be produced by a random process is less than a predetermined alpha level. This means that it is implausible that a random process could have produced the effect.”

Which construct is this a glossary definition of?

- A. Statistical significance.
- B. Power.
- C. Type I error.
- D. Type II error .
- E. Random error.

Answer: A

289. “The mistaken idea that random events are not independent. A gambler may believe that a long run of good or bad luck has to change. The gambler’s fallacy arises from a misunderstanding of the law of large numbers. The idea that a random process will behave in a predictable way on average over a long run of observations can be misunderstood to imply that there is ‘a law of averages’ that serves to change the probability of random events based on past events.

However, coins, dice and other things that generate random outcomes do not have memories.” What type of fallacy is this a glossary definition of?

- A. The significance fallacy.
- B. The gambler’s fallacy.
- C. The causal fallacy.
- D. The operational fallacy.
- E. The psychological fallacy.

Answer: B

290. Which of the following statements is true? [TY9.1

- A. A negative correlation is the same as no correlation.
- B. Scatterplots are a very poor way to show correlations.
- C. If the points on a scatterplot are close to a straight line there will be a positive correlation.
- D. Negative correlations are of no use for predictive purposes.
- E. None of the above.

Answer: E

291. If a calculation of Pearson’s r yields a value of $-.96$, which of the following statements is false? [TY9.2]

- A. The observed correlation between variables is negative.
- B. There is a small amount of negative covariance between variables relative to random error.
- C. A high score on one variable is associated with a low score on the other.

- D. This correlation is useful for predictive purposes.
- E. Points on a scatterplot would resemble a straight line.

Answer: B

292. As part of a psychology assignment Kate has to calculate Pearson's r to measure the strength of association between two variables. She finds that $r = -.2$ and that this is significant at her selected alpha level of .05. What should she conclude? [TY9.3]

- A. That there is a significant but small relationship between the two variables.
- B. That there is a non-significant but large relationship between the variables.
- C. That there is a significant and moderate relationship between the variables.
- D. That the two variables are unrelated.
- E. That variation in one variable is associated with most of the variation in the other.

Answer: A

293. The correlational fallacy refers to which of the following? [TY9.4]

- A. The idea that a correlation can be statistically significant without being psychologically meaningful.
- B. The idea that a strong correlation between variables does not mean that one predicts the other.
- C. The idea that a correlation between variables does not mean that one variable is responsible for variation in the other.
- D. The idea that correlation does not justify prediction.
- E. Both (a) and (c)

Answer: C

294. "Effects which reflect the impact of one independent variable averaged across all levels of other independent variables, rather than the impact of an interaction between two or more independent variables." What is this a glossary definition of?

- A. Main effects.
- B. Average effects.
- C. Significant effects.
- D. Non-interaction effects.
- E. Isolation effects.

Answer: A

295. A group of researchers conducts some research in which they identify a significant positive correlation ($r = .42$) between the number of children people have and their life satisfaction. Which of the following is it inappropriate to conclude from this research? [TY9.5]

- A. That having children makes people more satisfied with their life.
- B. That someone who has children is likely to be happier than someone who does not.
- C. That the causes of life satisfaction are unclear.
- D. That the consequences of having children are unclear.
- E. That it is possible to predict someone's life happiness partly on the basis of the
- F. number of children they have.

Answer: A

296. Which of the following statements is true of the problem of restricted range? [TY9.6]

- A.** Restricted range can reduce the size of correlations.
- B.** Restricted range can lead to a violation of the assumption of bivariate normality.
- C.** Restricted range can produce regression to the mean.
- D.** All of the above.
- E.** Answers (a) and (b) only.

Answer: D

297. If an experimenter observes a correlation of -1 between two variables, which of the following is false? [TY9.7]

- A.** One variable is completely predictive of the other.
- B.** One variable is completely responsible for variation in the other. a. Knowledge of the value of one variable allows one to know with certainty the value of the other.
- C.** A higher score on one variable is associated with a lower score on the other.
- D.** All the variation in one variable is associated with variation in the other.

Answer: B

298. If the correlation between people's wealth and a measure of their psychological well-being is $.40$, how much of the variation in their scores on the well-being measure will be associated with variation in their wealth? [TY9.8]

- A.** 60%
- B.** 40%
- C.** 16%
- D.** 4%
- E.** It is impossible to say without information about how psychological well-being is defined.

Answer: C

299. A researcher conducts some research in which they identify a significant positive correlation ($r = .42$) between the number of children a person has and their life satisfaction. Which of the following is it inappropriate to conclude from this research?

- A.** That having children makes people more satisfied with their life.
- B.** That someone who has children is likely to be more happy than someone who doesn't.
- C.** That the causes of life satisfaction are unclear.
- D.** That the consequences of having children are unclear.
- E.** That it is possible to predict someone's life happiness partly on the basis of the number of children they have.

Answer: A

300. A researcher conducts a survey with 221 participants who each complete 24 measures designed to assess the impact of social and psychological factors (such as demands, social support and role clarity) on stress in the workplace. As part of her analysis she investigates the correlations between pairs of these variables. How many degrees of freedom will her analysis have?

- A.** 221

- B. 220
- C. 219
- D. 24
- E. 23

Answer: C

301. "A graph plotting the scores on one variable against the scores on another." What type of graph is this a glossary definition of?

- A. A line graph
- B. A bar graph
- C. A scatterplot
- D. An angiogram
- E. A scattergram

Answer: C

302. "A relationship between two variables that can be described by a straight line. The equation for such a line is $y = a + bx$, where b is the slope of the line (its gradient) and a is the y intercept (where it cuts the vertical axis)." Which type of relationship is this a glossary definition of?

- A. A straight-line relationship
- B. An $a + b$ relationship
- C. A bx relationship
- D. A curvilinear relationship
- E. A short-term relationship

Answer: A

303. "A measure of the degree of linear association between two variables." What is this a glossary definition of?

- A. A correlation coefficient.
- B. A covariance coefficient.
- C. Covariance.
- D. A product-moment coefficient.
- E. A linear coefficient.

Answer: A

304. "The amount of variation in one variable associated with variation in another variable (or variables). In the bivariate case this is given by r^2 ." What is this a glossary definition of?

- A. Variance.
- B. Covariance.
- C. Common variance.
- D. Linear correlation.
- E. Estimated variance.

Answer: C

305. “A barrier to the correct interpretation of results that arises when the range of scores is limited because they are clustered in the region of the maximum scale value.” What specific type of effect is this a glossary definition of?

- A.** Restricted range effect.
- B.** Maximum value effect.
- C.** Floor effect.
- D.** Ceiling effect.
- E.** Doppler effect

Answer: D

306. Which of the following is a pooled variance estimate that constitutes the denominator of an F-ratio? [TY10.1]

- A.** The between-cells mean square (MS_B).
- B.** The mean of the sampling distribution.
- C.** The sum of the deviations from the grand mean.
- D.** The grand mean.
- E.** The within-cells mean square (MS_W).

Answer: E

307. Which of the following statements is true? [TY10.2]

- A.** In one-way ANOVA the total sum of squares comprises two main sources of variance: within-groups variance and between-groups variance. Each has the same number of degrees of freedom.
- B.** In one-way ANOVA the total sum of squares comprises two main sources of variance: within-groups variance and between-groups variance. Each has its own number of degrees of freedom.
- C.** In one-way ANOVA the total sum of squares comprises three main sources of variance: within-groups variance, between-groups variance and error variance. Each has the same number of degrees of freedom.
- D.** In one-way ANOVA the total sum of squares comprises three main sources of variance: within-groups variance, between-groups variance and information variance. Each has the same number of degrees of freedom.
- E.** In one-way ANOVA the total sum of squares comprises three main sources of variance: within-groups variance, between-groups variance and information variance. Each has its own number of degrees of freedom.

Answer: B

308. What is the point of calculating the value of η^2 in relation to particular F- and p-values? [TY10.2]

- A.** η^2 is a hypothesis-testing measure that can tell us whether a particular F-value is significant.
- B.** η^2 is the square of α and can tell us whether a particular p-value is significant.
- C.** η^2 is a measure of effect size that can tell us whether a particular F-value is significant.
- D.** η^2 is a measure of effect size that can tell us whether a particular p-value is significant.
- E.** η^2 is a measure of effect size that can tell us how much variance a particular effect accounts for.

Answer: E

309. A researcher, Isobel, conducts one-way analysis of variance in which she compares the final marks of students who have studied psychology at one of five different institutions, A, B, C, D and E. The study looks at the marks of 100 students, 20 from each institution. On the basis of a given theory, the researcher plans to make four comparisons: between A and B, A and C, C and D, and C and E. Three other researchers make the following observations:

X: 'If Isobel used an experimentwise alpha level of .01, a Bonferroni adjustment would mean that each of these tests had an alpha level of .0025.'

Y: 'If Isobel used an experimentwise alpha level of .05, a Bonferroni adjustment would mean that each of these tests had an alpha level of .0025.'

Z: 'If Isobel used an experimentwise alpha level of .05, a Bonferroni adjustment would mean that each of these tests had an alpha level of .0125.'

Who is correct? [TY10.4]

- A. Only X.
- B. Only Y.
- C. Only Z.
- D. X and Y.
- E. X and Z.

Answer: E

310. An experimental psychologist conducts a study examining whether the speed with which two shapes can be identified as similar or different depends on whether the stimuli are (a) of equal or unequal size and (b) symmetrical or asymmetrical. The mean reaction times for the four cells of the design are as follows: equal symmetrical (M = 132 ms), unequal symmetrical (M = 148 ms), unequal asymmetrical (M = 142 ms), unequal asymmetrical (M = 182 ms). Which of the following is true? [TY10.5]

- A. A line graph in which these data are plotted suggests that there might only be a main effect for size.
- B. A line graph in which these data are plotted suggests that there might only be a main effect for symmetry.
- C. A line graph in which these data are plotted suggests that there might only be a main effect for size and an interaction between size and symmetry.
- D. A line graph in which these data are plotted suggests that there might only be a main effect for symmetry and an interaction between size and symmetry.
- E. A line graph in which these data are plotted suggests that there might be main effects for size and symmetry and an interaction between size and symmetry.

Answer: E

311. Which of the following statements is false? [TY10.6]

- A. One difference between ANOVA and t-tests is that ANOVA allows researchers to compare responses of more than two groups.
- B. One difference between ANOVA and t-tests is that ANOVA does not make assumptions about homogeneity, normality and independence.
- C. One difference between ANOVA and t-tests is that ANOVA can be used to examine

simultaneously the impact of more than one variable.

- D. One difference between ANOVA and t-tests is that ANOVA is based on analysis of the ratios of variances.
- E. One difference between ANOVA and t-tests is that ANOVA uses two separate degrees of freedom (one for between-cells variance, one for within-cells variance).

Answer: B

312. A researcher conducts a study examining the impact of social support on depression in which he studies how four independent groups that each receive a different type of social support (financial, emotional, intellectual, none) react to a stressful experience. There are 20 people in each group. Which of the following statements is true? [TY10.7]

- A. There are 4 degrees of freedom for the between-cells variance.
- B. There are 78 degrees of freedom for the within-cells variance.
- C. If ANOVA yielded a between- groups F-value of -2.18 this would be significant with alpha set at $.05$.
- D. If ANOVA yielded a between- groups F-value of 0.98 this would be significant with alpha set at $.01$.
- E. None of the above statements is true.

Answer: E

313. Which of the following statements about the F-distribution is false? [TY10.8]

- A. The distribution is asymmetrical.
- B. The distribution is one-tailed.
- C. Higher values of F are associated with a higher probability value.
- D. The distribution is positively skewed.
- E. If the amount of between-cells variance is equal to the amount of within-subjects variance, the value of F will be 1.00 .

Answer: C

314. The SPSS ANOVA output below is from a study in which participants were randomly assigned to one of four conditions in which they were given different instructions to encourage them to continue. Which of the following statements is true? There is no possibility at all that the results are due to chance.

- A. It would be useful to supplement the p-value with a measure of effect size.
- B. With an alpha level of $.01$, ANOVA reveals a significant effect for Instruction.
- C. As groups are randomly assigned, we need to compute a z-score in order to gauge the size of these effects relative to chance.
- D. Both (a) and (b).

Answer: B

315. The SPSS ANOVA output below is from a study in which participants were randomly assigned to one of four conditions in which they were given different instructions to encourage them to continue. Which of the following statements is true?

- A. ANOVA shows that there was no effect for Instruction.

- B.** With an alpha level of .05, ANOVA reveals a significant effect for the Instruction.
- C.** With an alpha level of .01, ANOVA reveals a significant effect for Instruction.
- D.** With an alpha level of .05, ANOVA reveals a significant effect for Intercept
- E.** With an alpha level of .01, ANOVA reveals a significant effect for Intercept.

Answer: B

316. "A hypothetical model in which mean responses differ across the conditions of an experimental design. This represents an alternative to the null hypothesis that the mean response is the same in all conditions." What is this a glossary definition of?

- A.** Hypothetical model.
- B.** Hypothetical difference model.
- C.** Difference model.
- D.** Effects model.
- E.** Experimental model.

Answer: D

UNIT – 2

EMERGENCE OF PSYCHOLOGY

WHAT IS PSYCHOLOGICAL THOUGHT IN SOME MAJOR EASTERN SYSTEMS: BHAGAVAD GITA, BUDDHISM, SUFISM AND INTEGRAL YOGA ?

THE PSYCHOLOGICAL THOUGHT IN SOME MAJOR EASTERN SYSTEMS: BHAGAVAD GITA, BUDDHISM, SUFISM AND INTEGRAL YOGA

The Bhagavad Gita is the best philosophical confluence of karma, bhakti and gyan yoga as Krishna's solution to Arjuna's problem is comprehensive, involving the behavioral (karma yoga), the emotional (bhakti yoga) and the intellectual (gyan yoga). The religious and philosophical importance of the Gita is well known. It is not only a well organized form of Indian life but also is considered a humanistic religion of the world.

Its universal importance is established by its translation in all recognized languages of the world. Some scholars consider it as greatest ideal of dharmashastra, some of ethics and of philosophy. A depth study of the Gita affirms that it embodies all the above mentioned aspects. Therefore, all these opinions of the scholars are complementary to each other. The philosophical approach does establish its importance but it has another approach that is psychological.

Psychological depiction is not confined to any race, time or space. It is perennial source of inspiration for all humans in all times. Gita darshan has been stabilized on the ground of psychology. Therefore, it is a unique achievement in the field of psychology.

After entering the war field, Arjuna's hesitation for performing his duties in place of showing enthusiasm for war, is obviously depiction of psychological situation. All individuals are caught into social and religious bondages. These bondages become part of life as these are inborn and cannot be easily broken. It is easily understood one's feeling of violence towards his elders, teachers and brothers as a momentary excitement but it cannot be given a definite form of violence.

The driving force in a human being is not his body and senses but his soul. Similarly, Arjuna could not attain that self confidence with which he can experience emptiness of his aspirations and desires. The Bhagavad Gita's depiction of how one can control one's impulses emotions, desires and other bodily activities is a pure psychology. Now, we need to focus on the situation how does Arjuna, the great warrior embrace cowardice?

Why and how does he adopt renunciation (tyagavriti) of Brahamana- dharma after deserting kshatriya swabhava? The psychological answer to this question is given in 27th chapter of Udyoga Parva of Mahabharata.

It is a psychological fact the nothing happens without a reason and its background. Sanjay had already prepared the background of Arjuna's cowardice. Before commencement of war, Sanjay, as a messenger of Dhritrashtra requests Yudhishtra not to wage war.

Arjuna who is present there during the conversation attentively listens to him. Sanjay Says:

He says that human life is momentary, full of sorrow and fickleness. Therefore, Yudhishtra should not wage the war; it is not according to his fame. Here, Sanjay tries to dishearten „Dharmprana“ Arjuna making him consider war as sin.

It implies that the desires hindering right conduct (dharmacharna) draw an individual towards themselves. Therefore, an intelligent person first destroys these desires and thereafter attains fame and admiration. Here Sanjay clearly points out that desire for kingdom is an obstacle to right conduct

(dharmacharana). If this desire is deserted, there will be no war. Moreover, Sanjay's next sentence makes Arjuna feel weak and confused.

It means the one who considers right conduct (dharma) as prime ideal among all three ideals- dharma, artha, and kama and leads his life accordingly, he gets fame and shines like sun. But the one who is devoid of dharma and whose intellect is associated with sin, he, despite owning the whole earth, suffers continuously. The next sentence of Sanjay again weakens Arjuna's heart as:

In this way, the war appeared before Arjuna as a form of a sin. His thought like „a desire for kingdom“, „sacrifice for others“ and „Kaurava must kill me“ etc. are symbols of inferiority caused by Sanjay's statements. Generally, attachment is considered as the greatest enemy of human being but the psychological perspective states that the greatest enemy is that power which induces the feeling of inferiority in the human being.

Here we find Sanjay in a role which weakens Pandavas side and strengthens Kaurava side with his politics. If we look at Arjuna's character, he was not a coward, due to his inferiority complex, he started to feel disheartened.

There is a need of a teacher who is superior, restrained and knows yoga to uplift Arjuna and the need was fulfilled by Sri Krishna. He came to know the inferiority of Arjuna after listening to his statements in no time. He tries to convince him as follows:

It is necessary to remind person's bravery, duties etc. in order to erase thoughts of inferiority and steers him to work patiently. He tells Arjuna that his enemies are afraid of him, they tremble with fear, they get disheartened after seeing his bravery, they are almost dead and he is just an instrumental cause. Krishna, also, clarifies the form of soul as eternal entity- to kill or to be killed

The attachment to body is not right because it is not eternal. The eternal soul never dies. Therefore he would not acquire sin of killing Kauravas and their people. But, if he deserts his Swadharma and will not involve in war then he will acquire sin. In chapter second, his preaching about 'Isthitpragyata' prepared the background to stabilize Arjuna's state of mind. At this Arjuna says:

It is very difficult to subdue mind which is restless, turbulent, and obstinate even more difficult than controlling the wind. But at the same time, Sri Krishna elevates Arjuna's spirit after motivating him. He says:

BUDDHIYOGA

Buddhi yoga (purpose of the Gita) is another worthy concept to look into.

Buddhi (intellect) is an ability to learn. A person has three abilities namely adjustment, learning and abstract thinking which are complementary to each other.

In the Gita Sri Krishna identifies himself with his intellect and he has defined an ideal person as 'Isthirbuddhi'. If it is necessary to have trained and enlightened reason for spirituality, the loss of reason and logic causes downfall and the loss of reason lead to destruction of the person. Sri Krishna imparts Buddhiyoga to Arjuna enlightening him with the light of his knowledge.

Arjuna gets illumined and accepts humbly that his illusion has now gone and he has regained memory.

He is now firm and free from doubt and is prepared to act according to His instructions

It means the faculty that is helpful in determination is called intellect. A person first should determine that the supreme soul is the complete entity everywhere. Such an intelligent person treats alike all creatures of world. The same idea is expressed in the following verse It means a truly wise person is one whose intellect treats equally a brahmana, an outcaste, a cow, an elephant, a dog and he considers others as his equal.

The concept of „Isthitpragya’ is reflected upon in a unique manner that is not found in the discussion of „intelligence“ of modern psychologists.

GITA AND HUMAN PSYCHOLOGY

Etymologically, the word ‘psychology’, with its origin attributed to the Greek psyche, means ‘study of the soul’. In the modern parlance, it means the science of mind and behaviour. Now, this inter-related triad of soul, mind and behaviour also constitutes the central concern of the Bhagavad Gita, which ultimately charts the course of harmonising the self (soul) with the absolute (Brahman), involving inter-alia an in-depth analysis of human mind and behavioural types.

The Freudian structural model of the psyche comprises three parts: the id, the ego and the super-ego. The id represents in-born tendencies, the instinctive drives and impulses ‘inherited at birth’ and ‘laid down in the constitution’ of a personality; it acts on the ‘pleasure principle’, seeking satisfaction of instinctual needs.

The ego acts on the ‘reality principle’, seeking to channel and meet the id’s drives of passion in realistic ways, factoring in the influence of the environment through reason and common sense, constantly conflicted by and constantly seeking to mediate among the id, the super-ego and the external world, with a latent predisposition for the id. Originally Freud termed ego to mean a sense of self, but later modified the meaning as a set of psychic functions, such as judgement, tolerance, reality testing, control, planning, defence mechanism, intellectual functioning and memory. Super-ego is the urge to perfection and represents internalised societal and parental standards of right and wrong behaviour – a type of conscience that punishes misbehaviour with sense of guilt. Freud stressed on the dominance of sexual drive in the subconscious id.

This part of his theory was however contested by his one-time colleague, Carl Jung, whose work on himself and on his patients convinced him that life has a spiritual purpose beyond material goals and that spiritual experience is essential to our well being.

According to Jung, man’s principal task is to discover and fulfill his deep innate potential in much the same way the caterpillar fulfills its potential to become a butterfly. Based on his study of Christianity, Hinduism, Buddhism, Taoism and other traditions, Jung suggested that ‘individuation’ – a journey of transformation to meet the self and also to meet the divine – is at the mystical heart of all religions.

includes Jung’s postulation of individuation as an integrated transformational process encompassing the ‘collective unconscious’, representing a deeper collective or social level of psychic functioning underlying the Freudian ‘personal unconscious’; people at an advanced stage of individuation tend to be harmonious, mature, humane and socially responsible, having a good understanding of the human nature and the universe.

In addition to these classical models of Freud and Jung, in contemporary psychology we come across other models, such as the Five Factor Model (FFM), listing the “big five” of openness, conscientiousness, extraversion, agreeableness and neuroticism to describe human personality.

Another notable post-Freudian model is Eric Berne’s Transactional Analysis, also called the Parent-Adult-Child model, integrating the psycho-analytic and cognitive approaches

As expressly stated in all these psychological theories, these are all ‘models’ to understand and characterise human mind and behaviour. Now, as we would try to explore here, Gita is also concerned with classifying personalities based on models: of the good, passionate and dull modes of mind; of the divine and demoniac endowments; of the devotee and nondevotee; of the steady and non-steady.

In science, the underlying hypothesis in modeling is that a super- imposition of plural models may provide a better understanding of the truth of nature. The same applies to understanding the truth of the human nature and spirit and its causal and driving principles.

In science, Niels Bohr propounded the Complementarity principle to get beyond the conundrum of duality: that some characteristics of an electron are explicable by its particle nature (deterministic model) while some others are explained by its wave nature (probabilistic model). Similarly, Gita makes the case that the human mind can be best understood as a super-imposition of the models of impressions (vāsanās), modes (guṇas), endowments (sampadas), and faiths (śraddhās).

The Holy Geeta entered my life in the autumn of 1993. I was sitting in Chennai’s Taj Coromandal one evening not knowing what to do when I happened to see the Holy Geeta by Swami Chinamayanandji. Something attracted me and I got down to reading it. In eight years am on my third read now. It has become my best friend. When I am feeling low, confused or lonely I open the Gita, read a few pages and feel content thereafter. The beauty is that the interpretation of various slokhas is different every time I read it. May be it has to do with the stages and situations in my life. The one by Swamiji is very good for a spiritually evolved person.

What I like in the one by Swami Rama is that it is easy to understand, very good for a person who is reading the Geeta for the first time

A bit about Swami Rama. Swamiji founded the Himalayan International Institute of Yoga Science and Philosophy, the Himalayan Institute Hospital Trust in India and many centers across the world. A student of both Himalayan cave monasteries and European universities, he founded the Himalayan Institute to create a bridge between the ancient teachings of the East and modern scientific approaches of the West.

Some people associate the Holy Geeta with Sanathan Dharam. To my mind it has universal application, shows us how to handle the problems of life, be happy in spite of ups and downs, perform duty without being attached to the fruits of action etc. The Geeta is eternal, as relevant today as it was thousands of years ago.

For your convenience I have reproduced the book verbatim. The format is as follows. It starts with an introduction followed by excerpts from individual chapters. Each chapter consists of slokhas with commentaries. Besides explaining the slokha, the commentary highlights the comparison between eastern and western psychology. It has my comments in brackets to help you distinguish it from the original text.

“The Bhagawad Gita is the fountainhead of eastern psychology and this commentary is designed to

draw out its psychological concepts and make them accessible to all students. These profound insights are intertwined with philosophical concepts, so the task undertaken here is to separate the psychological principles and to explain their practical application.

The word philosophy is a compound of two words, philo and Sophia, which means 'love for knowledge'. There are 18 chapters in the Gita each describing a different aspect of the process of self-transformation. The aim of the Gita is to teach the aspirant how to establish equanimity in his internal life and in his activities in the external world, to help him develop that tranquility within, and to explain the art and science of doing actions skillfully and selflessly.

The book aims at helping you understand your inner potentials, it is not possible to function effectively and harmoniously in the external world, for all the things happen within before they are expressed externally. Sri Krishna modified and simplified the Vedic and Upanishadic knowledge with the Geeta.

Modern psychologists attempt to help the client modify his conscious attitudes and unconscious behaviors, but their analysis lacks the depth and profundity found in the Gita. Most modern therapists do not explore the purpose and meaning of life. They do not go to the root of the problem but analyze it without understanding the fundamental cause.

By contrast Sri Krishna presents a philosophical foundation for understanding the purpose of life and the way to live life harmoniously, and he offers Arjuna practical advice on living and coping with the world".

PSYCHOLOGICAL THOUGHT IN BUDDHISM

Buddhist psychology is primarily about self-knowledge- finding out more about who you are, understanding your decisions, actions, thoughts, feelings, etc. It is an expression of the Delphic dictum *Know Thyself* and the injunction that transformative spiritual paths throughout time and geography have demanded as the central ingredient in authentic happiness.

Buddhist psychology is 'radical,' as it aims to challenge your worldview (as all authentic spirituality and psychology does). It is radical in that it addresses the basis or foundation of our psychological functioning, our sense of who we are, and our relationships with others and with the world. As a result, the fruit of applying the psychological insights of the Buddha requires diligence, perseverance and discernment as they will naturally encounter the resistances and obstacles inherent in our conditioned nature.

It is not a coincidence that Buddhism finds itself so welcome in the western world since the last decades of the preceding century.

While the appeal certainly includes those who have converted to Buddhism as a faith and have adopted the practices, liturgies and meditations of whatever form of Buddhism speaks to them, the more unique and far-reaching impact of Buddhism, as a psychology, has taken place in academia and among clinical researchers, who have observed that the Buddhist understanding of consciousness, mind, behavior, motivation, personality and psychopathology bear a close resemblance to perspectives held in western psychology and psychotherapy.

While the Buddha was not a psychiatrist or psychologist in the formal sense of the word, the vast majority of his recorded teachings, are explicitly concerned with the sources of emotional suffering and their amelioration. No doubt there is much, much more to Buddhism than the psychology he

elucidates.

Yet, an argument will be made that these more 'religious' elements, for the want of a better word, or possibly 'experience-far' aspects, are of appeal to those who seek a religious Buddhism, a Buddhism that provides for a level of faith and understanding that speaks to the needs of their heart, but which can be separated out, and set aside, for those who do not seek such a religious experience (possibly content with their own existing faith, or with none at all) but who rather wish to deepen their self-knowledge and happiness.

It is these experience-near or psychological Buddhism that speaks loudly in the West and which may be anticipated to be the legacy of the Buddhist encounter with the West.

Let's examine some of the confluences of Western and Buddhist psychology. There is certainly a high degree of overlap in goals and content areas of both disciplines that focus directly understanding human behavior, the source or conditions for unhappiness and ways to reduce, attenuate or even eliminate such unhappiness. Indeed the Buddhist corpus has extensive psychological writings - very explicit and detailed - and not found in other religious traditions.

Thus it is not surprising that some aspect of Buddhist psychology has been of interest to those professions in the west dedicated to alleviating human suffering: medicine, psychiatry, psychology, nursing, social work. The professional journals for each of these disciplines have published so much scientific research (especially related to mindfulness practice) that to fully describe the studies would require a book in itself. The Dalai Lama has explicitly encouraged interaction between western disciplines to further establish links with science and clinical practice.

The Mind and Life Institute is an expression of this venture of cooperation. Elements of Buddhist psychology have been integrated into psychotherapeutic practices for a variety of psychopathological conditions, including depression, anxiety, addiction and stress.

Scientific writers from the entire range of clinical psychology and psychiatry, ranging from psychoanalysis to cognitive to behavioral to humanistic theory, have all addressed aspects of Buddhist psychology.

Not surprising, the Buddhist traditions that have been of greatest appeal to western science and psychology have been those that appear to contain a higher proportion of experience-near aspects (Theravadin, Zen) because they carry much less religious baggage and more easily translated into Western concepts. Less impactful has been the teachings of Mahayana and Tibetan or tantric Buddhism which include a strong element of experience-far teachings and thus are more difficult to translate into concepts that are digestible by the western mind. Nevertheless, even these traditions reflect a more esoteric psychology that does find resonance in the West and which full certainly continue to attract significant interest.

GOAL OF BUDDHIST PSYCHOLOGY

Buddhist psychology, simply put, is concerned with the alleviation of human suffering, distress, and dissatisfaction. However, the Buddhist idea of suffering much broader than what is usually the focus of western psychology. The notion of suffering includes the entire range of human dissatisfaction and anguish and not the clinical disorders described by psychiatry.

And it is also important to note that for the most part the Buddha is referring to emotional suffering rather than physical suffering, per se. The emphasis is on the mental aspects of physical pain rather

than the pain itself. The Buddha's practical project of the understanding and relief of human anguish was also a potent counterforce to metaphysical speculation which the Buddha eschewed.

The pursuit of metaphysical, logical or theoretical issues for their own sake was avoided.

Such questions could not be answered and spending time on them simply distracted from the urgency of the message the Buddha wished to share. This could also be understood as the Buddha's advice to leave questions about the nature of the universe, matter, and reality to those disciplines equipped to study and address them (e.g., science). The domain of science was the area of human endeavour which could answer such questions. The Buddha was primarily concerned with the human mind and its activity.

Much of what the Buddha taught could eventually be empirically and personally evaluated by those who were diligent and persistent. This is an important consideration for those who distinguish experience-near (psychological) and experience-far (religious aspects of Buddhism). While the former could be realized and experienced by anyone who put in the requisite effort, that did not mean it would be easy.

Any profound and transformative understanding of mind would require dedication and perseverance and could not be learned from simply hearing about it or reading it. The Buddha's approach was empirical and scientific- it did not draw on dogma, philosophy or received wisdom. Analytic and experiential investigation worked together to provide the transformative knowledge the Buddha wished to teach us.

The Buddha does not ask that his claims be taken on blind faith, although some faith is necessary to even begin self-exploration. Examine his words on the basis of your reason, experience, and intuition. All of us have the seed of Enlightenment, of authentic happiness, bliss waiting to 'blossom' if nourished.

BUDDHIST PSYCHOLOGY AS A SCIENCE OF CONSCIOUSNESS

We pay extreme attention to our physical bodies (vanity, cosmetics, clothes). We can invest incredible amounts of time towards achievements such as careers, sports, art, money and social standing. We pursue social relationships as a key aspect of our happiness. One can make the argument that our sciences and technologies are devoted to increasing comfort, convenience, pleasure, and so on. There is no doubt that we are highly focused on preserving our physical lives, our social status and relationships, and our sensory and lifestyle. Our education system can be said to be geared to achieving all of these aims, all of which are admirable and good. But little attention is paid to mind or consciousness. It is not taught in school, by caregivers, or friends. This may reflect the Western ambivalence towards mind. Many psychologists have either denied the existence of consciousness or have diminished its influence in our lives; modern neuroscience research has reduced consciousness to brain activity that may have not have any causal agency. Yet, consciousness is precisely the focus of Buddhist psychology.

Andrew Olendzki has done an excellent job at describing the key components of Buddhist psychology and it would be valuable to reiterate some of his conclusions here. Buddhist psychology focuses on the direct experience, consciousness, awareness, mind, subjectivity, of the individual. Buddhist psychology can be descriptive phenomenology of mind, a science of experience. Its

contribution is the Buddha's advice to explore the dynamics of subjectivity as it unfolds in the present moment through the practice of mindfulness meditation. Modern scientific views of mind and behavior have tended toward reductionist explanations, explaining mind in terms of physical structures and brain processes. Olendzki has argued that the reductionist approach doesn't explain lived human experience, the qualia of experience. The absence of the brain in the Buddha's account of mind leaves a place for the contribution of western science but also suggests that to understand the mind, in the manner that the Buddha discusses, does not *require* contributions of neuroscience. The Buddha, through his advocacy of a meditative approach to wisdom, points to a process view of experience consisting of several interdependent processes, functions, and events (i.e. dharmas).

FIVE INSIGHTS OF BUDDHIST PSYCHOLOGY:

(I) CENTRALITY OF CONSCIOUSNESS/ SUBJECTIVITY

The radically psychological nature of Buddhist psychology is evidenced by the need to explore the mind through meditation and other forms of contemplation. It is not necessary to explain it, where it comes from, which part of the brain and so on, which is a major focus of many western scientific disciplines. Our subjectivity consists of moments of awareness that appear seamless but with attention placed on it, within the present moment, can reveal how our cognitive processes culminate in the mental phenomena we experience. Investigating this moment, right here, right now, is where wisdom can arise.

(II) HUMAN EXPERIENCE MANIFESTS THROUGH 6 SENSE SYSTEMS

Along with the 5 senses and their corresponding experiences, mind is considered to be a sense organ, and cognitive events are sense objects. The traditional account of consciousness describes its emergence from interaction of sense organ (e.g., eye) and sense object (e.g., visual object) creating sensory experience (e.g., visual consciousness). Everything we know depends on the activity of these 6 senses. While later developments in Buddhist philosophy posit additional senses, the traditional scriptures focus on these six.

(III) ALL EXPERIENCE IS CONSTRUCTED

The radically psychological nature of Buddhist psychology can be observed in the emphasis on what appears. What appears is a transformation or translation of the external environment into an internal language of consciousness (e.g., photons >> sight; chemicals >> taste, smell; vibration >>> hearing; pressure >> touch; brain activity >>> cognition). The transformation of raw sensory activation into sensory experience is so radical that no way to know what pre-constructed reality is. All we can know is our own subjectivity. Any discussion of what 'reality' is will always be limited by what our senses will permit and what our mind can conceive.

The study of reality is the study of the human construction of experience. And whatever such reality may be is irrelevant to the real purpose of the Buddha's message, to transform delusion into wisdom. This project requires us to explore our inner world. Of course, each individual has their unique, subjective, constructed reality

(IV) EXPERIENCE IS CONSTANTLY CHANGING- AN INCESSANT

SUCCESSION OF EVENTS

Each perception, sensation, cognition, image, memory, feeling is a process that can never be experienced identically again. Every moment is unique. Our brains have evolved to reduce our awareness of such flux to increase our ability to survive. For reasons of adaptation sensory reality is filtered thus distorting our experiences. Three major forms of perceptual distortion are described by the Buddha: perceptions of permanence (perceptual-linguistic), satisfaction (cognitive) and self (metacognitive) are examples of this distortion-tendency.

(V) MIND/BODY (THE SELF) REVEALED THROUGH 5 INTER-DEPENDENT PROCESSES

Five processes or 'aggregates' define the self (i.e., mind/body). These five processes consist of physicality, consciousness, perception, affect, and habit. The Buddhist posits a view of self as an interaction among these five processes to produce the coherent sense of identity and 'I'-ness that defines who we are. It is not accurate to claim that there is no self within Buddhist psychology. This would be absurd. What the Buddha clarifies is that the self we experience has no essence or substance but consists of these 5 constantly arising, abiding and subsiding.

BUDDHISM AND WESTERN PSYCHOLOGY

Assessment of Buddhism in terms of modern western psychology started when British Indologist Rhys Davids translated *Abhidhamma Pitaka* from Pali and Sanskrit texts in 1900. She published the book entitled it, "Buddhist Manual of Psychological Ethics".

In 1914, she wrote another book "Buddhist psychology: An inquiry into the analysis and theory of mind" The mid-twentieth century saw the collaborations between many psychoanalysts and Buddhist scholars as a meeting between "two of the most powerful forces" operating in the Western mind. A variety of renowned teachers, clinicians and writers in the west such as Carl Jung, Erich Fromm, Alan Watts, Tara Brach, Jack Kornfield, Joseph Goldstein, and Sharon Salzberg among others have attempted to bridge and integrate psychology and Buddhism, from time to time, in a manner that offers meaning, inspiration and healing to the common man's suffering.

Buddhism and Western Psychology overlap in theory and in practice. Over the last century, experts have written on many commonalities between Buddhism and the various branches of modern western psychology like phenomenological psychology, psychoanalytical psychotherapy, humanistic psychology, cognitive psychology and existential psychology.

BUDDHISM AND PHENOMENOLOGICAL PSYCHOLOGY

Any assessment of Buddhism in terms of psychology is necessarily a modern western invention. Western and Buddhist scholars have found in Buddhist teachings a detailed introspective phenomenological psychology. Rhys Davids in her book "Buddhist Manual of Psychological Ethics" wrote, "Buddhist philosophy is ethical first and last. Buddhism set itself to analyze and classify mental processes with remarkable insight and sagacity".

Buddhism's psychological orientation is a theme Rhys Davids pursued for decades as evidenced by her other writings. *Abhidhamma Pitaka* articulates a philosophy, a psychology, and ethics as well; all integrated into the framework of a program for liberation. The primary concern of the *Abhidhamma* (or Abhidharma in Sanskrit), is to understand the nature of experience, and thus the reality on which it focuses is conscious reality. For this reason, the philosophical enterprise of the *Abhidhamma* shades off into a phenomenological psychology.

Later on long-term efforts to integrate Abhidhammic psychology with Western empirical sciences have been carried out by other leaders such as Chogyam Trungpa Rinpoche and the 14th Dalai Lama.

In introduction to his 1975 book, *Glimpses of the Abhidharma*, Chogyam Trungpa Rinpoche wrote: "Many modern psychologists have found that the discoveries and explanations of the abhidharma coincide with their own recent discoveries and new ideas; as though the abhidharma, which was taught 2,500 years ago, had been redeveloped in the modern idiom".

Every two years, since 1987, the Dalai Lama has convened "Mind and Life" gatherings of Buddhists and scientists.

Reflecting on one Mind and Life session in March 2000, psychologist Daniel Goleman, the author of the best-selling "Emotional Intelligence" and "Destructive Emotions: A Scientific Dialogue with the Dalai Lama" noted; "since the time of Gautama Buddha in the 5th century BC, an analysis of the mind and its workings has been central to the practices of his followers. This analysis was codified during the first millennium, after his death within the system called *Abhidhamma* (or Abhidharma in Sanskrit), which means ultimate doctrine".

BUDDHISM AND PSYCHOANALYTICAL PSYCHOTHERAPY

Psychoanalyst Carl Jung wrote the foreword to Zen's scholar Daisetz Teitaro Suzuki's introduction to Zen Buddhism, first published together in 1948. In his foreword, Jung highlights the enlightenment experience as the unsurpassed transformation to wholeness for Zen practitioners. "The only movement within our culture which partly has, and partly should have, some understanding of these aspirations for such enlightenment is psychotherapy" Psychoanalysts like Karen Horney and Fritz Perls studied Zen- Buddhism. Karen Horney was intensely interested in Zen Buddhism during the last years of her life.

Richard Wilhelm was a translator of Chinese texts into German language of the I Ching, Tao Te Ching and 'the secret of the goldenflower', with a forward written by Carl Jung. R D Laing, another noted psychoanalyst, went to Ceylon, where he spent two months studying meditation in a Buddhist retreat.

Later on, he spent time learning Sanskrit and visiting Govinda Lama, who had been a guru to Timothy Leary and Richard Alpert. Suzuki, Fromm and other psychoanalysts collaborated at a 1957 workshop on "Zen Buddhism and Psychoanalysis" in Cuernavaca, Mexico. In his contribution to this workshop, Fromm declared:

"Psychoanalysis is a characteristic expression of the Western man's spiritual crisis, and an attempt to find a solution. The common suffering is the alienation from oneself, from one's fellow men, and from nature; the awareness that life runs out of one's hand like sand, and that one will die without

having lived; that one lives in the midst of plenty and yet is joyless”.

Fromm continues: “Zen is the art of seeing into the nature of one's being; it is a way from bondage to freedom; it liberates our natural energies; and it impels us to express our faculty for happiness and love.

” “What can be said with more certainty is that the knowledge of Zen, and a concern with it, can have a most fertile and clarifying influence on the theory and technique of psychoanalysis.

Zen, different as it is in its method from psychoanalysis, can sharpen the focus, throw new light on the nature of insight, and heighten the sense of what it is to see, what it is to be creative, it is to overcome the affective contaminations and false intellectualizations which are the necessary results of experience based on the subject-object split”.

Referencing Jung and Suzuki's collaboration as well as the efforts of others, humanistic philosopher and psychoanalyst Erich Fromm noted; “there is an unmistakable and increasing interest in Zen Buddhism among psychoanalysts”. Erich Fromm also wrote the forward to a 1986 anthology of Nyanaponika Thera's essays on Buddhist philosophy.

There have been many other important contributors, to the popularization of the integration of Buddhist meditation with psychology, including Kornfield, Joseph Goldstein, Tara Brach, Epstein and Nhat Hanh.

Psychoanalysis, pioneered and popularized by such philosophers/psychoanalysts rests upon the idea that uncovering and making conscious buried complexes and memories is a therapeutic process. The relocation of a complex or neurosis from the unconscious to the conscious easily equates to the principles inherent in right meditation and right understanding. One might recall that on Jung's deathbed, he was reading a translation of Hsu Yun's dharma discourses and was reputedly very excited by the succinct and direct methods of Chan's practice in working with the unconscious.

BUDDHISM AND EXISTENTIAL PSYCHOLOGY

Buddha said that life is suffering. Existential psychology speaks of *ontological anxiety* (dread, angst). Buddha said that suffering is due to attachment.

Existential psychology also has some similar concepts. We cling to things in the hope that they will provide us with a certain benefit.

Buddha said that suffering can be extinguished. The Buddhist concept of nirvana is quite similar to the existentialists' freedom. Freedom has, in fact, been used in Buddhism in the context of freedom from rebirth or freedom from the effects of karma. For the existentialist, freedom is a fact of our being, one which we often ignore. Finally, Buddha says that there is a way to extinguish suffering. For the existential psychologist, the therapist must take an assertive role in helping the client become aware of the reality of his or her suffering and its roots.

Likewise, the client must take an assertive role in working towards improvement—even though it means facing the fears they've been working so hard to avoid, and especially facing the fear that they will “lose” themselves in the process.

BUDDHISM AND COGNITIVE-BEHAVIOR THERAPY PRINCIPLES

Buddhistic mindfulness practices have been explicitly incorporated into a variety of psychological treatments. More specifically psychotherapies dealing with cognitive restructuring share core principles with ancient Buddhist antidotes to personal suffering.

Fromm distinguishes between two types of meditative techniques that have been used in psychotherapy: (i) auto-suggestion used to induce relaxation; and (ii) meditation “to achieve a higher degree of non-attachment, of non-greed, and of non-illusion; briefly, those that serve to reach a higher level of being”. Fromm attributes techniques associated with the latter to Buddhist mindfulness practices.

Two increasingly popular therapeutic practices using Buddhist mindfulness techniques are Jon Kabat-Zinn's Mindfulness-based Stress Reduction (MBSR), and Marsha M. Linehan's dialectical behavioral therapy (DBT). Other prominent therapies that use mindfulness include mindfulness-based cognitive therapy (MBCT) and Steven C. Hayes' Acceptance and commitment therapy (ACT). Mindfulness-based stress reduction Kabat-Zinn developed the 8-week MBSR program over a 10-year period with over 4,000 patients at the University of Massachusetts Medical Center. Describing the MBSR program, Kabat-Zinn writes: “This ‘work’ involves above all the regular, disciplined practice of moment-to-moment awareness or *mindfulness*, the complete ‘owning’ of each moment of your experience, good, bad, or ugly.

This is the essence of full catastrophic living.” Kabat-Zinn, a one-time Zen practitioner, goes on to write: “Although at this time, mindfulness meditation is most commonly taught and practiced within the context of Buddhism, its essence is universal. Yet it is no accident that mindfulness comes out of Buddhism, which has as its overriding concerns the relief of suffering and the dispelling of illusions”.

Not surprisingly, in terms of clinical diagnoses, MBSR has proven beneficial for people with depression and anxiety disorders; however, the program is meant to serve anyone experiencing significant stress.

DIALECTICAL BEHAVIORAL THERAPY

In writing about DBT, Zen practitioner Linehan states: “As its name suggests, its overriding characteristic is an emphasis on ‘dialectics’ – that is, the reconciliation of opposites in a continual process of synthesis. This emphasis on acceptance as a balance to change flows directly from the integration of a perspective drawn from the practice of Buddhism with Western psychological practice.”

SIMILARLY, LINEHAN WRITES:

“Mindfulness skills are central to DBT. They are the first skills taught and are reviewed every week. The skills are psychological and behavioral versions of meditation practices from Eastern spiritual training. Linehan has drawn heavily from the practice of Zen. Controlled clinical studies have demonstrated DBT's effectiveness for people with borderline personality disorder.

Dr. Albert Ellis, has written that many of the principles incorporated in the theory of rational-emotive psychotherapy are not new; some of them were originally stated several thousands of years ago, by Taoist and Buddhist thinkers. To give one example, Buddhism identifies anger and ill-will as basic

hindrances to spiritual development. A common Buddhist antidote for anger is the use of active contemplation of loving thoughts. This is similar to using a CBT technique known as “emotional training” which Ellis described.

The school of Behaviorism describe (or reduce) human functions to principles of behavior, which can be manipulated to create positive effects in the life of the patient. In the Noble Eightfold Path we see reflections of this approach in the exhortations to Right Action, Right Speech and Right Livelihood. One may consider the story of the Buddha who was approached by a rich but miserly man who wanted to develop his spiritual life but was constrained by his seeming inability to share his wealth with others. The Buddha addressed this problem by telling him to get into the habit of using his right hand to give his left hand items of value and in doing so learn the art of giving!

Cognitive and cognitive-behaviorists focus more on training the mind to review and question assumptions, phobias, fears and beliefs. These therapists are typically associated with such techniques as visualization and positive self-talk designed to teach, or unlearn, principles that are, respectively, helpful or unhelpful.

Again, the noble eightfold path and its focus on right mindfulness and right thinking are the corollary in Buddhist thought.

BUDDHISM AND OTHER PSYCHOTHERAPY PRINCIPLES

Gestalt Therapy is an approach created by Fritz Perls, based heavily on existentialist philosophy and significantly, Zen Buddhism (among other influences). In Gestalt, the premise is we must work with the whole person, the “gestalt” in German, which echoes the wisdom of Right Understanding. Its techniques encourage Right Mindfulness, and the focus on the immediate, phenomenological and experiential reality of the here and now, in the physical, emotional and mental realms.

David Brazier in his book *Zen Therapy* makes a thoughtful comparison of some principal Buddhist concepts and person-centered (Rogerian) Therapy. Developed by Carl Rogers, this therapeutic approach includes virtually all effective therapy, either in principle or technique. In basic terms, its goal is to provide the patient a safe place, an environment where he or she may express their problems. The therapist does not direct the process, but works on the assumption the patient has the resources to deal with their own “cure” and self-growth, provided the environment is supportive of them. Like the Buddha, this non-authoritative approach suggests the patient can be “a light unto themselves”. Although the therapist may do little more than provide active and empathic listening, and reflect and validate the thoughts and emotions of the struggling patient, they nonetheless, provide three crucial components for change to occur; unconditional positive regard, empathy and congruence (or genuineness). These are the elements that are considered essential to create an environment where the individual can grow, learn and evolve.

This is of particular interest to the Buddhist student who is taught that all suffering stems from the three “bitter roots” or “poisons” of greed, hatred and delusion. Brazier demonstrates how, from a therapeutic perspective, Person-Centered Therapy counters each of these “poisons”; empathy is the “antidote” to hate, unconditional positive regard provides a model of acceptance of self and other which counters the grasping, needy nature of greed, and congruence (genuineness) is the opposite of delusion. Delusion itself, as Brazier suggests, could just as well be translated as “incongruence”, the separation of self and mind from what is real and what is present.

CONCLUSIO

Buddha was commonly referred to as “the great physician” and like any therapist, made it his aim to identify, explain and end human suffering. All therapists do have similar aims. Four Noble Truths are the method to adopt a diagnostic format to explain suffering and its cure; the 1st Noble Truth identifies the disease, the 2nd provides etiology, the 3rd gives a prognosis, and the 4th suggests a remedy.

Philosopher and Orientalist Alan Watts once wrote: If we look deeply into such ways of life as Buddhism, we do not find either philosophy or religion as these are understood in the West. We find something more nearly resembling psychotherapy. The main resemblance between these Eastern ways of life and Western psychotherapy is in the concern of both with bringing about changes of consciousness, changes in our ways of feeling our own existence and our relation to human society and the natural world.

What Buddhism is really all about is returning to this life, your very own little life, with a “new attitude.” By being more calm, more aware, a nicer person morally, someone who has given up envy and greed and hatred and such, who understands that nothing is forever, that grief is the price we willingly pay for love... this life becomes at very least bearable. We stop torturing ourselves and allow ourselves to enjoy what there is to enjoy.

Buddha was a unique psychotherapist. His therapeutic methods helped millions of people throughout the centuries. Today the Western world has realized the psychological essence of Buddhism. Many Psychotherapeutic systems in the West are derived from Buddha's teaching. Buddha showed empathy and non-judgmental acceptance to everyone who came to him. He helped people to gain insight and helped in growth promotion while eliminating troubling and painful emotions. His therapeutic methods are exceptional and can be applied for all times. Prince Gautama gave his entire life in understanding and then propagating his philosophy. People have devoted their entire lives to studying and understanding his philosophy. Being a student of modern psychiatry, I do not claim to be an expert in Buddhist philosophy and/or religion. This essay is just an expression of what little I have understood on His philosophy and an opportunity to offer my deep tribute to one of the greatest psychotherapists the world has ever produced!

PSYCHOLOGICAL THOUGHT IN SUFISM

From the 9th century onwards, Sufism has encapsulated Islamic spirituality. This is the loving heart of Islam, still alive, thriving and widely influential today. It is not the Islam of fundamentalists: quite the reverse.

From the earliest days, ascetic Muslim contemplatives practised fasting, praying and meditation in seclusion, just like the desert mothers and fathers of the Christian tradition, the earliest monks and nuns. Perhaps because they wore rough garments made of wool (*suf* in Arabic), these people came to be known as ‘Sufis.’ Sufism soon became the name of a mystical path by which people seek the truth of divine love and knowledge through direct personal experience of God. Sufis are said to take precious care of the ‘spiritual heart’ through ‘muraqaba,’ a practice akin to meditation.

Their aim and ambition is to grow increasingly attuned to the ever vigilant Divine Presence within. Dedicated Sufis are constantly meditating on the words of the Islamic holy book, the *Qur’an* (Koran).

Sufism is often considered external to the mainstream doctrine of Islam, and has at times encountered opposition and hostility. Many of the great Muslim thinkers were Sufis, however, as were the most successful missionaries. In addition, these humble living examples of wisdom, compassion and love were held in great esteem and affection by ordinary people, those less capable of disentangling the legal and theological intricacies of more formal religion. Two aspects of Sufism well known in western culture are, of course, Rumi and the 'whirling dervishes'.

Jalaladdin Rumi (1207–1273) went through a most powerful spiritual awakening as a young man. Influenced by his beloved teacher, Shams of Tabriz, his heart full of divine light, he became a supreme poet and faithful interpreter of the truths to be found in the *Qur'an*.

By means of sometimes mysterious language, he was able to guide others to a love of God. The *Qur'an* statement, that 'Allah loves them and they love him' quickly became the basis for love-mysticism championed by Rumi, as in the following quatrain:

'Love is here like the blood in my veins and skin, It has emptied me of myself and filled me with the Beloved, His fire has penetrated all the atoms of my body. Of "me" only my name remains; the rest is Him.' Rumi, known too by the honorary title 'Mawlana', also favoured and promoted 'whirling'. This is a form of extended rotatory dancing to sacred music in formal groups while repeating inwardly the name of 'Allah'. It induces a trance-like state of consciousness, and is a central aspect of Sufi worship performed by the renowned Dervishes, some of whom are still practising their traditional 'Sema' (whirling) ceremonies today. Whirling, meditation, prayer, 'dhikr' (regular study and remembrance of the *Qur'an*) and reciting poetry, especially love poetry, are all integral to devotional Sufi spiritual practice.

It is not true that Sufism is a men-only tradition. A woman called Rabi'a (d. 801) who lived in Iraq was, for example, one of the best loved of all the early Sufis. Revered Sufi teacher, Ibn al-Arabi (d. 1240), was first taught the spiritual path in his native Spain by two female Sufis. Later there were Sisterhoods among the different orders of Sufism, as well as Brotherhoods. And women attend Bektashiyya ceremonies, without even wearing veils. Many women follow the Sufi tradition today.

At the heart of Sufism is the idea that humankind, the most honourable of creatures, is bound by covenant to carry the Divine Trust. It follows that if the ego forgets the Divine purpose of creation, viewing itself as existing independent of its Creator, it is betraying that sacred Trust. Now, the modern ego continually quests for self-satisfaction and self-adoration. Sufi practices, like those of many other world religions, enable people to combat this tendency, seeking to discover and bring forth the higher or 'true' self, that spark within each person, constantly attuned to the spiritual dimension.

The Sufi seeks to live according to eternal, selfless spiritual values, rather than transient, mercenary worldly ones. Neuro-scientific studies reveal that practices like meditation, chanting and whirling all improve harmony between the dualist, verbal, intellect of the brain's left hemisphere and the holistic, silent, poetic intuition of the right. That Christianity, Judaism, Buddhism, Zen, Taoism, and Hinduism's Vedanta all promote similar practices, aimed equally at conquering the tyranny of the ego, indicates a comforting degree of uniformity among travellers along the pathway to spiritual maturity, whatever their religious origin.

The term "Sufi psychology" is probably a deceptive one, because it implies that there is a relatively homogenous doctrine of the psyche that the majority of the Sufis would subscribe to. It is not the case. However, one can point out the terms most frequently used and expound on the meanings of these notions.

Drawing from Qur'anic verses, virtually all Sufis distinguish between Nafs, Qalb, Sirr and Ruh. These concepts designate various psychospiritual "organs" or, sometimes, faculties of sensory and supra-sensory perception.

NAFS

Nafs is usually translated as soul or psyche. Its etymology is rooted in "breath" (similar to Biblical or Kabbalistic nefesh and is common to virtually all archaic psychologies where the act of breathing was connected with life, animating otherwise lifeless object. In this respect, ancient notions of "Atman" in Hinduism (cf. German noun "Atem", breath, respiration) or Greek "pneuma" (as well as Latin "spiritus")-all equate the basic visible process of breathing with energizing principle that confers existence to an individual human being.

Some Sufis consider under the term "Nafs" the entirety of psychological processes, encompassing whole mental, emotional and volitional life; however, the majority of Quranic-based Sufis are of the opinion that Nafs is a "lower", egotistical and passionate human nature which, along with Tab (literally, physical nature), comprises vegetative and animal aspects of human life.

Synonyms for Nafs are devil, passion, greed, avarice, ego-centredness etc. The central aim of the Sufi path is transformation of Nafs (technical term is "Tazkiya-I-Nafs" or "purgation of the soul") from its deplorable state of ego-centredness through various psychospiritual stages to the purity and submission to the will of God. Although the majority of the Sufi orders have adopted convenient 7 maqams (maqams are permanent stages on the voyage towards spiritual transformation), and some still operate with 3 stages, the picture is clear: the Sufi's journey begins with Nafs-I-Ammare (self-accusing soul) and ends in Nafs-I-Mutma'inna (satisfied soul)- although some Sufis's final stage is, in their technical vocabulary, Nafs-I-Safiya wa Kamila (soul restful and perfected in God's presence). In essence, this is almost identical to Christian paradigm of "vita purgativa" and various stages the spiritual aspirant traverses in the journey towards God.

QALB

The next term, Qalb, stands for heart. In Sufi terminology, this spiritual heart (not to be confused with the pump in the breast) is again variously described. For some, it is the seat of beatific vision. Others consider it the gate of Ishq or Divine love. Yet, for the majority, it is the battleground of two warring armies: those of Nafs and Ruh or spirit. Here, one again encounters terminological confusion: for the Sufis influenced by Neoplatonism, a "higher" part of Nafs is equated to the Aql or intellect (called Nafs-I-Natiqa) or "rational soul" and is the central active agent in spiritual battle: Ruh or spirit, notwithstanding its name, is rather passive in this stage. In short, cleansing of the Qalb or heart is a necessary spiritual discipline for travellers on the Sufi path. The term for this process is Tazkiah-I-Qalb and the aim is the erasure of everything that stands in the way of purifying God's love or Ishq.

SIRR

The third faculty is Sirr, or "the secret", located for the majority in the middle of the chest. Emptying of the Sirr (Taqliyya-I-Sirr) is basically focusing on God's names and attributes in perpetual remembrance or Dhikr, hence diverting one's attention from the mundane aspects of human life and fixing it on the spiritual realm. The "emptying" signifies negation and obliteration of ego-centred human propensities.

RUH

Ruh or spirit is the fourth "entity" and the second contender in the battle for human life. Again, opinions on Ruh differ among Sufis. Some deem it coeternal with God; others consider it a created entity. Be as it may, Ruh is the plateau of consensus for the majority of Sufis, especially the early ones (before 11th/12th century C.E.). For those Sufis with Gnostic leanings (which can be found in Bektashi or Mevlevi orders), Ruh is a soul-spark, immortal entity and transegoic "true self", similar to the Christian concepts of "synteresis" or "Imago Dei", or Vedantist notion of "jiva", as well as a Tibetan Buddhist "shes-pa", principle of consciousness and Taoist "shen" or spirit.

But, the majority of the Sufis would consider this an unnecessarily extravagant speculation and would stick to the more orthodox notion of dormant spiritual faculty that needs to be worked upon by constant vigil and prayer in order to achieve the Tajliyya-l-Ruh, or Illumination of the spirit. Ironically, this spiritual faculty is frequently referred to in terms one encounters in connection with Nafs- "blind" life force or life current that needs to be purified by strict religious observances in order to achieve illumination.

So, in these four "organs" or faculties: Nafs, Qalb, Sirr and Ruh, and the purificative activities applied to them, the basic orthodox Sufi psychology is contained. The purification of elementary passionate nature (Tazkiya-l-Nafs), followed by cleansing of the spiritual heart so that it may acquire a mirror-like purity of reflection (Tazkiya-l-Qalb) and become the receptacle of God's love (Ishq), fortified by emptying of egoic drives (Taqliyya-l-Sirr) and remembrance of God's attributes (Dhikr), gloriously ending in illumination of the spirit (Tajjali-l-Ruh)- this is the essential Sufi spiritual journey. Other spiritual faculties, like Khafi (the arcane) and Akhfa (the most arcane) are employed in other Sufi orders like Naqshbandi, but this is beyond general basic consensus.

THE NEED TO KNOW SUFISM

Human cognitions and behaviors are determined largely by a set of facts and values. The facts are mostly derived from the science and the values have their origin in religious or non-religious philosophies such as humanism and existentialism. Spirituality being an integral part of most of the religious philosophies provides the value system for the majority of people and thereby influences their well-being. Recognizing this, the spiritual well-being, in accordance with the social and cultural patterns, was accepted as one of the important determinants of health by the World Health Organization during the 37th World Health Assembly in 1984.

Spiritual teaching has already found its place in the curriculum of many medical schools in the Western world. From a mental health perspective, spirituality seems to have a far greater role as these operate on the same ground – the brain or as some would like it call it the mind or the soul. In fact, there are studies that show positive as well as the negative impact of the spiritual and religious beliefs and practices on the physical and mental well-being of people who subscribe to spiritual or religious practices.

Sufism, having a large following both in the Muslim world and outside coupled with migration of large numbers of people from eastern Sufi oriented lands to the west, is a rapidly growing form of spirituality that needs to be understood in terms of its impact on the mental well-being of its followers and the potential interactions in the mental health care clinical settings.

From a more philosophical point of view, Sufism provides an opportunity to understand the source of religious knowledge in general and Islamic knowledge (revelation) in particular. In Sufi traditions,

it is believed that Sufis can have similar knowledge revealing experiences as are the source of religious knowledge in the form of revelation of the Quran (the scripture of Islam) to Muhammad (the Prophet of Islam).

The study of these Sufi experiences which share phenomenological ground with the prophetic experiences of revelation provides a possibility for the scientific study of the sources of religious knowledge. From day-to-day clinical practice to research, the study of the normal and abnormal perceptual/experiential phenomena and its implications form an integral part of the mental-health related sciences and puts the students of mental-health sciences in a coveted position to study the Sufi experiences.

HISTORICAL BACKGROUND OF SUFISM

The term Mysticism had its beginning in the mystery cults of the Greeks, which involved a close circle of devotees who because of their innate capacity were believed to have the knowledge of the divine revealed to them.

Etymology aside, mysticism has been practiced since ages across all the cultures and has been a vital part of the major religions of the world. Perhaps it represents an innate desire of the man to understand himself and the world around. All forms of mysticism aspire for a union with the divine and believe that it is only possible through the purification of soul to receive direct knowledge and revelation from the divine.

Islam began in 610 AD and established itself through the teachings of Muhammad believed to be revealed to him by God through the archangel Gabriel primarily among the Arab pagan and Christian communities. The close contact between the Muslim and the Christian communities during the formative years of Islam had its influence on the development of the Sufism – the mystic traditions of Islam.

Sufism established itself within the traditions of the Islam as laid down in the Quran believed to be revealed to Muhammad by God. The Sufis believe that communion with God is possible through Muhammad, who was the recipient of the knowledge of the heart (*Ilm-e-Sina*) besides the outer knowledge (*Ilm-e-safina*).

Ali, one of the Muhammad's companions and son-in-law, is considered to be the first Sufi to whom the *Ilm-e-Sina* was revealed by Muhammad to be taught to those capable of understanding it. Contrary to the mainstream, some schools of thought in Islam denounce Sufism as heretical and consider it an innovation in Islam. However, the concept of God, the possibility of esoteric knowledge and the ways to access God through purification of self by means of prayer, fasting and repentance that form the foundations of Sufism find their source in the Quran and the teachings of the prophet known as *Hadith*.

Sufism in the beginning was primarily an individual endeavor. The Sufis would usually live in isolation practicing self-mortification and were distinguished by a cloak of wool (*Suf*), a tradition of Muhammad, which is believed to be the origin of the word Sufi.

A group of such devout lived a life of poverty and incessant prayer and fasting on a stone bench in front of Muhammad's mosque.

These people of the bench (*Ashab-e-suffa*), 45 to over 300 in number, were given to much weeping

and repentance and are believed to be the origin of the Sufism.

However, the name Sufi was given to such ascetics only around the second century of death of Muhammad. The Sufis in the early period were primarily ascetics and Sufism had not yet evolved into a fully developed system of theosophical doctrines, which became the core feature of the later Sufism.

The companions of Muhammad like Bilal, Salman Farsi, Ammar bin Yasir were the early mystics. Later with the spread of Islam Sufism flourished in Iraq, Syria, Egypt, Persia and Central Asia and gave birth to the renowned Sufis like Rabia Basri, Hasan Basri, Junayd Baghdadi, Dhun Nun Misri, etc., around the 9th and 10th century.

As the early Sufi masters started teaching those in search of divine, a distinct tradition in the form of closely-knit communities centered around these masters flourished. The transformation of such communities into those, which shared a spiritual lineage, took place around the 11th century and led to the formation of Sufi orders (*silsilas*), chains through which they would eventually link their disciples to Muhammad

The early Sufi orders like Muhasibis, Qassaris, Junaydis, Nuris, Sahlis, Hakimis, Kharrazis, Sayyaris, and Tayfuris though limited to particular geographic locales were influential in the development of Sufi thought.

Later major Sufi orders with a wider appeal were established around Sufi masters like Qadri by Abdul Qadir Jilani (Baghdad), Chishti by Abu Ishaq Shami (Syria), Suharwardi by Abu Najib Suharwardi, Yasavi by Ahmed Yasavi (Kazakhstan), Kubrawiya by Najmuddin Kubra (Central Asia), Rifai by Ahmed Rifai (Iraq), Shadhili by Abul Hasan Shadhili (Morocco), Mevlavi by Jalal ud Din Rumi (Konya), Naqshbandi by Bahauddin Naqshband (Bukhara), Nimatullahi by Nuruddin Muhammad Nimatullah (Syria) and Tijani by Abbas Ahmad ibn al Tijani (Algeria). The Sufi orders practiced presently run in hundreds but most of these represent the offshoots of the earlier ones.

The 13th century considered the golden age of Sufism was marked by the development of comprehensive mystical and theosophical doctrines of Sufism by the Sufi scholars like Ibn ul Arabi of Spain, Ibn ul Farid of Egypt and the popular Persian Sufi poet Jalal ud Din Rumi. After the golden era the Arab-Muslim world produced only a few notable Sufi scholars though the influence of Sufi orders continued to grow.

The rise of Wahabism in the late 18th and 19th century that condemned Sufism as a heresy and the social and political reforms in the Muslim world during the 20th century that considered Sufism as an impediment to development restricted the growth of Sufi philosophy and confined it to closely-knit circles of spiritual education.

Apart from the Christian asceticism, Hinduism had a significant influence on Sufism both in terms of the philosophical basis and the meditation practices, which started much before Sufism reached the Indian subcontinent

The concept of existential unity of being (*wahdat-ul-wujood*) propounded by Ibn ul Arabi in the 13th century bears striking similarity to the Advaita philosophy (unified Brahma-Jnana) of the Puranas (ancient Hindu religious texts).

The concept of *wahdat-ul-wujood* has been a dominant philosophy in the later day Sufis which brought them closer to the Hindu mystics like Ramanand, Chaitanya, Ramanuja, Namdev, Mira Bai, Tukaram, and Ramdas, resulting in social movements like the Bhakti movement.

The Sufis also incorporated some of the meditation techniques from the Hindu mystics like the breathing techniques to facilitate their Sufi practices. In the 11th century, Saifuddin Kaziruni from Iran was the first Sufi to settle in the Indian subcontinent.

Later the subcontinent became home to some of the great Sufi saints and scholars such as Moinuddin Chishti, Nizamuddin Awliya, Fariduddin Ganj-i-Shakar, and Qutbuddin Bakhtiar Kaki, whose teachings were influential in much of the growth and acceptance of Islam.

SUFISM: THE ESSENCE

The ultimate aim of the Sufi is communion with God through spiritual realization, which is achieved through the knowledge revealed by Quran (*ilm*) and the practice of Islam (*amal*).

Since its inception the Sufi philosophy has revolved around the concept of God and the ways and nature of communion with him. The early Sufis adhered strictly to the Quran in their interpretation of the concept of the God as infinite, eternal, unchangeable, creator, all-powerful, merciful and the cause of all existence. With the growth of Sufi philosophy, the concept of God changed from the one as the cause of all existence to the idea of God as the only real existence. This philosophy reached its ultimate in the concept of the *wahdat-ul-wujoo* Sufis regards the soul as the agency for communication with God. It is the higher soul, as Sufis believe, created before any human being came into existence, consisting of heart (*qalb*), spirit (*ruh*), and conscience (*sirr*) that has the ability to know God. The *sirr* is regarded by many Sufis to represent the "secret shrine of God himself, wherein he knows man and man can know him."

The heart (*qalb*) has an important place in Sufism and is considered to contain the divine spark that leads to spiritual realization. Sufis cherish the revelation by God that "I, who cannot fit into all the heavens and earths, fit in the heart of the sincere believer." For the heart (*qalb*) to reflect the truth as it is, it has to be cleansed of the rust of worldly influences.

The concept of the covenant (*misaq*) described in Quran "And (remember) when thy Lord brought forth from the children of Adam, from their reins, their seed, and made them testify of themselves (saying): Am I not your Lord? They said: Yea, verily. We testify. (That was) lest ye should say at the Day of Resurrection: Lo! Of this we were unaware" forms the basis of the Sufi philosophy of communion with God.

There is another soul (*nafs*) that Sufis regard as the seat of passions that creates hurdles in the communion of the higher soul with God. The *nafs* has to be transformed from *nafs-e ammara* (lustful soul; cf. Id) to *nafs-e lawwama* (self-blaming soul; cf. ego) and ultimately into *nafs-e mutmaenna* (peaceful soul; cf. super-ego) to return to truth.

Muhammad, has a special place in Sufism. The spiritual enlightenment or the ascendance of the higher soul for communion with God is believed to go through a chain of transmissions to Muhammad as through him only can the communion be achieved. Sufis refer to the saying of Muhammad "the first thing that Allah created was my light, which originated from his light and derived from the majesty of his greatness" as a basis for this belief.

Sufis believe that the ascendance is possible only through the process of purification of the soul – the way (*tareeqa*).

PSYCHIC EXPERIENCES IN SUFISM DIFFERENT PERSPECTIVES

Spiritual or psychic experiences are a quite common occurrence across cultures and religions. Though there are no specific studies related to Sufism, surveys reveal the percentage of people having had psychic experiences to range from 20% to 45%; the frequency varying with the time, gender, religion, etc.

Surprisingly the experiences share many features notwithstanding the differences in practices, beliefs, and cultures within which they occur. The psychic experiences occur in the domains of thought, perception and feeling (a complex perceptual experience) and share certain features regardless of the domain. The psychic experiences, partly based on individual accounts of Sufis, are immediate, usually transient, ineffable, unanalyzable, involving intimate association with a unique other self, transcending time, space and person, and felt as a deep sense of bliss.

Historically, psychic experiences have been attributed to divine experiences, possession by demons, regarded as heresy and even insanity. The interpretations have varied with the political and religious environs of the times and have been influenced by the societal class of the claimant, the content of the experiences vis-à-vis the existing political and religious norms, gender, etc. The experiences have been interpreted to promote or discredit a particular political thought and even used as a plea for insanity. The case of two famous Sufis who claimed extreme forms of mystical experiences, Mansur al Hallaj and Bayazid Bastami needs a mention here. Both were and are considered as great Sufis on one hand and as heretics on the other and were even sentenced to death during their times for heresy.

Psychic experiences involve some experiences beyond the normal and Sufis claim these to be the source of ultimate knowledge (*marifa* or gnosis). The possibility of such knowledge yielding experiences has been questioned from philosophical and scientific perspectives. Kant rejected the possibility of the knowledge of ultimate as falling outside the sphere of human experience and hence its irrational nature. Sufi philosophers have argued for the possibility of such experiences as being only an extension of normal human experiences. The Sufi philosopher Fakhruddin Iraqi considered the possibility of these experiences as located in different orders of time and space (divine time and space) consequent to changes in the level of human consciousness.

The greatest impediment in the study of psychic experiences has been the subjective nature of these experiences, which contrasts with the classical objective nature of science.

SUFISM AND PSYCHOTHERAPY

Spiritual and religious beliefs form an important means of coping with stress for a large number of people but unfortunately this has received little attention by the mental health professionals. Recently, however, religion and spirituality have been incorporated into the therapeutic process and have shown promising results.

The assimilation of spirituality into the psychotherapeutic process has been either in the form of an augmentation of an already existing therapeutic technique – spiritually augmented cognitive

behavior therapy or the development of new techniques where spirituality itself forms the core – transpersonal psychotherapy.

Though Sufi beliefs and practices have been incorporated into the transpersonal psychotherapy but there exists no literature about the incorporation of these into the cognitive behavior therapy models.

Spiritually augmented cognitive behavior therap.

Spiritually augmented cognitive behavior therapy is primarily a cognitive behavior therapy which incorporates the individual's belief system, specifically the spiritual, to focus on the existential issues. The therapist works with the individual's spiritual beliefs and practices like meditation, prayer, etc. but at no point attempts to instill his own beliefs or beliefs never held by the patient into the therapeutic process.

The therapy spans over 10-16 sessions, each session lasting 45-70min conducted once a week. The therapy has demonstrated efficacy in controlled trials with reduction of relapse and re-hospitalization in the treatment group.

The Sufi themes of patience (*sabr*), trust in God (*tawwakul*), contentment (*rida*), and God as the ever-forgiver may have a significant impact in changing the negative cognitive schemas and coupled with the Sufi practices of remembrance of god (*zikr*) and thankfulness (*shukr*) may provide an appropriate framework for spiritually augmented cognitive behavior therapy for the Sufi believers.

TRANSPERSONAL PSYCHOTHERAPY

Transpersonal psychotherapy is based on the premise that human beings are essentially spiritual beings and hence the core qualities associated with spirituality form the goals of transpersonal psychotherapy.

The role of the therapist in transpersonal psychotherapy has been seen variously as ranging from a spiritual guide to a “fellow spiritual sojourner.” The therapist does not promote any specific spiritual philosophy and it is the client who leads and determines the spiritual content of the therapy.

Different spiritual practices, including Sufism, yoga, *qigong*, *aikodo* have been incorporated into the transpersonal psychotherapy. Transpersonal psychotherapy has been used for the

treatment of abnormal grief, spiritual crises, psychotic disorders and substance use disorders. Transpersonal psychotherapy can provide the basis for engagement of traditional faith healers with the mental health care services and given the magnitude of people who seek traditional faith healers this can have significant public health impact.

SUFISM AND MENTAL HEALTH CARE SERVICES

A vast number of the mentally ill people in the community go untreated or seek the help of spiritual healers in most of the developing countries. The reasons lie in the belief systems of the people which foster a spiritually oriented explanation of the mental illnesses and the practically non-existent mental health care services in most of the rural settings. The large number of mentally ill people thronging the shrines (*dargah*) of Sufi saints to seek cure is a testimony to this. The Erwadi (India) fire at the shrine of the Sufi saint Shaheed Valiyullah leading to the death of 28 mentally ill people should be a grim reminder of the cost of neglecting the incorporation of people's spiritual beliefs into the mental health care services. The incorporation of spiritual/Sufi elements into the mental

health care services needs to be a two-fold process:

1. Incorporation of the spiritual/Sufi healers into the mental healthcare delivery system which may include basic training in identification of mental illnesses and appropriate referrals when needed.
2. Incorporation of the spiritual/Sufi beliefs and practices into the therapeutic process which may increase the utilization of mental health services by a largely spiritually oriented population. The integration of spiritual beliefs and practices into the mental health care delivery system needs efforts both at the organizational and individual level. Sensitization of the trainees in the mental health profession to spiritual issues needs to be given an impetus

The focus of the training should be on understanding of spirituality as an important part of the individual seeking help and a thorough understanding of the belief systems of the people in the practice area.

CONCLUSION

Sufi beliefs and practices form an integral part of the belief system of not only the majority of the Muslim world but also the western world where it is gaining popularity. Sufism provides a vital link to the understanding of revelation – the source of religious knowledge in Islam as well as other Semitic religions, and influences the mental health of its believers and practitioners in a significant way.

Unfortunately, there is little in terms of research based evidence to draw any conclusions in both these directions. There is a need for research to evolve scientifically sound means of incorporation of Sufi beliefs and practices into the mental health care system before any dogmas strike their roots. At the same time, mental health professionals should not slide into the role of preachers and start promoting the Sufi beliefs and practices; the role should rather be restricted to utilizing these beliefs and practices where it forms a part of the belief system.

PSYCHOLOGICAL THOUGHT IN INTEGRAL YOGA

Psychology: The Perpetual Discovery While physical and life- sciences have made rapid advances and known Nature to some extent, psychology the science of human thought - has not made similar progress. It has yet to know the many hidden possibilities of our mind. Modern Western psychology basically suffers from the materialistic error of making the study of the mind dependent upon our knowledge of the body. It suffers, too, from "a sceptical error which prevents any bold and clear eyed investigation of the hidden profundities of our subjective existence; the error of conservative distrust and recoil which regards any subjective state or experience that departs from the ordinary operations of our mental and psychical nature as a morbidity or a hallucination, - just as the Middle Ages regarded all new science as magic and a diabolical departure from the sane and right limits of human capacity; finally, the error of objectivity which leads the psychologist to study others from outside instead of seeing his true field of knowledge and laboratory of experiment in himself. "!

It must study all the facts of consciousness or, rather, all the planes of consciousness as well as the processes of the Inconscient, the subconscious and the superconscious self. To discover, possess and utilise them all should be the aim of psychology. Our deeper and greater self which is the source of all the facts of our consciousness is not inconscient in its nature, it is essentially superconscious and concealed from our waking self. It is this supreme discovery that opens before the individual the possibility of endless evolution.

Modern psychology proceeds on two divergent lines of investigation. On the one hand it accepts

the Inconscient as the basis of all existence, and like all other physical sciences studies the Inconscient forces working in Matter; it then works 'as a continuation of physiology', and regards Mind as a phenomenal result of the working of these forces. The ' Inconscient is thus raised to the level of a godhead. For modern psychology, "The Inconscient is greater than the conscient; it is the god, the magician, the creator whose action is far more unerring than the ambitious but blundering action of the conscious mentality."? For it, the plant kingdom is more perfectly guided in its growth process precisely because it is part of an unintelligent action whereas the conscious mentality of man is prone to error, open to ignorance and falsehood. The Inconscient, by the law of heredity and intuitive adaptation ensures the perpetuation of healthy and good types of species. Whereas man promotes degeneracy by misusing heredity in the false environment of his social life. A constructive science of eugenics, properly developed by man, could usefully accelerate usefully the selective process of Nature to the advantage of the human race.

There is the other line of psychological enquiry which leads us into the domain of occultism and the psychics. This investigation may not be as positive and tangible in its conclusions as the former, but it is wider and broader based, and capable of a much deeper and surer action. It embraces and explains our surface awareness; it indicates clearly the presence of a hidden Consciousness, subliminal to our waking state, perfect in power and action. The surface mind is only an appearance, a limited action of this subliminal Consciousness. The Upanishadic seers, too, arrive at the realisation of Brahman as the supreme Bliss of Existence after a series of graded experiences. Brahman is progressively realised by them as Matter, Life, Mind and infinite Knowledge, and finally as Bliss, - the highest mode of experience that an individual can reach. Unlike the premise of modern psychology, for which the Inconscient is the basis, the supremely Conscient is the truth of all existence for the Ancients. Ancient Indian psychology speaks of three states of awareness - the waking; the dream and that of deep sleep, jagrat, swapna, susupti. There is the strata of the inmost self that transcends them all - turiya. The Superconscient is unknown and unknowable to the human mind; it is self-collected and concentrated, all-embracing and all-possessing. It is the consciousness of manifold oneness and all delight, it is the omniscient and all-blissful womb of everything. It is unknown to the waking mind.

YOGA: THE PSYCHOLOGY OF SELF-PERFECTION

Yoga is one of the means of knowing man and the workings of cosmic forces through Nature and life. It is the study of the human mind, and of the greater mind expressing itself in all beings and things. It leads to the perception of the divine Intelligence and Will working through individual and cosmic evolution. Yoga is a powerful and perfected method of union with this divine Intelligence and Will. It provides a path of quick and conscious seeking and union with the Divine on one or more planes of our being. While the physical and vital mind looks upon outer things, Yoga penetrates the surface appearances and reaches the reality within them. It is a conscious method of turning within by the practice of three movements, - purification, concentration and identification. The mind as it is constituted deforms Reality and reflects only the physical reality; it reflects even the physical universe not very perfectly and accurately because of its inherent limitation and incapability. The object of purification is to enable the mind to receive the light from above and reflect the Truth fully and perfectly.

The method of Yoga apart from being ethical is essentially psychological. It implies or, rather, necessitates "the consummate practice of a perfect psychological knowledge." It is this practice that transforms philosophical abstraction into spiritual concreteness and the Yogin becomes 'a channel

of God-consciousness and Godaction'. This perfect self-perfection which ensures a fundamental oneness with the Divine both in his being and nature is termed as *siidrsya-mukti*. This identity of the law of one's being with the in-dwelling Divine is what the Gita calls *siidharmya-gati*, and is attained only by an effective and total conversion of the limited and imperfect mental-vital nature of the seeker. The 'thinking mortal matter' of man conceals the Immortal, and Yoga is the most effective means of helping man to extricate himself from the stranglehold of surface life and surface-values and realise the Immortal. Yoga is the unveiling of the Godhead within; it is the best guide to self-exploration and self-conversion. While modern psychology with its scientific and materialistic basis deals with surface mind and surface values, Integral Yoga Psychology with its spiritual and supramental basis takes into consideration the whole nature of the real man. Man is essentially God in a closed chrysalis of animal-physical life. Yoga helps him to discover his real self, his infinite spiritual foundation. His mind-life-body complex is used by the spirit within him as a means for a unique individual and communal experience. It is for the purpose of its self-manifestation in the universe. "The spirit is an infinite existence limiting itself in apparent being for individual experience. It is an infinite consciousness which defines itself in finite forms of consciousness for joy of various knowledge and various power of being. It is an infinite delight of being expanding and contracting itself and its powers, concealing and discovering, formulating many terms of its joy of existence, even to an apparent obscuration and denial of its own nature. In itself it is eternal *Sachchidananda*, but this complexity, this knotting up and unravelling of the infinite in the finite is the aspect we see it assume in universal and in individual nature. To discover the eternal *Sachchidananda*, this essential self of our being within us, and live in it is the stable basis, to make its true nature evident and creative of a divine way of living in our instruments, supermind, mind, life and body, the active principle of a spiritual perfection.:" For the effectuation of its secret purpose in Nature the supreme Spirit uses Supermind, mind, life and body as its four effective instruments. Whereas the Supermind is a self-luminous infinite knowledge and a self-creative limitless power and grounded in unity, the mind is partially illusioned, limited and caught up in 'the separative action of diversity'. Because of its limitation and divisive nature mind works even as a power of ignorance.

While life is a link between mind and body, it is the creative energy of the Spirit that, operating within the parameters of physicality and mentality, supports and effects the formulations of the substance of matter and of mind. Life-energy is essentially the power of consciousness working and emerging in matter. It liberates mind from matter's stranglehold, it liberates all other higher powers too and makes it possible for their action in the material world. Likewise mind, too, is a power of consciousness that awakens in vitalised matter to its own awareness as well as to the awareness of all things around it. But mind and life are not restricted in their activity to material existence alone, they have their own planes of existence wherein their power of action is unrestricted, free and full. Life and mind are involved in matter, and seek to emerge and evolve out of it progressively because of a secret pressure exerted from above from their own native planes in addition to their own demiurge from within. Even as they are capable of subtler and greater and freer action, matter too is capable of refinement and transformation into subtler forms of the substance of Spirit. It contains within it the secret powers of life, mind, illumined mind, intuitive mind, Overmind and the gnosis.

The Concept of Mind in Yoga Mind, as the Gita puts it, is the cause of both man's bondage and release:

"*mana eva manusyiruum kiiranam bandha-moksayoh*" Liberation lies in the perfect control of mental modifications, *cittavrttis*. It therefore becomes necessary to know clearly the mechanism of the mind - its structure and its functions. Mind or *antahkarana*, according to most schools of Indian

philosophy, is composed of three vehicles, manas, ahamkara, and buddhi. Vedanta describes it as the antahkarana-catustaya. It is of the nature of not-Self and is the cause of both bandha and moksa. Citta in Patanjali's Yoga psychology is the mind-stuff or, rather, the mind without its thought-content. In the Yoga-system, mind is mutable and can evolve into cittas or modes of mental existence which are divided into five categories. Pramanas or right knowledge, viparyaya or false knowledge, vikalpa or imagination, nidra or sleep and smriti or memory. Whereas citta-bhumis are different psychological dispositions. There are five states of citta: ksipta-avastha, which is dominated by rajas, mudha-avastha which is characterised by tamas, viksipta-avastha which is a mixed state of sattva and rajas, ekagra-avastha in which only sattva reigns supreme and niruddha-avastha in which one is even above sattva, and beyond all modifications or change. For Yoga, mind is all-pervasive and infinite in number as each is related to a purusha. In the context of its all-pervasive nature, mind or citta is called the karana-citta. It is this that holds within itself the karya-citta as its manifestation. Again, it is karya-citta that further transforms itself as the asmita, the ten jnanendriyas and karmendriyas and the life faculties. Mind is continually changing into its many states, and is of the nature of flux. There are three distinct forms of its modifications - knowledge, willing and feeling. The citta comes into contact with the external world through the medium of the sense-modifications. In the first stage which is that of indeterminate perception the external world is presented before the buddhi.

THE PSYCHOLOGICAL CRISIS AND THE SUPERCONSCIENT

Humanity today is passing through a crisis; it is a crisis 'more mental than material.' We are mentally diseased, morally depleted and spiritually uprooted. It is a crisis of consciousness, a crisis of the soul. Our present crisis, as one American sociologist put it, is 'total, epochal and global'. Our civilisation is on the decline, its disintegration is imminent. The challenge calls for a consciousness-response capable of comprehending problems of cosmic dimensions. Psychological counselling and surface therapeutic treatments are absolutely insufficient to cure our deeper malaise.

There is a serious inner cleavage that calls for a total integration of personality. Our mental ill-health is the index of our psychological disintegration.

psychological change, an integral personality transformation. We have lost contact with our depth-dimension, we have lost the meaning of life itself. Ours is an age of anxiety and of ego-obsession resulting in psychological and emotional imbalances. Excessive and exclusive pursuit of physical sciences has created a vacuum of meaning in our lives; it has alienated us from the truth of our existence. Our individual ego is matched only by our group or nation ego in its blind self-aggrandisement. Though science has succeeded in breaking physical barriers between nations, the psychological distances still remain almost unaffected. There is, therefore, a genuine need to have a new centre of integration in our individual and group awareness, a new dimension of consciousness to take charge of personal, national and international affairs.

Individual self-interest needs to be symbiotically blended with cosmic awareness. The egocentric pattern of our present-day life-style has to be substituted by socio-centric and cosmo-centric attitudes. It is here that modern psychology can seek the guidance of Indian Yoga systems. It is in the creation of a spiritually integrated man that lies the key to a new world-order, which implies the action of the Superconscient. Adequate appreciation and application of both psychological and spiritual values in life is necessary for the establishment of an ordered and stable society. Technically and technologically we live in an atomic age, but mentally and emotionally we still belong to the Middle Ages. Psychoanalysis, analytical psychology and other psycho-bio-scientific approaches to

the understanding of the psychological process in the human situation have their limitations, and fail to cure the malaise of the race. The malady is too deep for the techniques evolved in Western psychology. Man, it is true, is a biological and psychological being, but he is a spiritual being too. We therefore need to go beyond modern psychology to accomplish the goals set before psychology by psychology itself. The Integral Yoga Psychology of Sri Aurobindo, both in its vision and action, encompasses the entire gamut of consciousness, transmutes the insights of Ancient Indian psychology and by presaging the shortcomings of psychological tools and techniques accomplishes the miracle of integral transformation of personality. There are hopeful signs of this new psychology entering more and more into the arena. The development of an Integral Yoga Psychology would be a powerful aid in cultivating and harnessing the manifold inner energies towards the highest fulfillment of the race as well as in the ushering in of a new world-order. It will also enable us to experience and explain satisfactorily the many higher planes of consciousness leading to the Superconscious. Man, at present, is not conscious of the subconscious, the subliminal and the Superconscious within.

He is aware only of his surface reality. Modern psychology is slowly becoming aware of the near depths, and not yet of the higher levels of consciousness. The aim of Integral Yoga Psychology is not only to discover them all, but to bring them into the open, into the part

and planes of human existence, and with their light and power transform them into the supernature of the Divine.

the physical mind is giving way to a deeper probe unfamiliar to the uninformed reason. But here, too, it seems to be bogged down by the common mistaken view that mind and spirit are the same, that all consciousness is restricted to the mind alone, and that the body is merely unconscious matter incapable of spirituality. But spirit and mind are not the same: mind is an instrument of consciousness.

Moreover, consciousness is not necessarily always spiritual. Also, it has to be realised that mind has parts, and not all the parts are spiritually inclined. While one part obeys the spiritual, the other can be strictly rational. If the psychic influence predominates, then it is the psychic mind. Psychology, no doubt, deals with mind and consciousness, but does not seek to find their true nature. It only tries to know their workings as well as the rule and law of these workings. Freud's psychoanalysis should never be associated with Yoga, for it takes up only the darkest and the most dangerous part of human nature - the lower vital - and attributes to it an action out of all proportion to its true role in human life. "Modern psychology is an infant science, at once rash, fumbling and crude. As in all infant sciences the universal habit of the human mind - to take a practical or local truth, generalise it unduly and try to explain a whole field of nature in its narrow terms - runs riot here. Moreover, the exaggeration of the importance of suppressed sexual impulses is a dangerous falsehood and it can have a nasty influence and tend to make the mind and vital more and not less fundamentally impure than before." 15 The subliminal has in it the secret of our surface existence and explains our surface activities, whereas the lower-vital subconscious is just a minor or an inferior part of it. The subliminal conceals a larger mind, a more powerful vital as well as a subtler physical consciousness. It is only by opening up to the spiritual and subconscious ranges of consciousness that both the subliminal and the surface nature can be purified. The lower subconscious is the darkest and the foulest part of human nature and should be handled with great caution and care, and with the right attitude. It is only after enriching the higher mind and the vital with the light and peace from above that one should turn to the subconscious and work for its purification. Sometimes the psychological process of purposeful indulgence may help in the exhaustion of a lower impulse, but more often it lends to continuous and repeated indulgence and its justification, and instead of

raising up the lower movements into the light and full knowledge of a higherbeing, it makes the subject a helpless victim of the ignorant nature. A guidance from a higher consciousness is always safe and a must for any desired change in the concealed subconscious.

INTEGRAL YOGA PSYCHOLOGY

- (i) Man by his very nature is spiritual. He is a dynamic psyche ever evolving, always integrating with the universe around him. He is a self-conscious mode of the infinite and the eternal though at present limited because of the compulsions of Nature's evolutionary process. He is a dual expression of both Being and Becoming, and manifests simultaneously the static and dynamic aspects of Reality. The static truth of his inmost existence - the impersonal eternal dimension - sanctions and supports, as it were, his creative nature, the historical dimension. The two dimensions, though distinguishable, are in fact inseparable. Integral Yoga Psychology aims at integrating the two dimensions with a view to intensify and advance the present evolutionary process. It attempts to bridge the gap between the distant ideal and the present human reality, - between the Superconscient wholeness and the existing limited self-awareness. According to Sri Aurobindo, this needs the intervention and supporting action of a cosmic and supracosmic consciousness-force, the Supermind. It is the Truth-Consciousness above that can unify this uniqueness of the individual with the relatedness of the universe in an ever glowing splendour of the transcendent. The three dimensions of the Divine the individual, the universal and the transcendent, are harmoniously and integrally effectuated in the action of the supramental.
- (ii) Man is essentially a psychological phenomenon. If psychology has to study man, it should reach and comprehend all the levels of his being, both inner and outer, and not limit itself to the mind. It is the Yogic approach to the phenomenon of man that gives an adequate account of human personality and carries with it a clarity and a certitude of its own. Man is not limited to his physical existence alone, he is beyond body, life and even mind. Psychology should therefore not restrict itself to the observation of his superficial nature. A whole world of supra-physical and spiritual phenomena have to be discovered and brought under control before psychology can hope to be a perfect and dynamic science. Our surface existence is only a part of our being, there are many other planes below and above that support and succour our external personality. For below our conscious nature is the massive Inconscient out of which life emerges. The Inconscient is much vaster, larger and deeper; it is the womb of our surface existence and its workings. Also, behind our frontal ego-nature is the kingdom of the subliminal with its manifold powers and provinces that determine and dictate our doings. Integral Yoga Psychology is founded upon the experience of the integral self as the harmonious and indivisible unity of uniqueness, relatedness and transcendence. The basic insights of Integral Yoga Psychology as set forth in the writings of Sri Aurobindo include:

The integral fullness or wholeness of the human-personality

- (1) The widest spectrum of experience ranging from the Inconscient to the Superconscient.
- (2) The synthesis and fulfilment of all yogic methods in the Integral Yoga of Sri Aurobindo.
- (3) The crowning vision of Integral Reality, and the realisation of the supreme potential of man.
- (4) The experience of the many planes or levels of consciousness reflecting the different dimensions of Reality.
- (5) The dynamic and creative union with the Supreme being resulting in the mounting

selfmanifestation of the Spirit.

WHAT IS ACADEMIC PSYCHOLOGY IN INDIA: PRE- INDEPENDENCE ERA; POST-INDEPENDENCE ERA; 1970S: THE MOVE TO ADDRESSING SOCIAL ISSUES; 1980S: INDIGENIZATION; 1990S: PARADIGMATIC CONCERNS, DISCIPLINARY IDENTITY CRISIS; ?

ACADEMIC PSYCHOLOGY IN INDIA: PRE-INDEPENDENCE ERA

The term Indian Psychology refers to the Psychologically relevant materials in ancient Indian thought. Usually this term does not cover modern developments in Psychology in India.

Modern Psychology at the beginning of the century emphasized sensation, perception and psychologists in India took out Indian theories of sensation and perception from the classics and create an Indian Psychology. For example Indian theories emphasise the notion that in perception the mind goes out through the senses and assumes the shape of the objects.

In 1934, Jadunath Sinha wrote a book on Indian theories of perception. As soon as Western Psychologists started studying cognition, Indian Psychologists started looking for Indian theories of cognition. In 1958, Jadunath Sinha wrote a book on Cognition. Later on modern Psychology started emphasising emotions, and in 1981, Jadunath Sinha wrote a book on Emotions and the Will.

The major part of ancient Indian scriptures (Hindu, Buddhist and Jain) emphasise self-realization, samadhi or nirvana. After 1960 Humanistic Psychology emerged and Psychologists became interested in paranormal dimensions of growth. Maslow's theory of self-actualization and transcendental self-actualization established the link to the major part of ancient Indian theories and methods and almost the whole of ancient Indian writings became psychologically relevant. Psychology of Consciousness, Parapsychology, Psychology of Mysticism, Psychology of Religion and Transpersonal Psychology borrow extensively from Indian writings.

The terms Oriental Psychology, Buddhist Psychology, Yoga Psychology, Jain Psychology, etc. are frequently found in modern psychological literature now. Many book lists in Psychology now include books on Yoga, Buddhism and Zen. There seems to be a paradigm shift in Western Psychology, a shift from the notion of mental disease and healing to personal growth, the reference point shifting from the statistical average or "normal" to the ideal or upper limits of man's potentiality.

The rudiments of the theory of consciousness can be traced back to the Indus valley civilization (6000 to 1500 B.C.). Artifacts of a man sitting in Padmasana have been obtained in excavations

The Swastika symbol was used in Indus valley script. Buddhist thought and methods (6th century B.C.) are in line with the objective spirit of modern science and the law of parsimony of science and Buddhism can be easily incorporated into a scientific framework.

The Psychological relevance of the four noble truths and eight-fold path and Sunya vada of Buddhism and Buddhist techniques of meditation are of considerable relevance in modern Psychology. Similarly Jain scriptures also are found to be relevant to Psychology in more than one way.

The Vedas date from about 1500 B.C. However, Upanishads (appendices to the Vedas, which date from 600 B.C.) which describe the Vedanta philosophy and provide the theoretical foundation of Jnana Yoga are of more direct relevance to Psychology.

The Bhagavat Gita gives a quintessence of Indian way of life and philosophy and it describes the four yogas, Karma, Bhakthi, Raja and Jnana. Several books have come on the psychological relevance of Gita. Maslow's theory of Meta-motivation is very similar to the concept of Nishkamakarma outlined in the Gita.

Patanjali's Ashtanga Yoga is a very systematic presentation of Rajayoga. Both Bhagavat Gita and Ashtanga Yoga are supposed to have been written around the turn of B.C. to A.D. Sankara's writings (8th century A.D.) on the different yogas as well as his Advaita philosophy are considered as classics in the area and are of great value to the Psychology of consciousness as well as personal growth. Modern interest in relaxation can be traced to studies on Savasana. Rising popularity of meditation practice links Psychology to Oriental religious practices and philosophy.

Indian literature on aspects of consciousness is vast, considering the classics and their commentaries. Mental states have been analyzed, classified and differentiated in detail. Similarly paranormal powers (siddhis) have been classified in detail. The process of personal growth and obstacles to growth have been examined thoroughly.

There is a great deal of maturity resulting from long experience in these areas reflected in the writings. Indian theories of linguistics, social behavior, crime, etc. are all based on the holistic approach and the broad-based intuitive understanding of behavior in contradistinction to Western theories which are piece-meal, analytic and situation specific.

The increasing importance given to the holistic approach and need for synthesis makes it possible to integrate modern Western Psychology with ancient Indian thoughts as well as methods.

THE PRE-INDEPENDENCE ERA

The Indian National Congress first convened in December 1885, though the idea of an Indian nationalist movement opposed to British rule dated from the 1850s. During its first several decades, the Congress Party passed fairly moderate reform resolutions, though many within the organization were becoming radicalized by the increased poverty that accompanied British imperialism. In the early 20th century, elements within the party began to endorse a policy of *swadeshi* ("of our own country"), which called on Indians to boycott of imported British goods and promoted Indian-made goods. By 1917 the group's "extremist" Home Rule wing, which was formed by Bal Gangadhar Tilak and Annie Besant the previous year, had begun to exert significant influence by appealing to India's diverse social classes.

In the 1920s and '30s the Congress Party, led by Mohandas (Mahatma) Gandhi, began advocating nonviolent noncooperation. The new change in tactics was precipitated by the protest over the perceived feebleness of the constitutional reforms enacted in early 1919 (Rowlatt Acts) and Britain's manner of carrying them out, as well as by the widespread outrage among Indians in response to the massacre of civilians in Amritsar (Punjab) that April. Many of the acts of civil disobedience that followed were implemented through the All India Congress Committee, formed in 1929, which advocated avoiding taxes as a protest against British rule. Notable in that regard was the Salt March in 1930 led by Gandhi. Another wing of the Congress Party, which believed in working within the existing system, contested general elections in 1923 and 1937 as the Swaraj (Home Rule) Party,

with particular success in the latter year, winning 7 out of 11 provinces.

When World War II began in 1939, Britain made India a belligerent without consulting Indian elected councils. That action angered Indian officials and prompted the Congress Party to declare that India would not support the war effort until it had been granted complete independence. In 1942 the organization sponsored mass civil disobedience to support the demand that the British "quit India." British authorities responded by imprisoning the entire Congress Party leadership, including Gandhi, and many remained in jail until 1945. After the war the British government of Clement Attlee passed an independence bill in July 1947, and independence was achieved the following month. In January 1950 India's constitution as an independent state took effect.

Psychology as an academic discipline made a new beginning in India in the first decade of this century. Review of research shows that Western theories and concepts still constitute the core of research and teaching programmes in most of the Indian universities.

This chapter argues that Indian psychologists live in two parallel worlds: one of west-oriented academic psychology to advance professional growth; and another of less formalized scholarship to satisfy their creative urges. As a result, academic psychology did not get enriched from diverse expertise and life experiences of Indian psychologists. Though psychology has traversed a long distance in India, lack of direction has cast doubts about the application of psychology in the context of a rapidly changing socio-economic scenario.

Psychology in India has remained dissociated from its own vast storehouse of knowledge inherent in the Indian philosophical texts. These scriptures and texts provide immense possibilities of developing psychological theories of self and human development. At the turn of the Millennium, psychology in India is returning to its roots and a new beginning seems to be in the offing.

For almost a century, academic psychology in India has continued to be an alien discipline. In the beginning of the last Century, psychology was imported lock-stock-barrel from the West and was first implanted in 1916 in Calcutta University. The Western model of research and teaching provided the basis on which Indian research grew for a long period.

For Indian psychologists trained in the western traditions, it has been a long journey to turn towards their own heritage and take Indian concepts and theories germane to understanding Indian social reality. Indeed, in this long history, concerns have been voiced from time to time to align psychology with contemporary social issues, so as to meet the challenges of rapid socioeconomic and global changes. Looking back, one gets an impression that psychology in India has come a long way to find its roots in its own native wisdom, though it still has to cover much ground to become a science of Indian origin. Throughout its existence as an alien implant, psychology has been struggling to ground itself in the Indian soil and adapt to local conditions.

Over the years this implant has grown, with branches spreading all over the country. However, it has not borne fruits as expected and has largely remained a sterile academic pursuit, as far as the real issues of national development are concerned.

The non-visibility of psychologists in various national forums gives rise to serious concerns about its relevance and future. What kind of psychology we aspire to have in the 21st century is contingent on a better understanding of the present state-of-the-art.

This chapter aims to examine the status of psychology in India as a scientific discipline, identifying the factors responsible for its retarded growth. This chapter also discusses the parallel movement now underway to rediscover the knowledge rooted in scriptures and folk practices, and explores its relevance in the present times. Three sets of arguments are put forward to explain the retarded growth of academic psychology in India.

One, which is more charitable, is the lack of a supportive intellectual climate. In a country where a vast population lives in a condition of subhuman poverty, and decisions about social developmental programmes are politically motivated, any scholarly pursuit is considered peripheral.

The academic institutions plagued by a rising student population, political manipulations and lack of funds have gradually become non-performers. There is no premium placed on excellence in teaching and research. Adair, Pandey, Begam, Pohan, and Vora (1995) conducted a study on 64 Indian psychologists through a mailed questionnaire. The survey revealed three major impediments to research productivity:

- (a) lack of supportive intellectual climate,
- (b) poor professional support, and inadequate research funding

Ostensibly, the lack of an academic culture and a non-supportive socio-political environment are greatly responsible for the prevailing state of affairs. It does explain the overall decline in the academic standards in the country.

It, however, throws no light on 'why is psychology in India lagging behind other sisterly disciplines, such as sociology, anthropology and economics?' It brings forth the second line of argument that there are some inherent limitations in psychology as a scientific discipline.

In recent years there have been several good publications which enable a critical evaluation of the development of psychology in India. Some of these writings (Dalal, 1990, 1996, 2002; Misra & Gergen, 1993; D. Sinha, 1986, 1996; J.B.P. Sinha, 1993) have critically evaluated the progress of psychology. The five surveys of research in psychology (Mitra, 1972; Pareek, 1980, 1981; J. Pandey, 1988, 2001, 2004) cover important research contributions since the beginning of the last century. Pareek and T.V. Rao (1974a), Pestonjee (1986), and NCERT (1981) compiled psychological measures developed in India. Reports prepared by the University Grants Commission (UGC, 1968, 1982, 1999) deal with teaching and research programmes in universities.

Some empirical studies (Adair, 1989) have examined the professional status of the discipline of psychology. More recently, Misra (in press), K. Kumar (2005, 2008), Pandey and Singh (2005), Paranjpe (2006) and Varma (2004) have provided incisive understanding of the current status of psychology in India. These publications have formed the basis of preparing this review chapter.

POST-INDEPENDENCE HISTORY OF PSYCHOLOGY IN INDIA

The history of the Republic of India began on 26 January 1950. The country had earlier become an independent dominion within the British Commonwealth on 15 August 1947

At the time of granting independence, the Muslim-majority north west and east of British India was separated into the Dominion of Pakistan, by the partition of India. The partition led to a population transfer of more than 10 million people between India and Pakistan and the death of about one

million people. Jawaharlal Nehru became the first Prime Minister of India and Sardar Vallabhbhai Patel became the Deputy Prime Minister and Minister of Home Affairs. The new Constitution of 1950 made India a secular and a democratic State.

Assassination of Mahatma Gandhi: The celebrations of independence had hardly died down when on 30 January 1948, a radical minded Hindu, Nathuram Godse, assassinated Gandhiji at Birla House, just before his evening prayers.

Refugee Problem: The Indian government had to stretch itself to the maximum to give relief to and resettle and rehabilitate the nearly six million refugees from Pakistan. By 1951, the problem of the rehabilitation of the refugees from West Pakistan was fully tackled.

However, the task of rehabilitating and resettling refugees from East Bengal was made more difficult by the fact that the exodus of Hindus from East Bengal continued for years. While nearly all the Hindus and Sikhs from West Pakistan had migrated in one go in 1947, a large number of Hindus in East Bengal had stayed on therein the initial years. However, as violence against Hindus broke out periodically in East Bengal, there was a steady stream of refugees from there year after year until 1971. Providing them with work and shelter and psychological assurance, remained a continuous and a difficult task.

Because of linguistic affinity the resettlement of the refugees from East Bengal could take place only in Bengal and to a lesser extent in Assam and Tripura. As a result, a very large number of people who had been engaged in agricultural occupations before their

displacement were forced to seek survival in semi-urban and urban contexts as the underclass.

Political Integration of India: At the time of independence, India was divided into two sets of territories—the first being the territories of “British India”, which were under the direct control of the Governor-General of India, and the second being the “Princely States”, the territories over which the Crown had suzerainty, but which were under the control of their hereditary rulers. In addition, there were several colonial enclaves controlled by France and Portugal. The political integration of these territories into India was a declared objective of the Indian National Congress, which the government of India pursued over the next decade. Through a combination of factors, Sardar Vallabhbhai Patel convinced the rulers of almost all of the hundreds of princely States to accede to India. Having secured their accession, they then proceeded to, in a step-by-step process, secure and extend the central government’s authority over these States and transform their administrations until, by 1956, there was little difference between the territories that had formerly been part of British India and those that had been part of princely States. Simultaneously, the government of India, through a combination of diplomatic and military means, acquired *de facto* and *de jure* control over the remaining colonial enclaves, which too were integrated into India.

The process, however, was not as successful in relation to the former princely State of Jammu & Kashmir, the accession of which to India was disputed by Pakistan, the State of Hyderabad, whose ruler was determined to remain independent, and the States of Tripura and Manipur, where active secessionist movements existed.

The Instruments of Accession were limited, transferring control of only three matters—Defence, Communication and External Affairs—to India, and would by themselves have produced a rather loose federation, with significant differences in administration and governance across the various States.

The first step in the process of complete merger, carried out between 1947 and 1949, was to merge

the smaller States that were not seen by the government of India to be viable administrative units either into neighbouring provinces, or with other princely States to create a “princely union”. The bulk of the larger States, and some groups of small States, were integrated through a different, four-step process. In return for agreeing to the extinction of their States as discrete entities, the rulers were given a privy purse and guarantees similar to those provided under the Merger Agreements.

First General Elections: Democracy took a giant step forward with the first general election held in 1951-52 over a four-month period. These elections were the biggest experiment in democracy anywhere in the world. The elections were held based on universal adult franchise, with all those twenty-one years of age or older having the right to vote. There were over 173 million voters, most of them poor, illiterate, and rural, and having had no experience of elections. The big question at the time was how would the people respond to this opportunity.

Reorganisation of States: Potti Sreeramulu’s fast-unto-death, and consequent death for the demand of an Andhra State in 1953 sparked a major re-shaping of the Indian Union. Pt Nehru appointed the States Reorganization Commission, upon whose recommendations, the States Reorganization Act was passed in 1956. Old states were dissolved and new States created on the lines of shared linguistic and ethnic demographics. The separation of Kerala and the Telugu-speaking regions of Madras State enabled the creation of an exclusively Tamil-speaking State of Tamil Nadu. On 1 May 1960, the States of Maharashtra and Gujarat were created out of the Bombay State.

POST-NEHRU INDIA:

Jawaharlal Nehru died on 27 May 1964. Lal Bahadur Shastri succeeded him as Prime Minister. In 1965 India and Pakistan again went to war over Kashmir, but without any definitive outcome or alteration of the Kashmir boundary. The Tashkent Agreement was signed under the mediation of the Soviet government, but Shastri died on the night after the signing ceremony. A leadership election resulted in the elevation of Indira Gandhi, Nehru’s daughter, as the third Prime Minister.

BIRTH OF NAXALISM:

The CPM had originally split from the united CPI in 1964 on grounds of differences over revolutionary politics, (equated with armed struggle) and reformist parliamentary politics. A section of the party, consisting largely of its younger cadres and inspired by the Cultural Revolution then going on in China, accused the party leadership of falling prey to reformism and parliamentary politics and, therefore, of betraying the revolution. They argued that the party must immediately initiate armed peasant insurrections in rural areas, leading to the formation of liberated areas and the gradual extension of the armed struggle to the entire country. To implement their political line, the rebel CPM leaders launched a peasant uprising in the small Naxalbari area of northern West Bengal. The CPM leadership immediately expelled the rebel leaders accusing them of left-wing adventurism, and used the party organization and government machinery to suppress the Naxalbari insurrection. The breakaway CPM leaders came to be known as Naxalites and were soon joined by other similar groups from the rest of the country. The Naxalite movement drew many young people, especially college and university students, who were dissatisfied with existing politics and angry at the prevailing social condition.

INDIA GOES NUCLEAR:

India achieved a major success in terms of a breakthrough in science and technology when the

Atomic Energy Commission detonated an underground nuclear device at Pokhran in the desert of Rajasthan on 18 May 1974. The Indian government, however declared that it was not going to make nuclear weapons even though it had acquired the capacity to do so. It claimed that the Pokhran explosion was an effort to harness atomic energy for peaceful purposes and to make India self-reliant in nuclear technology.

GREEN REVOLUTION AND OPERATION FLOOD:

India's long-standing food crisis was resolved with greatly improved agricultural productivity due to the Green revolution. The government-sponsored modern agricultural implements, new varieties of generic seeds and increased financial assistance to farmers that increased the yield of food crops such as wheat, rice and corn, as well as commercial crops like cotton, tea, tobacco and coffee. Increased agricultural productivity expanded across the States of the Indo-Gangetic plains and Punjab. Under Operation Flood, government encouraged production of milk and improved rearing of livestock across India. This enabled India to become self-sufficient in feeding its own population, ending two decades of food imports.

EMERGENCY:

Economic and social problems, as well as allegations of corruption caused increasing political unrest across India, culminating in the Bihar Movement. In 1974, the Allahabad High Court found Indira Gandhi guilty of misusing government machinery for election purposes. Leading strikes across India, that paralyzed its economy and administration, Jay Prakash Narayan even called for the Army to oust Mrs. Gandhi. In 1975, Mrs. Gandhi advised President Fakhruddin Ali Ahmed to declare a state of emergency under the Constitution, which allowed the Central government to assume sweeping powers to defend law and order in the nation. Many civil liberties were suspended and elections postponed at national and State levels. Non-Congress governments in Indian states were dismissed, and nearly 1,000 opposition political leaders and activists were imprisoned and a programme of compulsory birth control was introduced.

Although, India's economy benefited from an end to paralyzing strikes and political disorder, many organs of government and many Congress politicians were accused of corruption and authoritarian conduct. Police officers were accused of arresting and torturing innocent people.

POST EMERGENCY:

Mrs. Indira Gandhi called for general elections in 1977, only to suffer a humiliating electoral defeat at the hands of the Janata Party, an amalgamation of opposition parties. *Morarji Desai became the first non-Congress Prime Minister of India.* The Desai administration established tribunals to investigate Emergency-era abuses, and Indira and Sanjay Gandhi were arrested after a report from the Shah Commission. But in 1979, the coalition crumbled and Charan Singh formed an interim government. The Janata Party became intensely unpopular due to its internecine warfare, and the fact that it offered no leadership on solving India's serious economic and social problems. Ultimately, the Janata Party split into its original constituents. The Janata Sangh emerged in its new avatar as the Bharatiya Janata Party.

Indira Gandhi and her Congress party splinter group, Congress (Indira) were swept back into power with a large majority in January 1980. But the rise of an insurgency in Punjab jeopardized India's security. In Assam also there were many incidents of communal violence between native villagers and refugees from Bangladesh, as well as settlers from other parts of India. When Indian forces, undertaking Operation Blue Star, raided the hideout of Khalistan militants in the Golden Temple—

Sikhs' most holy shrine— in Amritsar, in June 1984, the inadvertent deaths of civilians and damage to the temple building inflamed tensions in the Sikh community across India. Northeast India was also paralyzed owing to the ULFA's clash with government forces.

On 31 October 1984, Prime Minister Indira Gandhi's own Sikh bodyguards assassinated her, and anti-Sikh riots erupted in Delhi and parts of Punjab, causing the deaths of thousands of Sikhs.

POST INDIRA GANDHI:

After the assassination of Mrs Indira Gandhi, the Congress party chose Rajiv Gandhi, her older son, as the next Prime Minister. The Parliament was dissolved and Rajiv led the Congress party to its largest majority in history (over 415 seats out of 545 possible) in the general elections, reaping a sympathy vote over his mother's assassination.

Rajiv Gandhi initiated a series of reforms—the license raj was loosened, and government restrictions on foreign currency, travel, foreign investment and imports decreased considerably. This allowed private businesses to use resources and produce commercial goods without government bureaucracy interfering, and the influx of foreign investment increased India's national reserves. Rajiv's encouragement to science and technology resulted in a major expansion of the telecommunications industry, India's space program and gave birth to the software industry and information technology sector.

In 1987, India brokered an agreement between government of Sri Lanka and rebel LTTE, and agreed to deploy troops for peacekeeping operation and to disarm the Tamil rebels. But the Indian Peace Keeping Force became entangled in outbreaks of violence—ultimately ending up fighting the Tamil rebels itself, and becoming a target of attack from Sri Lankan nationalists.

Rajiv Gandhi's image as an honest politician was shattered when the Bofors scandal broke, revealing that senior government officials had taken bribes over defence contracts with the Swedish manufacturer. As the Defence minister in Rajiv Gandhi's government, Mr V.P. Singh had unearthed the Bofors scandal, and was sacked from the party and office. Becoming a popular crusader for reform and clean government, he led the Janata Dal coalition to a majority in 1989 elections. He was supported by BJP and the Leftist parties from outside. Becoming Prime Minister, Singh started to implement the controversial Mandal commission report, to increase the quota in reservation for low caste Hindus. The BJP protested these implementations, and took its support back, following which he resigned. Chandra Shekhar split to form the Janata Dal (Socialist), supported by Rajiv's Congress. This new government also collapsed in a matter of months, when Congress withdrew its support.

Post Rajiv Gandhi: On 21 May 1991, while former Prime Minister Rajiv Gandhi campaigned in Tamil Nadu on behalf of Congress (I), a Liberation Tigers of Tamil Eelam (LTTE) female suicide bomber assassinated him and many others. In the elections, Congress (I) won 244 Parliamentary seats and put together a coalition, returning to power under the leadership of Mr P.V. Narasimha Rao. This Congress-led government, which served a full 5-year term, initiated a gradual process of economic liberalisation and reform, which opened the Indian economy to global trade and investment. India's domestic politics also took new shape, as traditional alignments by caste, creed, and ethnicity gave way to a plethora of small, regionally-based political parties.

In 1992, India was rocked by communal violence between Hindus and Muslims that killed over 10,000 people, following the **Babri Mosque demolition** by Hindu extremists in the course of the Ram Janmabhoomi dispute in Ayodhya. The final months of the Rao-led government in the spring of 1996 suffered the effects of several major political corruption scandals, which contributed to the worst electoral performance by the Congress Party in its history as Bharatiya Janata Party emerged as largest single party.

Era of Coalitions: The Bharatiya Janata Party (BJP) emerged from the May 1996 national elections as the single-largest party in the Lok Sabha but without enough strength to prove a majority on the floor of the Parliament. Under Prime Minister Atal Bihari Vajpayee, the BJP coalition lasted in power 13 days. With all political parties wishing to avoid another round of elections, a 14-party coalition led by the Janata Dal emerged to form a government known as the United Front. A United Front government under former Chief Minister of Karnataka H.D. Deve Gowda lasted less than a year. Congress (I) withdrew support in March 1997.

Inder Kumar Gujral replaced Deve Gowda as the consensus choice for Prime Minister of a 16-party United Front coalition. In November 1997, the Congress Party again withdrew support for the United Front. New elections in February 1998 brought the BJP the largest number of seats in Parliament (182), but this fell far short of a majority. On March 20, 1998, the President inaugurated a BJP-led coalition government with Mr Vajpayee again serving as Prime Minister.

First Sikh Prime Minister of India: In January 2004, Prime Minister Vajpayee recommended early dissolution of the Lok Sabha and general elections. The Congress Party-led alliance won a surprise victory in elections held in May 2004. Manmohan Singh became the first Sikh Prime Minister of India.

First Female President of India: In 2007, Ms Pratibha Patil became India's first female President. Long associated with Nehru-Gandhi family, Pratibha Patil was a low-profile Governor of Rajasthan before emerging as the favoured Presidential candidate.

2009 Elections: In the 2009 General Election, the Congress-led United Progressive Alliance won a convincing and resounding 262 seats, with Congress alone winning 206 seats. Mr Manmohan Singh was re-elected as the Prime Minister

2014 Elections: On 16 May 2014, ending the BJP's 10-year political 'vanvaas', Narendra Damodardas Modi scripted a never-before win for the party, helping it cruise to power on its own steam at the Centre by breaking a three-decade old trend of fractured mandates. BJP attained a comfortable majority of 282 seats on its own.

20TH CENTURY PSYCHOLOGY IN INDIA:

A western implant Indian scriptures dating back thousands of years extensively dealt with the analysis of states of consciousness and contents of mental activities. The important feature of this early exposition is that it is mostly experiential and is a culmination of centuries-old tradition of self-verification. In the ancient Indian scriptures no rigid distinction among religion, philosophy, and psychology was maintained.

The overriding consideration was to help individuals in their pursuit of self-realization and liberation from the miseries of life. In this world-view, the source of all suffering was presumed to be within the person, and thus the emphasis was on exploring the 'world within', to alleviate the suffering. The goal was to seek enduring harmony of spirit, mind and body for everlasting happiness. The yoga system evolved very sophisticated mind-control techniques in this pursuit. In contemporary literature this broad field of inquiry is referred to as „Indian Psychology“.

These rich traditions, however, had little bearing on academic psychology implanted in India as a Western science during the British rule. Scientific psychology with laboratory work was a novel approach, not having any parallel in traditional Indian psychology. Psychology was first introduced as a subject in the Philosophy Department at Calcutta University.

Brojendra Nath Seal who was the then King George V Professor of Mental and Moral Philosophy drafted the first syllabus for experimental psychology and established a laboratory for demonstration purpose in 1905. Eleven years later this laboratory was upgraded as the first psychology department, the Department of Experimental Psychology.

Narendra Nath Sengupta, who chaired this department, had his education at Harvard University with Hugo Munsterberg, a student of William Wundt. Laboratory research at Calcutta in the areas of depth perception, psychophysics, and attention inspired early work at other centres. Recognizing the scientific nature of research, psychology was included as a separate section in the Indian Science Congress in 1923.

Thus, psychology in India at an early stage acquired the status of a science along with physical and biological sciences, something which Western psychology achieved only after a long struggle. The Indian Psychological Association was founded in 1924 and the Indian Journal of Psychology, the first psychology journal in India, appeared the very next year.

Before these experimental traditions could consolidate, Sengupta left Calcutta. He was succeeded by Girindra Shekhar Bose. Being a medical doctor and a psychiatrist who was in close contact with Sigmund Freud, Bose showed much enthusiasm to promote psychoanalysis.

In 1922 he founded the Indian Psychoanalytic Society, which two years later was affiliated with the International Psychoanalytic Society. Bose received his Ph.D. from Calcutta on the 'concept of repression', the first Ph.D. from any Indian University in psychology. He established the Lumbini Park Mental Hospital in Calcutta in 1940, and in 1947 brought out a journal 'Samiksha'.

The Department started an Applied Psychology Wing in 1938, when Jung, Meyers, and Spearman were invited to the Silver Jubilee Session of the Indian Science Congress.

TWO WORLDS OF INDIAN PSYCHOLOGISTS

The concepts and theories in Western psychology have their genesis in the social upheavals in Europe in the 19th Century with the metamorphosis from an agrarian to an industrial society. The discipline evolved to comprehend the complex social realities and the problems of industrialization. With the imperial expansion of modern capitalism, the influence of western knowledge in the colonized societies was inevitable. The popularity of English-medium education made writings of western thinkers accessible to Indian scholars.

A large body of this knowledge was alien, even in contradiction to that which was prevalent in the colonized traditional societies. The contradictions were more glaring in colonies, like India, having

a strong sense of cultural identity and a rich heritage of scholarly work. In the West, psychology had moved away from theology and philosophy, and had developed its own methods of inquiry based on the natural science models.

Indian psychologists saw that in applying western psychology there was an opportunity of developing a secular identity distinct from that of religion and philosophy, which was not possible within indigenous intellectual traditions integrating philosophy, spirituality and psychology.

Moreover, due to the neglect of many centuries, Indian psychology was not well equipped to examine the contemporary world and did not have tools to explain the existing social and moral decay of the Indian society. There were no new concepts, theories and methods in Indian psychology applicable to the changing individual and social order.

How Indian psychologists before Independence lived in two different worlds can be illustrated with some examples. Sir Brojendra Nath Seal, who established the first psychology laboratory in the country to promote experimental psychology, was a great historian of ancient Indian science and was the inspiration for Jadunath Sinha to bring out his monumental work on Indian psychology. N. N. Sengupta who was trained to be an experimental psychologist had a large number of non-empirical papers in scientific journals.

His writings covered the whole range from the psychology of mysticism to the psychology of Western dance. Sengupta did not stay in Calcutta for long and joined the Philosophy Department at Lucknow University. There he coauthored a book with an eminent sociologist, Radhakamal Mukherjee, 'Introduction to Social Psychology' in the year 1928. The orientation of this book was more sociological than psychological. As Rajanarayan (1983) wrote in his biographical note, he turned religious and got interested in mystical traditions and published work in this area. Girindra Shekhar Bose had, along with his important work in the area of psychoanalysis, serialized an interpretation of the holy Gita in the prestigious Bengali magazine 'Pravasi' without any direct reference to psychoanalytic concepts (Nandy, 1995). Bose also wrote a long commentary on Indian sacred texts in Bengali, titled 'Purana Pravesa'.

Gopalswami, who was at Mysore, came from an affluent background and maintained interest in two diverse fields - intelligence testing and animal laboratory work and besides, he had his own private radio station and was involved in various cultural activities. These illustrations are cited to give some clues about how Indian psychologists managed to live simultaneously in two worlds with little overlap. Thus it is no surprise that Indian psychologists remained apolitical all along.

There is no reflection in their work of the predominant social and political movements, even that of the freedom movement. Indian psychologists remained on the edge of the society, as far as their professional activities were concerned. Their research lacked continuity, commitment and conviction. The situation changed only marginally after Independence.

It may be argued that a vast majority of Indian psychologists have shied away from Indian psychological perspectives because of this attitude and the religio-philosophical context in which those perspectives are embedded. But, paradoxically a majority of them share the same socio-cultural context with the rest of the Indian population and are guided by the same religio-philosophical perspectives, which have shaped the attitudes, emotions, motivations, morals, values, etc., of the Indian masses in their day-to-day living! As Kiran Kumar (2008) observed, this situation has created some kind of a split in the personality – psychologist as a professional vs. psychologist as a person – and it has contributed for lack of creativity and originality in what one does, and draining of personal

resources and energy resulting in „burn out“ among many.

A psychologist in his/her role as a scientist conducts the professional activities with one set of assumptions and beliefs and as a person lives and acts with another set of assumptions and beliefs among fellow humans.

One reason why Indian psychologists could live in two parallel worlds was probably because the colonial rulers did not see much utility of psychology in consolidating their empire. This, for example, was not true in the case of sociology and social anthropology, which had much to contribute to the smooth functioning of the colonial administration in India (Dhanangare, 1985).

Indian culture and society was totally unfamiliar to the colonial officials when they first arrived. The unique systems of caste, religion, tribal and rural communities, rituals, beliefs, traditions were all baffling to an Englishman. These had no parallel in the experiences of the Western societies.

Thus, in the absence of proper understanding of Indian social realities the colonial administrators were facing many problems in their smooth functioning. There was much urgency and support for research on these topics.

Neither Indian psychology nor western psychological research held any such promise and were largely ignored. It is understandable that the Britishers did not promote psychology in India in the same way as they did in the case of sociology and social anthropology.

THE 1970S CRISIS: THE CORE DEBATES

Since the growth of knowledge is socially conditioned, the developments of psychology in India including its theories and concepts need to be appreciated in the local and global historical and sociocultural matrix in which the country has been positioned. Being a developing country with millennia-old culture, a richly diverse society, and a two-century-long colonial past, India is currently aspiring to emerge as a self-reliant and economically strong nation. Faced with the challenge of socioeconomic transformation, the country has been engaged in efforts toward industrialization, modernization, and globalization.

Navigating through this difficult terrain has been a complex challenge and has shaped the developments in the academic disciplines also. India has been engaged with rapid growth of higher education and rapid expansion of professional institutions to meet the increasing demand for trained personnel in various service sectors like health, administration, banking, police, military, and management. The cultural complexity of India due to diversity in ecology, language, religion, family structure, and uneven introduction of technology has put a challenge before the planners to ensure social welfare through democratic processes. This context has shaped the course of higher education in general and psychology in particular.

The challenge to relate India's past and modern psychology was a main concern in the early period and continued since then. In fact, the search for a distinct identity for psychology in the Indian context has remained a key issue. Theoretical innovations came from the real world as well as the difficulties faced in applying psychological knowledge to the diverse problems faced in the Indian conditions. In the course of the disciplinary journey, the theoretical-conceptual ambience of the works of Indian psychologists has undergone several shifts in themes, alignments, and emphases.

The teaching and research in modern psychology began largely as an extension of the EuroAmerican tradition in the British period. Its initial emphasis was not so much on questioning and doubting the Western concepts and methods, but on preserving the essential configuration of the discipline and keeping it as similar to the one in the Western world, as possible. We also note that there existed a tradition of British psychoanalysts who tried to offer interpretations of the Indian psyche to justify the British rule.

(Citing Christine Hartnack's work Vahali (2011) has discussed at length how early British psychoanalysts tried to create universal psychoanalytic conceptualizations that explain away Indian experiences of selfhood, or view them as essentially inferior, less worthy or simply pathological, or otherwise deficient. It acted as a tool to justify social oppression and colonial rule). In the mainstream critical paradigmatic questions of ontology and epistemology were sidelined to give space for the newly emerging positivist scientific enterprise. We find that the Western model of research and teaching provided the initial necessary direction to Indian psychologists. Dependence on Western thought was deemed legitimate owing to unexamined theoretical suppositions about the universality of psychological knowledge. It was largely in the 1970s that many psychologists raised the issue of insufficient and inadequate attention to social psychological problems.

The Indian psychologists realized that they had been indifferent to the vast and rich collection of knowledge inherent in the Indian texts. However, the commitment to scientific inquiry was venerated and debates related to the philosophy of science and related arguments could not receive due attention until the 1980s (Mukherjee 1980; Misra and Gergen 1993; Varma 1995). Also, there has been a constant pressure for problem solving and application in the social world (Sinha 1986).

EARLY EFFORTS

Keeping in mind the colonial background of modern learning in India, the mandate of initiating scientific psychology in the prevalent Wundtian tradition and subsequently in the behaviorist tradition was a natural choice. The eagerness to attain an independent identity for the discipline constituted the package of academic delivery consisting of empirical work, positivist metatheory, a universalistic stance, and the presumption of cultural immunity of psychological concepts and theories.

In terms of the institutional structure, psychology was earlier a part of philosophy departments. Separate psychology departments were started largely between 1940 and 1960. In order to maintain a separate identity, the teaching and research practices opted to fashion themselves as differently as possible from the parental discipline of philosophy and similar to the physical and natural science disciplines. To this end, they over-emphasized experimental psychology and psychometry – the distinctive features of the new science – and made them the core of psychology curricula which continues till today. Indeed, empiricism and quantification made possible the flourishing of an empiricist-positivist brand of psychology aimed at generating and testing nomothetic laws as objectively as possible.

However, it will be a mistake to ignore another feature of the academic prowess of the first generation of Indian psychologists.

They were also cognizant of their cultural roots and tried to address the academic as well as non-academic audiences. In a pioneering work entitled *The Science of the Emotions*, Bhagwan Das (1908) presented a rich account of the Indian science of affect. G. S. Bose wrote about the

Upanishads and mythology in Bangla language and had an academic fascination for psychoanalysis (see Dalal 2002).

Early researchers did attend to the theoretical issues and noted the importance of traditional knowledge but did not reject modern theories. It is interesting to note that even during the early part of the development in India, many indigenous lines of inquiry were also prevalent. Examples that highlight this trend include Asthana's (1950) work on Sāṃkhya theory of personality and Indra Sen's (1986) elaboration of the integral psychology of Sri Aurobindo. E.G. Parameshwaran started research on the Triguṇa (sattva, rajas, and tamas) theory (Uma et al. 1971) which has been followed by several studies (see Salagame 2011).

We also find works on the Indian typology of personality (Krishnan 1976/2002) and tantra (Mukerji 1926). Some notable works were undertaken from the Western tradition for further study. For instance, Asthana (1960) proposed that perceptual distortion is the function of the valence which an object acquires from the field structure in which it exists.

In this way he tried to resolve the differences between gestalt and learning theories and incorporated Lewin's field theory. In the area of learning theories, the S-R theory was challenged by Kothurkar (1968).

A Socially Relevant Psychology In the 1980s, several lines of investigation across many domains of social psychological processes showed that many of the phenomena reported in Western research literature required different explanations rooted in the Indian cultural milieu. Examples of this kind are found in the areas of social cognition. Thus predictions from attribution theory with socially and culturally specific causal categories were tested for understanding achievement, health, and other aspects of human behavior (Dalal 1988).

The change took place when psychologists found the applications of Western theories/methods to be either ineffective or irrelevant in real life situations in India. A selective overview of some of these developments in key areas is presented below. Human cognition: Researches on attention, emotion, and consciousness (see Srinivasan 2011), by using multiple methods and approaches, have shown cross-cultural aspects of emotion as well as of meditation, in terms of underlying neurophysiology. There are also researches on philosophical aspects of cognition that view cognition and other mental phenomena as central to the functioning of all living beings.

To put it another way, the fundamental principles governing cognition run from a single cell to human societies. Planning is a key intellectual function.

Extending the earlier work on PASS (Planning, Attention, Successive, and Simultaneous Processes) theory, Das et al. (2000) have brought out its significance in various cognitive functions.

PSYCHOLOGY OF POVERTY AND DEPRIVATION:

The study of poverty and deprivation has been an important area of research where researchers in different parts of the country (e.g., Rath at Bhubaneswar, A.K. Singh at Ranchi, D. Sinha at Allahabad, L.B. Tripathi and G. Misra at Gorakhpur) moved in many directions and have mapped the diverse effects of poverty, social disadvantage, and deprivation (for a comprehensive review see Misra and

Tripathi 2004). Most of these studies have situated deprivation in the experiential-environmental context and have traced its detrimental influences back to aspects of development

The detrimental effects of poverty are accentuated by the unfavorable proximal environment of the child.

Thus, intervention should address not only the cognitive-attentional drawbacks of the children but also the conditions prevailing in the family and school settings. They should be planned to create in the people a sense of empowerment to effect change in their life conditions. Unfortunately, the planning rooted in the Western model of development often ignores the traditional attitudes, beliefs, and values, and considers them antithetical to development ideology.

There is growing evidence that social-psychological problems of Indian society are now being increasingly addressed by psychologists.

THE CHALLENGE OF ACHIEVEMENT:

The economic and social development was an important concern for a developing country like India. The theoretical analysis by McClelland underscored the significance of achievement motivation (n-Ach) as a driving engine for development. The lack of emphasis on individualistic and competitive spirit and independence were identified as the main causes of underachievement. This became the basis for a major intervention program at Kakinada in Tamil Nadu, as reported in *Motivating Economic Achievement* (McClelland and Winter 1969). It provided impetus for promoting entrepreneurship.

The relevance of achievement motivation theory was, however, Indian challenged (e.g., Sinha 1968). The perceived value of various achievement goals is determined by the expectations of significant others. The concepts of "extension motivation" (Pareek 1968), "dependency proneness" (Sinha 1968), "achievement value" (Mukherjee 1974), and "dissatisfaction-based achievement motivation" (Mehta 1972) are important contributions.

MOVE TOWARD INDIGENIZATION

The indigenous thought systems remained neglected because there was a strong aversion toward them owing to doubts regarding their scientific status, contemporaneous relevance, and ontological suppositions (see Gergen et al. 1996). Psychological theories and constructs were taken as intrinsically biological, materialistic/objective in content, and quantitative in methodological approach.

Therefore psychology, like other natural and physical sciences, was thought to be culture and psychological processes as distributed/shared uniformly across diverse cultures and sub-cultures. This spurred the need for a radical change in cross-cultural psychology's universalist stance, and its almost exclusive focus on the discovery of panhuman patterns of behavior.

"There was an implicit assumption that the definition of... concepts and their measurement as proposed by the Western research workers will also hold good in our cultural context" (Mukherjee 1980). The signs of efforts to outgrow the alien frame were noticed in the 1970s. The search for a new identity became a major question. Culture-specific concepts, and a search for culturally appropriate methods and tools were emphasized and the relevance of culture was realized. In this context, the interaction with cross-cultural and cultural psychologists has provided important impetus. Gradually, blending scientific ways with indigenous concepts emerged as an important academic agenda (Sinha 1997). Ramanujan (1990) has emphasized context sensitivity as the key feature of Indian

way of thinking. Critical reflections (Misra and Gergen 1993; Nandy 2004; Varma 1995) have drawn attention to the limitations of natural science-based approaches and to new possibilities. It was realized that an understanding of Indian social reality would benefit from indigenous psychological knowledge and the discipline should contribute to the programs of socioeconomic development. Rao (2002, 2011) has discussed human cognitive processes from the perspective of

Sāṃkhya Yoga system. According to this system, there are two principles that govern our existence – puruṣa (consciousness) and prakṛti (matter).

Puruṣa is pure consciousness and has no quality or characteristics of its own; it is inert and formless. Prakṛti, on the other hand, is the material basis of our being. In Yoga, citta denotes the functional mind, which comprises of not only the cognitive processes, the ego and the senses, but also contains instinctual tendencies (vāsnās) inherited from previous lives and the effect of past actions in the present life (saṃskāras).

They influence our cognitions and predispose us to behave in certain ways. In Yoga, citta controls our actions. Information processing in citta may take place at three levels that is, buddhi, ahaṃkāra (egoic self), and manas. Manas, the central processing unit, selects information provided by the sensory system and processes them.

Ahaṃkāra (the emotional self) appropriates the processed information from manas and considers it as required by the perceiving person. And, buddhi decides and plans the actions and reactions in an appropriate manner.

At the start of the 1960s, American social psychology was a thriving and active field of study. The discipline was still a relatively new one, but it had prospered during and after World War II, contributing to and directing wartime work on a variety of topics including attitudes, morale, rumor, propaganda, prejudice, leadership, and intergroup conflict (Capshew, 1999; Faye, 2007, 2011; Herman, 1995). Social psychology, which had maintained a rather marginal existence since the early 1900s, therefore grew significantly in the immediate postwar period: from 1948 to 1960, membership in the Social and Personality Psychology division of the American Psychological Association grew by 297%, a number exceeded only by the growth of the division of School Psychology (Tryon, 1963).

The period immediately following the War has been described by some as the “golden age” of social psychology (House, 2008; Sewell, 1989), characterized by interdisciplinary teams of researchers working on socially relevant issues with substantial federal support (House, 2008).

It was a period when many of the classic and well-known studies were done, including Leon Festinger’s (1957) work on cognitive dissonance, Solomon Asch’s (1951) conformity research, and Stanley Milgram’s (1963) work on obedience to authority.

These classic studies seemed to demonstrate the possibilities of social psychology in uncovering repeatable, robust effects and in addressing significant, real-world phenomena ranging from seemingly irrational cult behavior to the role of obedience in the Holocaust. Furthermore, these years were strikingly productive ones for social psychology, as judged by the sheer number of studies conducted, the growth in methodological approaches, and the amount of data collected (Cartwright, 1979). The field also began to acquire the markings of an established discipline in the postwar period, including the founding of two societies: the Society for Experimental Psychology in 1965

and the Society for Personality and Social Psychology in 1974.

A number of different journals were also established, including the *Journal of Personality and Social Psychology* and the *Journal of Experimental Social Psychology*, both founded in 1965. The golden age, however, was rather short-lived. The late 1950s and early 1960s witnessed a noticeable decline in the optimism and self-assuredness of social-psychological writings and internal criticisms began to pepper the literature (Allport, 1954; Asch, 1952; Sears, 1951).

Furthermore, the post-war pronouncements of the vast promise and potential of social psychology are noticeably absent during this period (Collier et al., 1991). In 1948, social psychologist Dorwin Cartwright had noted that the war had brought the field to maturity and a year later, he spoke of the "growing prestige of social psychology" (Cartwright, 1949, p. 199). By 1979, however, he noted a distinct change:

"the general level of excitement that characterized social psychology immediately after the war has all but disappeared" (Cartwright, 1979, p. 87). Otto Klineberg similarly noted that the self-confidence of the postwar period "has yielded in recent years to growing doubts and the search for new directions" (Klineberg, 1976, p. 156).

Indeed by the 1960s and 1970s, social psychology appeared in the literature as a field that had once had excellent prospects for a bright and productive future but had somehow failed to live up to these early expectations.

PROBLEMS OF METHOD

The 1970s crisis was a multifaceted one, involving several interrelated and contentious issues. Not everyone felt a crisis was at hand, and those that did could not agree on the central problems of the field or the causes of those problems. Nonetheless, the first and perhaps most visible concern leading up to a declaration of crisis was a dissatisfaction with the dominance of laboratory experimentation.

Psychologists, modeling their approach on that of the natural sciences and particularly German physiology and psychology, had adopted experimentation in the late nineteenth century and by the start of the twentieth century, more than 40 psychological laboratories had been established (Benjamin, 2000; Danziger, 1990). Social psychology soon followed suit and experimentation

gained prominence in the 1920s and '30s, when social psychology had begun moving towards disciplinary status as a subfield of general psychology (Danziger, 2002). In 1937, psychologist Stuart Henderson Britt aptly summed up the approach that would come to dominate social psychology throughout the twentieth century: Social psychology of the "present" can be typified by one word: empirical. The empirical method may be characterized by three important techniques: the experimental method; the use of first-hand observation; and the employment of statistics (Britt, 1937, p. 464). Britt went on to note that the empirical method, and particularly experimentation, was the primary method of distinguishing social psychology from social philosophy.

With increased sophistication in statistical techniques, the adoption of operationism, and the incorporation of the language of variables (Danziger, 1997), experimentation gained an even stronger foothold and by the 1960s, it had become the distinguishing mark of a scientific social psychology.

In 1949, approximately 30 percent of studies in the leading social psychology journal involved some form of experimental manipulation; by 1969, this number had risen to 87 percent (Higbee & Wells, 1972). In the early 1960s, however, the experimental method came under considerable scrutiny in the social-psychological literature.

Several scholars began publishing results that questioned the validity of such experiments (Orne, 1962; Rosenthal, 1966; Rosenthal & Rosnow, 1969). These authors demonstrated that experimental results may be strongly influenced by the artificial mechanics of the experiment.

Martin Orne, for example, argued that research subjects are not passive receivers of experimental stimuli; instead, they actively interpret and give meaning to the experimental situation, seek out cues regarding researchers' hypothesis, and frequently attempt to act as "good subjects," trying to help confirm hypotheses.

The experimental situation, Orne (1959, 1962) argued, contains cues or "demand characteristics" that participants use to try to ascertain the purpose, meaning, or goal of the situations in which they find themselves. These cues become strong stimuli for participant behavior.

In this way, the experiment becomes a social problem-solving situation for participants and resulting behaviors may be due in large part to demand characteristics rather than to the variables that are of direct interest to the researcher.

PROBLEMS OF RELEVANCE

Related to discussions of method was the debate regarding the social relevance of social-psychological findings. In a 1974 survey of graduate students and faculty members in psychology, half of the respondents indicated that psychology's lack of relevance to real-world social problems was one of its gravest difficulties (Lipsey, 1974).

In this same vein, the first public diagnosis of a disciplinary crisis came in an article titled "Crisis in social psychology: The relevance of relevance" (Silverman, 1971). In this article, Irwin Silverman noted that despite serious external pressures to produce results relevant to pressing social problems, "social psychologists have not provided much data that are relevant to social ills" (p. 583). Silverman went on to argue that the problem of relevance was in fact a direct result of problems of method: data from social psychology gathered in artificial laboratory experiments "may relate very much to the motives and feelings and thoughts of subjects about their role in the experiment and very little to their lives outside of it" (p. 584).

Others concurred with this assessment, noting that the experimental situation was a highly artificial one, involving groups of strangers rather than individuals embedded in social situations and social relationships. Because of this, social psychology did not reflect reality and therefore had little to say about real-world phenomena (Gergen, 1973).

Other aspects of experimentation, including the use of college students as participants, were also pinpointed as the reason behind social psychology's lack of relevance in the world outside the laboratory (Weber & Cook, 1972). Even classic studies in the field that seemed to be highly socially relevant were not immune to such critiques. In fact, they became exemplars of the irrelevance of the field.

This was the case with Milgram's obedience research. In what is perhaps the most well-known set of studies in the history of psychology, Stanley Milgram (1963) demonstrated that research participants will administer increasingly strong and potentially harmful electrical shocks to another individual when ordered to do so by an authority figure.

Milgram and others interpreted his robust and dramatic results as shedding significant light on the Holocaust by showing how ordinary individuals come to commit seemingly unthinkable and cruel acts (Milgram, 1964). Milgram's work, however, became the target of much criticism.

A significant portion of this criticism focused on how relevant the findings really were to understanding something as complicated as the actions of perpetrators in the Holocaust. Some suggested that the participants' obedience towards the experimenter resulted from the trust they placed in science and the academy.

PROBLEMS OF THEORY AND APPROACH

As the crisis wore on, many authors began to argue that problems of method and relevance were simply symptoms of a set of much larger and far more substantive issues, including the theoretical approach of the field, the disciplinary orientation, and, according to

some, the inadequacy of the entire philosophy on which social psychology had been founded.

Some discussions of theoretical orientation were focused on the simplicity of social-psychological theory. It was believed that social psychology had become too consumed with theories built on small, repeatable effects, resulting in theories with a very limited scope.

This focus had resulted in a lack of integrative theories that could unite social-psychological findings and capture the complexity of social individuals in complex social systems (Back, 1963; McGuire, 1969, 1976; Pepitone, 1976).

Social psychologists were therefore left with what one author described as "miniature theories" (Back, 1963) and "simple a-affects-b" hypotheses (McGuire, 1976). The most prominent theories—cognitive dissonance theory, the risky shift paradigm, and social learning theory—were considered by many to be isolated from one another, exploring small corners of social cognition, emotion, and behavior without any linkage to other theories or experimental findings. Others argued that the field's theoretical problems stemmed from the individualistic and reductionist approach of social psychologists.

It was held that social-psychological studies and theories—focused on individual motivation, interpersonal processes, and social cognition—had failed to account for the role of macrosocial phenomena such as social structure, class, political systems, and culture (Back, 1963; Backman, 1980; Pepitone, 1976; Sherif, 1977; Smith, 1978). Pepitone (1976), for example, identified the cause of the crisis as a "misplaced theoretical unit of analysis" (p. 641). He argued that social psychologists automatically attribute research findings to individual motivation and psychological processes without considering the normative social world on a larger scale as a possible determinant of individual behavior.

As an example, Pepitone referred to the often observed phenomenon where the perceived payoff of a goal increases as the suffering required to obtain it also increases. Dissonance theorists would attribute the finding to an individual's desire to decrease discomfort caused by sustaining two

inconsistent cognitions. Pepitone argued that the finding may just as well be the result of shared cultural norms revealed by adages such as “no pain, no gain”.

The debate regarding the relative roles of macro- and microsocial phenomena in social psychology was also reflected in ongoing discussions about the relationship, or lack thereof, between psychological and sociological forms of social psychology (Archibald, 1976; Boutilier, Roed, & Svendsen, 1980; House, 1977; Moscovici, 1972; Stryker, 1977). By 1960, social psychology was primarily a subdiscipline of general psychology; that is, it was practiced primarily by psychologists, in psychology departments, following the principles and methods of general psychology (Collier et al., 1991).

Its focus was, for the most part, on individual cognition, emotion, and behavior in relation to various social stimuli, such as the presence of another individual, the judgments of group members, or the presentation of a persuasive message (Farr, 1996; Greenwood, 2004).

Despite the dominance of such psychological forms of social psychology, sociologists had also maintained traditions of social psychology within their own discipline. Sociological variants of social psychology frequently used non-experimental, observational studies to examine face-to-face interactions between individuals, as was the case for symbolic interactionists who examined the meaning created in these interactions (House, 1977).

Sociological social psychologists also employed survey methods to examine the relationships between psychological processes and attributes, such as personality or self-image, and macrosocial phenomena, such as social class and race (House, 1977).

DIAGNOSING DISCIPLINARY CRISIS

The 1970s crisis in American social psychology provides an interesting case study of a discipline in the midst of a self-diagnosed crisis and raises interesting questions regarding how and why such crises are diagnosed. During and after the crisis, some scholars suggested that the issues raised in the context of the crisis were not new issues at all:

They noted that the controversies of the crisis were in fact the same philosophical problems that had plagued the social sciences since their inception, including issues of determinism, mechanistic causality, individualism versus holism, and nomothetic versus idiographic approaches (Rosnow, 1983; Shaw, 1974). This evaluation is supported by Fay Berger Karpf's (1932) monograph reviewing the field. Karpf noted that two of the central problems in the newly developing field were controversies over how psychologically or sociologically-oriented the field should be and what methods would be most appropriate for the field (Karpf, 1932).

Similarly, as early in 1933, Saul Rosenzweig had outlined the social-psychological aspects of the subject-experimenter relationship and noted that it was already “a well-known fact that experimentation in human psychology presents serious difficulties” (Rosenzweig, 1933, p. 337).

Contemporary scholarship on the history of social psychology likewise demonstrates that many of the same issues that were debated during the crisis had been contentious ones throughout the discipline's history.

The Progress of the Indigenization of Psychology in India in 1980s A Review Sinha (1994) claimed that “indigenization is a global phenomenon” (p. 180), i.e., it is a necessity in all countries and across all disciplines. In India, there have been repeated, aperiodic calls for indigenization of psychology following the initial call of Durganand Sinha (1973) to make psychology relevant to the Indian context and to serve the needs of the Indian people. In the past decade much has been written about the

state of, type of, extent of, sources of indigenization of psychology in India, and of the positive and negative factors influencing its progress. The writings of Adair, Puhan, and Vohra (1993), Dalal (1996), D. Sinha (1994), and J.B.P. Sinha (2000) among others have each concluded that indigenization in India is slowly but steadily progressing.

Taking their reality into account, Indian psychologists have imported the concept and suited it to serve the purpose of indigenization process. J. B. P. Sinha (2000) has argued that given the pluralistic nature of the Indian society and its people, the openness to diversity among Indians, and the relative comfort with dissonance of an Indian scholar, no single route is best for the growth of psychology in India; rather a number of approaches to making psychology relevant will not only help but also ensure the survival of the indigenization movement.

Three routes have been identified as possibilities for Indian psychology to travel to make research in psychology more relevant. The first and commonly accepted route is the use of Indian traditional knowledge, categories, and theories to explain basic psychological phenomena such as motivation and personality.

However, indigenization in India has not been limited to the development of a cultural psychology or of unique principles heavily based on language, as has been the case in the Philippines, Taiwan, and Mexico. Ethnic or cultural psychology has been recognized as a source for an indigenous psychology in India, but it is only treated as one of several routes that indigenization may take and is the least popular route.

A prime reason for India not following the culture-based route to indigenization is the difficulty in defining or agreeing upon what would be appropriately culturally derived in India. The difficulty arises from the size, diversity, and complexity of the populace in India. There are large differences in the languages spoken, religions practiced, caste, and tribal affiliations of people. There are six religions that are actively practiced in India, of which there are two dominant religions (according to the 1991 Census 82.41 percent are Hindus and 11.67 percent are Muslims), and eighteen languages are officially recognized, each with a distinct script and literature. In the 1991 Census the number of people who spoke any one language ranged from 39.85 (Hindi) to .01 (Sanskrit). Approximately 10 percent of the Indian population is tribal. Most of these groups live in remote parts of the country and many of their ways of organizing their world are primitive.

Thus it is difficult to agree on the topics that would be classed as topics of national importance or be culturally appropriate. Would psychologies based on ancient Hindu texts (it would not apply to more than 15 percent of the population) be more culturally appropriate than those based on Muslim texts (it would apply to a smaller but a significant percentage)? Which Hindu text would classify as national and cultural is another dilemma, given that Hinduism itself has more than eighteen ancient books of philosophy and teachings and there is no widespread agreement on which one of them is the key text. Also, if psychologies based on Muslim texts were indigenous would they be different from the psychologies of Islamic nations such as Sultanate of Oman or Iraq. The diversity indicates that rather than having one national/indigenous psychology it is more appropriate to envisage that there would be multiple indigenous psychologies.

Thus the route of cultural psychology as practiced in Mexico or Philippines cannot be the only route for indigenization in psychology and it is often the least popular route in India.

This is also because majority of the urban psychologists and psychology students do not identify with the "cultural" ways and means (Dalal, 1996).

THE PRESENT STUDY

This chapter reports on the extent of cultural/socially-relevant research by each route based on the abstracts published in the Indian Psychological Abstracts and Reviews from 1998 to 2002 (Volume 1).

Each year two issues of this journal were published thus nine issues were included in this study. The journal divides the published abstracts into specializations: Cognitive, Personality, Cross-Cultural and Indigenous Psychology, Life Span and Developmental Psychology, Women and Family Studies, Educational Psychology, Organization Behavior and Industrial Psychology, Social psychology, Clinical Psychology, Research Methods and Psychometrics, Experimental Psychology, Physiological Psychology, and General Psychology.

The abstracts for experimental and physiological psychology and research methods and psychometrics were not included in this study. For each of the other sections abstracts were rated by the author on whether the article was theoretical or empirical, and if empirical, whether it fell under any of the three categories of socially/culturally relevant research:

Research that was cultural in nature, being based on indigenous conceptualization or theory. This included, for example, the work on the role of outcome orientation vs. process orientation on motivation and stress derived from the Bhagwad Gita, an ancient Hindu text; the giving theory of motivation derived from the ancient Vedas, and the role of practicing yoga and meditation in developing the self and its relation to the workplace.

- (a) Socially relevant research that was undertaken on country-specific topics such as crowding or population explosion, epidemiological surveys of, for example, the incidence of violence towards women in a certain region, or substance abuse among college students. This category also included research on HIV/AIDS and on caste, and
- (b) Western concepts and theories that were tested and their findings were compared to those obtained in Indian settings. For example, the work on learned helplessness, its application, or validity tested within Indian samples, the use of Somatic Inkblot Series for diagnosing schizophrenia or other mental illnesses presented by Indian patients; Piagetian conservation among Indian children; or studies on procedural and distributive justice.

QUANTITATIVE RATINGS OF INDIGENOUS RESEARCH DEVELOPMENTS

A total of 2,531 articles were included in this study of which 636 were theoretical, with the rest (n=1895) or 75.6 percent of the total articles being empirical. The largest proportions of empirical articles were in the clinical psychology section (21.3 percent) followed by social psychology (15.6 percent) and organizational behavior and industrial psychology (15.1 percent).

Table 1 presents the number and percentage of empirical articles that were rated as being socially or culturally relevant under each route. Overall, approximately one quarter of the articles in the last five years were rated as being culturally/socially relevant using one of the three routes. There were also variations in the extent to which a particular route was used. The largest volume of research was in the category of socially relevant topics.

The largest percentage of abstracts was in the study of socially relevant topics (the second route) in the section on women and family studies (50%) followed by those in the section on social

psychology (35%). In sections of clinical, women and family studies and cognitive psychology there were no studies that could be classified as based on the cultural or ethnic route. The largest percentage of studies using the third route, that is testing western concepts in Indian settings, were in the section on industrial and organizational psychology.

For example, there are studies that use western scales to measure commitment among different groups of employees (for example, working in private and public sector corporations) or that measure stress of various occupational groups, or the correlates of the Big 5 personality traits with job satisfaction among school teachers.

CONCLUSIONS

From the above observations and data generated by examining the research trends in published research in India, it is possible to conclude that there is a visible trend toward making the practice and research of psychology more relevant to the Indian context. In fact, as pointed out by J. 13. P. Sinha (1993), though the bulk of psychology research in India continues to be replicative a small but significant portion of it is relevant to the Indian context. This study finds that the small portion is now grown to a quarter of the total research produced.

The foregoing has provided few examples of the range of indigenous developments within Indian psychology. The review is not exhaustive because of space limitations. However, it would not be wrong to say that India has responded more uniquely to the definition of indigenization (D. Sinha, 1996).

Durganand Sinha (1973) championed the goal of an Indian psychology that would be relevant to Indian society. His concern was that psychologists were more focused on the psychology of the west rather than being as attentive as they should have been to the context and issues within their own society. It may not have occurred in his lifetime, but there is evidence in the recent research pursued by Indian psychologists that a strong recognition and incorporation of the Indian context has developed in their selection of topics and research activities.

1990S: PARADIGMATIC CONCERNS

Mind and consciousness are the most fascinating and wonderful phenomena in the universe. It has fascinated man throughout history. Questions about mind, self and consciousness have been raised not only by psychologists and philosophers but also by thinkers from diverse fields e.g. Physics, Biology, and Neuroscience. Their work within their own disciplines inevitably brought the urgency to look into the place of mind and consciousness in the entire scheme of creation. Several writings by great thinkers like Shroedinger, Sherrington, Penfield, J Eccles, Kothari, etc. eloquently testify it.

Questions about mind, self and consciousness were at the heart of Indian psychology which we find shrouded in the religio- philosophical traditions of India dating back to more than two thousand years. However it remained largely unrecognized and unappreciated in mainstream psychology both in India and other parts of the world. There is only an occasional reference to Indian psychology. According to Hall & Lindzey "One of the richest sources of well formulated psychologies are Eastern religions... Most major Asian religions have at their core a psychology little known to the masses of adherents to the faith, but quite familiar to the appropriate professionals, be they yogis, monks or priests"

Why these rich and profound knowledge systems about the inner world have largely remained unrecognized by mainstream psychology? Why there is a resistance in psychologists both in India and foreign lands to even acquaint themselves with Indian psychology to examine its value. Both these questions need to be examined if psychology is to really evolve and get enriched by the insights of Indian Psychology

There are three reasons for Indian Psychology remaining unknown to mainstream Psychology:

1. Insights about the inner world were a part of the religio-philosophical traditions of India which have profound knowledge systems as their foundation. However, the foundational knowledge systems were very complex and due to the metaphysical or spiritual nature of its subject matter it was inaccessible to masses unless they had the necessary inclinations for it. Moreover, it required deeply questioning mind, introspective nature and existential orientation. Traditionally it was imparted by the teacher to only those who were prepared enough to fathom its depths. Thus, the knowledge systems remained confined to limited number of scholars and sages. However, it is important to note that the vision which emanated from it had widely influenced the Indian culture. One is in awe of the mighty foresights and understanding of the sages and seers of this country who found ingenious methods to communicate such a profound knowledge and wisdom to common man. Indian culture, its festivals, folk traditions, mythology, art, music, religious practices, rites and rituals of the community are testimony to it. Psychology adopted the paradigm of physical sciences including its methods. The antithesis between science and religion, as witnessed by last two centuries, have made the followers of science including psychologists sceptical of religio-philosophical systems of knowledge. Though hard core science like Physics has revolutionized its world view but other disciplines including psychology has remained unaffected by such changes. The thinkers in the field of Psychology have been feeling a sense of dissatisfaction at its limited view of man and it is being increasingly realized that its paradigm is of limited value to its subject matter and its ultimate goals. It has not yet found revolutionary ideas and insights as in Physics to break the limits of its horizon.
2. The writings of Indian Psychology are largely inaccessible in a format familiar to psychologists. It is shrouded in religio-philosophical traditions of India which is ignored by modern day scholars who are steeped into scientism. It is considered by large majority of us as unscientific and religious orthodoxy and therefore no effort is made to acquaint oneself and examine the rich literature that exists in these traditions.

THE PROBLEMS OF SCIENTISM IN PSYCHOLOGY

Following the model of scientific method, Psychology presumed that it can identify all the factors/causes that influence man's mind and behaviour. Vast number of empirical studies have been done investigating every possible factor that may influence and shape personality and behaviour. However, it has often confirmed at best the common sense knowledge which did not sharpen the skills for prediction and control – the ultimate goal of science. It has not given us tools to bring desirable changes in one-self. Though insights emerging from Clinical Psychology have made valuable contribution in understanding the inner workings of mind and personality at conscious, subconscious and unconscious levels but it has failed to guide and even define what could be the possibilities of human perfection.

Looking at the contributions of mainstream Psychology one can broadly put it in two categories: (a) mind as an instrument of cognition (b) understanding the forces that shape our personality and

behaviour. It has quite ingeniously applied experimental method to study the cognitive functions of the mind and gathered important insights about the cognitive processes of the mind. However the experimental method was found to be inappropriate for the latter category of issues. The whole approach of using objective methods and studying others to collect relevant data has at best approximated common sense wisdom. It is these issues where mainstream Psychology can immensely benefit from the Indian Psychology. However, the challenge before us is to present the insights of Indian psychology in a form that can be understood by the people working in the field of psychology. It is by no means an easy task and needs open dialogue that is free from all other compulsions.

INDIAN PSYCHOLOGY

Mainstream Psychology has its origin in the western cultures. It is interesting to note that thinkers of the west made great strides in knowing and understanding the mysteries of the outer world whereas the thinkers in India pursued with great passion the inquiry into the mysteries of the inner world.

Insights about the inner workings of mind forms a central core of Indian psychology. It has the potential of revolutionizing our understanding of man in the same way as Modern Physics did to our understanding of the universe.

The questions around which Indian Psychology is woven, may be broadly formulated as follows:

- What is the nature of I/self? What is its relation to the entire creation, i.e. Universe?
- What is birth and death of "me"? How "I" begin and end?
- How can one free oneself from the vicissitudes of life and its sufferings called 'samsara'?
- How to choose amongst multiple options that life presents to each one of us. In Bhagvad-Gita the dialogue between Arjuna and Krishna starts with this issue;
- How to live at peace with oneself, others and the larger world including insentient and sentient beings?

In brief we can sum up the above questions as "what is the nature of "I"/self (called Atman) viz a viz the nature of phenomenal world" and "how do we maximize ours as well as others well being.

Such questions in Indian psychology led to deep analysis of mind, problems of identity and complexities of human life. The deliberation on these issues resulted into insights and vision which encompassed not only man and his life but the whole creation. This was a holistic picture which saw connectivities operating in the entire creation/nature. It had the potential of transforming man's life in a manner which is the ideal of every human being, variously termed as "sthitpragya" or "Samat-vayoga" (unshakeable mental equilibrium).

Inquiry into the nature of "I" or "Self" resulted into two different streams of thought in Western & Indian cultures. Western psychology has viewed self as a unifying force within, which is all the time dynamically absorbing the experiences and at the same time determining the behaviour and quality of experience. It is constantly getting shaped and reshaped by the interactive forces of biochemistry, environment and its own unique way of perceiving itself and its circumstances. Different personality theories represent various perspectives to explain the shaping of self or personality.

With the exception of Sir C.G. Jung, these theories have not clearly differentiated between self and personality.

Insights into the nature of self in Indian psychology revealed the witnessing nature of "I" called Atman. Upanishads say that Atman or Brahman alone is the fundamental reality whose nature is pure awareness. This is the substratum of the whole creation including mind. Mind is called Antahkaran, i.e. instrument of knowledge of inner world. It consists of four-fold constituents:

- Manas: Perceptions, feelings, desires, thoughts
- Buddhi: intellect which is the faculty of discrimination and choice.
- Chitt: Memory

Ahankar: Ego, Sense of individuality or Dehatma-buddh

Manas is by nature extremely unsteady. It can be disciplined by intellect whose capacity of choice and discrimination can be enhanced by introspection, knowledge and education. Ahankar (ego) or Dehatma-buddhi is a case of misplaced identity which is the root cause of ignorance about the real nature of Self leading to sufferings in life. The relationship amongst self, mind, intellect and ego is beautifully brought out in the following sloka of Kathopanishad:

*Atmanam rathinam vidhi shariram rathmev tu Buddhi tu sarathim vidhi manah pragrhavev cha!
Know the Self/soul as the rider, the body as the chariot, the intellect as the charioteer, and the mind as the reins; the organs are the horses and the sense objects the roads; the soul with the body, organs and mind is designated by the sages as the relisher of experience.*

How do we comprehend the nature of Self which appears to be highly abstract to common sense view of ourselves that identifies self with body and mind. Upanishads carry a very comprehensive analysis to reveal the nature of Self:

- subject-object analysis: common notions of self are critically examined to show the problems in our thinking and conclusions,
- analysis of waking, dream & sleep: the analysis of three states of man's being is done to show that our notions about self are based on partial view of our states of being i.e 'waking state' while completely neglecting dream and sleep states.

SUBJECT-OBJECT ANALYSIS.

"I" or "Self" is intimately experienced as the subject or knower of everything external as well as internal world. All modifications of mind e.g. perceptions, thoughts and emotions are only objects

o knowledge and not the subject. In the words of Sri Radhakrishnan "the body, the sense organs, the mind and the ego all lay claim to being the self of man. Before enquiry man takes one or other of them as self. But philosophical enquiry reveals their non-self character, it reveals each one of them as an object and not a subject."

Who is the subject then? To know the subject / knower means to objectify it and necessitating yet another knower leading to regress ad infinitum. Yet all forms of knowledge necessitate the existence of knower. Upanishads call this subject / knower as "Atman" whose nature is pure consciousness.

After showing the dissimilarity between knower (self) and known (mind) it analyzes the relationship between the two. The knower and the known are the two apparent aspects of one basic reality.

Known is not independent of knower because its existence depends on the knower. Just as pot's existence is not independent of the clay; pot is only name and form of the same basic substance, i.e. clay. Similarly known is not an independent reality, known and knower are one only. Thus the whole world, inner and outer, is resolved in one alone; Upanishads call it "atman", the resolving point of knower and known whose nature is pure consciousness. Atman = Brahman is the most profound statement of the Upanishads indicated by the following Mahavakyas:

- aham brhamasmi (I am brhaman)
- tat tvamasi (that thou art)
- ayam atma brhama (this atman is brhaman)
- sarvam idam khalu brhaman (all this is brhaman)

What is the nature of atman? What is brhaman? What kind of equation the above statements are talking about? To understand the meaning of atman and brhaman one needs to know their etymological roots

- Atman – that which pervades everything
- Brhaman – derived from the root "brh" meaning "to grow" or "to increase"; when noun is formed from "brh" it means bigness, unconditioned by any form, space or time.

These statements may look utterly confusing to one who is not familiar with Indian Psychology, Comprehension of these Mahavakya require formidable shifts in one's thinking and conclusions that man makes universally about himself and the world, namely

- I am the body and the mind (Dehatma Buddhi)
- The unquestionable reality of the physical world

It is the burden of these conclusions which is the biggest barrier in comprehending the vision of Indian Psychology. The paradox of man is that he can deny his own self through a wrong self-image. Thus Atman which appears to be conditioned by body and mind (known by us as "I") is in fact limitless. Just as space confined by room is same as space all over, similarly Atman which appears to be confined (identified) by body and mind is in fact without any confines, therefore, called Brhaman. It is in this sense that Atman is called the real self which is Brhaman. Its nature is defined as "Sat" (truth), "Chit" (consciousness), Anandam (ever blissful).

- Sat – Truth or reality. Truth is defined as that which can not be negated.
- Chit – Consciousness. It is not contingent quality which rises or sinks with the presence or absence of objects. It is "svatahasiddham" i.e. it is self-evident; no other proof is required to prove its existence. Just as one light does not require another light to prove its existence. This self-revealing consciousness is not an adventitious quality of the self, it is the very being of the self, i.e. self is identical with consciousness. Its very nature is knowledge 'Pragya'
- Anandam – bliss, devoid of any impurities, inadequacies, everfullness.

Thus reality is one alone, it is non-dual. It pervades every thing sentient or insentient. Isopanisad eloquently said: "Ishawasyamidamsarvam yatkinch jagatyam jagat" (everything is pervaded by brhaman alone).

Analysis of knower and known has already revealed the error of locating "I/self in body and mind as

both belong to the realm of “known” (objects of knowledge) and not the “knower”. It was also seen that knower can not become the object of knowledge as in itself it is a self-contradiction. Finally the logical necessity of tracing the known to knower resulted into the two being one alone, i.e.

Atman or Brhaman, whose nature is pure consciousness. There cannot be anything away or beyond consciousness, not knowing is also within knowledge. Every phenomena of the world including space and time is within consciousness, in that sense Atman is neither born nor dies.

How do we reconcile this vision with the phenomenal experience of everyday world. We need to remember that Truth can be altogether different from the appearances. In fact if we examine carefully we would find that knowledge always contradicts commonsense notions. Just as the earth appears stationary and sun seems to travel from east to west, which is only an apparent reality (called “Vyavaharik Satya”). Its falsity is revealed by the knowledge that it is earth which is rotating on its axis, causing the shifts in the position of the sun. This is called Paramarthic Satya or absolute reality. Thus in the light of Paramarthic Satya, the falsity of appearance (Vyavaharik satya) is revealed.

ANALYSIS OF THREE STATES – WAKING, DREAM AND SLEEP

Mandukya Upanishad analyzes the three states- waking, dream and sleep and shows the necessity of a common substratum which gives continuity to “I” experience. We spend our whole life alternating amongst these three states yet when it comes to defining our identity, we exclusively take into account waking state alone.

The conclusion that “I am body and mind” is essentially arising during the waking state. When we examine dream and sleep states this identity gets questioned. Logically there should not be any experience or knowledge without experiencer or knower; then who is this knower without body-mind identity (“I” sense of waking state). Similarly in sleep, there is no experience of anything yet experience of “sound” sleep is there. We carry on the feeling of having good sleep when we wake-up, in other words the memory of sound sleep persists upon waking up. Logically there can not be memory without experience and an experience without the experiencer is not possible.

Thus the above analysis reveals that the waking identity is only one type of identity and its firmness and persistence gets challenged when the very nature and process of experiencing in dream and sleep states is examined. It puts forth the need to re-examine our firm conclusion about the self only on the basis of waking identity (identity with body and mind) and needs deliberation on the principle which is more inclusive and fundamental. Upanishads call it Atman whose nature is pure awareness. Thus awareness / consciousness whose nature is “self-luminosity” or “knowing” persists through three states of waking, dream and sleep. It is upholder (adhishthanam) of the entire universe of names and forms including space and time.

Shankaracharya, one of the greatest thinkers of the world, said:

“There is some entity, eternal by nature, the basis of the experience of egoism, the witness of the three states of waking dream and sleep and distinct from the five sheaths, who knows everything that happens in the waking, dream and sleep states, who is aware of the presence or absence of the mind and its functions, and who is the basis of the notion of egoism.

In the words of **Jodson Herrick**— Awareness itself has no locus, because the conscious act has

properties that are not definable in terms of the spatial and temporal units which are employed in the measurement of the objects and events of our objective world.”

Great thinkers from diverse disciplines reached the similar vision of truth despite very dissimilar fields of their endeavour. **George Wald**, a noted biologist and noble laureate said “Just the contrary of consciousness first appearing as a late outgrowth of the evolution of life on this and other planets, I come to the view that this universe breeds life and consciousness, because consciousness is its source and because the stuff of this universe is ultimately mind-stuff. What we recognize as the material universe, the universe of space and time and elementary particles and energies, is actually an avatar, the materialization of primal consciousness. In that case there is no waiting for consciousness to arise. It is there always, at the beginning as at the end. What we wait for in the evolution of life is only the culminating avatar, the emergence of self-conscious bodies that can articulate consciousness, that can give it a voice, a culture, literature and art, and Science.”

Professor Kothari pointed out the similarity between visions of reality obtained by Quantum Mechanics and Upanishads:- “The Concept of oneness in Quantum Mechanics is a totally, fundamentally, new concept. We have a most remarkable thought-provoking analogy drawn from modern physics for the great Upanisadic formula; the different individual selves on the empirical plane are one and the same on the transcendental plane”.

In his Nobel address **Delbruck (1969)** said: “Even if we learn to speak about consciousness as an emergent property of nerve sets, even if we learn to understand the processes that lead to abstraction, reasoning and language, still any such development presupposes a notion of truth that is prior to all these efforts and that can not be conceived as an emergent property of it, an emergent property of a biological evolution.

We find a strikingly similar conclusion by **Schroedinger**, great physicist of 20th century, in the epilogue “Determinism and Free Will”. He said “two incontrovertible facts are (a) My body is a machine (b) Its motions are under my control. The only possible inference from these two facts is, I think that I, I in the widest meaning of the word, that is to say, every conscious mind that has ever said or felt “I”, am the person, if any, who controls the “motions of the atoms” according to the laws of nature.... In itself the insight is not new. Earliest records to my knowledge date back some 2,500 years or more. From the early great Upanishads the recognition Atman = Brahman (The personal self, equal the omnipresent, all comprehending eternal self) was in Indian thought considered, far from being blasphemous, to represent the quintessence of deepest insight into the happenings of the world.”

Insights of clinical and personality psychology show us vividly the role that self-image plays in our day to day life. We not only act as unified self but we also hold certain image about it. The entire dynamics of inner life revolves around the positive or negative experiences with regard to the self-image. Self reflection or objectivity entails distancing from our own selves and trying to have a revision of it. It is like enhancing the witnessing character of our selves. Thus comprehending the non-self character of our identities makes it easy to deal with our reactions. Not only this, it also shows us egocentricity in our thinking and actions. Thus in a limited way the development of this self distancing or objectivity itself resolves several problems. Bhagavad Gita analyzes in great length the inner dynamics which plays havoc in our lives and create problems and sufferings. It details the effectiveness of Karma yoga and Gyanyoga as sure ways of emancipating ourselves from the vicissitudes of inner life. More of it would be discussed later.

THE ABOVE DISCUSSION CAN BE SUMMARIZED AS FOLLOWS:

The notion of self in Western Psychology is a case of misplaced identity

- Locating and identifying the self is problematic, if only waking state is taken into account,
- This change in vision requires thorough de-conditioning of mind also called "Antahkaran-sudhi". The process of Inner purification requires an introspective analysis of our thinking, feeling and reactions. This gradually shows us how our own thinking and ways of dealing with life situations are often instrumental in creating more problems and sufferings for ourselves.

WESTERN & INDIAN PSYCHOLOGY

How the above discussion is relevant to Psychology. For comprehending its relevance we need to take a re-look at the goal of psychology. The ultimate goal of psychology is to reveal the mysteries of the inner world. Therein lies the hope of solving man's problems and maximizing his effectiveness. Indian and Western psychology do not differ in terms of the goals. However the difference lies in the approach and the paradigm within which they operate.

The developments in Physics showed that the order of nature is different in large and small objects. At macro level the nature works within a deterministic design with laws that can help in precise prediction and control. However, at micro-level the whole order of nature's working undergoes change. "Contrary to Newtonian Physics, Quantum mechanics tells us that our knowledge of what governs the events at sub-atomic level is not nearly what we assumed it would be. It tells us that we can not predict sub-atomic phenomena with any certainty. We only can predict their probabilities" Gary Zukav (1979).

According to modern physics, Nature at micro-level defies precision in prediction and control, the hallmark of classical Physics. Not only this, it questions the independence of observer and observed as the very nature of observed gets altered by the act of observation.

"Philosophically, however, the implications of Quantum mechanics are psychedelic. Not only do we influence our reality, but, in some degree, we actually create it" Gary Zukav (1979). It shows striking similarity with the phenomena of the inner world.

Mind and phenomena of inner world obviously belongs to the micro world subtler than atoms and its constituent electrons and protons etc. Taking the lead from Modern Physics, mind can not be understood through exploration of deterministic laws and therefore it needs a paradigm shift within which it is currently operating.

Search for truth cannot set limits to itself; it has to exhaust all possible ways of explorations. It requires unbiased examination of facts as they are and constant reformulations of our worldview till our questions and doubts are answered to our satisfaction.

The dissatisfactions from the state of contemporary psychology are mounting and efforts towards the search for "meaningful psychology" are increasing appreciably. Bruner (1990) says: "the wider intellectual community comes increasingly to ignore our journals, which seems to outsiders principally to contain intellectually unsituated little studies, each a response to a handful of like little studies. Inside psychology, there is a worried restlessness about the state of our discipline, and the beginnings of a new search for means of reformulating it."

There is a long road between notions of man in Western and Indian Psychology. Scientism in

mainstream Psychology has piled up a heavy, layered and deeply entrenched views about man and his/her inner world. Opening of new horizons is an arduous task This is a ripe state for taking a new plunge. Indian psychology promises to offer further breakthrough in understanding man's inner world.

Comprehending Indian psychology is not easy. It is not like noticing a fact, but far more like achieving a great possibility through a strenuous effort. Mere knowing is not sufficient to grasp the view

o Indian psychology. The long journey of inner purification is important to comprehend its deliberations. Inner purification demands freedom from conditioned ways of thinking. It requires introspective orientation, critical self examination and willingness for change.

Existential questioning becomes pre-requisite condition to even begin this inward journey. A mind that is free from conditionings becomes the master of itself. It slowly attains freedom from all enslaving tendencies. Such a state of mind is called sthithpragya, the highest perfection of man, a man of self-realisation. It is called Moksha. Moksha is the highest goal of life. Knowledge leads to liberation (sa vidya va vimuktaye) is a very profound statement of the Upanisads. Dehatmabudhi, a case of misplaced identity, is the root cause of all notions and complexes which keep creating problems and sufferings for us.

NEED FOR A SHIFT IN PARADIGM

Paradigm within which mainstream psychology operates is, that, man is a creation in the Universe. Just as everything in nature is governed by the laws of nature similarly our body and mind are also governed by universal laws. Science offers the best methodology to study such laws of Nature, therefore, mind would also reveal its secrets when studied by scientific methods. New paradigm emerging from Indian psychology is that pure consciousness alone is the fundamental reality. The entire universe including body, mind and senses is only a manifestation of this reality and belongs to the same category as the material world. Man's identity does not lie in body and mind but in Atman. Misplaced identity is the root cause of all our problems and sufferings. There can never be an end to man's search for happiness and meaning till he discovers his own essential nature i.e. pure consciousness qualified as Sat + Chit + Anandam. Pure consciousness is the most fundamental reality and the ultimate truth of all creation, manifest or unmanifest. Different schools of Indian Thought are unanimous in saying that the true nature of man and its identity lies in Consciousness and not in body and mind, though they have adopted different methods for articulating it.

Mind and body are also creations in nature and follow orderly functions. Analysis of life situations, its impact on oneself and others can give a clue to understand its order of functioning. Indian Psychology stresses self-inspection and self-experimentation to achieve self-mastery and perfection. It exhorts discipline of oneself and not of others. Wisdom is acquired by introspection, reflection and experimentation with one's own self in the light of spiritual knowledge (Atmagyan). It has redefined the goal of life from pursuit of happiness to freedom (Moksha) revealing fantastic understanding of the order of the inner world.

As earlier discussed Psychology faces twofold challenges – understanding cognitive processes and maximizing effective living. It is already collaborating with neuroscience to unravel the mystery of human cognition. However it needs to open up to Indian Psychology for broadening its horizons for the latter. Psychology can not be value neutral in this regard as it can not shy away from the fact that human beings are inherently beset with the dilemma of making choices in life and it needs firm ground for doing it.

DISCIPLINARY IDENTITY CRISIS

One of the more familiar ways of reviewing the state of any discipline in academic research is by gauging the quality of literature that circulates in its academic journals and books.

Publications in the ordinary parlance are like academic currencies which decide the fate of academicians by rating their performance. However publication rate may not always be desirable or wisest of procedures to ascertain disciplinary development, but it continues to be the most commonly used yardstick of progress (for details on the previous ICSSR Indian psychology reviews, see Pandey, 2004: 342-370)

There are then some other mediums of reviewing the state, progress, and chief concerns of a discipline that entail conducting surveys with practitioners and researchers from the concerned discipline, inviting experts or wise-men/women for reflections and critical appraisal.

Besides undertaking process-outcome analysis, meta-analysis of research findings, models or theories based on leading concepts and appraisals of goals set, achieved and other similar mechanics, are commonly employed to map and 'measure' the growth of a discipline.

Reading psychological literature in the popular Indian psychological journals does not make a pleasant or tremendously illuminating reading most of the times. I have identified some reasons behind the uncreative, repetitive appearance of the literature which at times seems to lack sound or engaging methodology and at other instances seem to present findings built on rather flawed arguments and methodology.

Most of the published literature can be classified into two broad categories: *mainstream-validated research* and *oppositional-indigenous research (or reactionary and nativist, as Crooks (1994:180) defines the second category)*.

In the first category are researches which attempt to replicate or validate popular Western theories and researches without much emphasis or rigour shown in picking up context-relevant methodology or clear theoretical-ideological considerations which guide their research questions in the first instance. There are instances of numerous inchoate researches found in abundance in Indian psychological journals, in projects and theses supervised in varied departments at both undergraduate and postgraduate levels the decay in the quality of research in the country is at once displayed in the rigmarole of regional conferences and the thematics chosen in such forums.

Indian mainstream researches focus on domains of social, cognitive, developmental and experimental psychology (in other words specialities that can cover the entire rubric of psychology otherwise!) where such lacunae (i.e. gaps between theory and methodology) can easily be spotted.

NEW AND INNOVATIVE SPACES

More original, socially relevant and astute researches in the country range from critical reflections and serious interrogations in areas of cultural psychology (Misra & Gergen, 1993), indigenous social psychology (Sinha, D. 1986; 1997; Sinha, J., 1984), cultural psychoanalysis (Kakar, 1989, 1995) and the consequent development of social sciences hermeneutic.

WHAT IS 2000S: EMERGENCE OF INDIAN PSYCHOLOGY IN ACADEMIA.

ISSUES: THE COLONIAL ENCOUNTER; POST COLONIALISM AND PSYCHOLOGY; LACK OF DISTINCT DISCIPLINARY IDENTITY ?

2000S: EMERGENCE OF INDIAN PSYCHOLOGY IN ACADEMIA. ISSUES:THE COLONIAL ENCOUNTER; POST COLONIALISM AND PSYCHOLOGY; LACK OF DISTINCT DISCIPLINARY IDENTITY

2000s: Emergence of Indian psychology in academi

Indian psychology is a twentieth-century phenomenon, though its roots go back to the Vedic period of the Indian sub-continent in Asia (originally known as Bharata), the exact date of which is still under debate. According to current historical reckoning, the Vedic period dates from about 3000 bce, although some Western scholars date it back to 10,000 bce, based on recent excavations in the site of the Indus Valley Civilization.

Though psychology, unlike astronomy, medicine, economics, law and polity, or literature, was not recognized as an independent branch of study in ancient India, there has been no dearth of psychological theorizing scattered in varied sources, including mythology and epics, literary texts, linguistics, texts on dramatics, sexology, medicine, philosophy, religion, and spirituality.

Concepts and models related to almost all aspects of human behavior, such as cognition, affect, and conation, can be found in these sources, especially those human potentials which are yet to find their way into mainstream psychology, such as intuition, paranormal phenomena, altered states of consciousness, and transcendent awareness or pure consciousness.

These topics are found not only in texts and treatises related to Vedic tradition but also in non-Vedic traditions such as Jainism and Buddhism. Yet no efforts at collecting and systematizing a vast body of psychological knowledge are evident until the beginning of the twentieth century.

The term Indian psychology was purportedly first used by Sri Aurobindo, well-known Yogi and freedom fighter of modern India, in 1910 in one of his writings on education. Perhaps the first published work on this subject is by Jadunath Sinha (1933), titled *Indian Psychology: Cognition*.

It is a work of extraordinary scope that brings together all the extant views on various cognitive processes, including intuition and extra sensory perception, available in the three major religious-spiritual traditions of India, namely Hinduism, Jainism, and Buddhism.

SINHA LATER PUBLISHED TWO ADDITIONAL VOLUMES:

Indian Psychology: Emotion and Will (1961) and *Indian Psychology: Epistemology of Perception* (1969). Together, these three volumes are a veritable gold mine of psychological concepts and perspectives. Other early contributions include those by Caroline Rhys Davids, who published *Buddhist Psychology* in 1914 and another volume, *The Birth of Indian Psychology and Its Development in Buddhism*, in 1936.

Other publications compared modern psychology and Indian psychological thought, including *Western Psychotherapy and Hindu Sadhana* by Hans Jacobs (1961) and *Yoga and Western Psychology: A Comparison*, by Geraldine Coster (1934).

Subsequently, Indians also authored additional books, most notably among them *Hindu Psychology*:

Its Meaning for the West (1948) and Mental Health and Hindu Psychology (1952) by Swami Akhilananda.

Although these initial attempts stimulated other traditional Indian scholars, their work was repudiated by academic psychologists of modern India who were trained in empirical traditions of mainstream psychology. Thus, early attempts at development of psychological thought of Indian origin fell into disrepute.

Contemporary Developments In the past two decades there has been a renewed interest in examining the vast psychological knowledge base available in different Indian traditions. This renewal of interest has been triggered by the influx of yoga and meditation practices to the West, studies of altered state phenomena, and growing recognition that concepts and theories of modern Western psychology often do not generalize to Asian cultures.

Some contemporary developments which are not completely in the mainstream, but address vital issues concerning human behavior, such as transpersonal psychology, humanistic psychology, positive psychology, energy psychology, women's spirituality, and holistic approaches to health, have found Indian psychology valuable because its concepts and theories account for many phenomena in which they are interested.

Thus, Indian psychology transcends the geographical boundaries of India in its relevance and usefulness to the understanding of human behavior. **Distinctive Features** Distinct aspects of Indian intellectual traditions provide perspectives for the term Indian psychology :

- 1) The traditions of India recognize consciousness, as distinct from psyche and soma, as a transcendental phenomenon serving as the ground state for the manifestation of all the other states, including waking (jaagrata), dream (swapna), and deep sleep (sushupti). This consciousness is termed turiya (in Sanskrit turiya means fourth). It is called fourth because it has no attributes and does not have characteristics of the other three, and yet supports them. All are altered states of mind.
- 2) Unlike the Cartesian mind-body split, Indian traditions view mind and matter as a continuum.
- 3) Mind-matter is understood to be the operation of three fundamental principles in the universe: sattva , rajas , and tamas , which represent illumination and creativity, energy, and inertia, respectively.
- 4) The person in Indian thought is understood to have three levels: the animal, the human, and the divine.

The divine aspect of the person present in humans is that pure consciousness which is also the foundation of the whole universe. Contemporary developments in physics, biology, chemistry medicine, and psychology are tending toward these ideas and thus vindicate the Indian perspective.

These fundamental views have shaped the Indian ethos and eidos for several thousand years and have provided a framework guiding the lives of millions of Indians. This influence is evident in the fourfold value system enunciated in Indian thought, which recognizes all aspects of human aspiration from the mundane to the spiritual. These aspects are dharma (right living), artha (wealth), kama (desires), and moksha (liberation).

Each person may aspire to all four; yet as a human being one is expected to aspire to self-realization/liberation, which is the ideal human aspiration. All aspects of human activity are conceptualized and understood within this framework of consciousness, which differs qualitatively from the understanding gained only from a waking-state perspective.

Development of Indian Psychology In the past three decades developments within Indian psychology have progressed both in theoretical and empirical directions. Conceptual clarifications, theory building, development of tools, and application of concepts in the fields of education, health, and organizational behavior are some of the major developments (Cornelissen, Misra, & Varma, 2011a, 2011b; Misra & Mohanty, 2000; Paranjpe, 1984, 1998; Rao, Paranjpe, & Dalal, 2008; Salagame, 2011).

Indian psychology is relevant and applicable in all aspects of human endeavor provided one is open enough to understand the underlying worldview. The scope of Indian psychology is from kamasutra to yoga sutra (from sexology to transcendental pursuits) (Salagame, 2011) and no aspect of human life is neglected. A major challenge in the development of Indian psychology has been related to the appropriate methodology to be used. Because many ancient Indian ideas and insights have emerged from transcendental phenomena, Indian psychologists have argued that

third-person methodologies are not appropriate to understand them. Firstperson methodologies are favored.

However, Indian psychology accepts a wide range of methodologies beyond observation, experimentation, and inference. In addition to those mentioned above, Indian psychology also accepts intuition and verbal testimony of an authority as means of valid knowledge.

Therefore, some argue that there is a place for first-, second-, and third-person methodologies, depending upon what one is studying.

The future of Indian psychology lies in its contribution to mainstream psychology as a way of enlarging the existing framework, rather than remaining isolated as a fringe movement. The fact that many non-Indians have been involved in the development of Indian psychology suggests that it will eventually attain universal significance.

THE COLONIAL ENCOUNTER

Are islands natural prisons? The answer to this question is encrypted in the history of modern colonial encounters, that is, the European discovery and characterization of tropical islands and their inhabitants, as the colonial history of the Andamans illustrates. The spatial history of the Andamans began much before their colonization as a leaf in the fantastic tales of ancient and medieval travelers. The Andamans entered history through these accounts and 'transformed into a place, that is, a space with a history'.

The British stepped into the historical trajectory of the Andamans as their empire was shifting away from the Atlantic and starting to focus on the Indian Ocean. With this a new era of 'modern globalization', with linkages between the Indian Ocean and the European-Atlantic economy, was emerging. The events as they unfolded in the Andamans were reminiscent of the Columbian encounters in the late fifteenth century, the sixteenth century colonial encounter between Indians and English in the New World

and the Tupinamba and Europeans in Brazil.¹ The violence in each case accompanied misanthropic characterization of the environments and peoples which the colonizers encountered. British

surveyors and administrators brought colonial experiences and characterizations from European encounters with the non-European world to the Andamans.

This is amply exemplified in the way disgust with the physical surroundings of the tropical islands was projected on to the natives in the Andamans. Over time, the need for physical violence diminished because an essential aspect of this hegemonic imagination was that it created and sustained spaces to which the aborigines had no physical access. Moral judgements were couched in scientific, albeit racialized, theories of environments and peoples.

As a result of being diachronically encoded into the Andamans' history, the colonial characterization of the Islands and their inhabitants displayed a tenacious staying power. This is reflected in the images that have come down to us today of the Andamanese cannibals. The establishment of the penal settlement was instrumental in lending permanence to the image of kalapani, the land of darkness and death, and its nationalist alter ego, muktirth.

At the heart of both metaphors, kalapani and muktirth, sustained and nourished by colonialism and nationalism, was the imagery of the Andamans as a natural prison. There was little endemic or innate in island geography for it to serve as a prison.

However, a particular imagery and perception of nature and landscape influenced the way that space was used, controlled and transformed. This book not only demonstrates this point in relation to the Andamans but has also sought to free the Islands from the 'island complex' and 'island metaphor', which was not always a product of geographical location but of the colonial encounter. It reveals that the island complex was mostly a Euro-centri-

assumption that located islands, especially tropical islands, at the margins and extremities of the civilized and knowable world.

This book, by employing the lens of spatial history, de-links the Andamans from the colonial spatio-geographic imagination, questions the historical conceit in transforming spatial stereotypes into acquired wisdom, and establishes that all prisons are simply human constructs.

decontextualized. More specifically, culturally focused research has been criticized for its tendency to ascribe observed group differences to East– West binaries (e.g., individualism–collectivism, Judeo-Christian versus Confucian, etc.). Moreover, there is little attention paid to the larger historical and contemporary contexts that shape – and reshape – the social lives of these so-called 'traditional' cultural variables such as Confucianism or collectivism. Paranjpe (2002, 35) characterized cross-cultural psychology publications as displaying 'a distinct disdain for history'.

Similarly, Gjerde and Onishi (2000, 216–217) charged that the culture and psychology approach suffers from 'lack of attention to the historical and ideological sources of "culture"'. There are, of course, many historical and ideological forces underlying cultural values and cultural identity; namely, societies elaborate cultural narratives to various ends at particular moments in time.

In particular, the relationship of these cultural elaborations to historical and contemporary legacies of colonialism have received scant attention in psychology, perhaps because most active scholarship on colonialism has taken place outside the disciplinary boundaries of psychology. Because we draw from discussions in colonial and postcolonial studies, which may be unfamiliar to some psychologists, we begin with a brief review of some key-relevant arguments. We then proceed with an examination of the link between colonialism (and postcolonialism) and psychology in two ways. First, we examine various ways in which colonial past continue to matter to the psychological

experiences of individuals in the present, particularly with respect to identity-related struggles and social functioning.

Second, we consider the relevance of colonial legacies to the practice and study of psychology in formerly colonized states. In this vein, we consider the significance and social life of hegemonic Western-centered psychologies in former colonies.

We make note of current efforts in various areas of social and cross-cultural psychology to build a knowledge base of the psychology from the perspectives of the individuals and groups with historical legacies of colonialization, as well as some of the ways in these efforts fall short because of their overreliance on the East– West cultural binaries to frame the indigenizing efforts. We end with a discussion of the challenges that lie ahead.

COLONIAL/POSTCOLONIAL DISCOURSES

Analysis of colonialism and its legacies necessarily calls for attention to its prominent ideological cornerstones: race and ‘culture’. For psychology, it is important to underscore that colonial discourses engage the psychological, taking up questions of the human capacity, pathology, and identity of the colonized.

Colonialism is a specific form of oppression. An increasingly rich literature explores how the colonial subject is made through elaborate systems that measure, compare, and explain human difference; these are the processes that justify that radical imposition of the colonizer on ‘inferior’ people in need of intervention.

Colonial regimes are elaborated discursively by differentiating between the colonizer’s ‘superior’ or ‘more civilized’ ways of life and the colonized people’s allegedly ‘inferior’ or ‘savage’ ways. Scholars look to a wide range of domains to observe this subject-making: from medicine, to city planning, to exhibition, to ethnography, to science, to history writing – and of course to more obvious arenas of social control such as schools and the military (Anderson, 2006; Chakrabarty, 2000; Mitchell, 1991; Young, 1990).

We consider that these colonial legacies are in fact part of a larger transcultural and historical project, namely, East–West distinction-making – and the practice of claiming the unique non-Western aspects of national culture that marks the East Asian modern self, which some scholars have called self-orientalizing practices (Gjerde & Onishi, 2000; Ong, 1999).

Moreover, this project has taken shape as a cultural coproduction between the East and the West (Hay, 1970). For example, anthropologist Aihwa Ong described how – in the post-Mao era – the Chinese state and media began to revive Confucianist ideology as a moral force that can serve to maintain cultural and ethnic continuities between mainland and overseas Chinese and to reign in the Western dangers of economic individualism and cultural excess.

In her work with the Chinese parents (who grew up with the anti-Confucian Maoist rhetoric during China’s Cultural Revolution) and their children born under the one-child policy, anthropologist Vanessa Fong (2004) details the complex and contradictory cultural and national identities of contemporary Chinese adolescents.

From these perspectives, which situate the cultural discourse within the modern historical and political context, the notion of Confucianism or collectivism as ‘cultural’ characteristics of ‘indigenous’

non-Western cultures begins to lose its meaning.

Importantly, these works show that there is more complexity to the discourse of the modern Asian selfhood beyond the idea of a power relationship typified by Western domination and native resistance. Thus, the sense of cultural self throughout the world is necessarily a conversation that is held in relationship to hegemony.

Western ideas/ ideologies: the collectivistic/individualistic distinction is as such best appreciated as one born in interaction.

For example, Liu (1995) showed through her analysis of translingual practice (e.g., translation and introduction of terms such as 'self' and 'individualism' into the Chinese language) that the ideology of individualism in China evolved in the context of China's violent encounters with the West as well as Japan.

In the case of former colonies, then, this matrix is further complicated. In summary, the vocabularies of cultural and psychological selfhood have long histories that intersect power relations, racial regimes, and colonial/imperial discourses. By now, it makes little sense to think of enduring cultural differences unmediated by these processes.

COLONIAL ENCOUNTERS AND IDENTITY

Many sociocultural anthropologists and archaeologists refer to the "colonial entanglement" as a way to emphasize the complexities and ambiguities of power relationships and identities of colonizers and their host communities in colonial encounters (for example, N. Thomas 1991; Dietler 1998). Work by Lightfoot, Deagan, and others has shown that the interregional interaction networks within which colonies are founded bring multiple groups into contact not just colonizers and host communities.

In these encounters, the social identities of colonizers, other foreign communities associated with the colonizers, and host communities can all change. Much, if not most, attention has focused on identity transformations in the host communities, often implicitly or explicitly relying on the traditional "acculturation" model of culture contact.

This model assumes a unidirectionality in which the dominant colonizing "donor" culture transforms the more passive indigenous "recipient" culture of the host community. Similarly, archaeologists have traditionally viewed the social identity of the colonizing group as essentially static, mirroring the culture of the homeland in both ideology and material culture. If items of material culture did not exactly mirror the material culture of the colonial homeland, then they were assumed to reflect a process of local emulation, in which elites (and others) in the host community selectively appropriated high-status symbols and items of colonial material culture.

COMPARATIVE ANALYSES OF COLONIAL ENCOUNTERS

The contributors to this volume examine colonial encounters from two complementary perspectives:

- (1) a "top-down" approach that focuses on local, regional, or interregional political economy, and
- (2) a "bottom-up" approach that emphasizes individual or small group agency as it relates to identity and its transformations. Clearly, these analytical foci are always intertwined at a fundamental level; both are necessary in order to develop a nuanced, holistic understanding of the

complexities of colonial encounters. In fact, one might argue that the very disjunctions and ambiguities that so characterize colonial encounters provide an ideal context for understanding the intersection of political economy and identity. The chapters in this book reflect these complementary approaches.

POST COLONIALISM AND PSYCHOLOGY

Of the theoretical resources typically taken as the underlying foundations of critical social psychology, elements, typically, each of Marxism, feminism, psychoanalysis, and, perhaps chiefly, the 'turn to text' characteristic of Post-Structuralism (Gough & McFadden, 2001; Hepburn, 2003; Parker, 1999, 2002; Walkerdine, 2002), one particular mode of critique remains notably absent, that of post-colonial theory.

What makes this omission so conspicuous is that much postcolonial theory is explicitly psychological in both its concerns and its critica

resources. Fanon's (1986) *Black Skin White Masks*, for example, makes ample reference to various psychological and psychoanalytic formulations as way of accentuating what one might term the 'identity trauma' of blackness in colonial contexts, and as way of articulating the depth and tenacity of the psychical components of racism (Bulhan, 1985).

Homi Bhabha (1983) likewise cross-references a series of psychoanalytic notions – chiefly that of the fetish, but also the condensation and displacement of the dreamwork, and the narcissistic aggressivity of the mirror-stage ego-formation – in his reformulation of that classic social psychological notion of the stereotype.

While the conceptual framework of psychoanalysis is absent in the writings of Steve Biko (1978), his political objectives are powerfully, even if strategically psychological in nature. It is by drawing upon the terms of this discourse of self, identity, subjectivity that certain of the key features of the Black Consciousness Movement come to light.

In many ways Black Consciousness takes as its goal exactly the consolidation of positive and politicized forms of black culture and identity, certainly inasmuch as they play their role in generating political solidarity amongst the oppressed.

Each of these above sets of critical formulations provide powerful ways of thinking the conjunction of the psychological and the political, the affective and the structural, the psychical and the governmental. We have as such a powerfully critical combination of registers that one would take to lie at the centre of critical psychology's ostensibly critical concerns (Hayes, 1989; Hook, 2004a). Why then have such post- or anti-colonial thinkers not featured more strongly in the conceptual resources of critical social psychology? How might their work, and their characteristic concerns – racism, colonial discourse, cultural dispossession, alterity

psychical mutilation, resistance, etc. - alert us to gaps in the growing orthodoxy of critical psychology.

To approach the question from another direction: what might be said to be the 'critical psychology' of these theorists, and particularly of Frantz Fanon and Steve Biko? How might their use of the register of the psychological within the political and their concerns with the cultural dynamics of colonisation alert us to the possibilities of psychology as a vocabulary of resistance?

Furthermore, what does each of these critics have to tell us about the crowning problematic of the colonial and postcolonial condition, namely that of racism, a phenomena that seems as political as it does psychical in nature? Before turning to a brief discussion of the work of each of the above theorists it will be necessary to underline what I mean when I refer both to 'critical social psychology' and 'postcolonial criticism'.

Critical social psychology and political critique There have been a series of attempted definitions of critical social psychology of late. Gough & McFadden (2001), for example, have put forward an understanding of a critical social psychology that 'challenges social institutions and practices – including the discipline of psychology – that contribute to forms of inequality and oppression' (p. 2).

This is a version of social psychology, they suggest, in which practitioners situate themselves within society and its problems, a social psychology which 'gets involved, which adopts particular positions in important debates on...issues such as prejudice, violence...crime, etc' (p. 2).

Valerie Walkerdine (2002) has similarly suggested a move away from the academy to politics, an understanding of a critical psychology that expresses a pronounced commitment to the theories of poststructuralism, and that stresses the importance 'not of psychology per se, but...of the subject and conceptions o

subjectivity for politics' (p. 1). Critical psychology she claims is hence 'an umbrella term which describes a number of politically radical responses to and differences from mainstream psychology...[including] perspectives of...feminism, ethnic and anti-racist politics' (Walkerdine, 2002, p. 2).

Tellingly however, Walkerdine (2002) comments on how the political commitment which has generated such anti-racist, feminist, gay liberation changes seems largely 'to have been lost' (p. 2) Hepburn (2003) thinks of critical social psychology as focussed on issues of politics, morality and social change, and as being predominantly concerned with issues of oppression, exploitation and human well-being.

Critical social psychology though is also 'critical of psychology itself...its assumptions, its practices' (p. 1). However, she notes (2003), this dual task of criticizing society and criticizing the discipline sometimes leads to these two factors working against one another.

Postcolonial criticism Having identified an area of concern within the general domain of critical psychology, we should now turn our attention to introducing the 'postcolonial'. In this connection, we may turn to Homi Bhabha who provides an adroit summary of both the concerns and the scope of postcolonial criticism.

(Although I will not discuss Bhabha's work in any detail here, he usefully enables us to frame the discussion of the writings of Fanon and Biko, and to emphasize at certain points, trenchant points of my overall argument). Postcolonial criticism, he writes 'bears witness to the unequal and uneven forces of cultural representation involved in the contest for political and social authority within the modern world' (1994, p. 171).

LACK OF DISTINCT DISCIPLINARY IDENTIT

Anthropology brought to the world of ideas and concepts in the 20th century a commitment to empirically-based field research, a concern for understanding the diversity of cultures, a respect for the functional legitimacy of those cultures, and skepticism about the utility of the introduction of

western ideas and technology. By the mid-point in the 20th century, the relatively young disciplines of psychology, demography and epidemiology became prominent in their separate domains providing varied perspectives on health issues. Psychology generated the primary theory and models of intervention for behavioral change that have been applied to a wide range of health concerns including mental health, substance abuse, lifestyle factors related to chronic disease, and HIV/AIDS. Demography, focused on population growth and transition, has played a central role in issues of fertility and family planning, infant and child morbidity, and reproductive health. A key element of international demography has been the Demographic and Health Survey (Macro International, 2005), which has been administered over 200 times in 70 countries. Epidemiological concepts and methods have become the hallmark of studies on infectious and chronic diseases in the US and internationally, and have established the designs and criteria for testing the efficacy of interventions and for monitoring disease vectors through sentinel surveillance. The interface of anthropology with psychology, demography, and epidemiology has involved mutual criticism for much of the latter part of the 20th century. On the one hand anthropology is seen as qualitative, anecdotal, utilizing small samples and limited in its generalizations. On the other hand, anthropologists viewed the three other disciplines as imposing universal theories and results, not providing sufficient recognition of cultural diversity and context, and not utilizing the perspectives of members of the population under study. The broad survey approaches of epidemiology and demography were critically viewed by anthropologists, whereas epidemiologists and demographers looked with some disdain on ethnographic methods. Nevertheless, each of the disciplines had sectors that reached out to one another evolving sub-fields such as personality and culture (Barnouw, 1963; Wallace, 1970), anthropological demography (Kertzer & Fricke, 1997), cultural and social epidemiology (Janes et al., 1986; Trostle, 2005), and cross-cultural psychology (Bingham et al., 1999; Lopez & Guarnaccia 2000). Furthermore, professionals within the respective disciplines have called for greater collaboration to address societal problems (e.g., Sherif, 1963; Janes et al., 1986; Kertzer & Fricke, 1997; Trostle, 2005). The rise of large scale NIH-funded domestic health projects in the realms of chronic disease, mental health, alcohol and drug abuse, and international projects funded by USAID have created the opportunities for the fields of anthropology, psychology and epidemiology to work together in addressing common problems. By the 1980s, research and intervention projects in minority and low income communities in the United States and in developing countries brought together representatives from multiple disciplines to address cultural differences, design interventions, promote behavioral change and evaluate efficacy. The growing degree of disciplinary collaboration was given even more impetus with the emergence of the HIV pandemic. Here was a problem that could not be the province of one discipline and required multiple and innovative approaches to treatment and prevention.

The collaborative process: facilitating and inhibiting factors This project team represented great diversity in terms of country of origin and residence (USA and India), institutional base (universities, nongovernmental institutions, private business and governmental agencies), discipline (anthropology, demography, medicine, microbiology, psychology, and public health), religion (Hindu, Muslim, Christian, and Jewish) and work experience (research and intervention), age (30–63), gender, and socioeconomic and educational background.

The enormous potential for positive production by such a diverse team is balanced with the equivalent potential for misunderstanding and miscommunication both professionally and interpersonally. In this section we examine the inhibiting and facilitating factors that influenced the process of collaboration.

Inhibiting factors Inhibiting factors reflected the influence of geographical distance, institutional

culture, language differences, and disciplinary and personal variations in belief systems and practices. The two parts of the RISHTA team, East and West, were 10,000 miles apart and had to depend on e-mail as the major mode of long distance communication. E-mail can greatly facilitate communication; for example, e-mails sent from the U.S. in the evening could be responded to by morning and e-mails sent in the evening from India were available in the U.S. by early morning. At the same time, e-mail can be a quicker mode of "miscommunication" as short statements are used to sort out complex issues or a lack of communication is viewed as a kind of message. E-mail correspondence thus became another forum for negotiating perspectives and modes of communication across disciplines and cultures. The two collaborating universities each had concerns about the nature of the project.

The demographic university in India was unsure about its role in intervention in local communities, because research and national policy had been its primary foci to date. There has also been some uncertainty expressed at IIPS as to demography's role in sexuality and sexual risk research. Some faculty at IIPS have been concerned that the interest in RISHTA among the demography graduate students has provided too much encouragement for them to focus their Master's and Ph.D. theses on sexual risk. At the same time, UCHC in the U. S. had not shown a strong commitment to international research. The Institute for Community Research primarily focused on local research and intervention but was committed to international work with other current projects in China, India, and South America.

The NIMH grant was received by the UCHC and funds were committed to a sub-contract with IIPS. In the original budget proposal it was envisaged that the U.S. University would receive 80% of the funds and the Indian university 20%. This was estimated largely due to the imbalance in the salaries that were ten times higher in U.S. than in India. However, over the lifetime of the project, additional funds from the U.S. side were allocated to the India side increasing Indian share to the total budget to 35%.

The additional funds were allocated to the India side due to the weakness of the US dollar, the rising costs of personnel in India and the costs associated with STD testing. On the India-side, the staff consists of 18 full-time staff and two faculty, whereas on the US- side there are one full-time faculty equivalent (PI, co-PI and statistician) and two full time staff.

The process of negotiating budgets for the IIPS sub-contract is primarily conducted by the PI (S. Schensul) and the co-PIs at IIPS. Despite the re-budgeting there is a sense on the India-side that flexible funds are always available on the US-side and that cost- overruns and expansion of the sub-contract is always possible, giving way to some degree of tension at the beginning and end of each grant year. What is Western: Greek heritage, medieval period and modern period. Structuralism, Functionalism, Psychoanalytical, Gestalt, Behaviorism, Humanistic-Existential, Transpersonal, Cognitive revolution, Multiculturalism

WESTERN: GREEK HERITAGE, MEDIEVAL PERIOD AND MODERN PERIOD. STRUCTURALISM, FUNCTIONALISM, PSYCHOANALYTICAL, GESTALT, BEHAVIORISM, HUMANISTIC-EXISTENTIAL, TRANSPERSONAL, COGNITIVE REVOLUTION, MULTICULTURALISM

Western psychology greek heritage

The roots of western psychology can be traced to Greek philosophy. The word psychology itself is derived from the Greek words 'psyche' which means soul and 'logos' which means study.

Psychology thus started as a part of philosophy and became an independent discipline much later.

Plato and Aristotle were among the first philosophers who thought about the mind. Plato believed that body and mind are two separate entities and mind could exist even after death. But he was positive in that education can bring change to the basic nature of the mind. Aristotle, who was the disciple of Plato, followed the feet of his teacher and believed in the body-mind duality. But he thought that of each of these is the manifestation of the other. He, but, was pessimistic about the role of education in changing the fundamental nature of humans.

Rene Descartes, the French philosopher and mathematician, who originated the Cartesian system of coordinates or the coordinate geometry, also believed in the body-mind duality. But he was open enough to consider that there is an uninterrupted transaction between the body and the mind

In the eighteenth century AD, John Locke, a British national, proposed that knowledge depends upon the experience based on the sense organ and that thinking is not innate. He also considered that the mind of a newly-born child is like a clean-slate on which anything can be written. Locke believed that knowledge occurs only when the sense organs interact with the outer world.

These two ideas – the body-mind duality and the ‘clean-slate’ mind – have been the strong roots of the western psychology for many decades. Only in the twentieth century western psychologists, especially Jung, Maslow and others, were able to break free from this limiting concepts.

In the twentieth century AD, German scientist E.H. Weber attempted a scientific approach in the study of the mind by his finding of the quantitative relation between stimulus intensity and the resultant sensory experience. This was later known as the Weber’s law.

Almost in the same period, G.T. Fechner, who is called the father of quantitative psychology, coined psycho-physics which is the quantitative study of external structures and sensory experience.

Then came Darwin with his revolutionary ‘origin of species’ which influenced psychology and human thought.

In 1879, Wilhelm Wundt, a German scientist, established the world’s first psychological lab at Leipzig, Germany. His aim was to prove that there is a physical activity for every mental activity. He opined that psychologists should study sensation, perception, and emotions.

In the first decade of the 20th Century AD, the Russian psychologist Ivan P. Pavlov made a path breaking finding when he was studying the digestion process in dogs. Before the experimental dog was given food, a bell was sounded. When this was repeated several times, the dog started salivating the very moment it heard the bell sound. Pavlov called this the conditioned reflex. This was one of the greatest findings that made radical changes in the field of psychology.

MAJOR SCHOOLS OF PSYCHOLOGY

Structuralism

Titchner and his followers said that consciousness can be analyzed into three—sensation, perception and feeling. Titchner and his followers are called structuralists and their main method for study of mind was introspection.

Functionalism:-

William James, the father of American

Psychology, J.R. Angell and John Dewey argued that psychologists should study the function of the mind and not its structure. These group of psychologists are called functionalists.

FREUD AND PSYCHO ANALYSIS

Sigmund Freud of Vienna, who is considered as the father of modern psychology, originated a new method called the Free Association Technique. Freud considered that mind has three parts – the conscious, the pre-conscious and the unconscious. He considered that 90% of the mind is the unconscious mind. He argued that Id (unconscious mind) is the seat of repression, and instincts. Freud further considered that behind any behavior is the libido energy.

He divided the personality into three – id, ego, superego. Of these, Id goes after pleasure and thus is said to be governed by the pleasure principle. Ego which is the organized part of Id is driven by the Reality Principle. Superego connects the id to the external world and is considered the conscience. Later, Erich Fromm, Karen Horney, Erik Erikson, Harry Sullivan and Otto Rank improved upon the ideas of Freud and so they are called Neo Freudians.

ALFRED ADLER AND INDIVIDUAL PSYCHOLOGY

Alfred Adler gave the focus to society because he thought that since we are social animals we should give emphasis on social factors.

He argued that, the will to power and superiority are thus more important than sex or will to pleasure. So, the individual will try to overcome the deficits he has or he thinks he has. He will try to show superiority or ambition. Inferiority complex is the most important concept Adler added to psychology. His psychology is called Individual Psychology.

JUNG AND ANALYTICAL PSYCHOLOGY

Carl Gustav Jung, like Adler, was in the psychoanalytical camp in the beginning, but later parted with Freud to create his own (school of) psychology called the Analytical Psychology. He dismissed the Freudian theory that the only motive that drive the unconscious is sex. Jung extended the concept of the unconscious beyond the individual. Thus he said that there is a collective unconscious besides the individual unconscious. He postulated that the racial memory of centuries is precipitated in the unconscious of each individual. According to him, the main ingredient of the collective unconscious is the archetype.

BEHAVIORISM

John B. Watson, also of America, proposed that psychologists as scientists should study observable human nature and not the concepts like mind, consciousness etc.

He and his followers tried to explain behavior based on stimulus and response. They are called behaviorists and their school of psychology is called behaviorism. Tolman, Hull and B.F. Skinner are the later behaviorists. Skinner originated operant conditioning which is one of the most used techniques for psychological therapy today.

GESTALT PSYCHOLOGY

Gestalt Psychology was a reaction to the over emphasis of reductionistic methods in psychology. The gestalt psychologists were against this blind reliance on analysis and reductionism. They

believed that behavior should be understood in a holistic way. Max Wertheimer, Wolfgang Kohler, Kurt Lewin were the first proponents of this school psychology.

HUMANISTIC PSYCHOLOGY

Some psychologists believed that neither Freud et al nor the behaviorists could include the complexity and uniqueness of man their studies of psychology. So a group of psychologists gave human experience more importance and they are called humanists. They argued that man is a subjective animal. The humanists counted that the motives for development and to become perfect are more important than sex, power etc. They brought back the dignity of man that Freud and others undignified. They denied Freudian unconscious or behavioristic environment as the ultimate basis of behavior and said that man is not a slave of either the unconscious or the situation. Gestalt psychology, Indian Psychology, Psychology of Consciousness, Environmental Psychology, Para Psychology are the schools of psychology that are included in Humanistic psychology. Gordon W Allport, Carl Rogers, and Abraham Maslow are some of the early proponents of humanistic psychology.

THE THREE MAJOR FORCES IN MODERN PSYCHOLOGY

There are three major forces in psychology. Freudian Psychoanalysis and the offshoots from it are considered the First Force in Psychology. This has been very dominant in the earlier part of the 20th century but has given way to the second force in psychology called behaviorism. Currently, behaviorism is also slowly reaching its end. Slowly, holistic and more natural ways are coming to the main stream.

This is the third force in psychology – the Humanistic Psychology. Many experts foresee that by the first or second decade of the 21st century, humanistic psychology will become the dominant major force. This is because that man will slowly come to realize that the origin of bliss is in himself and so man will turn to himself for truth, beauty, happiness, success, and achievement. Neither Freudian psychology nor Behaviorism can be of definite help in this stage.

MEDIEVAL PERIOD AND MODERN PERIOD OF PSYCHOLOGY

The Middle Ages has had a poor reputation among twentieth-century psychologists. Edwin Boring, in *A History of Experimental Psychology* (New York, 1929), held that late medieval thinking was based largely on theology and hence tended to be opposed to science. Gregory Zilboorg, in his *History of Medical Psychology* (New York, 1941), claimed that medieval medical practitioners were afraid to look into either normal or abnormal psychology and that the mentally ill were frequently regarded either as possessed by a devil or as witches. Introductory texts have occasionally taken this argument several stages further, claiming that the mentally ill in the Middle Ages were liable to be tortured or burnt at the stake as a consequence of the belief that they were possessed by a devil.

Historians of psychology in the later twentieth century did not substantiate claims that the mentally ill were routinely treated with cruelty in the Middle Ages. Moreover, they generally took a more sympathetic view of the period, finding that medieval philosophers, physicians, and even theologians produced and debated interesting theories of human behavior, although they seem to have done little to test them experimentally.

THE MIDDLE AGES

The Middle Ages are reckoned to run from the fourth or fifth century CE to the middle or end of the fifteenth century CE. A period of nearly 1,000 years naturally saw a great deal of change, not only politically, but also intellectually. In Western and Central Europe at least, the first part of the Middle Ages (until the eleventh century), is known as the Dark Ages, when the relative political and economic backwardness of society, which followed the collapse of the Roman Empire in the west and the breakdown of the Mediterranean world, was reflected in an apparently impoverished intellectual culture.

Few writings of any kind survived from this period, and ancient writers like Plato and Aristotle seem to have been little read. Read more about The Middle Ages.

MEDIEVAL PSYCHOLOGY

There was no formal discipline called psychology in the Middle Ages, but a number of medieval writers, particularly those from the thirteenth century, discussed concerns similar to those of present day psychologists. More important, at least a few, for example, Avicenna and Albertus Magnus (1193-1280), seem to have been genuinely interested in psychological theory. It is possible to discern at least two important psychological traditions in the writing of this period: a medical and a philosophical one, both stemming from ancient predecessors. Read more about Medieval Psychology. From a 21st-century perspective, looking to our medieval ancestors for help in understanding the mind would seem to be a backward step. Those were the days, we think, of supernatural forces intervening in human affairs, and with views of medicine, biology and psychology that strike the modern reader as primitive and unsatisfyingly pre-scientific. A progressive view of human knowledge that sees it as inexorably proceeding towards greater understanding would suggest that we have little to learn from a psychology dating from the days before science.

Yet ideas about the mind in the medieval period, itself a huge span of time (from the late classical period to the 15th century) that saw many shifts in thought, were much more sophisticated than that caricature would allow. Here, we set out some prominent medieval models of mind and their implications for understanding memory, imagination, emotion and the relations between mind and body. Why should we look back to medieval ideas about the mind? One reason is that the Middle Ages saw considerable engagement with questions of mind, body and affect, and the development of sophisticated thinking about psychology – at least among the educated élite, many of them clerics, who read and wrote the texts that have been passed down to us. Another reason is that medieval texts open onto a psychology that was not dominated, as many recent discourses are, by essentially Cartesian notions of mind/body dualism. Before Descartes, mind and body were seen to interlink in ways that have a remarkably modern flavour.

Understanding medieval psychology, though, is fraught with problems. Interpreting any texts or images from so long ago requires a shift of belief systems, in order to appreciate the ontology and background of assumptions with which medieval thinkers operated. Social and cultural contexts were very different. Western medieval writing assumed a Christian thought world, and writing was frequently seen as the domain of men. Psychology was most of all the realm of theologians, who were interested in questions of desire, will, intention, sin and virtue. We cannot look for a straightforward cross-section of medieval thought: much writing is by religious men, and personal testimonies and accounts of experience are inevitably filtered through assumptions concerning gender, class and religious belief – as well as genre.

But hazards are also opportunities: medieval piety foregrounded affective experience, meditation

and prayer, and the need to shun distractions in order to stay focused on those tasks. We can also look to imaginative fiction, which offers especially valuable insights into cultural attitudes and experience, of both men and women, and which suggests how ideas of mind, body and affect carried over into secular culture.

SENSORY AND EMOTIONAL CHARGE

We aim to show how medieval writers approached the mind, highlighting some areas in which their ideas are particularly relevant to, and even prescient for, today's scientific psychology. Just as modern psychology can be understood as a development of and challenge to Cartesian ideas about the separation of mind from body, so medieval writers about the mind were working from the starting point of a particular intellectual landscape. Hippocrates' theory of the four humours, developed by Galen in the second century CE, underpinned the notion of a mind-body continuum, for humours shaped both mind and body. The distinction between mind and body was complex and more fluid than in post-Cartesian thought, complicated by ideas of the soul, by different views on where in the body faculties were situated, and by the integration of thought and affect.

The term 'mind' originated with the concept of memory, but quickly came to overlap with notions of the soul, and took on at least some aspects of current definitions of mind. Aristotle had situated the rational or intellective quality within the soul, and had located the heart as the centre of the senses and cognitive faculties; Galen by contrast associated these with the brain.

Neo-Platonic theories situated the immortal and rational part of the soul in the head, and the appetites and emotions in the trunk of the body. In the fourth century, St Augustine saw the will as a faculty of the (superior) soul and associated emotions with the (lower) body, but also saw emotions as having both cognitive and bodily aspects (Kemp, 1990).

MEDIEVAL COGNITIVE PSYCHOLOGY

Medieval ideas about cognitive psychology derive from two major sources, the writings of Aristotle and especially his work on the soul, the *De Anima*, and the theory of the inner senses, which was laid down in late antiquity. Aristotle's *De Anima* may be the most popular psychological text of all time: It was prescribed reading for Bachelor of Arts degrees throughout Europe until the end of the Middle Ages. The book is short and at times obscure, but it offers a systematic account of psychology with Aristotle's ideas about other disciplines. Because of its obscurity, a number of medieval scholars wrote books or commentaries in which they set out what they thought Aristotle meant. Those by Averroes and Aquinas are probably the best known. Read more about Medieval Cognitive Psychology.

MENTAL ILLNESS IN THE MIDDLE AGES

Medieval ideas about mental illness were almost as bewildering an assortment as our own, but a unifying theme was supplied by the cognitive theory outlined here. It was generally believed that the normal waking person's activities were under the control of the mind. In cases of insanity this control was disrupted or corrupted and behavior would then, like an animal's, be simply determined by the inner senses and the appetites. Consequently, in later medieval legal theory and practice, and in the writings of theologians, the insane were not held accountable for their actions. Read more about Mental Illness in the Middle Ages.

STRUCTURALISM OF PSYCHOLOGY

Structuralism, in psychology, a systematic movement founded in Germany by Wilhelm Wundt and mainly identified with Edward B. Titchener. Structuralism sought to analyze the adult mind (defined as the sum total of experience from birth to the present) in terms of the simplest definable components and then to find the way in which these components fit together in complex forms.

The major tool of structuralist psychology was introspection (a careful set of observations made under controlled conditions by trained observers using a stringently defined descriptive vocabulary). Titchener held that an experience should be evaluated as a fact, as it exists without analyzing the significance or value of that experience. For him, the “anatomy of the mind” had little to do with how or why the mind functions. In his major treatise, *A Textbook of Psychology* (1909–10), he stated that the only elements necessary to describe the conscious experience are sensation and affection (feeling). The thought process essentially was deemed an occurrence of sensations of the current experience and feelings representing a prior experience.

Although structuralism represented the emergence of psychology as a field separate from philosophy, the structural school lost considerable influence when Titchener died. The movement led, however, to the development of several countermovements that tended to react strongly to European trends in the field of experimental psychology. Behaviour and personality were beyond the scope considered by structuralism. In separating meaning from the facts of experience, structuralism opposed the phenomenological tradition of Franz Brentano’s act psychology and Gestalt psychology, as well as the functionalist school and John

B. Watson’s behaviourism. Serving as a catalyst to functionalism, structuralism was always a minority school of psychology in America.

CULTURE-AND-PERSONALITY STUDIES

Culture-and-personality studies, also called **psychological anthropology**, branch of cultural anthropology that seeks to determine the range of personality types extant in a given culture and to discern where, on a continuum from ideal to perverse, the culture places each type. The type perceived as ideal within a culture is then referred to as the “personality” of the culture itself, as with duty-bound stoicism among the English and personal restraint among traditional Pueblo Indians.

Culture-and-personality studies apply the methods of psychology to the field of anthropology, including in-depth interviews, role playing, Rorschach tests, elaborate biographies, studies of family roles, and dream interpretation. Most popular in the 1930s and '40s, psychological anthropology is exemplified by the works of American anthropologist Ruth Benedict, especially *Patterns of Culture* (1934) and *The Chrysanthemum and the Sword* (1946). Benedict and other proponents of culture-and-personality studies directed the attention of anthropologists to the symbolic meanings and emotional significance of cultural features that had hitherto been considered primarily through functional analysis; at the same time, they led psychologists to recognize the existence of an inevitable cultural component in all processes of perception, motivation, and learning.

Culture-and-personality studies lost traction in the 1960s and '70s, an era characterized by shifting scholarly sensibilities and the critical reexamination of many fundamental anthropological concepts.

NEUROPSYCHOLOGY

Observations on behaviour with neurological observations on the central nervous system (CNS), including the brain. The field emerged through the work of Paul Broca and Carl Wernicke (1848–1905), both of whom identified sites on the cerebral cortex involved in the production or comprehension of language. Great strides have since been made in describing neuroanatomical systems and their relation to higher mental processes. The related field of neuropsychiatry addresses itself to disorders such as aphasia, Korsakoff syndrome, Tourette syndrome, and other CNS abnormalities. See also laterality.

COGNITIVE PSYCHOLOGY

Cognitive psychology, Branch of psychology devoted to the study of human cognition, particularly as it affects learning and behaviour. The field grew out of advances in Gestalt, developmental, and comparative psychology and in computer science, particularly information-processing research. Cognitive psychology shares many research interests with cognitive science, and some experts classify it as a branch of the latter. Contemporary cognitive theory has followed one of two broad approaches: the developmental approach, derived from the work of Jean Piaget and concerned with “representational thought” and the construction of mental models (“schemas”) of the world, and the information-processing approach, which views the human mind as analogous to a sophisticated computer system.

FUNCTIONALISM OF PSYCHOLOGY

U.S. during the late 19th century that attempted to counter the German school of structuralism led by Edward B. Titchener. Functionalists, including psychologists William James and James Rowland Angell, and philosophers George H. Mead, Archibald L. Moore, and John Dewey, stressed the importance of empirical, rational thought over an experimental, trial-and-error philosophy. The group was concerned more with the capability of the mind than with the process of thought. The movement was thus interested primarily in the practical applications of research.

The union between theory and application reached its zenith with John Dewey’s development of a laboratory school at the University of Chicago in 1896 and the publication of his keystone article, “The Reflex Arc Concept in Psychology” (1896), which attacked the philosophy of atomism and the concept of elementarism, including the behavioral theory of stimulus and response. The work of John Dewey and his associates stimulated the progressive-school movement, which attempted to apply functionalist principles to education. In the early and mid-20th century, an offshoot theory emerged: the transactional theory of perception, the central thesis of which is that learning is the key to perceiving.

Although functionalism has never become a formal, prescriptive school, it has served as a historic link in the philosophical evolution linking the structuralist’s concern with the anatomy of the mind to the concentration on the functions of the mind and, later, to the development and growth of man.

PARAPSYCHOLOGY,

Discipline concerned with investigating events that cannot be accounted for by natural law and knowledge that cannot have been obtained through the usual sensory abilities. Parapsychology studies the cognitive phenomena often called extrasensory perception, in which a person acquires knowledge of other people’s thoughts or of future events through channels apparently beyond the

five senses. It also examines physical phenomena such as the levitation of objects and the bending of metal through psychokinesis.

Though belief in such phenomena may be traced to earliest times, parapsychology as a subject of serious research originated in the late 19th century, partly in reaction to the growth of the spiritualist movement. The Society of Psychical Research was established in London in 1882, and similar societies were later founded in the U.S. and in many European countries. In the 20th century research into parapsychology was also conducted at some universities, notably at Duke University under J. B. Rhine

PSYCHOANALYTIC OF PSYCHOLOGY

The rise of pharmacological treatments for emotional distress and psychiatric conditions has led some to proclaim the end of psychoanalysis – or to dismiss it as having an insufficient basis in scientific data. But it would be a mistake to count this form of talk therapy out. Research suggests that the psychoanalytic approach still plays an important therapeutic role. And Freud's theory of mind remains a fundamental part of many talk therapies, including psychoanalysis.

Psychoanalysis is a method of treating emotional difficulties that involves communication between a psychoanalyst and an individual, with the goal of gaining insight into the individual's inner world and how it affects his or her emotions, behavior, and relationships.

Psychoanalysis is also a system of ideas about the human mind and personality. Although both the method and the theory have advanced since Freud's day, some of his basic ideas continue to shape our thinking about human behavior and functioning.

One fundamental Freudian concept is the powerful effect of the unconscious part of the mind on our feelings, actions, relationships, and endeavors. Unconscious conflicts can cause anxiety, moodiness, or depressive thoughts; troubling personality traits; or difficulties at work or in finding or maintaining long-term relationships. Many such problems have their roots in past experiences and relationships.

Psychoanalysis seeks to bring troubling unconscious forces into conscious awareness. With the insights gained during analysis, the patient can work at improving relationships and productivity, interrupt self-defeating or self-destructive patterns, and perhaps even unlock creative potential

HOW IT WORKS

The psychoanalyst and patient meet three to five times a week. This intensive schedule of one-on-one sessions helps establish the psychoanalyst's office as a place where the patient can safely free-associate – that is, talk about whatever comes to mind, whenever it comes to mind – and develop a deep bond with the analyst. The frequent meetings also encourage the emergence of the patient's full range of personality traits and behavior patterns, an important step on the path to self-understanding. Use of the couch, a holdover from Freud's day, is no longer required. Some people find that lying down facilitates free association and helps them focus their thoughts inward. Others find it more helpful to sit face to face with the analyst.

Psychoanalysis is a collaborative effort. As the patient free-associates, the analyst listens carefully and helps her grasp the underlying unconscious sources of her difficulties. To encourage this awareness, the analyst not only interprets ongoing patterns (interpretations the patient is welcome to amend, reject, or supplement), but also encourages the patient to re-experience them in the safety of the analytic setting. In psychoanalytic parlance, this is known as "transference." The patient re-lives her life's story by transferring to the analyst feelings and attitudes she originally experienced

in her relationships with other people.

For example, a woman consistently arrives 10 or 15 minutes late for her appointments, and the analyst learns that she also does this with her boss and her husband. By examining the feelings the analyst arouses as she talks about her reasons for being late — or perhaps realizing her anger with authority figures — she can begin to become conscious of her motives for wanting to make others wait for her or become angry at her.

Psychoanalysis is a lengthy process, usually requiring several years — 5.7 years, on average, according to one survey — to resolve long-standing difficulties, such as self-defeating behavior patterns or problems forming personal relationships. One reason it can take so many sessions is that, like old habits, maladaptive life patterns "die hard." There may be many variations to work through. The hope is that over time, the individual can recover lost emotional connections, give up unhealthy ones, and adapt more effectively to her current circumstances.

Psychoanalysis may help with such complaints as "I have difficulty finding a suitable partner," "I never feel excited about my friendships," or "I keep missing deadlines at work and sabotaging my career." Less intensive psychotherapy may be more appropriate for short-term concerns such as "I'm very sad that my child is leaving for college," unless these feelings are related to longer-standing behavior patterns. Distressing symptoms such as phobias, anxieties, and depression also respond to psychoanalysis, sometimes with the help of a medication.

Health insurance may cover part — though given the current emphasis on short-term treatment, generally not all — of the cost of psychoanalysis. Treatment is often available for a reduced fee at a psychoanalytic training institute (see "How to find a psychoanalyst"). Also, the analyst and patient may work out a lower fee or method of delayed payments.

HOW IT DIFFERS FROM OTHER PSYCHOTHERAPY

There are many types of psychoanalytically informed psychotherapy, and many approaches used in psychotherapy today grew out of classical psychoanalysis. These variant forms are usually less intensive versions of psychoanalysis. Expressive and psychodynamic psychotherapy, for example, emphasize the importance of finding unconscious motivations and gaining insight into one's actions and feelings. By contrast, short-term structured therapies such as cognitive behavioral therapy, which is outside the psychoanalytic tradition, focus on resolving current symptoms and behavioral problems without necessarily developing insight into their origins.

Psychoanalysis may not be for everyone, but many women with emotional difficulties can benefit from psychodynamic psychotherapy — that is, meeting with a therapist once a week to discuss painful feelings that may underlie a specific problem or pattern of thinking or behavior. Like psychoanalysis, it assumes that the unconscious is involved and that past experiences and relationships can affect the present. Psychodynamic psychotherapy can last anywhere from a few months to several years. Both psychoanalysis and psychodynamic psychotherapy can be combined with medication, couples' therapy, group therapy, or family therapy.

QUALIFICATIONS FOR PSYCHOANALYSTS

For many years, psychoanalytic training in the United States was available only to medical doctors, but now there are several reputable psychoanalysis programs that don't require an M.D. for admission. They generally do require an advanced degree, however. Psychologists (Ph.D. or Psy.D.) and

clinical social workers(M.S.W. or C.S.W.) as well as psychiatrists and other M.D.s are al eligible for training as psychoanalysts. The training includes four tofive years of classes and supervised work with patients, and an aspiring psychoanalyst must undergo psychoanalysis herself.

GESTALT OF PSYCHOLOGY

Gestalt psychology is a school of thought that looks at the human mind and behavior as a whole. When trying to make sense of the world around us, Gestalt psychology suggests that we do not simplyfocus on every small component. Instead, our minds tend to perceive objects as part of a greater whole and as elements of more complex systems. This school of psychology played a major role in the modern development of thestudy of human sensation and perception.

A BRIEF HISTORY

Originating in the work of Max Wertheimer, Gestalt psychologyformed partially as a response to the structuralism of Wilhelm Wundt. While Wundt was interested in breaking down psychological mattersinto their smallest possible part, the Gestalt psychologists were instead interested in looking at the totality of the mind and behavior. The guiding principle behind the Gestalt movement was that the whole was greater than the sum of its parts.

The development of this area of psychology was influenced by anumber of thinkers, including Immanuel Kant, Ernst Mach, and Johann Wolfgang von Goethe. The development of Gestalt psychology was influenced in part by Wertheimer's observations one day at a train station. He purchaseda toy stroboscope which displayed pictures in a rapid sequence mimic the appearing movement. He later proposed the concept ofthe Phi phenomenon in which flashing lights in sequence can leadto what is known as apparent motion.¹

In other words, we perceive movement where there is none. Moviesare one example of apparent motion. Through a sequence of still frames, the illusion of movement is created. "The fundamental 'formula' of Gestalt theory might be expressed inthis way," Max Wertheimer wrote. "There are wholes, the behavior of which is not determined by that of their individual elements, but where the part-processes are themselves determined by the intrinsic nature of the whole. It is the hope of Gestalt theory to determine the nature of such wholes."

MAJOR GESTALT PSYCHOLOGISTS

There were a number of thinkers who had an influence on Gestaltpsychology. Some of the best-known Gestalt psychologists included:

Max Wertheimer: Regarded as one of the three founders of Gestaltpsychology, Wertheimer is also known for his concept of the phi phenomenon. The phi phenomenon involves perceiving a series of still images in rapid succession in order to create the illusion of movement.

Kurt Koffka: Know as one of the three founders of Gestalt psychology, Kurt Koffka had diverse interests and studied manytopics in psychology including learning, perception, and hearingimpairments.

Wolfgang Kohler: Also a key founding figure in the history of the Gestalt movement, Kohler also famously summarized Gestalt theor by saying, "The whole is different than the sum of its parts." He wasalso known for his research on problem-solving, his criticisms of

the introspection used by the structuralists to study the human mind, and his opposition to behaviorism.

GESTALT LAWS OF PERCEPTUAL ORGANIZATION

Have you ever noticed how a series of flashing lights often appear to be moving, such as neon signs or strands of Christmas lights? According to Gestalt psychology, this apparent movement happens because our minds fill in the missing information. This belief that the whole is greater than the sum of the individual parts led to the discovery of several different phenomena that occur during perception.

ORGANIZATION

In order to better understand how human perception works, Gestalt psychologists proposed a number of laws of perceptual organization, including the laws of similarity, Prägnanz, proximity, continuity, and closure.

SIMILARITY

The law of similarity suggests that similar items tend to be grouped together.² If a number of objects in a scene are similar to one another, you will naturally group them together and perceive them as a whole. For example, a series of circles or squares stacked together will be viewed as a series of columns rather than just individual shapes.

PROXIMITY

The law of proximity suggests that objects near each other tend to be viewed as a group.² If you see a number of people standing close together, for example, you might immediately assume that they are all part of the same social group.

At a restaurant, for example, the host or hostess might assume that people seated next to each other in the waiting area are together and ask if they are ready to be seated. In reality, they may only be sitting near each other because there is little room in the waiting area or because those were the only open seats. Gestalt psychology also helped introduce the idea that human perception is not just about seeing what is actually present in the world around us. Much of what we perceive is heavily influenced by our motivations and expectations.

A WORD FROM VERY WELL

Gestalt psychology did face criticism, particularly in that many of its central concepts can be difficult to define and examine experimentally. While this approach may have lost its identity as an independent school of thought in psychology, its central ideas have had a major influence on the field of psychology as a whole.

Gestalt psychology has largely been subsumed by other fields of psychology, but it had an enormous influence. Other researchers who were influenced by the principles of Gestalt psychology including Kurt Lewin and Kurt Goldstein went on to make important contributions to psychology. The idea that the whole is different than its parts has played a role in other areas including our understanding of the brain and social behavior.

BEHAVIORISM OF PSYCHOLOGY

Behaviorism is a theory of learning which states all behaviors are learned through interaction with the environment through a process called conditioning. Thus, behavior is simply a response to environmental stimuli. Behaviorism is only concerned with observable stimulus-response behaviors, as they can be studied in a systematic and observable manner. The behaviorist movement began in 1913 when John Watson wrote an article entitled 'Psychology as the behaviorist views it,' which set out a number of underlying assumptions regarding methodology and behavioral analysis:

BASIC ASSUMPTIONS

ALL BEHAVIOR IS LEARNED FROM THE ENVIRONMENT:

Behaviorism emphasizes the role of environmental factors in influencing behavior, to the near exclusion of innate or inherited factors. This amounts essentially to a focus on learning. We learn new behavior through classical or operant conditioning (collectively known as 'learning theory'). Therefore, when born our mind is 'tabula rasa' (a blank slate). Psychology should be seen as a science: Theories need to be supported by empirical data obtained through careful and controlled observation and measurement of behavior. Watson (1913) stated that: 'Psychology as a behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is ...prediction and control.' (p. 158) The components of a theory should be as simple as possible. Behaviorists propose the use of operational definitions (defining variables in terms of observable, measurable events). Behaviorism is primarily concerned with observable behavior, as opposed to internal events like thinking and emotion: While behaviorists often accept the existence of cognitions and emotions, they prefer not to study them as only observable (i.e., external) behavior can be objectively and scientifically measured.

Therefore, internal events, such as thinking should be explained through behavioral terms (or eliminated altogether). There is little difference between the learning that takes place in humans and that in other animals: There's no fundamental (qualitative) distinction between human and animal behavior. Therefore, research can be carried out on animals as well as humans (i.e., comparative psychology). Consequently, rats and pigeons became the primary source of data for behaviorists, as their environments could be easily controlled.

BEHAVIOR IS THE RESULT OF STIMULUS-RESPONSE:

All behavior, no matter how complex, can be reduced to a simple stimulus-response association). Watson described the purpose of psychology as: 'To predict, given the stimulus, what reaction will take place; or, given the reaction, state what the situation or stimulus is that has caused the reaction.' (1930, p. 11). Types of Behaviorism Historically, the most significant distinction between versions of behaviorism is that between Watson's original 'methodological behaviorism,' and forms of behaviorism later inspired by his work, known collectively as neobehaviorism (e.g., radical behaviorism).

METHODOLOGICAL BEHAVIORISM

Watson's article '*Psychology as the behaviorist views it*' is often referred to as the 'behaviorist manifesto,' in which Watson (1913, p.158) outlines the principles of all behaviorists: 'Psychology as the behaviorist views it is a purely objective experimental branch of natural science. Its theoretical goal is the prediction and control of behavior. Introspection forms no essential part of its methods, nor

is the scientific value of its data dependent upon the readiness with which they lend themselves to interpretation in terms of consciousness. The behaviorist, in his efforts to get a unitary scheme of animal response, recognizes no dividing line between man and brute. The behavior of man, with all of its refinement and complexity, forms only a part of the behaviorist's total scheme of investigation'.

RADICAL BEHAVIORISM

Radical behaviorism was founded by B.F Skinner and agreed with the assumption of methodological behaviorism that the goal of psychology should be to predict and control behavior.

Skinner, like Watson, also recognized the role of internal mental events, and while he agreed such private events could not be used to explain behavior, he proposed they should be explained in the analysis of behavior. Another important distinction between methodological and radical behaviorism concerns the extent to which environmental factors influence behavior. Watson's (1913) methodological behaviorism asserts the mind is tabula rasa (a blank slate) at birth. In contrast, radical behaviorism accepts the view that organisms are born with innate behaviors, and thus recognizes the role of genes and biological components in behavior.

THE HISTORY OF BEHAVIORISM

- Pavlov (1897) published the results of an experiment on conditioning after originally studying digestion in dogs.
- Watson (1913) launches the behavioral school of psychology, publishing an article, *Psychology as the behaviorist views it*.
- Watson and Rayner (1920) conditioned an orphan called Albert B (aka Little Albert) to fear a white rat.
- Thorndike (1905) formalized the *Law of Effect*.
- Skinner (1936) wrote *The Behavior of Organisms* and introduced the concepts of operant conditioning and shaping.
- Clark Hull's (1943) *Principles of Behavior* was published.
- B.F. Skinner (1948) published *Walden Two*, in which he described a utopian society founded upon behaviorist principles.
- Journal of the *Experimental Analysis of Behavior* begun in 1958.
- Chomsky (1959) published his criticism of Skinner's behaviorism, "*Review of Verbal Behavior*."

BEHAVIORISM SUMMARY BASIC ASSUMPTIONS

Psychology should be seen as a science, to be studied in a scientific manner. Behaviorism is primarily concerned with observable behavior, as opposed to internal events like thinking. Behavior is the result of stimulus–response (i.e., all behavior, no matter how complex, can be reduced to a simple stimulus – response features). Behavior is determined by the environment (e.g., conditioning, nurture).

AREAS OF APPLICATION

Gender Role Development Behavioral Therapy Phobias Education Behavior-Modification Psychopathology Depression. Relationships Moral Development Aggression Addiction **Strengths** The behaviorist approach provides clear predictions. This means that explanations can be scientifically tested and supported with evidence. Real life applications (e.g., therapy) Emphasizes objective measurement. Many experiments to support theories. Identified comparisons between animals (Pavlov) and humans (Watson & Rayner - Little Albert)

LIMITATIONS

Ignores mediational processes Ignores biology (e.g., testosterone) Too deterministic (little free-will) Experiments – low ecological validity Humanism – can't compare animals to humans Reductionist.

CRITICAL EVALUATION

An obvious advantage of behaviorism is its ability to define behavior clearly and to measure changes in behavior. According to the law of parsimony, the fewer assumptions a theory makes, the better and the more credible it is. Behaviorism, therefore, looks for simple explanations of human behavior from a very scientific standpoint. However, behaviorism only provides a partial account of human behavior, that which can be objectively viewed. Important factors like emotions, expectations, higher-level motivation are not considered or explained. Accepting a behaviorist explanation could prevent further research from other perspectives that could uncover important factors.

In addition, humanism (e.g., Carl Rogers) rejects the scientific method of using experiments to measure and control variables because it creates an artificial environment and has low ecological validity.

Humanistic psychology also assumes that humans have free will (personal agency) to make their own decisions in life and do not follow the deterministic laws of science. Humanism also rejects the nomothetic approach of behaviorism as they view humans as being unique and believe humans cannot be compared with animals (who aren't susceptible to demand characteristics). This is known as an idiographic approach.

The psychodynamic approach (Freud) criticizes behaviorism as it does not take into account the unconscious mind's influence on behavior, and instead focuses on externally observable behavior. Freud also rejects the idea that people are born a blank slate (tabula rasa) and states that people are born with instincts (e.g., eros and thanatos).

Biological psychology states that all behavior has a physical/organic cause. They emphasize the role of nature over nurture. For example, chromosomes and hormones (testosterone) influence our behavior too, in addition to the environment.

Cognitive psychology states that mediational processes occur between stimulus and response, such as memory, thinking, problem-solving, etc. Despite these criticisms, behaviorism has made significant contributions to psychology. These include insights into learning, language development, and moral and gender development, which have all been explained in terms of conditioning.

The contribution of behaviorism can be seen in some of its practical applications. Behavior therapy and behavior modification represent one of the major approaches to the treatment of abnormal behavior and are readily used in clinical psychology.

TERMINOLOGY

CLASSICAL CONDITIONING

Classical conditioning refers to learning by association, and involves the conditioning of innate bodily reflexes with new stimuli.

STIMULUS

Any feature of the environment that affects behavior. E.g. in Pavlov's experiments food was a stimulus.

RESPONSE

The behavior elicited by the stimulus. E.g. in Pavlov's experiments salivation was a response.

OPERANT CONDITIONING

Operant conditioning involves learning through the consequences of behavior.

POSITIVE REINFORCEMENT

Presenting the subject with something that it likes. e.g., Skinner rewarded his rats with food pellets.

NEGATIVE REINFORCEMENT

Reward – in the sense of removing or avoiding some aversive (painful) stimulus. e.g., Skinner's rats learned to press the lever in order to switch off the electric current in the cage
Punishment Imposing an aversive or painful stimulus. e.g., Skinner's rats were given electric shocks.

SOCIAL LEARNING THEORY

Social Learning Theory posits that people learn from one another, via observation, imitation, and modeling. The theory has often been called a bridge between behaviorist and cognitive learning theories because it encompasses attention, memory, and motivation.

REDUCTIONISM

Reductionism is the belief that human behavior can be explained by breaking it down into smaller component parts. Reductionists say that the best way to understand why we behave as we do is to look closely at the very simplest parts that make up our systems, and use the simplest explanations to understand how they work. Behaviorism reduces all behavior (no matter how complex) to stimulus-response associations.

HUMANISTIC-EXISTENTIAL PSYCHOTHERAPY

The humanistic approach was introduced in the 1940's in the United States. It can be traced to Abraham Maslow as the founding father, but through time has become closely associated with Carl Rogers. The humanistic and existential approach distinguishes itself from other therapeutic styles

by including the importance of the client's subjective experience, as well as a concern for positive growth rather than pathology. Whereas the key words for humanistic psychotherapy are genuineness, empathy and unconditional positive regard, the major themes of existential therapy are the client's responsibility and freedom.

Humanistic and existential approaches share a belief that clients have the capacity for self-awareness and choice; however, they differ in their theoretical perspectives. The humanistic perspective views human nature as basically good, with a potential to maintain healthy, meaningful relationships and to make choices that are in the best interest of oneself and others. The humanistic therapist accompanies/guides clients to free themselves from assumptions and positions that might be blocking them from living fuller lives. The psychologist encourages and highlights growth and self-actualization, while maintaining that clients have an innate capacity for responsible self-direction. For the humanistic psychologist, not being one's true self is the source of problems.

The existentialist, on the other hand, is more interested in guiding/accompanying clients to find philosophical meaning while they face anxiety. This is done by exploring the importance of choosing to think and act authentically and responsibly. According to existential psychology, the fundamental problems clients face are rooted in anxiety over isolation, loneliness, despair, and, eventually, death. The existential psychologist assumes that the clients' problems are due to not being able to use their judgment or make choices enough/well enough in order to create meaning in their lives.

When outside influences may play a role in the clients' limited ability to carry out choices, the existential psychologist and the clients will confront these influences in order to move forward.

HUMANISTIC AND EXISTENTIAL THERAPIES

Humanistic and existential psychotherapies use a wide range of approaches to case conceptualization, therapeutic goals, intervention strategies, and research methodologies. They are united by an emphasis on understanding human experience and a focus on the client rather than the symptom. Psychological problems (including substance abuse disorders) are viewed as the result of inhibited ability to make authentic, meaningful, and self-directed choices about how to live. Consequently, interventions are aimed at increasing client self-awareness and self-understanding.

Whereas the key words for humanistic therapy are *acceptance* and *growth*, the major themes of existential therapy are client *responsibility* and *freedom*. This chapter broadly defines some of the major concepts of these two therapeutic approaches and describes how they can be applied to brief therapy in the treatment of substance abuse disorders. A short case illustrates how each theory would approach the client's issues. Many of the characteristics of these therapies have been incorporated into other therapeutic approaches such as narrative therapy.

Humanistic and existential approaches share a belief that people have the capacity for self-awareness and choice. However, the two schools come to this belief through different theories. The humanistic perspective views human nature as basically good, with an inherent potential to maintain healthy, meaningful relationship and to make choices that are in the interest of oneself and others. The humanistic therapist focuses on helping people free themselves from disabling assumptions and attitudes so they can live fuller lives. The therapist emphasizes growth and self-actualization rather than curing diseases or alleviating disorders.

This perspective targets present conscious processes rather than unconscious processes and past

causes, but like the existential approach, it holds that people have an inherent capacity for responsible self-direction. For the humanistic therapist, not being one's true self is the source of problems. The therapeutic relationship serves as a vehicle or context in which the process of psychological growth is fostered. The humanistic therapist tries to create a therapeutic relationship that is warm and accepting and that trusts that the client's inner drive is to actualize in a healthy direction.

The existentialist, on the other hand, is more interested in helping the client find philosophical meaning in the face of anxiety by choosing to think and act authentically and responsibly. According to existential therapy, the central problems people face are embedded in anxiety over loneliness, isolation, despair, and, ultimately, death. Creativity, love, authenticity, and free will are recognized as potential avenues toward transformation, enabling people to live meaningful lives in the face of uncertainty and suffering. Everyone suffers losses (e.g., friends die, relationships end), and these losses cause anxiety because they are reminders of human limitations and inevitable death.

The existential therapist recognizes that human influence is shaped by biology, culture, and luck. Existential therapy assumes the belief that people's problems come from not exercising choice and judgment enough—or well enough—to forge meaning in their lives, and that each individual is responsible for making meaning out of life. Outside forces, however, may contribute to the individual's limited ability to exercise choice and live a meaningful life. For the existential therapist, life is much more of a confrontation with negative internal forces than it is for the humanistic therapist.

In general, brief therapy demands the rapid formation of a therapeutic alliance compared with long-term treatment modalities. These therapies address factors shaping substance abuse disorders, such as lack of meaning in one's life, fear of death or failure, alienation from others, and spiritual emptiness. Humanistic and existential therapies penetrate at a deeper level to issues related to substance abuse disorders, often serving as a catalyst for seeking alternatives to substances to fill the void the client is experiencing.

The counselor's empathy and acceptance, as well as the insight gained by the client, contribute to the client's recovery by providing opportunities for her to make new existential choices, beginning with an informed decision to use or abstain from substances. These therapies can add for the client a dimension of self-respect, self-motivation, and self-growth that will better facilitate his treatment. Humanistic and existential therapeutic approaches may be particularly appropriate for short-term substance abuse treatment because they tend to facilitate therapeutic rapport, increase self-awareness, focus on potential inner resources, and establish the client as the person responsible for recovery. Thus, clients may be more likely to see beyond the limitations of short-term treatment and envision recovery as a lifelong process of working to reach their full potential.

Because these approaches attempt to address the underlying factors of substance abuse disorders, they may not always directly confront substance abuse itself. Given that the substance abuse is the primary presenting problem and should remain in the foreground, these therapies are most effectively used in conjunction with more traditional treatments for substance abuse disorders. However, many of the underlying principles that have been developed to support these therapies can be applied to almost any other kind of therapy to facilitate the client-therapist relationship.

USING HUMANISTIC AND EXISTENTIAL THERAPIES

Many aspects of humanistic and existential approaches (including empathy, encouragement of affect, reflective listening, and acceptance of the client's subjective experience) are useful in any type

of brief therapy session, whether it involves psychodynamic, strategic, or cognitive-behavioral therapy. They help establish rapport and provide grounds for meaningful engagement with all aspects of the treatment process.

While the approaches discussed in this chapter encompass a wide variety of therapeutic interventions, they are united by an emphasis on *lived* experience, authentic (therapeutic) relationships, and recognition of the subjective nature of human experience. There is a focus on helping the client to understand the ways in which reality is influenced by past experience, present perceptions, and expectations for the future. Schor describes the process through which our experiences assume meaning as *apperception*. Becoming aware of this process yields insight and facilitates the ability to choose new ways of being and acting.

For many clients, momentary circumstances and problems surrounding substance abuse may seem more pressing, and notions of integration, spirituality, and existential growth may be too remote from their immediate experience to be effective. In such instances, humanistic and existential approaches can help clients focus on the fact that they do, indeed, make decisions about substance abuse and are responsible for their own recovery.

ESSENTIAL SKILLS

By their very nature, these models do not rely on a comprehensive set of techniques or procedures. Rather, the personal philosophy of the therapist must be congruent with the theoretical underpinnings associated with these approaches. The therapist must be willing and able to engage the client in a genuine and authentic fashion in order to help the client make meaningful change. Sensitivity to "teachable" or "therapeutic" moments is essential.

WHEN TO USE BRIEF HUMANISTIC AND EXISTENTIAL THERAPIES

These approaches can be useful at all stages of recovery in creating a foundation of respect for clients and mutual acceptance of the significance of their experiences. There are, however, some therapeutic moments that lend themselves more readily to one or more specific approaches. The details of the specific approaches are laid out later in this chapter. *Client-centered* therapy, for example, can be used immediately to establish rapport and to clarify issues throughout the session. *Existential* therapy may be used most effectively when a client is able to access emotional experiences or when obstacles must be overcome to facilitate client's entry into or continuation of recovery (e.g., to get someone who insists on remaining helpless to accept responsibility). *Narrative* therapy may be used to help the client conceptualize treatment as an opportunity to assume authorship and begin a "new chapter" in life. *Gestalt* approaches can also be used throughout therapy to facilitate a genuine encounter with the therapist and the client's own experience. *Transpersonal* therapy can enhance spiritual development by focusing on the intangible aspects of human experience and awareness of unrealized spiritual capacity. These approaches increase self-awareness, which promotes self-esteem and allows for more client responsibility, thus giving the client a sense of control and the opportunity to make choices. All of these approaches can be used to support the goals of therapy for substance abuse disorders.

DURATION OF THERAPY AND FREQUENCY OF SESSIONS

Although many aspects of these approaches are found in other therapeutic orientations, concepts like empathy, meaning, and choice lie at the very heart of humanistic and existential therapies. They are particularly valuable for brief treatment of substance abuse disorders because they increase therapeutic rapport and enhance conscious experience and acceptance of responsibility. Episodic

treatment could be designed within this framework, with the treatment plan focusing on the client's tasks and experience between sessions. Humanistic and existential therapies assume that much growth and change occur outside the meetings. When focused on broader problems, these therapies can be lifelong journeys of growth and transformation. At the same time, focusing on specific substance abuse issues can provide a framework for change and more discrete goals. These techniques will also work well in conjunction with other types of therapy.

INITIAL SESSION

The opening session is extremely important in brief therapy for building an alliance, developing therapeutic rapport, and creating a climate of mutual respect. Although the approaches discussed in this chapter have different ways of addressing the client's problems, the opening session should attempt the following:

- Start to develop the alliance
- Emphasize the client's freedom of choice and potential for meaningful change
- Articulate expectations and goals of therapy (how goals are to be reached)

Developing the alliance can be undertaken through reflective listening, demonstrating respect, honesty, and openness; eliciting trust and confidence; and applying other principles that emerge from these therapies. The therapist's authentic manner of encountering the client can set the tone for an honest, collaborative therapeutic relationship. Emphasizing freedom of choice and potential for meaningful change may be deepened by a focus on the current decision (however it has been reached) to participate in the opening session. Expectations and goals can be articulated through strategic questions or comments like, "What might be accomplished in treatment that would help you live better" or "You now face the choice of how to participate in your own substance abuse recovery."

Because of time constraints inherent in approaches to brief substance abuse treatment, the early phase of therapy is crucial. Unless the therapist succeeds in engaging the client during the early phase, the treatment is likely to be less effective. "Engaging" includes helping the client increase motivation for other aspects of substance abuse treatment such as group therapy.

Moreover, the patterns of interaction established during the early phase tend to persist throughout therapy. The degree of motivation that the client feels after the first session is determined largely by the degree of significance experienced during the initial therapeutic encounter. A negative experience may keep a highly motivated client from coming back, whereas a positive experience may induce a poorly motivated client to recognize the potential for treatment to be helpful.

COMPATIBILITY OF HUMANISTIC AND EXISTENTIAL THERAPIES AND 12-STEP PROGRAMS

Humanistic and existential approaches are consistent with many tenets of 12-Step programs. For example, existential and humanistic therapists would embrace the significance stressed by the "serenity prayer" to *accept* the things that cannot be changed, the *courage* to change what can be changed, and the *wisdom* to know the difference. However, some would argue against the degree to which Alcoholics Anonymous (AA) identifies the person's "disease" as a central character trait, or the way in which some might interpret the notion of "powerlessness." The principles of existentialism, free choice, and free will may appear incompatible with the 12-Step philosophy of acceptance

and surrender. Yet, such surrender must result from conscious decisions on an individual's part. The AA concept of rigorous self-assessment--of accepting one's own personal limitations and continually choosing and rechoosing to act according to certain principles as a way of living life--are compatible with both existential and humanistic principles.

RESEARCH ORIENTATION

The predominant research strategy or methodology in social science is rooted in the natural science or rational-empirical perspective. Such approaches generally attempt to identify and demonstrate causal relationships by isolating specific variables while controlling for other variables such as personal differences among therapists as well as clients. For example, variations in behavior or outcomes are often quantified, measured, and subjected to statistical procedures in order to isolate the researcher from the data and ensure objectivity. Such strategies are particularly useful for investigating observable phenomena like behavior. Traditional approaches to understanding human experience and meaning, however, have been criticized as an insufficient means to understanding the *lived* reality of human experience. Von Eckartsberg noted, "Science aims for an ideal world of dependent and independent variables in their causal interconnectedness quite abstracted and removed from personal experience of the everyday life-world" (Von Eckartsberg, 1983, p. 199). Similarly, Blewett argued, "The importance of human experience relative to behavior is beyond question for experience extends beyond behavior just as feeling extends beyond the concepts of language" (Blewett, 1969, p.22). Thus, traditional methodological approaches seem ill-suited for understanding the meaning of human experience and the process by which self-understanding manifests itself in the context of a therapeutic relationship.

A humanistic science or qualitative approach, which has its roots in phenomenology, is claimed to be more appropriate for the complexities and nuances of understanding human experience (Giorgi, 1985). The personal and unique construction of meaning, the importance of such subtleties as "the relationship" and the "fit" in therapy, and shifts in internal states of consciousness can be quantified and measured only in the broadest of terms. A more subtle science is required to describe humans and the therapeutic process.

Rather than prediction, control, and replication of results, a humanistic science approach emphasizes understanding and description. Instead of statistical analysis of quantifiable data, it emphasizes narrative descriptions of experience. Qualitative understanding values uniqueness and diversity--the "little stories" (Lyotard, 1984)--as much as generalizability or grander explanations. Generally, this approach assumes that objectivity, such as is presumed in rational empirical methods, is illusory. For the qualitative researcher and the therapist, the goals are the same: openness to the other, active participation, and awareness of one's own subjectivity, rather than illusory objectivity. Intersubjective dialog provides a means of comparing subjective experiences in order to find commonality and divergence as well as to avoid researcher bias.

Because humanistic and existential therapies emphasize psychological process and the therapeutic relationship, alternative research strategies may be required in order to understand the necessary and sufficient conditions for therapeutic change. For example, Carl Rogers "presented a challenge to psychology to design new models of scientific investigation capable of dealing with the inner, subjective experience of the person" (Corey, 1991, p 218). Some 50 years ago, he pioneered the use of verbatim transcripts of counseling sessions and employed audio and videotaping of sessions long before such procedures became standard practice in research and supervision.

TRANSPERSONAL THERAPY

Transpersonal psychology emerged as a "fourth force" in psychology in the late 1960s and has strong roots in humanistic and existential psychologies, Jungian analysis, the East-West dialog, and ancient wisdom traditions. Transpersonal therapy may be thought of as a bridge between psychological and spiritual practice.

A transpersonal approach emphasizes development of the individual beyond, but including, the ego. It acknowledges the human spiritual quest and recognizes the human striving for unity, ultimate truth, and profound freedom. It cultivates intuitive ways of knowing that complement rational and sensory modes. This approach also recognizes the potential for growth inherent in "peak" experiences and other shifts in consciousness. Although grounded in psychological theory, transpersonal practitioners also tend to incorporate perspectives from ancient wisdom traditions.

The practice of transpersonal therapy is defined more by its orientation and scope rather than by a particular set of techniques or methods (Boorstein, 1980). Wittine suggests five postulates for a transpersonal psychotherapy (Wittine, 1989):

Transpersonal psychotherapy is an approach to healing and growth that recognizes the centrality of the self in the therapeutic process.

1. Transpersonal psychotherapy values wholeness of being and self-realization on all levels of the spectrum of identity (i.e., egoic, existential, transpersonal).
2. Transpersonal psychotherapy is a process of awakening from a limited personal identity to expanded universal knowledge of self.
3. Transpersonal psychotherapy makes use of the healing restorative nature of subjective awareness and intuition in the process of awakening.
4. In transpersonal psychotherapy, the therapeutic relationship is a vehicle for the process of awakening in both client and therapist.

Integrating insights and practices in everyday life is the goal of every therapy. Bringing the transpersonal dimension to the forefront may involve the following:

- Exploration of "inner voices" including those of a higher self that provides guidance for growth of the individual (Rowan, 1993)
- Refinement of intuition or nonrational knowing
- Practice of creativity in "formal" (art) or informal (personal relationships) encounters
- Meditation
- Loving service
- Cultivation of mindfulness

USE OF DREAMS AND IMAGER

These techniques may be taught and supported explicitly in the therapy session. At times, a therapist may directly cultivate shifts in consciousness (e.g., through meditation [Weil, 1972], or imaginal work [Johnson, 1987]), providing immediate insight and inspiration that may not be available through more conventional means (Hart, 1998). This may provide clients with a skill they can practice on their own; initiating such activity represents a potential for brief intervention.

Transpersonal therapy recognizes the need for basic psychological development to be integrated with spiritual growth (Nelson, 1994). Without such integration there is danger of "spiritual bypassing," where issues of basic psychological functioning are avoided in the name of spiritual development. In other words, the basic psychological work should be undertaken first.

Substance abuse disorders may be seen broadly as an attempt to fill a spiritual void. They may also be understood as a means for the ego to defend itself against a natural drive for growth. If growth were to occur, the ego might find its dominance relinquished. Addiction, like spirituality, also raises questions of surrender (May, 1991): for example, to what and to whom do we surrender? In a culture and a psychology that are dominated by issues of rational ego control, what is the role of constructive surrender (regularly described in spiritual traditions)? How does constructive surrender become destructive and distorted in substance dependency? In addition, substance abuse may be understood as a means for shifting out of a normal waking state of consciousness. This may be an attempt to fulfill an innate drive (Weil, 1972) for nonrational consciousness.

RESPONSE TO THE CASE STUDY

As the existentialists remind us, there is nothing like death to rivet our attention. A glimpse of death—for example, seeing the aftermath of a serious car crash—reminds the witness of how valuable life is, bringing up other issues as well. Sandra is now confronted with death due to AIDS. This opportunity to face death and life squarely provides a chance to reconsider and reprioritize her life. In fact, it could be argued that the best catalyst to brief therapy may be a death sentence precisely because it has the potential to wake up an individual. In many respects, helping the client wake from habitual, mechanical routines that are often based on ego protection and move toward an appreciation that the individual is not bound to or defined by a limited ego, is the goal of transpersonal therapy. This can be seen as a transformation of identity.

Many inspiring instances of people facing death, including death through AIDS, have shown that emergent spirituality can change the quality and direction of existence very quickly. For treatment, the basic sharing of these experiences with a group of others in a similar predicament often quickly moves the client beyond isolation and a sense of self-separateness to connect intimately with others who understand her situation. This community may not only bring comfort and support but also a deep sense of communion with humanity. In this instance, breaking through the shell of isolation may enable Sandra to begin to make new connections with her family and with herself. A sense of interconnection, a central postulate and experience in the wisdom traditions, may replace her perceived isolation.

Sandra may use this opportunity of facing possible death to begin to encounter and let go of such feelings as guilt, shame, disappointment, and anger that have kept her life less satisfying than it could be. Accessing the imaginal through art or dreams, for example, can provide a clear and symbolic expression of unresolved issues. The use of rituals or rites-of-passage inspired by the wisdom traditions can provide some catalyst for shifting her consciousness through forgiveness and release.

The therapist may engage in a wide variety of methods (e.g., imagery, art, or dream work, meditation, rituals), but the heart of the work is in the simple and humane spirituality that is embodied by the therapist's loving presence along with the therapist's openness to explore the full range of human experience directly. For Sandra, this experience may be seen as an opportunity for practicing love

and forgiveness, moving out from behind rigid self-separateness, facing fears, and transforming her self-definition.

Unlike most forms of psychotherapy that concentrate on improving mental health, transpersonal therapy takes a more holistic approach, addressing mental, physical, social, emotional, creative, and intellectual needs, with an emphasis on the role of a healthy spirit in healing. To facilitate healing and growth, transpersonal therapy places great emphasis on honesty, open-mindedness, and self-awareness on the part of the therapist as well as the client.

WHEN IT'S USED

Transpersonal therapy is used to treat anxiety, depression, addictions, phobias, and other mood and behavioral problems. Those who are open to exploring their spiritual side, becoming more spiritually aware, or finding a spiritual path, or who are having trouble finding meaning in their life, may benefit from transpersonal therapy.

What to Expect Transpersonal therapists use meditation, guided visualization, hypnotherapy, dream work, art, music, journaling, mindfulness practices, and other techniques that can help you explore your spiritual self and create meaning in your life. With the therapist's guidance, you will find, build, and expand on your inner strengths and resources to create a more balanced life and a healthier state of mind.

HOW IT WORKS

Transpersonal therapy is a holistic healing intervention that evolved from the humanistic work of American psychologist Abraham Maslow in the 1960s. It integrates traditional spiritual rituals into modern psychology and emphasizes positive influences and role models rather than concentrating on negative experiences. This intervention is based on the idea that humans are more than mind and body but are also composed of intangible, or transcendent, factors that make up the whole person. Just as your mind and body sometimes require treatment, your spirituality and other intangible aspects of yourself often require healing of a sort.

A transpersonal therapist may draw from a variety of different religions and spiritual practices for tools and methods that can help you explore various levels of consciousness and use your spirituality to guide you through troubled times.

WHAT TO LOOK FOR IN A TRANSPERSONAL THERAPIST

Look for an experienced licensed or certified counselor, psychotherapist, or other mental health professional with additional training in holistic forms of healing and one or more spiritual pathways. In addition to these credentials, it is important to find a therapist with whom you feel comfortable working.

COGNITIVE REVOLUTION IN PSYCHOLOGY BEHAVIORISM AND THE COGNITIVE REVOLUTION

Behaviorism's emphasis on objectivity and focus on external behavior had pulled psychologists' attention away from the mind for a prolonged period of time. The early work of the humanistic psychologists redirected attention to the individual human as a whole, and as a conscious and self-aware being. By the 1950s, new disciplinary perspectives in linguistics, neuroscience, and computer

science were emerging, and these areas revived interest in the mind as a focus of scientific inquiry. This particular perspective has come to be known as the cognitive revolution (Miller, 2003). By 1967, Ulric Neisser published the first textbook entitled *Cognitive Psychology*, which served as a core text in cognitive psychology courses around the country (Thorne & Henley, 2005).

Although no one person is entirely responsible for starting the cognitive revolution, Noam Chomsky was very influential in the early days of this movement. Chomsky (1928–), an American linguist, was dissatisfied with the influence that behaviorism had had on psychology. He believed that psychology's focus on behavior was short-sighted and that the field had to re-incorporate mental functioning into its purview if it were to offer any meaningful contributions to understanding behavior (Miller, 2003).

European psychology had never really been as influenced by behaviorism as had American psychology; and thus, the cognitive revolution helped reestablish lines of communication between European psychologists and their American counterparts.

Furthermore, psychologists began to cooperate with scientists in other fields, like anthropology, linguistics, computer science, and neuroscience, among others. This interdisciplinary approach often was referred to as the cognitive sciences, and the influence and prominence of this particular perspective resonates in modern-day psychology (Miller, 2003).

COGNITIVE PSYCHOLOGY

Cognitive psychology is radically different from previous psychological approaches in that it is characterized by *both* of the following:

1. It accepts the use of the scientific method and generally rejects introspection as a valid method of investigation, unlike phenomenological methods such as Freudian psychoanalysis.
2. It explicitly acknowledges the existence of internal mental states (such as belief, desire, and motivation), unlike behaviorist psychology.

Cognitive theory contends that solutions to problems take the form of algorithms, heuristics, or insights. Major areas of research in cognitive psychology include perception, memory, categorization, knowledge representation, numerical cognition, language, and thinking.

MULTICULTURAL PSYCHOLOGY

Culture has important impacts on individuals and social psychology, yet the effects of culture on psychology are under-studied. There is a risk that psychological theories and data derived from white, American settings could be assumed to apply to individuals and social groups from other cultures and this is unlikely to be true (Betancourt & López, 1993). One weakness in the field of cross-cultural psychology is that in looking for differences in psychological attributes across cultures, there remains a need to go beyond simple descriptive statistics (Betancourt & López, 1993). In this sense, it has remained a descriptive science, rather than one seeking to determine cause and effect. For example, a study of characteristics of individuals seeking treatment for a binge eating disorder in Hispanic American, African American, and Caucasian American individuals found significant differences between groups (Franko et al., 2012). The study concluded that results from studying any one of the groups could not be extended to the other groups, and yet potential causes of the differences were not measured.

This history of multicultural psychology in the United States is a long one. The role of African American psychologists in researching the cultural differences between African American individual and social psychology is but one example. In 1920, Cecil Sumner was the first African American to receive a PhD in psychology in the United States. Sumner established a psychology degree program at Howard University, leading to the education of a new generation of African American psychologists (Black, Spence, and Omari, 2004). Much of the work of early African American psychologists (and a general focus of much work in first half of the 20th century in psychology in the United States) was dedicated to testing and intelligence testing in particular (Black et al., 2004). That emphasis has continued, particularly because of the importance of testing in determining opportunities for children, but other areas of exploration in African-American psychology research include learning style, sense of community and belonging, and spiritualism (Black et al., 2004).

The American Psychological Association has several ethnically based organizations for professional psychologists that facilitate interactions among members. Many psychologists who identify with specific ethnic groups or cultures are most interested in studying the psychology of their communities. These organizations play an important role in supporting research and treatment in the communities they serve and are building a more comprehensive understanding of the psychological impact that race, ethnicity, and systems of oppression have upon individuals and communities.

SUMMARY OF THE HISTORY OF PSYCHOLOGY

Before the time of Wundt and James, questions about the mind were considered by philosophers. However, both Wundt and James helped create psychology as a distinct scientific discipline. Wundt was a *structuralist*, which meant he believed that our cognitive experience was best understood by breaking that experience into its component parts. He thought this was best accomplished by introspection.

William James was the first American psychologist, and he was a proponent of *functionalism*. This particular perspective focused on how mental activities served as adaptive responses to an organism's environment. Like Wundt, James also relied on introspection; however, his research approach also incorporated more objective measures as well. Sigmund Freud believed that understanding the unconscious mind was absolutely critical to understand conscious behavior. This was especially true for individuals that he saw who suffered from various hysterias and neuroses. Freud relied on dream analysis, slips of the tongue, and free association as means to access the unconscious. Psychoanalytic theory remained a dominant force in clinical psychology for several decades.

Gestalt psychology was very influential in Europe. Gestalt psychology takes a holistic view of an individual and his experiences. As the Nazis came to power in Germany, Wertheimer, Koffka, and Köhler immigrated to the United States. Although they left their laboratories and their research behind, they did introduce America to Gestalt ideas. Some of the principles of Gestalt psychology are still very influential in the study of sensation and perception.

One of the most influential schools of thought within psychology's history was behaviorism. Behaviorism focused on making psychology an objective science by studying overt behavior and deemphasizing the importance of unobservable mental processes. John Watson is often considered the father of behaviorism, and B. F. Skinner's contributions to our understanding of principles of operant conditioning cannot be underestimated.

As behaviorism and psychoanalytic theory took hold of so many aspects of psychology, some began to become dissatisfied with psychology's picture of human nature. Thus, a humanistic movement within psychology began to take hold. Humanism focuses on the potential of all people for good.

Both Maslow and Rogers were influential in shaping humanistic psychology.

During the 1950s, the landscape of psychology began to change. A science of behavior began to shift back to its roots of focus on mental processes. The emergence of neuroscience and computer science aided this transition. Ultimately, the cognitive revolution took hold, and people came to realize that cognition was crucial to a true appreciation and understanding of behavior.

Four founding paths of academic psychology - Wundt, Freud, James, Dilthey

WILHELM WUNDT PSYCHOLOGY

Wilhelm Wundt opened the Institute for Experimental Psychology at the University of Leipzig in Germany in 1879. This was the first laboratory dedicated to psychology, and its opening is usually thought of as the beginning of modern psychology. Indeed, Wundt is often regarded as the father of psychology. Wundt was important because he separated psychology from philosophy by analyzing the workings of the mind in a more structured way, with the emphasis being on objective measurement and control.

This laboratory became a focus for those with a serious interest in psychology, first for German philosophers and psychology students, then for American and British students as well. All subsequent psychological laboratories were closely modeled in their early years on the Wundt model.

Wundt's background was in physiology, and this was reflected in the topics with which the Institute was concerned, such as the study of reaction times and sensory processes and attention. For example, participants would be exposed to a standard stimulus (e.g. a light or the sound of a metronome) and asked to report their sensations.

Wundt's aim was to record thoughts and sensations, and to analyze them into their constituent elements, in much the same way as a chemist analyzes chemical compounds, in order to get at the underlying structure. The school of psychology founded by Wundt is known as voluntarism, the process of organizing the mind.

During his academic career Wundt trained 186 graduate students (116 in psychology). This is significant as it helped disseminate his work. Indeed, parts of Wundt's theory were developed and promoted by his one-time student, Edward Titchener, who described his system as Structuralism, or the analysis of the basic elements that constitute the mind. Wundt wanted to study the structure of the human mind (using introspection). Wundt believed in reductionism. That is, he believed consciousness could be broken down (or reduced) to its basic elements without sacrificing any of the properties of the whole.

Wundt argued that conscious mental states could be scientifically studied using introspection. Wundt's introspection was not a causal affair, but a highly practiced form of self-examination. He

trained psychology students to make observations that were biased by personal interpretation or previous experience, and used the results to develop a theory of conscious thought.

Highly trained assistants would be given a stimulus such as a ticking metronome and would reflect on the experience. They would report what the stimulus made them think and feel. The same stimulus, physical surroundings and instructions were given to each person. Wundt's method of introspection did not remain a fundamental tool of psychological experimentation past the early 1920's. His greatest contribution was to show that psychology could be a valid experimental science.

Therefore, one way Wundt contributed to the development of psychology was to do his research in carefully controlled conditions, i.e. experimental methods. This encouraged other researchers such as the behaviorists to follow the same experimental approach and be more scientific. However, today psychologists (e.g. Skinner) argue that introspection was not really scientific even if the methods used to introspect were. Skinner claims the results of introspection are subjective and cannot be verified because only observable behavior can be objectively measured.

Wundt concentrated on three areas of mental functioning; thoughts, images and feelings. Some of these areas are still studied in cognitive psychology today. This means that the study of perceptual processes can be traced back to Wundt. Wundt's work stimulated interest in cognitive psychology.

On the basis of his work, and the influence it had on psychologists who were to follow him, Wundt can be regarded as the founder of experimental psychology, so securing his place in the history of psychology. At the same time, Wundt himself believed that the experimental approach was limited in scope, and that other methods would be necessary if all aspects of human psychology were to be investigated.

FREUD PSYCHOLOGY

Sigmund Freud (1856 to 1939) was the founding father of psychoanalysis, a method for treating mental illness and also a theory which explains human behavior.

Freud believed that events in our childhood have a great influence on our adult lives, shaping our personality. For example, anxiety originating from traumatic experiences in a person's past is hidden from consciousness, and may cause problems during adulthood (in the form of neuroses).

Thus, when we explain our behavior to ourselves or others (conscious mental activity), we rarely give a true account of our motivation. This is not because we are deliberately lying. While human beings are great deceivers of others; they are even more adept at self-deception.

Freud's life work was dominated by his attempts to find ways of penetrating this often subtle and elaborate camouflage that obscures the hidden structure and processes of personality.

His lexicon has become embedded within the vocabulary of Western society. Words he introduced through his theories are now used by everyday people, such as anal (personality), libido, denial, repression, cathartic, Freudian slip, and neurotic.

THE CASE OF ANNA O

The case of Anna O (real name Bertha Pappenheim) marked a turning point in the career of a young Viennese neuropathologist by the name of Sigmund Freud. It even went on to influence the future direction of psychology as a whole. Anna O. suffered from hysteria, a condition in which the patient exhibits physical symptoms (e.g., paralysis, convulsions, hallucinations, loss of speech) without an

apparent physical cause. Her doctor (and Freud's teacher) Josef Breuer succeeded in treating Anna by helping her to recall forgotten memories of traumatic events.

During discussions with her, it became apparent that she had developed a fear of drinking when a dog she hated drank from her glass. Her other symptoms originated when caring for her sick father. She would not express her anxiety for her father's illness but did express it later, during psychoanalysis. As soon as she had the opportunity to make these unconscious thoughts conscious her paralysis disappeared.

Breuer discussed the case with his friend Freud. Out of these discussions came the germ of an idea that Freud was to pursue for the rest of his life. In *Studies in Hysteria* (1895) Freud proposed that physical symptoms are often the surface manifestations of deeply repressed conflicts.

However, Freud was not just advancing an explanation of a particular illness. Implicitly he was proposing a revolutionary new theory of the human psyche itself. This theory emerged "bit by bit" as a result of Freud's clinical investigations, and it led him to propose that there were at least three levels of the mind.

THE UNCONSCIOUS MIND

Freud (1900, 1905) developed a topographical model of the mind, whereby he described the features of the mind's structure and function. Freud used the analogy of an iceberg to describe the three levels of the mind.

On the surface is consciousness, which consists of those thoughts that are the focus of our attention now, and this is seen as the tip of the iceberg. The preconscious consists of all which can be retrieved from memory.

The third and most significant region is the unconscious. Here lie the processes that are the real cause of most behavior. Like an iceberg, the most important part of the mind is the part you cannot see.

The unconscious mind acts as a repository, a 'cauldron' of primitive wishes and impulse kept at bay and mediated by the preconscious area.

For example, Freud (1915) found that some events and desires were often too frightening or painful for his patients to acknowledge, and believed such information was locked away in the unconscious mind. This can happen through the process of repression.

Sigmund Freud emphasized the importance of the unconscious mind, and a primary assumption of Freudian theory is that the unconscious mind governs behavior to a greater degree than people suspect. Indeed, the goal of psychoanalysis is to make the unconscious conscious.

The third and most significant region is the unconscious. Here lie the processes that are the real cause of most behavior. Like an iceberg, the most important part of the mind is the part you cannot see. The unconscious mind acts as a repository, a 'cauldron' of primitive wishes and impulse kept at bay and mediated by the preconscious area.

For example, Freud (1915) found that some events and desires were often too frightening or painful for his patients to acknowledge, and believed such information was locked away in the unconscious mind. This can happen through the process of repression.

Sigmund Freud emphasized the importance of the unconscious mind, and a primary assumption of

Freudian theory is that the unconscious mind governs behavior to a greater degree than people suspect. Indeed, the goal of psychoanalysis is to make the unconscious conscious.

PSYCHOSEXUAL STAGES

In the highly repressive "Victorian" society in which Freud lived and worked women, in particular, were forced to repress their sexual needs. In many cases, the result was some form of neurotic illness. Freud sought to understand the nature and variety of these illnesses by retracing the sexual history of his patients. This was not primarily an investigation of sexual experiences as such. Far more important were the patient's wishes and desires, their experience of love hate, shame, guilt and fear – and how they handled these powerful emotions. It was this that led to the most controversial part of Freud's work – his theory of psychosexual development and the Oedipus complex. Freud believed that children are born with a libido – a sexual (pleasure) urge. There are a number of stages of childhood, during which the child seeks pleasure from a different 'object.'

DREAM ANALYSIS

Freud (1900) considered dreams to be the *royal road to the unconscious* as it is in dreams that the ego's defenses are lowered so that some of the repressed material comes through to awareness, albeit in distorted form. Dreams perform important functions for the unconscious mind and serve as valuable clues to how the unconscious mind operates.

On 24 July 1895, Freud had his own dream that was to form the basis of his theory. He had been worried about a patient, Irma, who was not doing as well in treatment as he had hoped. Freud, in fact, blamed himself for this, and was feeling guilty.

JAMES PSYCHOLOGY

William James was a psychologist and philosopher who had a major influence on the development of psychology in the United States. Among his many accomplishments, he was the first to teach a psychology course in the U.S. and is often referred to as the father of American psychology. James was also known for contributing to functionalism, one of the earliest schools of thought in psychology. His book *The Principles of Psychology* is considered one of the most classic and influential texts in psychology's history. He was also the brother of the noted writer Henry James and diarist Alice James.

"The art of being wise is the art of knowing what to overlook," William James once wrote.¹ Learn more about his life, career, ideas, and contributions to psychology in this brief biography.

He was often called the father of American psychology and is best known for:

- Functionalism
- James Lange Theory of Emotion
- Pragmatism William James' Early Life

William James was born into an affluent family. His father was deeply interested in philosophy and theology and strove to provide his children with an enriched education. The James children traveled to Europe frequently, attended the best possible schools, and were immersed in culture and art, which apparently paid off - William James went on to become one of the most important figures in

psychology while his brother Henry James became one of the most acclaimed American novelists.

Henry James was the author of several acclaimed works, including *The Portrait of a Lady* and *The Ambassadors*. Early in school, William James expressed an interest in becoming a painter. While Henry James Sr. was known as an unusually permissive and liberal father, he wanted William to study science or philosophy. Only after William persisted in his interest did Henry permit his son to formally study painting. After studying painting with the famed artist William Morris Hunt for more than a year, James abandoned his dream of being a painter and enrolled at Harvard to study chemistry. While two of James' brothers enlisted to serve in the American Civil War, William and Henry did not due to health problems.

TIMELINE OF EVENTS

- Born January 11, 1842 in New York City
- 1869 - Received M.D. from Harvard
- 1875 - Began teaching psychology at Harvard
- 1882 - Death of William's father, Henry James Sr.
- 1890 - Published *The Principles of Psychology*
- 1892 - Turned lab over to Hugo Munsterberg
- 1897 - Published *Will to Believe and Other Essays*
- 1907 - Published *Pragmatism* and officially resigned from Harvard
- Died August 26, 1910, at the age of 68

THE CAREER OF WILLIAM JAMES

As the family money began to dwindle, William realized he would need to support himself and switched to Harvard Medical School. Unhappy with medicine as well, he left on an expedition with naturalist Louis Agassiz, although the experience was not a happy one.

"I was, body and soul, in a more indescribably hopeless, homeless, and friendless state than I ever want to be in again," he later wrote. Developing health problems and severe depression, James spent the next two years in France and Germany. This period played an important role in shifting his interest in psychology and philosophy.

After graduating from Harvard Medical School in 1869, James continued to sink into depression. Following a period of inactivity, the president of Harvard offered James a position as an instructor of comparative physiology in 1872. Three years later, James began teaching psychology courses. While he famously commented that "the first lecture on psychology ever heard being the first I ever gave," James went on to teach at Harvard until 1907. In addition to his other important contributions, James helped shape the course of psychology by teaching the many students that passed through his classroom.

James also founded one of the first psychology laboratories in the United States. His classic textbook *The Principles of Psychology* (1890) was widely acclaimed, but some were critical of James' personal, literary tone. "It is literature," psychologist Wilhelm Wundt famously commented, "it is beautiful, but it is not psychology."³ Two years later, James published a condensed version of the work titled *Psychology: The Briefer Course*. The two books were widely used by students of psychology and were known to most as "the James" and "the Jimmy" respectively.⁴

JAMES WILLIAMS' THEORIES

James' theoretical contributions to psychology include the following:

- **Functionalism:** James opposed the structuralist focus on introspection and breaking down mental events to the smallest elements. Instead, James focused on the wholeness of an event, taking into the impact of the environment on behavior.⁵
- **James-Lange Theory of Emotion:** The James-Lange theory of emotion proposes that an event triggers a physiological reaction, which we then interpret.⁶ According to this theory, emotions are caused by our interpretations of these physiological reactions. Both James and the Danish physiologist Carl Lange independently proposed the theory.
- **Pragmatism:** James wrote extensively on the concept of pragmatism. According to pragmatism, the truth of an idea can never be proven.⁷ James proposed we instead focus on what he called the "cash value," or usefulness, of an idea.

WILLIAM JAMES' INFLUENCE ON PSYCHOLOGY

In addition to his enormous influence, many of James' students went on to have prosperous and influential careers in psychology. Some of James' students included Mary Whiton Calkins, Edward Thorndike, and G. Stanley Hall.

DILTHEY PSYCHOLOGY

If one wants to see a kind of psychology which Dilthey would regard as explanative and based on incorrect assumptions about the nature of the human *psyché*, I suggest Jerry Fodor's "Methodological Solipsism Considered as a Research Strategy in Cognitive Psychology", in Dreyfus, Hubert, and Hall, Harrison, (eds.), *Husserl, Intentionality and Cognitive Science*, Cambridge, Mass.: M.I.T. Press, 1982, pp.277-303. This article illustrates very well the kind of faculty psychology which Dilthey dislikes. It also well illustrates the 'synthetic' approach which Dilthey attributes to explanative psychology, namely, the identification of elementary psychological entities, in Fodor's case, mental representations and modules for processing the same and then the synthesis of these elements and modules into a merely causally interrelated whole which is supposed to provide a model of such and such a psychological process, e.g., cognition, perception and the like.

1. For two instructive accounts of naturalism, see the articles on naturalism in *The Blackwell Companion to Metaphysics* and the *Encyclopaedia of Philosophy*.
2. In these notes, I occasionally refer to Dilthey's text simply as *Ideas*.

DILTHEY'S IDEAS CONCERNING A DESCRIPTIVE AND ANALYTIC PSYCHOLOGY—CHAPTERS ONE AND TWO

It is common to divide Dilthey's views on the need for, and nature of, a grounding of the so-called human studies into two periods, a 'psychological' one extending through the 1880's up to just before the turn of the century, and a more 'hermeneutic' one from, say, 1900 onwards. This distinction

appears to me to be at best artificial although it is certainly true that around 1900 or slightly before Dilthey did move from talking about the fundamental method and approach of the human studies as descriptively psychological to hermeneutic. This reflects, I think, an appreciation on Dilthey's part that by and large the human studies investigate domains of human reality which, due to differences in culture and tradition, or perhaps the passage of time, are no longer readily accessible. Thus, it is wrong to assume that the kind of activity which the student humanist engages in when studying different or past cultures is just an extension to new domains of an ability to understand others, their actions and their works which we exercise in everyday life.

Because wherever there is distance and difference, human reality is not effortlessly intelligible, the understanding displayed by the human studies is not just a reflective, more explicit version of what we do in unproblematic everyday contexts. A genuinely *hermeneutic* effort is needed; the people, the cultures or the acts one is studying are so to speak broken texts whose meaning is not directly accessible; it must rather be discerned in the vehicles which express them in a manner not strictly comparable to how we effortlessly understand one another in everyday contexts.

Talk of the method and approach of the human studies as descriptive obscures this difference entirely. At the same time, it would be wrong to exaggerate the difference between Dilthey's so-called 'psychological' and his 'hermeneutic' periods. Much is preserved, in particular, his central terminology of the 'psychological' or 'psychical nexus' (*psychischer Zusammenhang*) and the holistic account of socio-cultural reality that goes with this term of art. In the next set of notes, I will start unpacking some of the things Dilthey says in the first two chapters of his "Ideas concerning a Descriptive and Analytic Psychology." This text was written in 1894 and thus belongs to his 'psychological' period. The first chapter is entitled "The Task of a Psychological Grounding of the Human Studies", the second, "The Distinction between Explanative and Descriptive Psychology". In particular, I want to concentrate on pp.138-150 of Chapter I and the whole of chapter II, which is quite short, namely, pp.154-158. In order, however, to understand properly what Dilthey is on about in these opening chapters, a few rough observations on the history of psychology are necessary. Very roughly, one can distinguish two strands and attitudes within contemporary psychology. On the one side there is, to appropriate a distinction from William James, a tender-minded kind of psychology: this is the kind of psychology we associate with the names of Freud, Jung, Binswanger, Klein, Fromm, R.D.

Laing and numerous others. It is often clinically and therapeutically oriented and in its theoretical accounts of its clinical and therapeutic methods it often, if not always and not always unambiguously, spurns any suggestion that it is a *natural* science at all, much less a natural science which could take physics as its model. On the other side there is the tough-minded kind of psychology, e.g., cognitive psychology, some brands of developmental psychology, the psychology of perception, and so on. This kind of psychology very often bumptiously proclaims its status as a natural science. Some prominent recent and contemporary representatives are Karmiloff-Smith, Smolenksy, Rumelhart, McClelland and many others.

We need to keep these two strands strictly apart in attempting to understand Dilthey. Although it has many roots and sources in the tradition of Romantic and philosophical psychology which was eventually eclipsed by the hard-nosed variety, the tender-minded variety of psychology strand is actually the younger. For it arose out of traditions of opposition to the general conceptions underlying the natural scientifically oriented brand. This latter brand in fact arose during Dilthey's life, and it is this brand of psychology which Dilthey has in mind when he speaks of 'erklärende Psychologie', i.e., 'explanatory' or 'explanative' psychology.

In Dilthey's time, psychology in this natural scientifically oriented sense was just starting to assert itself. One of the first people to articulate the idea of a natural scientifically oriented 'explanatory' psychology was Kant's successor at Königsberg, Johann Friedrich Herbart (1776-1841).

Although he insisted that in psychology one still needed a number of indispensable metaphysical presuppositions, in particular, in order to account for the unity of psychological phenomena and the particular way they change, he insisted that one could have a 'physics of the mind' („Physik des Geistes“) which utilised mathematical and quantitative techniques, thereby enabling psychology to constitute itself as a genuine science. Herbart's followers, e.g., Waitz (1821-1864) and Drobisch (1802-1896), in these notes I was unable to discuss the third fundamental characteristic, namely, the human propensity to regard certain kinds of action as not just wise or unwise, but morally right or wrong.

elaborated on these ideas unlike by the mid-century numerous thinkers were claiming that psychology had to be done as an independent, empirical discipline, without any debt to, or baggage from, traditional philosophy and metaphysics. Mid-nineteenth century scientists, doctors and philosophers like Wundt (1832- 1920), Helmholtz and Fechner (1801-1887) set about establishing a psychology whose model was physics and which conceived its object of study as neither made of immaterial substance, nor identical with the human soul. Psychology thus conceived was to be neutral about these kinds of issue, although of course the more it succeeded in cognising psychological phenomena without having to talk about immaterial substances or of souls, the less plausible it made these doctrines. (Something similar applies in the case of physics and God.)

Dilthey identifies a number of contemporary traditions and individual thinkers as the first advocates of this idea of an independent, natural scientifically oriented psychology which takes physics as its model, hence similarly aims to exploit experimental and mathematical techniques. In this connection, he mentions.

- 1) the tradition of associationist psychology, which stems from the British empiricists Locke, Berkeley and Hume;
- 2) Herbart (1776-1841), who has already been mentioned;
- 3) Friedrich Albert Lange (1828-1875), the early Neokantian author of the very influential book *Geschichte des Materialismus (The History of Materialism)*; and
- 4) the English psychologist Herbert Spencer and Taine. A natural scientifically oriented psychology conceives its task as that of identifying the constituent elements, causal laws and mechanisms of psychological phenomena, just as physics identifies constituent elements, causal laws and mechanisms of physical phenomena.

Identification of the fundamental elements of things and of how these fundamental elements interact causally to produce certain kinds of phenomenon is what Dilthey means by the *explanation* of such phenomena. A science which aims to explain in this sense is precisely an explanatory or explanative science. As Dilthey puts it, "(u)nter einer erklärenden Wissenschaft ist jede Unterordnung eines Erscheinungsgebietes unter einen Kausalzusammenhang vermittelt einer begrenzten Zahl von eindeutig bestimmten Elementen (d.h. Bestandteilen de Zusammenhangs) zu verstehen." (S.139) It should be noted that while such explanative science and the explanations it comes up with may very well and perhaps even ideally take mathematical form, this is not necessary. Many natural scientific explanations, from contemporary explanations of the origin of the universe to

genetic explanations of hereditary disease are strictly qualitative, even though they may involve much calculation around the edges.

Dilthey points out that explanative psychology in this sense works essentially with hypotheses. Insofar as to form a hypothesis is to formulate a general proposition hopefully valid for all cases on the basis of a limited number of cases, there is nothing to object to this. But, says Dilthey, the formulation of hypotheses has acquired a more definite, specific sense in natural scientific contexts, and thus in all disciplines which, like explanative psychology, seek to model themselves on natural sciences. According to Dilthey, we do not experience the causal interconnectedness of things, but only their temporal succession. When a flame causes water to boil, I see the flame burning in close proximity to the kettle, and I also see the water boiling in the kettle. I do not, however, see in addition to these two events any further event of the flame's causing the water to boil. In order to establish that a causal connection exists between these two events, I must test out the *hypothesis* that such a connection exists by putting kettles on flames a number of times. I will then have a highly probable degree of certainty that a causal connection exists. (S.140-141).

But, ask Dilthey, can this approach be transferred across to our psychological life? (S.142) That the representatives of an explanative psychology do intend such a transferral, and that there are a number of points at which this idea is problematic, are things Dilthey wants to show in the course of this work. We can, or as Dilthey seems to suggest, get a better preliminary understanding of what it means thus to conceive psychology on the model of natural science, and where this idea goes wrong by appreciating the following: in contemporary explanative psychology we do indeed find, as a matter of fact, *lots* of hypotheses. Unfortunately, this is an embarrassment of riches: "Ein Kampf aller gegen alle tobt auf ihrem Gebiete nicht minder heftig als auf dem Felde der Metaphysik. Noch ist nirgends am fernsten Horizonte etwas sichtbar, was diesen Kampf zu entscheiden die Kraft haben möchte." (S.142) Dilthey seems to be voicing about contemporary explanative psychology much the same sentiment that Kant voiced about traditional metaphysics: "... (s)o far ... are the students of metaphysics from exhibiting any kind of unanimity in their contentions, that metaphysics has rather to be regarded as a battle-ground ... in which no participant has ever yet succeeded in gaining even so much as an inch of territory, not at least in such manner as to secure him in its permanent possession." Given the subsequent development of explanative psychology, indeed, of any kind of psychology, Dilthey is making a quite valid point. Since the rise of explanative and experimental psychology in the late nineteenth century, there have been a succession of attempts to establish psychology on the same kind of sure footing which physics, in particular through Sir Isaac Newton, was able to establish itself.

Newton's mechanics provided a research framework for future scientists which lasted approximately 250 years. And in a certain sense Newton's work has not been superseded, even today: most standard engineering and technological work utilises classical mechanics, indeed, classical mechanics are often used in the design of experimental apparatus and instruments used in theoretical physics of a quite high-powered kind. Finally, many people regard Newton's theory as just a special case of which Einstein provided the more general theory.

Nothing like this has occurred in psychology. Initially, in the late nineteenth century there was associationist psychology which derived from classical empiricism and was often highly introspectionist in nature. That is, it was quite happy to maintain that psychological data and even laws could be discovered by the psychologist's observing how he or she experienced things. Such observation of one's own mental life was known as 'inner perception', something of which Dilthey himself makes

much mention.

But in the late nineteenth century, psychologists began calling introspection into question, denying that it provided the kind of empirical data a natural scientifically oriented psychology could profitably use. The point was not, or not just, that the observations one made about what went on in one's own breast were no more reliable and infallible than ordinary observation of external things. The point was rather that no matter how reliable or infallible such data were, they were of limited use in experimental, explanative psychology.

The aim of such a psychology is to establish the various mechanisms and lawful connections whereby physical things out there cause psychological phenomena 'in the mind'; and conversely, things 'in the mind' cause things to happen in the physical world. About these mechanisms and laws very little knowledge is gained by introspection. What is needed is experimentation from a third-person, non-introspectionist point of view—experimentation involving diverse test subjects which would seek to correlate their introspective reports of their psychological states and events with observations made by the experimenter of various physical and physiological facts, events and changes.

Eventually, this hostility to introspection went so far that one did not merely deny that it could establish anything of scientific interest. One increasingly began to declare that the phenomena allegedly introspected did not really exist. At least from the standpoint of the natural scientifically oriented psychologist one could regard the entities talked about in introspective reports, e.g., colour sensations, feelings, perceptions, beliefs, desires, intentions and the like as entities postulated by a bad or false theory, and thus with precisely the same status as witches and fairies. This hostility to what had traditionally been understood by psychological phenomena gather pace during the late nineteenth century, culminating in the first decades of the twentieth century in the movement known as behaviourism. (The canonical text of this movement was J.B. Watson's book *Behaviourism*, which appeared in 1912.) This was a kind of experimental, natural scientific psychology which tried to do without any talk of mental or psychological entities, except in a behavioural sense. If beliefs, desires, intentions and the like existed at all, then only as dispositions to behave: to say that I believe that it is raining is simply to say that I will tend to do such things as put on my raincoat, open up an umbrella, or put my newspaper over my head, etc., before I go outside.

Although behaviorism received some competition from the so-called Gestalt psychologists, it was the dominant school of psychology at least in Anglo-american countries for many decades. But by the fifties it was quite clear to most people that behaviourism was not the promised equivalent to Newtonian mechanics, that foundation which would allow a scientific psychology to march relentlessly forward for hundreds of years. So people began looking for a completely new approach. By the late fifties, if not earlier, psychologists and philosophers of psychology believed they have found the new approach. They began to re-invent the mental—but only because the model of the computer suggested how one could acknowledge the mental and important elements in a scientific psychology without lapsing back into unscientific introspectionism.

Thinking was like the running of a computer programme, beliefs like the stored information used by the programme and desires the various objectives the programme served. The task of scientific psychology was thus to come up with models of the programmes we humans run when thinking and acting. Psychology thus conceived is known as functionalism, or more accurately, as computationalism, which is one way of spelling out the idea that beliefs, desires, perceptions are mental

functions, i.e., neuro- physiological configurations with certain properties to change, and be changed by, other such configurations. (Analogously, when a computer is running a certain programme, its hardware is configured to respond and interact in certain ways.)

Unfortunately, various problems with this conception have arisen. The computationalist attempt to spell out the general functionalist idea has not delivered the long-awaited foundation for the sure march forward of psychological and in particular, of cognitive science, which is of course the psychology of cognition and perception. Enthusiasm for it is thus waning and now the latest fashion is the idea of neural networks and, more latterly, the idea that the human psyché can be modelled scientifically by conceiving it as a non-linear dynamical system.

So Dilthey is quite right, indeed prescient, in his observation that there is in psychology a situation not unlike that in what I particularly despise, namely, metaphysics. That there is indeed this situation is indeed something of which many natural scientifically oriented psychologists show themselves to be painfully aware. Just like so many economists, many psychologists protest over and over again that what they are doing is 'science'. Contrast this to the much more relaxed attitude of many contemporary physicists, who are rightly quite sure that physics, whatever it is, is a huge success, who thus do not feel any need to defend the status of physics as a science (or anything else).

Dilthey gives his own example of a fundamental hypothesis which he regards as subject to endless, undecidable controversy. This appears to be the standard reductive materialist hypothesis that psychological facts and events are caused in law-like ways by physical and physiological facts and events, and are indeed reducible to these latter. (I take it by speaking of "die Zurückführung aller Bewußtseinserscheinungen auf atomartig vorgestellte Elemente, welche in gesetzlichen Verhältnissen auf einander wirken ..." (S.142-143), Dilthey does intend not merely an epiphenomenalism, but a genuine reductionism.)

Dilthey points out that proponents of explanative psychology like to defend their making of such hypotheses by appeal to the natural sciences, by which Dilthey of course means physics and chemistry (see S.139). But I think he is trying to say that this begs the crucial question of whether psychology may in fact such natural sciences as its model. If the answer to this question is 'Yes', then certainly this characteristic defence is sufficient; one may indeed respond that, as the experience and history of the natural sciences show, we may have every confidence that the *current* controversial character of this hypothesis will, by further work and experiment, be overcome. But until this question has been answered affirmatively one may just as legitimately take the long-standing controversial character of such hypotheses as indicating that something is wrong in one's conception of what psychology is and thus what it may take as its model.

ISSUES: CRISIS IN PSYCHOLOGY DUE TO STRICT ADHERENCE TO EXPERIMENTAL-ANALYTICAL PARADIGM (LOGICAL EMPIRICISM)

This article looks at the main symptoms of the crisis in psychology. The author believes that in addition to the traditional manifestations that have dogged psychology since it emerged as an independent science, there have appeared some new symptoms. The author identifies three fundamental "ruptures": "vertical" ruptures between various schools and trends, "horizontal" ruptures between natural science and humanitarian psychology and "diagonal" ruptures between research (academic) and practical psychology. In the author's opinion, these manifestations of the crisis of psychology have recently been compounded by the crisis of its rationalistic foundations. This situation is

described in terms of the cognitive systems in psychology which include:

- 1) meta-theories;
- 2) paradigms;
- 3) sociodigms and
- 4) metadigms.

PERMANENT CRISIS

One of the key features of the methodological self-consciousness of psychology that has accompanied it since its first steps is a permanent sense of crisis invariably registered since the times of W James (James, 1890; etc.). The following are the commonly noted symptoms of the crisis:

- the disjointed character of the psychological science, a lack of conceptual unity;
- lack of a single universally shared theory;
- the mosaic-like and unsystematic character of psychological knowledge;
- lack of universal criteria of verification and authenticity of knowledge;
- non-cumulative nature of knowledge, with each new psychological trend declaring all the preceding psychology to be a collection of misconceptions and artifacts;
- separation of the whole personality into memory, thought, perception, attention and other mental functions, each leading a strange independent existence;
- various "parallelisms"-psycho-physical, psycho-physiological, psycho-biological and psycho-social - which psychology feels unable to resolve for itself, "puzzles," to borrow T. Kuhn's words (Kuhn, 1962); and others. True, at least three circumstances mitigate the permanent sense of crisis. First, in terms of their attitude to methodology psychologists may be divided into 4 main categories:
 - 1) those who are largely indifferent to general methodological issues; methodological rigorists who adhere to traditional, largely Positivist, research standards
 - 2) methodological anarchists generally sharing Paul Feuerabend's "anything goes" credo; and
 - 3) methodological liberals who combine post-modernists and more traditional research approaches. By far the largest number of psychologists belongs to the first group, which makes the psychological community not very sensitive to the "eternal" methodological problems of psychology. Secondly, psychologists have got used to its permanent crisis which they often perceive as the normal state of their "abnormal" science. This sentiment, among other things, strengthens the long-standing conviction of the "special path" of psychology whereby its status cannot be assessed by comparing it to the natural sciences regarding their dissimilarity as a manifestation of the crisis of psychology (Gergen, 1994, etc.).

Third, psychology's methodological discourse expresses a kind of "poetics" of crisis, perceived in a positive light as something that stimulates the development of the psychological science, makes it more perceptive of methodological problems, etc., which prevents a sense of permanent crisis degenerating into a sense of permanent frustration. Studiedly optimistic statements such as "it is unclear whether there was a crisis or not, but it's good it's over" (McGuire, 1976) have gained some currency.

"Horizontal" Rupture The division of psychology into various schools that look like psychological empires is one of the commonly known symptoms of the permanent crisis of psychology. The number of "psychological empires keeps growing as new "states within the psychological state" such as social constructionism, dialectical psychology, etc. are added to the traditional ones such as cognitivism, behaviorism, and psychoanalysis (Smith, 2001)

The proliferation of schools of thought that cannot find a common language (Ohlsson, 2007) is a great irritant to psychologists who seek to unite these schools in larger "types of psychology" such as "German-Austrian" and "North-American psychology" (Toomela, 2007). It multiplies the number of horizontal demarcation lines within the psychological science.

Such demarcations of the psychological science are reproduced and consolidated in psychological practice because its main areas of research give rise to corresponding trends in practical psychology. The feeble unification trends, far from diminishing, tend to increase entropy because their product as a rule is new, independent research currents that bear little resemblance to their "progenitors".

The main challenges in the way of integration of psychology spring not so much from the multiplicity of schools and trends arising on the basis of psychological meta-theories, as from their incommensurability, to use T. Kuhn's term. Each "psychological empire" lives according to its own laws including the rules of generating psychological knowledge, criteria of its authenticity, verification methods, etc. Meanwhile, the psychological meta-theories that underlie research trends are "more than theories". C.H. Franklin rightly notes that psychological theories are rules which prescribe what the researcher should do and how (Franklin, 1982), i.e. psychological theories effectively perform paradigmatic functions. Naturally, most psychological theories generate a huge body of empirical studies carried out on their basis and such publications as Psychological Abstracts bring together both under the heading of "theory" and, as is well known, the results of empirical studies inspired by this or that psychological theory are usually interpreted on the basis of that theory, thus repeatedly reproducing the "methodological circle" described by K. Danziger (Danziger, 1985). As a result the so-called "crucial experiments" designed to establish which of the conflicting theories is the right one turn out to be largely ineffective because empirical data are interpreted in terms of one of the theories being "verified," which inevitably they confirm. Contrary to Thomas Huxley's dismal statement that "the great tragedy of science is that an ugly fact can kill a beautiful theory" (Huxley, 1902, p. 63) facts per se are unable not only to "kill" a psychological theory, but even to seriously damage it.

To add to the picture, the majority of psychological theories have an "upper" and "lower" tie-ins: the "upper" being the underlying philosophical ideas of the nature of man and society and the "lower" having to do with the personal and psychological traits of their authors. As L. Hjelle and D. Ziegler stress, all the theories of personality are based on certain philosophical premises regarding the nature of man (Hjelle, Ziegler, 1992). For example, psychoanalysis adheres to a "gloomy concept of the human nature" (Ibid.) which flows from Freud's study of mentally disturbed people, and humanistic psychology is wedded to the idea that man is inherently good and capable of self-improvement (Ibid.).

L. Hjelle and D. Ziegler emphasize the "lower-end" tie-in of psychological theories regarding the need to explain it as a general methodological principle and claiming that in order to understand the principles preached by this or that student of personality one needs information about his/her religious and social-economic status, the size of his/her family and the sequence of their birth relations with

parents, education and professional experience(Ibid.).

Earlier the idea was expressed by B. Eiduson who believed that the theories of human nature are less an intellectual means of expressing the objective reality than the psychological traits of its authors (Eiduson, 1962). And J. Richards stressed that the theories any science develops bear the footprints of the personality of their authors, but that there is not a single scientific discipline in which the link stands out in such bold relief as in psychology (Richards, 1987). Not surprisingly, to borrow an apt metaphor from Agnew and Pyke, scientific research is similar to a love affair, and rejection of a once recognized theory is akin to jilting a sweetheart and requires more than just negative information about the sweetheart (Agnew, Pyke). As a result, psychological theories are not just "more", but "much more" than theories, at least much more than the term means in natural sciences, and the theoretical disunity of psychology is something more than the coexistence of various concepts within that science.

LOGICAL EMPIRICISM

Logical empiricism is a philosophic movement rather than a set of doctrines, and it flourished in the 1920s and 30s in several centers in Europe and in the 40s and 50s in the United States. It had several different leaders whose views changed considerably over time. Moreover, these thinkers differed from one another, often sharply. Because logical empiricism is here construed as a movement rather than as doctrine, there is probably no important position that all logical empiricists shared—including, surprisingly enough, empiricism and while most participants in the movement were empiricists of one form or another, they disagreed on what the best form of empiricism was and on the cognitive status of empiricism. What held the group together was a common concern for scientific methodology and the important role that science could play in reshaping society. Within that scientific methodology the logical empiricists wanted to find a natural and important role for logic and mathematics and to find an understanding of philosophy according to which it was part of the scientific enterprise.

MAPPING THE MOVEMENT

The term 'logical empiricism' has no very precise boundaries and still less that distinguishes it from 'logical positivism'. It is therefore hard to map. 'Logical empiricism' here includes three groups:

- (1) the Vienna Circle, here taken broadly to include those who were part of various private discussion groups, especially that around Moritz Schlick, and also the members of the more public Ernst Mach Society (Verein Ernst Mach),
- (2) the smaller, but perhaps more influential Berlin Society for Empirical Philosophy (later called the Berlin Society for Scientific Philosophy), and those influenced by or who interacted with members of the first two groups and shared an intellectual kinship with them. Besides Vienna and Berlin, there were important centers of the movement in England, France, Scandinavia, at several universities in the U.S., and even China

This characterization includes thinkers who disagreed with doctrines espoused by members of the original groups and even some who defined themselves in opposition to the movement. This results in a vague boundary, but it suffices to identify a movement in which a large number of able philosophers self-consciously participated and to distinguish logical empiricism from other movements.

SOME MAJOR PARTICIPANTS IN THE MOVEMENT

The logical empiricist movement is the sum of the interwoven trajectories of its members, so one way of describing that movement is to trace those various trajectories. To do so in detail for all those involved would take rather longer than the movement lasted. That would be inappropriate for one entry in an encyclopedia, especially one in which entries for many of the members will appear independently. The thumbnail sketches of the work of some representative figures below show the breadth and international character of the movement. While the list is long, it covers only a small fraction of those involved and leaves out many important thinkers.

A. J. AYER (1910–1989)

An English philosopher in the tradition of British empiricism, Ayer visited the Vienna Circle in 1932–33. His book *Language, Truth, and Logic* (1936) was a best seller after World War II and represents logical positivism to many English speakers.

RUDOLF CARNAP (1891–1970)

German by birth, he taught in Vienna, Prague, Chicago, and Los Angeles. He was one of the leaders of the Vienna Circle and of logical empiricism, especially of those within the movement whose formulations were more liberal, e.g., with respect to the criterion verification. He defended logical and methodological pluralism and worked to develop an epistemic approach to probability.

WALTER DUBISLAV (1895–1937)

A German logician and philosopher of science, Dubislav was one of the founders, with Reichenbach and Grelling, of the Berlin Society of Empirical (later Scientific) Philosophy.

HERBERT FEIGL (1902–1988)

Born in what is now the Czech Republic, Feigl studied in Vienna with Schlick and Hahn. He emigrated to the U.S. before most other logical empiricists would do so. He taught at the Universities of Iowa and Minnesota and founded both *Philosophical Studies*, with Wilfrid Sellars, and the Minnesota Center for the Philosophy of Science. He is best known for his work on the mind-body problem.

ISSUES

It is not possible in an essay of this scope to trace all the issues that the logical empiricists addressed or even to treat any one of them with completeness. What is possible is to highlight some salient issues, clear away some misconceptions about them, and sketch a bit how those issues were developed over time. The first is a related set of concerns: empiricism, verificationism, and anti-metaphysics. The second is the logical empiricists' treatment of logic and mathematics as analytic. Third is the related issues of the unity of science and reduction. And finally, comes the issue of probability. Given what has already been said, the reader should be aware that none of the doctrines discussed below was shared by all members of the logical empiricist movement.

EMPIRICISM, VERIFICATIONISM, AND ANTI-METAPHYSIC

Since antiquity the idea that natural science rests importantly on experience has been non-controversial. The only real questions about the sources of scientific knowledge are: Are there parts of science that do not rest on experience or rest also on something other than experience? If so what account can we give of those parts? And to the extent that science does rest on experience how

can we know that it does? There is another question about science related to these, though not strictly about the sources of science, and that is: Why, in making claims about the world, should we be scientific as opposed to say mystical? The difficulty is that any scientific answer to this last question would reasonably be thought to beg the very question it purports to address.

Long before the twentieth century the prevailing opinion was that Euclidean geometry, standard mathematics, and logic did not rest on experience in any obvious way. They were largely presupposed in our empirical work, and it was difficult to see what if anything might disconfirm them. Geometry was a special case and might be handled in different ways that we shall not discuss here. That leaves logic and mathematics.

ANALYTICITY

Logic, mathematics, and mathematical geometry had traditionally seemed to be confirmationally "different". Indeed it is hard to indicate any conditions under which any parts of them would be disconfirmed. Leibniz had called them truths of reason. Hume said that they represented relations of ideas. Kant had held that the truths in these areas were a priori. Mathematics and geometry were not analytic for Kant, but logic was. Kant had two criteria of analyticity, apparently thinking them equivalent. First, in subject-predicate sentences, an analytic sentence is one in which the concept of the predicate is contained in that of the subject. Second, an analytic sentence is one whose denial is self-contradictory. This seems to include not only the sentences whose surface logical form would be of the required sort but also those that can be got from such logical truths by making substitutions that were conceptually equivalent. The more modern rough analog of this is to say that the analytic sentences are those that are true in virtue of logic and definition.

INDIC INFLUENCES ON MODERN PSYCHOLOGY INDIC INFLUENCES ON MODERN PSYCHOLOGY

This is only the beginning of an outline which I hope others on the Yoga Psychology list will help to flesh out. I am basing the information here primarily on two sources: J.J. Clarke's "Oriental Enlightenment: The Encounter Between Asian and Western Thought" and Eugene Taylor's introduction to "The Physical and Psychological Effects of Meditation: A Review of Contemporary Research with a Comprehensive Bibliography, 1931 - 1996. The outline begins with some distinctions between psychology, psychotherapy and psychiatry. Then there is a quick and extremely brief overview of the basic historical trends in psychology. Finally, there is a list with brief descriptions of some of the major individuals who have brought Indic influences to bear on psychology.

PSYCHOLOGY, PSYCHOTHERAPY AND PSYCHIATRY

"Psychology", as taught in universities throughout the world, refers to an academic discipline, and a science which was established in the late 19th century. Several times on the Yoga Psychology list, there has been reference to "science" as if the only real science is that which deals with physics and the brain. However, the research methodology of psychology has been dealing with human experience for over 120 years, even if often or mostly in a reductionist fashion. Psychological science includes a wide variety of disciplines, including developmental psychology, personality psychology, social psychology, comparative or evolutionary psychology, and among the applied psychological disciplines, educational, sports and neuropsychology. Typically, at least in the United States, a psychologist has a Ph.D. (Doctorate).

"Psychiatry" is a subspecialty of the medical profession. A practicing psychiatrist usually has at least

an M.D., though sometimes a Ph.D. as well. Psychiatrists are primarily focused on psychopathology, treating mental illness. Historically (until approximately 50 years ago) this meant serious mental illness - the psychoses, manic-depression, major depression, obsessive-compulsive disorder, etc. With the increasing monetarization of the profession, there has been an widening array of so-called disorders which have increased to the extent that virtually nobody may be said to be free of mental illness.

"*Psychotherapy*" refers to a healing practice whose beginnings are associated for the most part with the psychoanalysis of Sigmund Freud, who was by training a neurologist, not a psychologist. For the first 50 years of the 20th century, most practitioners of psychotherapy were psychiatrists, which means their training was in the field of medicine. By the 1970s, psychoanalysis had begun to fall out of favor, and the biological approach (drugs, essentially, though electro-convulsive therapy has had a resurgence as well) has gradually come to predominate, not in a small way because of the influence of the pharmaceutical companies. Psychiatrists receive very little training in psychology. Psychologists make use of psychoanalytic ideas and practices, though there are uniquely psychological contributions to therapy such as behavioral therapy, cognitive-behavioral therapy and humanistic therapy, to name the most widely used approaches.

HISTORICAL OVERVIEW

The psychologist Cyril Burt once summarized the modern history of psychological science in this way: "Psychology first lost its soul, then it lost its mind, until it was finally in danger of losing consciousness altogether". The official beginning of the science of psychology is 1879, when Wilhelm Wundt established the first psychological laboratory in Leipzig, Germany. The first formal school of psychology was the introspectionist school. Previously, psychology had been the domain of the philosophers. In an attempt to separate philosophy and science, psychologists no longer referred to the "soul".

The "introspection" of this early school of psychology was an extremely superficial and reductionist cataloging of sensory experience. There was little progress made during the 30 or 40 years this school was in existence. (Though William James wrote his famous "*Principles of Psychology*" during this period, he failed to establish a separate school or approach to psychology).

The second psychological school represented a radical break from the Introspectionists, and was initiated in 1913 by John Watson, the first behaviorist. He called for the elimination of all references to internal experience (this is what Burt was referring to as psychology "losing its mind"). B. F. Skinner, several decades later, took this a step further, referring to the brain as a "black box", and refusing acknowledgment of any sort of consciousness at all.

In the late 1950s, the cognitive "revolution" was initiated, often considered to be officially begun with George Miller's article, "*The Magic Number 7, plus or minus 2*" (this refers to the amount of "bits of information" which the average human being can carry in their memory - the reference to the ancient magic number "7" was made consciously, though the idea that mystical associations were to be taken seriously was strenuously avoided. You might say that psychological science was finally beginning to regain consciousness at this time!

Since the 1950s, there have no longer been separate competing "schools" of psychology, a problem which has plagued the field of psychotherapy, which has over 400 separate and non-integrated

theories of how therapy works. The above-mentioned divisions of psychology - developmental, personality, social, etc - are considered specialty areas of one discipline, not competing schools of thought, much like nuclear physics and astrophysics, as opposed to the conflicting theories of cognitive therapy and psychoanalysis.

Generally speaking, university departments of psychology hold the purely scientific disciplines in much higher esteem than the applied disciplines of psychotherapy, educational psychology, etc. The names "Freud" and "Jung" are rarely even mentioned past the introductory courses of psychology. Many people who are familiar with popular versions of psychology have heard of the "four forces of psychology" (psychoanalysis, behavior therapy, humanistic therapy, transpersonal therapy).

Technically, these are 4 divisions of psychotherapy, and have little connection with the world of scientific psychology. Even within the world of mainstream psychotherapy, the field of transpersonal psychotherapy is considered a fringe discipline. This should be kept in mind for the rest of this outline, as it is in the area of transpersonal theory that the Indic traditions have had the most direct influence.

INDIC INFLUENCES ON MODERN PSYCHOLOGY

Gustav Fechner:

(I'm writing this partly from memory, and will try to find more in the future. I invite anyone who has more knowledge of Fechner's work to send corrections and additional information). Fechner was a physiologist with interests in mystical traditions. I believe his interests included Indian philosophy, but I'm not positive. Here is an interesting quotation which shows a surprisingly modern - or even post-modern - approach to science:

"That gravitation extends throughout the whole world is a matter of faith; that laws which are traceable in our limited realm extend limitlessly in space and time is a matter of faith; that there are atoms and light waves is a matter of faith; the beginning and the goal of history are matters of faith; even in geometry there are things we take upon faith, such as the number of the dimensions of space and the definition of parallel lines. Indeed, strictly speaking everything is a matter of faith which is not directly experienced... Ultimately the best faith is that which is least contradictory in itself and to all knowledge and to our practical interest.

ONE OF THE OTHER MAJOR FIGURES IN TRANSPERSONAL PSYCHOLOGY INCLUDE:

Charles Tart, an academic psychologist, who published "Altered States of Consciousness" in 1969, which contained an attempt to bring together systems thinking and ideas from teachings on Hindu and Buddhist meditation. Claudio Naranjo, a psychiatrist, began writing in the late 1960s on: Gestalt therapy and Buddhist meditation. Robert Ornstein, a psychologist, in 1971 published "The Psychology of Consciousness", which incorporates ideas from Sufism, Buddhism, Taoism and Hinduism.

Allan Weinstein, a psychologist, (named "Swami Ajaya" by the Indian Yoga teacher Swami Rama) wrote in 1976 "The Evolution of Consciousness and Psychotherapy". This book is particularly notable as it was published before Ken Wilber's first book, and includes the idea, derived independently from Wilber, of a spectrum of consciousness. However, the ideas in the book are much more closely drawn from Yoga and Vedanta, with the latter being fully acknowledged. Indian "psychology" is

depicted as far more subtle and sophisticated than the work of Freud or Jung. Also, unusual in transpersonal writings, Indian psychology is taken to deal with virtually all of the areas which many modern writings feel are better handled by Freud and Jung.

Daniel Goleman, a psychologist and former chief editor of the periodical "Psychology Today", wrote "The Varieties of Meditative Experience" in 1977. Goleman is worth dwelling on for a bit. A friend of Richard Alpert, he went to India to study Hindu and Buddhist meditation. He returned to study psychology at Harvard. He wrote his dissertation studying under Herbert Benson. I'm not absolutely sure of this, but if my memory is correct, it was Goleman who, in what I think was a spark of inspiration with decidedly mixed results, suggested that meditation could be presented in a palatable form to modern secularized individuals as a form of "stress management". He took ideas developed in the 1920s by the physiologist Walter Cannon and later refined by Hans Selye in the 1950s as the "stress cycle" (dealing with the continual arousal of the autonomic nervous system leading to nervous exhaustion). He then suggested that the technique of meditation primarily served to deactivate this stress cycle. At the time, I thought this was a brilliant way of bringing meditation into the mainstream. However, over the years, I've come to see that the result is that meditation has been reduced to something negligible compared to its original purpose. Goleman, for example, defines meditation in "Varieties" as "an attitude of attentional manipulation". Anyone with any meditative experience knows that bringing this sort of attitude to the practice of meditation is likely to lead to headaches and irritability rather than a transformation of consciousness! In any case, the whole development of stress management and the wider disciplines of health psychology, behavioral medicine and complementary medicine, needs a whole study. Each of these fields has been deeply impacted by Indian practices and ideas, and many of the new centers for alternative and complementary medicine are making big efforts to hide this connection.

WHAT IS ESSENTIAL ASPECTS OF KNOWLEDGE PARADIGMS: ONTOLOGY, EPISTEMOLOGY, AND METHODOLOGY. PARADIGMS OF WESTERN PSYCHOLOGY: POSITIVISM, POST-POSITIVISM, CRITICAL PERSPECTIVE, SOCIAL CONSTRUCTIONISM, EXISTENTIAL PHENOMENOLOGY, AND CO-OPERATIVE ENQUIRY PARADIGMATIC CONTROVERSIES?

ESSENTIAL ASPECTS OF KNOWLEDGE PARADIGMS: ONTOLOGY, EPISTEMOLOGY, AND METHODOLOGY. PARADIGMS OF WESTERN PSYCHOLOGY: POSITIVISM, POST-POSITIVISM, CRITICAL PERSPECTIVE, SOCIAL CONSTRUCTIONISM, EXISTENTIAL PHENOMENOLOGY, AND CO-OPERATIVE ENQUIRY. PARADIGMATIC CONTROVERSIES

Essential aspects of knowledge paradigms: Ontology, epistemology, and methodology

A review of literature from leaders in the field leads to a deep understanding of the meaning of a research paradigm. For example, in *The Structure of Scientific Revolutions* American philosopher Thomas Kuhn (1962) first used the word paradigm to mean a philosophical way of thinking. The word has its aetiology in Greek where it means pattern. In educational research the term paradigm is used to describe a researcher's 'worldview' (Mackenzie & Knipe, 2006). This worldview is the perspective, or thinking, or school thought, or set of shared beliefs, that informs the meaning or interpretation of research data.

Or, as Lather (1986) explains, a research paradigm inherently reflects the researcher's beliefs about the world that s/he lives in and wants to live in. It constitutes the abstract beliefs and principles that shape how a researcher sees the world, and how s/he interprets and acts within that world. When we say that it defines the researcher's worldview, we mean that a paradigm constitutes the abstract beliefs and principles that shape how a researcher sees the world, and how s/he interprets and acts within that world. It is the lens through which a researcher looks at the world. It is the conceptual lens through which the researcher examines the methodological aspects of their research project to determine the research methods that will be used and how the data will be analysed.

Guba and Lincoln (1994) who are leaders in the field define a paradigm as a basic set of beliefs or worldview that guides research action or an investigation. Similarly, the gurus of qualitative research, Denzin and Lincoln (2000), define paradigms as human constructions, which deal with first principles or ultimates indicating where the researcher is coming from so as to construct meaning embedded in data. Paradigms are thus important because they provide beliefs and dictates, which, for scholars in a particular discipline, influence what should be studied, how it should be studied, and how the results of the study should be interpreted.

The paradigm defines a researcher's philosophical orientation and, as we shall see in the conclusion to this paper, this has significant implications for every decision made in the research process, including choice of methodology and methods. And so a paradigm tells us how meaning will be constructed from the data we shall gather, based on our individual experiences, (i.e. where we are coming from). It is therefore very important, that when you write your research proposal for HDR, you clearly state the paradigm in which you are locating your research.

ESSENTIAL ELEMENTS OF A PARADIGM

According to Lincoln and Guba (1985), a paradigm comprises four elements, namely, epistemology, ontology, methodology and axiology. It is important to have a firm understanding of these elements because they comprise the basic assumptions, beliefs, norms and values that each paradigm holds. Therefore, in locating your research proposal in a particular research paradigm, the understanding is that your research will uphold, and be guided by the assumptions, beliefs, norms and values of the chosen paradigm. It is therefore important that you demonstrate that you know what each of these elements mean.

EPISTEMOLOGY OF A PARADIGM

Epistemology has its aetiology in Greek where the word episteme, means knowledge. Put simply, in research, epistemology is used to describe how we come to know something; how we know the truth or reality; or as Cooksey and McDonald (2011) put it, what counts as knowledge within the world. It is concerned with the very bases of knowledge – its nature, and forms and how it can be acquired, and how it can be communicated to other human beings. It focuses on the nature of human knowledge and comprehension that you, as the researcher or knower, can possibly acquire so as to be able to extend, broaden and deepen understanding in your field of research. Schwand (1997) defines it as the study of the nature of knowledge and justification. And so, in considering the epistemology of your research, you ask questions like: Is knowledge something which can be acquired on the one hand, or, is it something which has to be personally experienced? What is the nature of knowledge and the relationship between the knower and the would-be known? What is the relationship between me, as the inquirer, and what is known? These questions are important

because they help the researcher to position themselves in the research context so that they can discover what else is new, given what is known. And so to understand the epistemological element of your paradigm, you should ask the very important question of how we know what we know?

This question is the basis for investigating 'truth'. Whereas it might be debatable as to whether there is such a thing as 'truth' (Davidson, 2000), if we take factual evidence as truth, then epistemology helps you to ask factual questions, such as how do we know the truth? What counts as knowledge? These are particularly important questions because one of the criteria by which higher degree research is judged is its contribution to knowledge. In trying to articulate the answers to the above questions, researchers can draw from four sources of knowledge. Those sources are intuitive knowledge, authoritative knowledge, logical knowledge, and empirical knowledge (Slavin, 1984). If you rely on forms of knowledge such as beliefs, faith, and intuition, then the epistemological basis of your research is intuitive knowledge. If you rely on data gathered from people in the know, books, leaders or organisations, then your epistemology is grounded on authoritative knowledge.

If you put emphasis on reason as the surest path to knowing the truth, then this approach is called rationalist epistemology or logical knowledge. On the other hand, if you put emphasis on the understanding that knowledge is best derived from sense experiences, and demonstrable, objective facts, then your approach leans towards empirical epistemology. Epistemology is important because, it helps you to establish the faith you put in your data. It affects how you will go about uncovering knowledge in the social context that you will investigate.

ONTOLOGY OF A PARADIGM

Ontology is a branch of philosophy concerned with the assumptions we make in order to believe that something makes sense or is real, or the very nature or essence of the social phenomenon we are investigating (Scotland, 2012). It is the philosophical study of the nature of existence or reality, of being or becoming, as well as the basic categories of things that exist and their relations. It examines your underlying belief system as the researcher, about the nature of being and existence. It is concerned with the assumptions we make in order to believe that something makes sense or is real, or the very nature or essence of the social phenomenon we are investigating. It helps you to conceptualise the form and nature of reality and what you believe can be known about that reality. Philosophical assumptions about the nature of reality are crucial to understanding how you make meaning of the data you gather. These assumptions, concepts or propositions help to orientate your thinking about the research problem, its significance, and how you might approach it so as to contribute to its solution.

Ontology is so essential to a paradigm because it helps to provide an understanding of the things that constitute the world, as it is known (Scott & Usher, 2004). It seeks to determine the real nature, or the foundational concepts which constitute themes that we analyse to make sense of the meaning embedded in research data. It makes you ask questions such as: Is there reality out there in the social world or is it a construction, created by one's own mind? What is the nature of reality? In other words, Is reality of an objective nature, or the result of individual cognition? What is the nature of the situation being studied? Ontology enables you to examine your underlying belief system and philosophical assumptions as the researcher, about the nature of being, existence and reality.

Philosophical assumptions about the nature of reality are crucial to understanding how you make meaning of the data you gather. These assumptions, concepts or propositions help to orientate your thinking about the research problem, its significance, and how you might approach it so as to

answer your research question, understand the problem investigated and contribute to its solution.

METHODOLOGY OF A PARADIGM

Methodology is the broad term used to refer to the research design, methods, approaches and procedures used in an investigation that is well planned to find out something (Keeves, 1997). For example, data gathering, participants, instruments used, and data analysis, are all parts of the broad field of methodology. In sum, the methodology articulates the logic and flow of the systematic processes followed in conducting a research project, so as to gain knowledge about a research problem.

It includes assumptions made, limitations encountered and how they were mitigated or minimised. It focuses on how we come to know the world or gain knowledge about part of it (Moreno, 1947). In considering the methodology for your research proposal, you should ask yourself the question: How shall I go about obtaining the desired data, knowledge and understandings that will enable me to answer my research question and thus make a contribution to knowledge.

In really simple terms, the three most common paradigms are explained below (and are shown in this epistemology diagram too, taken from here):

- **Positivists** believe that there is a single reality, which can be measured and known, and therefore they are more likely to use quantitative methods to measure and this reality.
 - **Constructivists** believe that there is no single reality or truth, and therefore reality needs to be interpreted, and therefore they are more likely to use qualitative methods to get those multiple realities.
 - **Pragmatists** believe that reality is constantly renegotiated, debated, interpreted, and therefore the best method to use is the one that solves the problem
- The table below (which I created) gives a more detailed overview of each paradigm (and contains subjectivism and critical too), and your own research paradigm could very well sit in between one of the paradigms. You could use a top down or a bottom up approach to decide where your research sits.

In a bottom up approach, you decide on your research question, then you decide which methods, methodology, theoretical perspective you will approach your research from. In reality, I believe it's probably neither strictly a top down or bottom up approach, you probably go back and forth till you find the right fit. I believe each research project would have a different research paradigm and hence a different theoretical perspective.

Applied, then to social psychology, it is important to understand the tension, throughout its history, between:

1. A more traditional experimental (quantitative) approach, which sees social reality as a set of facts to be known for all time by measuring people in the laboratory;
2. A more critical, discursive (qualitative) approach, which sees social reality as mutually constructed between people in the real world."

However, I must add that pragmatism (and hence mixed methods research) is also being increasingly used in social sciences.

THE ADOPTION OF NARRATIVE WITHIN PSYCHOLOGY

Narrative approaches have been applied diversely through a vast number of distinct fields. These include history[20–22], philosophy[23], sociology[24,25], anthropology[26], education[27,28], social-work[29,30] and psychology[31–33]. However, the foundations of the broad area that is now referred to as the narrative approach in psychology have their roots mainly in writings within literary theory[34].

A considerable body of work now exists in relation to policy-making and policy analysis[35,36][see, for example, 35,36], with an ever-increasing proportion of this work looking at climate change and environmental research[17,19]. The turn to narrative ways of understanding human action and experience has its theoretical place within what has generally been termed 'the interpretative turn' in the social sciences[37,38]. When adopted by psychology, the interpretative turn was a way in which certain writers such as Bruner[32] intended to 'return' to a theoretical position of understanding individual psychology that had been seen to be overwhelmingly dominated by mechanistic metaphors[39] and the normative 'cognitive revolution'[32]. According to Bruner, the cognitive revolution, which developed from the 1950s alongside the evolution of the information communication technologies, was an attempt to understand human actions and psychological processes as being analogous to those of a computer, using as its base a computational information-processing metaphor to explore how individuals make sense of their world[32]. Similarly, Sarbin argues that the dominant worldview in modern Western civilisation relies on the 'root metaphor' of mechanism[39]. He argues that by drawing on such a metaphor we come to understand and explain our lives in terms of 'drives' and 'forces' that determine the causes of behaviour that underpin human experience.

CONCLUSION

This essay started by asserting that the work existing on the topic of pro-environmental behaviours within environmental psychology has not had the wide social impact needed to address the challenges arising as a result of climate change. Whilst we know more about people's decision-making and attitudes and the factors that influence behaviours as a result of the 40 years of work on pro-environmental behaviours, there hasn't been a subsequent change in the way in which people act in relation to energy.

The essay has argued that owing to the complexity associated with climate change, energy use and sustainability, the use of a normative social cognitive paradigm starts from a position that removes people from their social and cultural context. A number of researchers from across the social sciences have, in the last decade, provided strong arguments for the value of adopting narrative approaches in understanding behavioural responses to climate change and the need to embed energy efficiency into daily practices.

Such work has looked at how people make sense of their lives and how energy policies can embed particular narratives within them in order to evoke particular individual responses and understand community-level approaches to environmental challenges. However, the move towards narrative within pro-environmental psychology remains in its infancy.

In this essay I have sought to redress this balance by exploring the development of what has become known as the 'narrative turn' in psychology, in order to provide a canvas upon which further applications of narrative within pro-environmental psychological research can build. The paper has reviewed ways in which various writers have adopted the narrative metaphor in attempting to understand individual and social understanding. As McAdams has argued, narratives are essential to our human development and understanding: "We are tellers of tales. We each seek to provide our

scattered and often confusing experiences with a sense of coherence by arranging the episodes of our lives into stories”

PARADIGMS OF WESTERN PSYCHOLOGY: POSITIVISM

As a philosophical ideology and movement, positivism first assumed its distinctive features in the work of Comte, who also named and systematized the science of sociology. It then developed through several stages known by various names, such as empiriocriticism, logical positivism, and logical empiricism, finally merging, in the mid-20th century, into the already existing tradition known as analytic philosophy.

The basic affirmations of positivism are (1) that all knowledge regarding matters of fact is based on the “positive” data of experience and (2) that beyond the realm of fact is that of pure logic and pure mathematics. Those two disciplines were already recognized by the 18th-century Scottish empiricist and skeptic David Hume as concerned merely with the “relations of ideas,” and, in a later phase of positivism, they were classified as purely formal sciences.

On the negative and critical side, the positivists became noted for their repudiation of metaphysics—i.e., of speculation regarding the nature of reality that radically goes beyond any possible evidence that could either support or refute such “transcendent” knowledge claims. In its basic ideological posture, positivism is thus worldly, secular, antitheological, and antimetaphysical.

Strict adherence to the testimony of observation and experience is the all-important imperative of positivism. That imperative was reflected also in the contributions by positivists to ethics and moral philosophy, which were generally utilitarian to the extent that something like “the greatest happiness for the greatest number of people” was their ethical maxim. It is notable, in this connection, that Comte was the founder of a short-lived religion, in which the object of worship was not the deity of the monotheistic faiths but humanity.

The proximate roots of positivism, however, clearly lie in the French Enlightenment, which stressed the clear light of reason, and in 18th-century British empiricism, particularly that of Hume and of Bishop George Berkeley, which stressed the role of sense experience. Comte was influenced specifically by the Enlightenment Encyclopaedists (such as Denis Diderot, Jean d’Alembert, and others) and, especially in his social thinking, was decisively influenced by the founder of French socialism, Claude-Henri, comte de Saint-Simon, whose disciple he had been in his early years and from whom the very designation *positivism* stems.

Comte’s positivism was posited on the assertion of a so-called law of the three phases (or stages) of intellectual development. There is a parallel, as Comte saw it, between the evolution of thought patterns in the entire history of humankind, on the one hand, and in the history of an individual’s development from infancy to adulthood, on the other. In the first, or so-called theological, stage, natural phenomena are explained as the results of supernatural or divine powers. It matters not whether the religion is polytheistic or monotheistic; in either case, miraculous powers or wills are believed to produce the observed events. This stage was criticized by Comte as anthropomorphic—i.e., as resting on all-too-human analogies. Generally, animistic explanations—made in terms of the volitions of soul-like beings operating behind the appearances—are rejected as primitive projections of unverifiable entities

The second phase, called metaphysical, is in some cases merely a depersonalized theology: the observable processes of nature are assumed to arise from impersonal powers, occult qualities, vital forces, or entelechies (internal perfecting principles). In other instances, the realm of observable

facts is considered as an imperfect copy or imitation of eternal ideas, as in Plato's metaphysics of pure forms. Again, Comte charged that no genuine explanations result; questions concerning ultimate reality, first causes, or absolute beginnings are thus declared to be absolutely unanswerable. The metaphysical quest can lead only to the conclusion expressed by the German biologist and physiologist Emil du Bois-Reymond: "Ignoramus et ignorabimus" (Latin: "We are and shall be ignorant"). It is a deception through verbal devices and the fruitless rendering of concepts as real things.

THE CRITICAL POSITIVISM OF MACH AND AVENARIUS

The influences of Hume and of Comte were also manifest in important developments in German positivism, just prior to World War I. The outstanding representatives of this school were Ernst Mach—a philosophical critic of the physics of Isaac Newton, an original thinker as a physicist, and a historian of mechanics, thermodynamics, and optics—and Richard Avenarius, founder of a philosophy known as empiriocriticism.

Mach and, along with him, Wilhelm Ostwald, the originator of physical chemistry, were the most prominent opponents of the atomic theory in physics and chemistry. Ostwald even attempted to derive the basic chemical laws of constant and multiple proportions without the help of the atomic hypothesis. To the positivist the atom, since it could not be seen, was to be considered at best a "convenient fiction" and at worst an illegitimate ad hoc hypothesis. Hans Vaihinger, a subjectivist who called himself an "idealistic positivist," pursued the idea of useful fictions to the limit and was convinced that the concept of the atom, along with the mathematical concepts of the infinite and the infinitesimal and those of causation, free will, the economic actor, and the like, were altogether fictitious, some of them even containing internal contradictions.

POST POSITIVISM OF PARADIGMS PSYCHOLOGY

Let's start our very brief discussion of philosophy of science with a simple distinction between **epistemology** and **methodology**. The term epistemology comes from the Greek word *epistēmē*, their term for knowledge. In simple terms, epistemology is the philosophy of knowledge or of how we come to know. Methodology is also concerned with how we come to know, but is much more practical in nature. Methodology is focused on the specific ways – the methods – that we can use to try to understand our world better. Epistemology and methodology are intimately related: the former involves the *philosophy* of how we come to know the world and the latter involves the *practice*.

When most people in our society think about science, they think about some guy in a white lab coat working at a lab bench mixing up chemicals. They think of science as boring, cut-and-dry, and they think of the scientist as narrow-minded and esoteric (the ultimate nerd – think of the humorous but nonetheless mad scientist in the *Back to the Future* movies, for instance). A lot of our stereotypes about science come from a period where science was dominated by a particular philosophy – **positivism** – that tended to support some of these views. Here, I want to suggest (no matter what the movie industry may think) that science has moved on in its thinking into an era of **post-positivism** where many of those stereotypes of the scientist no longer hold up.

Let's begin by considering what positivism is. In its broadest sense, positivism is a rejection of metaphysics (I leave it to you to look up that term if you're not familiar with it). It is a position that holds that the goal of knowledge is simply to describe the phenomena that we experience. The purpose of science is simply to stick to what we can observe and measure. Knowledge of anything beyond that, a positivist would hold, is impossible. When I think of positivism (and the related philosophy of logical positivism) I think of the behaviorists in mid-20th Century psychology. These were the

mythical 'rat runners' who believed that psychology could only study what could be directly observed and measured. Since we can't directly observe emotions, thoughts, etc. (although we may be able to measure some of the physical and physiological accompaniments), these were not legitimate topics for a scientific psychology. B.F. Skinner argued that psychology needed to concentrate only on the positive and negative reinforcers of behavior in order to predict how people will behave – everything else in between (like what the person is thinking) is irrelevant because it can't be measured.

In a positivist view of the world, science was seen as the way to get at truth, to understand the world well enough so that we might predict and control it. The world and the universe were deterministic – they operated by laws of cause and effect that we could discern if we applied the unique approach of the scientific method. Science was largely a mechanistic or mechanical affair. We use deductive reasoning to postulate theories that we can test. Based on the results of our studies, we may learn that our theory doesn't fit the facts well and so we need to revise our theory to better predic

reality. The positivist believed in *empiricism* – the idea that observation and measurement was the core of the scientific endeavor. The key approach of the scientific method is the experiment, the attempt to discern natural laws through direct manipulation and observation.

OK, I am exaggerating the positivist position (although you may be amazed at how close to this some of them actually came) in order to make a point. Things have changed in our views of science since the middle part of the 20th century. Probably the most important has been our shift away from positivism into what we term *post-positivism*. By post-positivism, I don't mean a slight adjustment to or revision of the positivist position – post-positivism is a wholesale rejection of the central tenets of positivism. A post-positivist might begin by recognizing that the way scientists think and work and the way we think in our everyday life are not distinctly different.

Scientific reasoning and common sense reasoning are essentially the same process. There is no difference in kind between the two, only a difference in degree. Scientists, for example, follow specific procedures to assure that observations are verifiable, accurate and consistent. In everyday reasoning, we don't always proceed so carefully (although, if you think about it, when the stakes are high, even in everyday life we become much more cautious about measurement. Think of the way most responsible parents keep continuous watch over their infants, noticing details that non-parents would never detect).

One of the most common forms of post-positivism is a philosophy called **critical realism**. A critical realist believes that there is a reality independent of our thinking about it that science can study. (This is in contrast with a **subjectivist** who would hold that there is no external reality – we're each making this all up!). Positivists were also realists. The difference is that the post-positivist critical realist recognizes that all observation is fallible and has error and that all theory is revisable.

In other words, the critical realist is *critical* of our ability to know reality with certainty. Where the positivist believed that the goal of science was to uncover the truth, the post-positivist critical realist believes that *the goal of science is to hold steadfastly to the goal of getting it right about reality, even though we can never achieve that goal!* Because all measurement is fallible, the post-positivist emphasizes the importance of multiple measures and observations, each of which may possess different types of error, and the need to use **triangulation** across these multiple errorful sources to try to get a better bead on what's happening in reality. The post-positivist also believes that all observations are theory-laden and that scientists (and everyone else, for that matter) are inherently biased

by their cultural experiences, world views, and so on. This is not cause to give up in despair, however. Just because I have my world view based on my experiences and you have yours doesn't mean that we can't hope to translate from each other's experiences or understand each other. That is, post-positivism rejects the **relativist** idea of the **incommensurability** of different perspectives, the idea that we can never understand each other because we come from different experiences and cultures. Most post-positivists are **constructivists** who believe that we each construct our view of the world based on our perceptions of it. Because perception and observation is fallible, our constructions must be imperfect.

So what is meant by **objectivity** in a post-positivist world? Positivists believed that objectivity was a characteristic that resided in the individual scientist. Scientists are responsible for putting aside their biases and beliefs and seeing the world as it 'really' is. Post positivists reject the idea that any individual can see the world perfectly as it really is. We are all biased and all of our observations are affected (theory-laden).

Our best hope for achieving objectivity is to triangulate across multiple fallible perspectives! Thus, objectivity is not the characteristic of an individual, it is inherently a social phenomenon. It is what multiple individuals are trying to achieve when they criticize each other's work. We never achieve objectivity perfectly, but we can approach it. The best way for us to improve the objectivity of what we do is to do it within the context of a broader contentious community of truth-seekers (including other scientists) who criticize each other's work. The theories that survive such intense scrutiny are a bit like the species that survive in the evolutionary struggle. (This is sometimes called the **natural selection theory of knowledge** and holds that ideas have 'survival value' and that knowledge evolves through a process of variation, selection and retention). They have adaptive value and are probably as close as our species can come to being objective and understanding reality.

Clearly, all of this stuff is not for the faint-of-heart. I've seen many a graduate student get lost in the maze of philosophical assumptions that contemporary philosophers of science argue about. And don't think that I believe this is not important stuff. But, in the end, I tend to turn pragmatist on these matters. Philosophers have been debating these issues for thousands of years and there is every reason to believe that they will continue to debate them for thousands of years more. Those of us who are practicing scientists should check in on this debate from time to time (perhaps every hundred years or so would be about right). We should think about the assumptions we make about the world when we conduct research. But in the meantime, we can't wait for the philosophers to settle the matter. After all, we do have our own work to do.

CRITICAL PERSPECTIVE OF PARADIGMS PSYCHOLOGY

At this point you have learned about four different theoretical paradigms we use to understand communication. One problem with these approaches is they often lack an explicit critique of the status quo of communication. Put another way, they serve as a general approach to understand communication norms rather than challenge them. We all realize that there are communication realities in the world that are hurtful and oppressive to particular people, and that there are people in the world that use communication to serve their own needs and interests.

THE NEED FOR CRITICAL THEORIES

The **Critical Theories Paradigm** helps us *understand how communication is used to oppress, and*

provides ways to foster positive social change (Foss & Foss; Fay). Critical Theories challenge the status quo of communication contexts, looking for alternatives to those forms of oppressive communication. These theories differ from other theoretical approaches because they seek praxis as the overarching goal. **Praxis** is *the combination of theory and action*. Rather than simply seeking to understand power structures, critical theories actively seek to change them in positive ways. Easily identifiable examples of critical approaches are Marxism, postmodernism, and feminism

These critical theories expose and challenge the communication of dominant social, economic, and political structures. Areas of inquiry include language, social relationships, organizational structures, politics, economics, media, cultural ideologies, interpersonal relationships, labor, and other social movements.

Cultural Studies focus on *understanding the real-life experiences of people, examining communication contexts for hidden power structures, and accomplishing positive social change as a result* (Dines and Humez; Kellner). According to Kellner, cultural studies involves three interconnected elements necessary for understanding, evaluating and challenging the power dynamics embedded in communication—political economy, textual analysis, and audience reception.

- **Political economy** focuses on *the macro level of communication*. Specifically, this part of cultural studies looks at the way media as text are situated in a given cultural context, and the political and economic realities of the cultural context. In the U.S., we would note that the political economy is one marked with gender, racial, and class inequities.
- **Textual analysis** involves *the process of deconstructing and analyzing elements of a media text*. If you wanted to look at a magazine with a critical eye, you would pay attention to the visual elements (the pictures in the ads; the celebrity photos, and any other drawings, cartoons or illustrations), the verbal messages (the text of the ads, the copy, captions that accompany the photographs), and the relationship between the advertisements and the copy. For example, is there an ad for Clinique eye shadow next to an article on the “hot new beauty tips for fall?” You would also want to pay attention to the representation of gender, race, and class identities as well. Are there any differences or similarities between the portrayal of white women and women of color? What sort of class identity is being offered as the one to emulate?
- **Audience reception** asks us to consider *the role of the text for the audience that consumes it*. You might want to learn why people read particular magazines—what purpose does it fill, what is the social function of this text?

ORIGINS OF CRITICAL THEORIES IN COMMUNICATION

Marxism is one of the earliest origins of critical theory. In addition, postmodernism, feminism, and postcolonialism have greatly influenced how critical theories have grown and expanded to challenge a greater number of social power structures. While each of these approaches examines a different area of oppression, all are critical approaches to enact great social changes, not only in western societies, but in cultures worldwide.

In the late 19th and early 20th centuries, Karl Marx’s ideas challenged the status quo of newly emerging industrial societies. As societies moved from agrarian-based economies to ones based in industrial manufacturing, there became an increasing division between the rich and the poor — much like the income inequality talked about so much today. Marx, in two of his most well-known works, *The Communist Manifesto* and *Capital*, argued that working class laborers were being oppressed by those in power, specifically the owners of manufacturing plants.

In any discussion of **Postmodernism**, another critical theoretical perspective, the difficulty of

defining the term is invariably part of the discussion. *Modern* refers to just now (from *modo* in Latin) and *post* means after.

Thus, this term translates into “after just now”—an idea that can be difficult to wrap our heads around. How do you, for example, point to or mark the period after just now? (Covino & Jolliffe, 76). In discussing the postmodern condition, Lyotard explained the relationship between those who have and don't have social power: “The [decision makers] allocate our lives for the growth of power. In matters of social justice and scientific truth alike, the legitimation of that power is based on optimizing the system's performance— efficiency” (27).

A third major influence on the development of the Critical Theories Paradigm comes from feminist theories. **Feminist theories** explore *power structures that create and recreate gendered differentiations in societies* (Foss & Foss; Dervin; MacKinnon). Critical feminist theories contend that gender relations are often oppressive to both men and women, and that they support an institution based on patriarchal values. Thus, critical feminist theories challenge dominant assumptions and practices of gender in ways that foster more equal and egalitarian forms of communication and social structures in society.

When discussing feminism and feminist theories we refer to a set of multiple and diverse theories. Feminist theories include a wide range of philosophical arguments, economic structures, and political viewpoints. Some of these include Marxist feminism, which focuses on the division of labor as a source of gender inequality, and liberal feminism, which asserts that men and women should have equal status in the culture—such as voting rights, educational and professional opportunities, and equal pay. Eco-feminism recognizes that all parts of the universe are interconnected and that oppression of women and other minorities is analogous to the oppression of the natural environment such as in the cutting down of natural forests to meet consumer demands for paper goods, or the killing of animals for the eating of meat.

CRITICAL THEORIES IN ACTION

Whether we listen to music on our phones, watch TV, go to the movies, or read a magazine, most of us consume media. Have you ever stopped to think about who puts together those messages? Have you wondered what their goals might be and why they want to send the messages they do? One way we can use critical theories is to examine who owns what media to determine what they are trying to accomplish (Croteau & Hoynes).

For example, why does General Electric want to own companies like RCA and NBC? Why does a company like Seagram's want to buy MCA (Universal Studios) and Polygram records? What world-views are these companies creating in the media they produce? These are all questions for which we might consider using theories from the Critical Theories Paradigm. Did you know that in 1983 50 corporations controlled most of the U.S. media (papers, television, movies, magazines, etc.) and that by 2004 that number has dropped down to five corporations (Bagdikian)? Using Critical Theories Paradigm, we can begin to examine the messages that so few companies are constructing and their impacts on how we understand the world around us as shaped through these messages.

Other examples from the critical paradigm include works that examine gender, consumerism, advertising, and television. In her work, *Who(se) Am I? The Identity and Image of Women in Hip-Hop* Perry examines the potential danger and damage to African-American women through their

objectification in Hip-Hop videos. Carole A.

Stabile examines the labor and marketing practices of Nike in her article, Nike, Social Responsibility, and the Hidden Abode of Production. Clint C. Wilson II and Felix Gutierrez discuss the portrayal of people of color in advertising in their article, Advertising and People of Color, while Jackson Katz explores mask of masculinity with his film, Tough Guise 2: The Ongoing Crisis of Violent Masculinity. We use critical theories to reveal a vast range of possible ideological structures that create and foster dominant world-views, and to challenge and change those ideologies that oppress others.

STRENGTHS

A significant strength of the Critical Theories Paradigm is that it combines theory and practice, seeking to create actual change from theoretical development. Rather than seeking prediction and control, or explanation and understanding, critical theories seek positive social change. The intent behind these theoretical perspectives is to help empower those whose world-views and ideological perspectives have not found equality in social contexts. At their best, critical theories have the potential to enact large-scale social change for both large and small groups of people.

WEAKNESSES

A potential weakness of critical theories is their dependence on social values. While empirical laws theories seek an objective reality, critical theories highlight subjective values that guide communication behaviors. When values conflict the question of "whose values are better?" emerges. Because values are subjective, answering this question is often filled with much conflict and debate. The example of gay marriage highlights a current debate taking place over ideological values. How do we define marriage? And, whose definition is best?

CRITICAL STANCE TOWARD TAKEN-FOR-GRANTED KNOWLEDGE

Social constructionism takes a critical stance toward psychology's taken-for-granted ways of understanding the world and ourselves. Psychology has modeled itself on the natural sciences. These assume the epistemological approach of positivism, the view that knowledge comes from objective, unbiased observation of the world and that there is a true or accurate description of people, events, and things that science endeavors to reveal.

Positivism assumes that the world comes to us ready-made, and our task is to discover its true nature. Within this epistemology, the experiment is the gold-standard research paradigm (see "Ontology and Epistemology and Positivism and Realism"). But social constructionism cautions us to be suspicious of our assumptions about how the world appears to be. For example, it may seem obvious to us that there are two naturally occurring categories of human being, men and women. But social constructionism bids us to seriously question whether the categories "man" and "woman" are simply a reflection of distinct types of human being and to consider instead that they are categories constructed by people themselves in the course of social interaction. The same is true of other highly socially relevant concepts, such as "race." While in former times, it may have seemed unquestionable that there exist different races of human beings, each with its own physical and psychological characteristics, research has failed to find any genetic basis for such distinctions; while human beings come in a diverse range of shapes, sizes, and colors, there is no evidence for the existence of genetically discrete races (see, e.g., Yudell et al. 2016).

We may ask why this matters and what social significance it has. The social constructionist would

argue that challenging the existence of such natural categories helps us to disrupt and destabilize many of the assumptions we hold about men and women and about nonwhite peoples, assumptions that underpin inequitable practices. The familiar arguments that particular characteristics (or lack of them) are natural for women or men, or for black people, are frequently used to defend inequalities.

SOCIAL CONSTRUCTIONISM

Social constructionism represents a radical challenge to mainstream psychology in both theory and research. It began to emerge in social psychology in the 1970s and 1980s as a recognizable body of work by those who would, today, refer to themselves as, for example, “critical psychologists” and “discursive psychologists.” Social constructionism poses a challenge to psychology’s individualistic, essentialist, and intrapsychic model of the person, replacing it with a radically social account of personhood and is, therefore, essentially a social psychology.

The taken-for-granted topics of mainstream psychology and social psychology, such as attitudes, motivation, personality, and emotion, were brought into question as structural features of the human psyche and instead seen as social constructions achieved through social interaction and language. As Craib (1997) points out, many social constructionist assumptions are fundamental to psychology’s disciplinary cousin, sociology, and it is a measure of the unhelpful separation of sociology and psychology since the early twentieth century that psychologists have only recently begun to engage with social constructionist ideas.

ORIGINS AND INFLUENCES

Although social constructionism is a relatively new term in the social sciences, especially psychology, its ideas and practices have a longer history in disciplines such as sociology, philosophy, and linguistics. The key tenet of social constructionism is that our knowledge of the world, including our understanding of human beings, is a product of human thought, language, and interaction rather than grounded in an observable and definable external reality.

Such an idea, although strange to many psychologists, is fundamental to longstanding concepts in the sociology of knowledge, such as ideology and false consciousness, which focus on how sociocultural forces construct our knowledge in particular ways. An important contributor to social constructionist thinking has been the micro-sociological approach of symbolic interactionism (see Berger and Luckmann 1966). George Mead, at the University of Chicago, had developed this approach from the earlier work of Herbert Blumer and later published his ideas in *Mind, Self and Society* (1934).

Mead had studied at Leipzig University under Wilhelm Wundt, who believed in the importance of sociocultural factors, such as myth, folk customs, and religion, in understanding human behavior and experience. Mead took up these ideas in his development of symbolic interactionism, which argues that people construct and negotiate identities for themselves and others through their everyday social interactions with each other. Language, as a system of socially shared symbolic meanings, is central to this constructive process.

In psychology, the emergence of social constructionism is usually dated from Gergen’s (1973) paper *Social Psychology as History* in which he argues that all knowledge, including psychological knowledge, is historically and culturally specific; we, therefore, must look beyond the individual and enquire into social, political, and economic realms for a proper understanding of the evolution of

present-day psychology and social life.

He argues that it is pointless to look for final descriptions of people or society, since the only abiding feature of psychological and social life is that it is continually changing. Social psychology, thus, becomes a form of historical undertaking, since all we can ever do is to try to understand and account for how the world and people appear to be at the present time.

Gergen's paper was written at the time of what is referred to as "the crisis in social psychology" (see, e.g., Harré and Secord 1972; Armistead 1974), which provided some of the momentum for social constructionist ideas in psychology. This crisis centered on worries about the way that social psychology's agenda was driven by the needs and motivations of powerful factions (government, the military, and commerce); social psychology as a discipline can be said to have emerged from the attempts by psychologists to provide the US and British governments during the Second World War with knowledge that could be used for propaganda and to manipulate behavior. Social psychology, therefore, had historically served, and was paid for by, those in positions of power, both in government and in industry.

Its theories and research findings often seemed to bring further oppression to relatively powerless and marginalized groups (women, ethnic minorities, working class people, and those of nonnormative sexual orientation), and this operated partly through the study of human phenomena in socially decontextualized laboratory environments, since experiments ignored the real-world contexts which, it was argued, give human conduct its meaning. There was a move to attend to this social context, as well as to explore human phenomena from the perspective of psychology's "subjects" themselves rather than privilege the perspective and voice of the relatively powerful researcher. These concerns encouraged social psychologists to embrace the ideas already flourishing in neighboring disciplines, including micro-sociology, and also fed into the burgeoning call to recognize qualitative research methods as legitimate and fruitful for the discipline of psychology.

EXISTENTIAL-PHENOMENOLOGICAL PSYCHOLOGY

This approach to psychology is inspired by the philosophical tradition developed by thinkers such as Buber, Kierkegaard, Nietzsche, Heidegger, Gadamer, de Beauvoir, Sartre, Marcel, Merleau-Ponty, and Levinas. Existential-phenomenology seeks to develop an in-depth, embodied understanding of human existence. It challenges approaches in psychology and psychiatry that view human beings in a reductionistic manner.

The program distinguishes itself by using this philosophical tradition as a foundation for psychotherapy and growth, and as a source of insight into the richness and diversity of human psychological experience. Existential-Phenomenological Psychology is humanistic in that it challenges the modern tendency to interpret the human condition through a set of narrow technological lenses. It engages with and appreciates the wisdom accumulated by the rich traditions of reflection on the human condition in the social sciences and humanities. It deepens our understanding of the experiences and perspectives of others through its focus upon the meanings that we make in our lives and the choices that are reflected in our understandings and actions.

The phenomenological dimension nourishes an openness to understanding the lives and needs of others by helping us to identify and set aside our theoretical and ideological prejudgments as we approach our work as therapists. Finally, the existential-phenomenological approach is ethical in recognizing that the fundamental characteristic of being human is to be responsible to others. According to J. H. van den Berg (1972), the development of phenomenological psychology began in

1894. At that time, Wilhelm Dilthey analyzed the methods of psychology and concluded that they had been derived from the physical sciences (e.g., physics, chemistry, biology, etc.) and were thus insufficient for a science of human beings (i.e., psychology). As van den Berg put it: Like the physicist, the psychologist tried to dissect the object of his studies; he tried to isolate the elementary factors of mental life to reconstruct actual mental life with these elementary factors. While it was obvious, even then, that . . . an all-embracing psychology, could not be achieved this way, Dilthey was the first to point this out In his opinion, the essential characteristic of the psychic aspect of human life is that it is . . . not a collection of elements. The psychologist . . . must try to find a method that originates from the subject itself. (pp. 126-127) As psychology continued to grow and develop since the time of Dilthey, more and more psychologists came to see the need for a new approach to psychology. For example, the Gestalt psychologists maintained that consciousness

EXISTENTIAL-PHENOMENOLOGICAL PSYCHOLOGY

cannot be broken down into discrete components and retain their meaningfulness (Lahey, 1989). That is, in order to attain a comprehensive understanding of a person's conscious awareness of the world, psychologists cannot simply put together a group of previously abstracted parts. Humanistic psychologists, such as Carl Rogers and Abraham Maslow, reacted against the movement in psychology to understand human behavior as nothing but the product of some elemental determining factor, such as unconscious drives or the law of stimulus-response.

However, I know of no tradition that has contributed more to the advance of psychology as an inquiry into human experience and behavior without resorting to impersonal logic, a sloppy eclecticism, or a theoretically and methodologically weak qualitative approach than the European (i.e., existential) phenomenological tradition. Phenomenological psychology has also continued to grow and develop since the time of Dilthey. Psychiatrists and psychologists such as Ludwig Binswanger, V. E. von Gebsattel, Erwin Straus, E. Minkowski, Aron Gurwitsch, Alfred Schutz, Ernest Schachtel, Medard Boss and many others contributed to phenomenological psychology's early development.

Seattle University, Saybrook University, The University of Dallas, Sonoma State University, The Michigan School of Professional Psychology, Point Park University, and the University of West Georgia, as well as explicitly phenomenological journals, such as the *Journal of Phenomenological Psychology*, *Phenomenology and Practice*, *The Indo-Pacific Journal of Phenomenology*, the *Humanistic Psychologist*,

The Journal of Humanistic Psychology, and *Phenomenology and the Cognitive Sciences*. However, many psychologists, if they are familiar with phenomenology at all, often misunderstand the philosophical-anthropological fundamentals of phenomenological psychology and phenomenological methodology.

Take any introduction to psychology text and search through it for an introduction to phenomenological psychology. I can almost guarantee that you will not find existential-phenomenology mentioned in the book at all. At best, you may find Viktor Frankl and/or Rollo May briefly mentioned under a section entitled "Humanistic Psychology."

My intention in writing this book is to provide a very brief introduction to existential-phenomenological psychology that instructors might use as a teaching tool for undergraduate or graduate

students. I will attempt to fashion the contents of the book according to the issues that I have experienced to be so often wondered about by students during my own years as a student of phenomenological psychology. It is my hope that this text will be resource for the reader to begin the process of becoming acquainted with phenomenological language.

In chapter one, I briefly argue in favor of the need for phenomenology by exposing some of the difficulties inherent to the predominant philosophical-anthropological viewpoints in Western thought. Chapter two lays out the most fundamental aspects of the phenomenological approach to data analysis and provides examples of phenomenological research results taken from the psychology of verbal aggression.

Chapter three demonstrates how a descriptive-interpretive viewpoint like existential-phenomenology can be used to clarify the central "object" of study in psychology: human existence. Chapter four, What Phenomenology is Not, has been included to dispel any misconceptions the reader might have or come across regarding what phenomenology is.

is large in the sense that its aim is to provide a way of thinking about and approaching psychology that differs radically from what has become common knowledge in the field. Too much time is wasted looking for how "the brain creates" mental processes—or worse, where the mind resides in the brain—despite the fact that these kinds of ideas disintegrate under the scrutiny of disciplined reflection and philosophic analysis. It seems to me that human beings are increasingly interpreting their lives in reductionistic terms as psychology grows in popularity.

CO-OPERATIVE ENQUIRY

Like any scientific research, psychological enquiry has the following goals: description, prediction, explanation, and control of behaviour, and application of knowledge so generated, in an objective manner. Let us try to understand the meaning of these terms. Description : In a psychological study, we attempt to describe a behaviour or a phenomenon as accurately as possible. This helps in distinguishing a particular behaviour from other behaviours. For example, the researcher may be interested in observing study habits among students.

Study habits may consist of diverse range of behaviours, such as attending all your classes regularly, submitting assignments on time, planning your study schedule, studying according to the set schedule, revising your work on a daily basis etc. Within a particular category there may be further minute descriptions. The researcher needs to describe her/his meaning of study habits. The description requires recording of a particular behaviour which helps in its proper understanding.

Prediction : The second goal of scientific enquiry is prediction of behaviour. If you are able to understand and describe the behaviour accurately, you come to know the relationship of a particular behaviour with other types of behaviours, events, or phenomena.

You can then forecast that under certain conditions this particular behaviour may occur within a certain margin of error.

For example, on the basis of study, a researcher is able to establish a positive relationship between the amount of study time and achievement in different subjects. Later, if you come to know that a particular child devotes more time for study, you can predict that the child is likely to get good marks in the examination. Prediction becomes more accurate with the increase in the number of persons observed.

Control : If you are able to explain why a particular behaviour occurs, you can control that behaviour by making changes in its antecedent conditions. Control refers to three things: making a particular behaviour happen, reducing it, or enhancing it. For example, you can allow the number of hours devoted to study to be the same, or you can reduce them or there may be an increase in the study hours. The change brought about in behaviour by psychological treatment in terms of therapy in persons, is a good example of control.

Application : The final goal of the scientific enquiry is to bring about positive changes in the lives of people. Psychological research is conducted to solve problems in various settings.

STEPS IN CONDUCTING SCIENTIFIC RESEARCH

Science is not so defined by what it investigates as by how it investigates. The scientific method attempts to study a particular event or phenomenon in an objective, systematic, and testable manner. The objectivity refers to the fact that if two or more persons independently study a particular event, both of them, to a great extent, should arrive at the same conclusion. For instance, if you and your friend measure the length of a table using the same measuring device, it is likely that both of you would arrive at the same conclusion about its length.

selects a theme or topic for study. Then s/he narrows down the focus and develops specific research questions or problems for the study. This is done on the basis of review of past research, observations, and personal experiences. For example, earlier you read that a researcher was interested in observing the study habits of students. For this purpose, s/he may identify different facets of study habits first, and then decide whether s/he is interested in study habit shown in the class or at home. In psychology we study a diverse range of problems related to behaviour and experiences. These problems may be related to

- (a) understanding our own behaviour (for example, how do I feel and behave when I am in a state of joy or grief? How do we reflect on our own experiences and behaviour? Why do we forget?);
- (b) understanding other individual's behaviour (for example, Is Abhinav more intelligent than Ankur? Why is someone always not able to complete her or his work on time? Can the habit of smoking be controlled? Why do some people suffering from chronic illness not take medicines?);
- (c) group influences on individual behaviour (for example, why does Rahim spend more time meeting with people than doing his work?, Why does a cyclist perform better when cycling before a group of persons than when cycling alone?);
- (d) group behaviour (for example, why does risk-taking behaviour increase when people are in a group?), and organisational level (for example, why are some organisations more successful than others? How can an employer increase the motivation of employees?). The list is long and you will learn about these various facets in subsequent chapters. If you are inquisitive, you can write down a number of problems which you may like to probe. After identification of the problem, the researcher proceeds by developing a tentative answer of the problem, which is called hypothesis. For example, based on the earlier evidence or your observation, you might develop a hypothesis 'greater is the amount of time spent by children in viewing violence on television, higher is the degree of aggression displayed by them'. In your research, you shall now try to prove whether the statement is true or false.

Collecting Data : The second step in scientific research is to collect data. Data collection requires developing a research design or a blueprint of the entire study. It requires taking decisions about the following four aspects:

- (a) participants in the study,
- (b) methods of data collection,
- (c) tools to be used in research, and
- (d) procedure for data collection. Depending upon the nature of the study, the researcher has to decide who would be the participants (or informants) in the study.

The participants could be children, adolescents, college students, teachers, managers, clinical patients, industrial workers, or any group of individuals in whom/ where the phenomenon under investigation is prevalent. The second decision is related to the use of methods of data collection, such as observation method, experimental method, correlational method, case study, etc. The researcher needs to decide about appropriate tools (for example, interview schedule, observation schedule, questionnaire, etc.) for data collection. The researcher also decides about how the tools need to be administered to collect data (i.e. individual or group).

This is followed by actual collection of data.

Drawing Conclusions : The next step is to analyse data so collected through the use of statistical procedures to understand what the data mean. This can be achieved through graphical representations (such as preparation of pie-chart, bar-diagram cumulative frequencies, etc.) and by the use of different statistical methods. The purpose of analysis is to verify a hypothesis and draw conclusions accordingly.

Revising Research Conclusions : The researcher may have begun the study with a hypothesis that there exists a relationship between viewing violence on television and aggression among children.

OVERVIEW OF CO-OPERATIVE INQUIRY

CI is a kind of action research, aimed at acquiring knowledge about human experience through action and joint reflection. The most comprehensive guide is Heron (1996). (Additional sources include Heron & Reason, 2001; Reason, 1994b, 1988d, 1994c; Reason & Bradbury, 2001; Reason & Heron, 1999; Reason & Rowan, 1981.) In its fullest form the researcher-subject distinction disappears and all participants are both co-researchers and co-subjects. Its defining features are (Heron, 1996, pp. 19-20).

PARADIGMATIC CONTROVERSIES

On the matter of hegemony, or supremacy, among postmodern paradigms, it is clear that Geertz's (1988, 1993) prophecy about the "blurring of genres" is rapidly being fulfilled. Inquiry methodology can no longer be treated as a set of universally applicable rules or abstractions. Methodology is inevitably interwoven with and emerges from the nature of particular disciplines (such as sociology and psychology) and particular perspectives (such as Marxism, feminist theory, and queer theory). So, for instance, we can read feminist critical theorists such as Olesen (Chapter 8, this volume) or queer theorists such as Gamson (Chapter 12, this volume), or we can follow arguments about

teachers as researchers (Kincheloe, 1991) while we understand the secondary text to be teacher empowerment and democratization of schooling practices. Indeed, the various paradigms are beginning to "interbreed" such that two theorists previously thought to be in irreconcilable conflict may now appear, under a different theoretical rubric, to be informing one another's arguments.

A personal example is our own work, which has been heavily influenced by action research practitioners and postmodern critical theorists. Consequently, to argue that it is paradigms that are in contention is probably less useful than to probe where and how paradigms exhibit confluence and where and how they exhibit differences, controversies, and contradictions. Major Issues Confronting All Paradigms In our chapter in the first edition of this Handbook, we presented two tables that summarized our positions, first, on the axiomatic nature of paradigms (the paradigms we considered at that time were positivism, postpositivism, critical theory, and constructivism; Guba & Lincoln, 1989). Since publication of that chapter, at least one set of authors, John Heron and Peter Reason, have elaborated upon our tables to include the participatory/cooperative paradigm (Heron, 1996; Heron & Reason, 1997, pp. 289-290).

Thus, in addition to the paradigms of positivism, postpositivism, critical theory, and constructivism, we add the participatory paradigm in the present chapter (this is an excellent example, we might add, of the hermeneutic elaboration so embedded in our own view, constructivism). Our aim here is to extend the analysis further by building on Heron and Reason's additions and by rearranging the issues to reflect current thought.

Our issues may be important because new or extended theoretical and/or field-oriented treatments for them are newly available and reflexivity are two such issues. This chapter reprises the original but adds the axioms of the participatory paradigm proposed by Heron and Reason (1997). It deals with seven issues and represents an update of selected issues first presented in the old "Voice" in the 1994 version of this book. It has been renamed "inquirer posture," and a redefined "voice" has been inserted in the current.

In all cases except "inquirer posture," the entries for the Participatory paradigm are those proposed by Heron and Reason; in the one case not covered by them, we have added a notation that we believe captures their intention. We make no attempt here to reprise the material well discussed in our earlier Handbook chapter. Instead, we focus solely on the issues in: axiology; accommodation and commensurability; action; control; foundations of truth and knowledge; validity; and voice, reflexivity, and postmodern textual representation. We believe these seven issues to be the most important at this time. While we believe these issues to be the most contentious, we also believe they create the intellectual, theoretical, and practical space for dialogue, consensus, and confluence to occur. There is great potential for interweaving of viewpoints, for the incorporation of multiple perspectives, and for borrowing or bricolage, where borrowing seems useful, richness enhancing, or theoretically heuristic. For instance, even though we ourselves social constructivists/constructivists, our call to action embedded in the authenticity criteria we elaborated in Fourth Generation Evaluation (Guba & Lincoln, 1989) reflects strongly the bent to action embodied in critical theorists' perspectives. And although Heron and Reason have elaborated a model they call cooperative paradigm, careful reading of their proposal reveals a form of inquiry that is post.

POSITIVE, POSTMODERN, AND CRITICALISM IN ORIENT

As a result, the reader familiar with several theoretical and paradigmatic strands of research will find that echoes of many streams of thought come together in the extended table. What this means

is that the categories, as Laurel Richardson (personal communication, September 12, 1998) has pointed out, "are fluid, indeed what should be a category keeps altering, enlarging." She notes that "even JS [we] write, the boundaries between the paradigms are shifting." This is the paradigmatic equivalent of the Geertzian "blurring of genres" to which we referred earlier.

Our own position is that of the constructionist camp, loosely defined. We do not believe that criteria for judging either "reality" or validity are absolutist (Bradley & Schaefer, 1998), but rather are derived from community consensus regarding what is "real," what is useful, and what has meaning (especially meaning for action and further steps). We believe that a goodly portion of social phenomena consists of the meaning-making activities of groups and individuals around those phenomena. The meaning-making activities themselves are of central interest to social constructionists/constructivists, simply because it is the meaning-making/sense-making/ attribution activities that shape action (or inaction). The meaning-making activities themselves can be changed when they are found to be incomplete, faulty (e.g., discriminatory, oppressive, or non liberatory), or malformed (created from data that can be shown to be false).

WHAT IS SIGNIFICANT INDIAN PARADIGMS ON PSYCHOLOGICAL KNOWLEDGE: YOGA, BHAGAVAD GITA, BUDDHISM, SUFISM, AND INTEGRAL YOGA. SCIENCE AND SPIRITUALITY (AVIDYA AND VIDYA). THE PRIMACY OF SELF-KNOWLEDGE IN INDIAN PSYCHOLOGY?

SIGNIFICANT INDIAN PARADIGMS ON PSYCHOLOGICAL KNOWLEDGE: YOGA, BHAGAVAD GITA, BUDDHISM, SUFISM, AND INTEGRAL YOGA. SCIENCE AND SPIRITUALITY (AVIDYA AND VIDYA). THE PRIMACY OF SELF-KNOWLEDGE IN INDIAN PSYCHOLOGY

Significant Indian paradigms on psychological knowledge: Yoga

PSYCHOLOGICAL KNOWLEDGE OF YOGA

"Is there therapy in the Vedas?" I was a bit taken aback by this inquiry from a young and dedicated yoga practitioner. He had been struggling for years with psychological problems. Although he had embraced a traditional path of yogic transformation, he found the help he needed in a more modern self-help process based on contemporary psychology. As I thought about his inquiry, however, the answer seemed obvious. Rich in a tradition of intact family and community support, those born in traditional India did not need to rely on specialists to sort out mental afflictions caused mostly by social dysfunction. Classical Indian philosophy, especially its traditions of yoga, does, however, have detailed information on the nature of the mind.

Inspired by my young friend's question and desiring to organize that information in a relevant way to help address the mental challenges so many people face today, I categorized the basic tenets of yoga psychology into five broad principles:

1. The mind is malleable.
2. There is a correlation between the form the mind assumes and how one feels.
3. The mind is swayed by the power of three main factors—karma, environment, and actions.
4. By controlling the form or mode the mind takes, one can substantially influence how one feels.

5. Full satisfaction can ultimately only be achieved by transcending the mind and realizing the true self.

The mind, like any mechanism, can be used more effectively when one knows its workings. This is especially important as the proper use of the mind is the basis of self-fulfillment. Yoga psychology thus speaks to the most important of all human aims: true happiness.

THE BASIC PRINCIPLES OF YOGA PSYCHOLOGY:

ONE: THE MIND IS MALLEABLE.

Subtle things are often described in more concrete ways to help us understand them. In the school of Yoga the mind is thus often described as supple, almost like clay, in that it can be easily molded and that external influences make indelible impressions

The significance of this description of the mind as supple (*Principle One*) is the correlation between the shape the mind assumes and one's accompanying moods (*Principle Two*) and that by understanding the main factors by which the mind is molded (*Principle Three*) one can influence how one feels (*Principle Four*). Most important, by this understanding, one can learn to shape the mind as a vehicle for its own transcendence and attain ultimate satisfaction (*Principle Five*).

TWO: THERE IS A CORRELATION BETWEEN THE FORM THE MIND ASSUMES AND HOW ONE FEELS.

Like everything in the world, the mind is composed of a combination of three modes of nature—*sattva guna* (goodness), *raja guna* (passion) and *tamo guna* (ignorance)—which are in flux. These subtle strands of matter, which are the elemental substrata of creation, also have specific intrinsic characteristics with particular symptoms and effects. Because there is a direct correlation between the modes of nature and how one feels, by identifying the present form or mode of the mind, one can also comprehensively understand its influence.

THREE: THE MIND IS SWAYED BY THE POWER OF THREE MAIN FACTORS—ONE'S KARMA, ONE'S ENVIRONMENT, AND ONE'S ACTIONS.

The modes of nature are constantly competing within the mind for influence. A particular mode gains prominence by its association with one of three factors: the weight of one's karma, the nature of one's environment, and the tenor of one's actions. How each affects the mind is comprehensively described in classical Indian thought.

1. The positive effect of karma (destiny) on consciousness is described in three basic ways: A. By understanding the message of destiny: Destiny is the language of God. Each event we experience is the Divine in the form of time (*kala*) telling us something essential about ourselves to help us grow. B. By understanding the proper response to destiny: *Sastra* (Indian sacred texts) also describes the appropriate response to each circumstance of destiny to ensure the healthiest development of the mind. C. By understanding how to align oneself with our innate nature born of destiny: Our basic nature is composed of latent impressions in the subconscious (*samskaras*) posited there at birth as a result of karma. *Sastra* describes the science of living in harmony with one's nature, which is the foundation of a peaceful mind.
2. The subtle effects of the diverse forms of the *environment* on consciousness are described by a thorough classification of the various objects of perception (sights, sounds, and so on) into

a gradation of modes that shape the mind according to their influence. For example, music within a specific mode can move the mind accordingly, either towards lethargy (music in the mode of ignorance), restlessness (music in the mode of passion), or peacefulness (music in the mode of goodness). All objects of perceptions can similarly be classified with predictable affects on the consciousness. Similarly, the subtle effects of the diverse forms of *action* are classified according to motive and understanding with their corresponding influence on the mind. For example, if one acts for self-purification or just adheres to moral or spiritual principles (actions in the mode of goodness) one's mind becomes more lucid, increasingly peaceful, and strong in will, the symptoms and effects of goodness. This understanding of how actions influence the mind also leads to a basic understanding of *dharma*. *Dharma* is the correct choice in any circumstance to ensure the healthiest affect on the mind. This very subtle science of prescribed action (*dharma*) is elaborately described in *sastra*.

FOUR: BY CONTROLLING THE FORM OR MODE OF THE MIND, ONE CAN SUBSTANTIALLY INFLUENCE ONE'S DESIRES AND FEELINGS.

All forms of therapy and self-help deal with guiding one to a greater self-awareness and personal satisfaction. By offering a system that accurately describes the nature of the mind, including a description of the internal and external factors that influence it, Classical Indian philosophy contributes substantially to the science of mental transformation.

FIVE: FULL SATISFACTION CAN ULTIMATELY BE ATTAINED ONLY BY RISING ABOVE THE MIND AND EXPERIENCING THE REAL SELF.

As the material mind is not the true self, no matter how much one transforms the mind to conform to higher forms of nature, perfect mental satisfaction will evade one for the following reasons:

1. The pleasure experienced by the mind is ultimately *superficial*, a joy experienced by identifying with something external to the self. Seeking such pleasure is akin to a person enjoying the pleasure of a dream. It is also a form of happiness that is *temporary* and therefore *full of duality*. Duality means that alongside this pleasure – which is connected with a false sense of self – there must also be the distress of pleasure lost when the body ends.

In this regard there is a tradition of *Sankhya* (analysis) that identifies all 24 material elements, including the mind, for the purpose of isolating the eternal or spiritual self for the attainment of happiness that is *real, eternal, and non-dual*.

Although yoga promotes an integrated, peaceful mind, it is not meant to be an end in itself, but a means to stabilize the mind for its highest purpose—realization of a higher state of consciousness. This is classically achieved through the practice of three core paths—work (*karma-yoga*), knowledge (*jnana-yoga*), and devotion (*bhakti-yoga*).

THE FUNDAMENTAL NATURE OF THE MIND

To understand the mind properly a basic understanding of its function is essential. One therefore has to be familiar with its context or purpose in the cosmos. In *Yoga, Sankhya*, and much of *Vedanta*, this world is described as pure awareness (*purusa* or soul) entangled or misidentified with matter (*prakrti*). Although the ultimate beginning of this dilemma is not a major concern for most, the immediate cause of this unwholesome juncture is; Out of egotism when the soul rejects its pure state

of selfless awareness, its consciousness is projected on a particular field of matter called the body (which includes the mind). As the changes in one's life that evoke duality and fear, such as disease and death, are happening in the body, not the true self, this unnatural and temporary state of identification is the root suffering. Awakening from it, or emancipation (*moksa*), is thus life's ultimate objective.

In context of this cosmic paradigm, the mind, called the *citta*, is the first sheath or covering of the soul. It functions as an instrument whereby the soul (*purusa*) enveloped in matter can either view the world to serve the false self (and suffer) or the pure self (and feel fulfilled). *Bhagavad-gita* thus aptly describes this function in the simple duality as the mind being either the friend or enemy of the soul. Similarly, the *Yoga Sutr*s describe thoughts born of the mind as either unhealthy (*klistha*) or healthy (*aklistha*).

To fulfill this dual role, the mind has different functions of thought. Although different schools ascribe slightly different roles to the different divisions of the mind, there is a basic agreement that the mind has three essential functions of thought:

1. manas – impulsive synthesis and response (initial categorization of all phenomena received through the senses and one's spontaneous like or dislike of them)
2. buddhi – reflective examination (judgment and will)
3. ahankara – relational response (self-identity and self-conceit)

Any system of transformation, whether to improve basic mental health or to achieve self-realization, is based on an understanding of at least some facsimile of these divisions.

Once the mind categorizes an object through a combination of these three functions of thought—our feelings, judgment, and sense of relationship—an impression of that object is imbedded within the mind. These latent impressions, called *samskaras*, created both i

this life and the past, determine how we view, feel, and respond to the world. They are the single most important factor in over-all well-being.

The first function of any system of self-improvement is thus to help one judge whether one's present thoughts based on these latent impressions represent the true nature of things. It then helps one create a more accurate perception through the tools available from that system.

THE HEALTHY AND UNHEALTHY MIND

As mentioned, the nature of the mind is the *samskaras* imbedded within it. We are born in a basic mental condition due to such *samskaras* carried from past lives and also face certain conditions and events in life that foster further *samskaras*.

Our formative years, where *buddhi* (intelligence) is underdeveloped, especially fashions the basis of one's mental health. *Buddhi* functions as a medium between the information coming through the senses and the final impression such data leaves on the consciousness. In other words, intelligence functions to translate our experiences in a reasonable way before they make impulsive and unhealthy *samskaras*. A child is thus especially susceptible to distorted impressions and even trauma because of this inability to digest his or her experiences by proper analysis into reasonable

memories. Stable parents, who affectionately monitor their child to protect him or her from such stirring events, and who deal properly with them, instill good *samskaras* in their child. Good *samskaras* mean impressions that reflect the true nature of things and produce thoughts that help one grow. Such parents especially provide a nurturing environment. Deep impressions of affection in the mind enable one to see the world with promise and to feel secure even in challenging circumstances. Bereft of such memories, one is prone to depression.

A child also needs reasonable boundaries set by the parents. Without a relatively fixed world set by the protective figure, the child lives in a world of flux determined by his whims and demands. As a result, impressions of anxiousness are imbedded in the child's mind, making him susceptible to excessive anxiety as he grows up to face a world of challenge and change.

Parents are the most important factor in the development of a strong mind. Thus a culture that is not structured to facilitate appropriate nurturing and reasonable boundaries molded by strong traditions of child rearing and community support will produce in various degrees mental instability, even if not at the level of trauma. Although the foundations of mental health are set in the formative years, it is important to remember that the mind is malleable. With the proper process of transformation, mental health can be attained at any stage of life.

ATTAINING MENTAL HEALTH

Especially in the modern world, people find themselves in societies where the support of community and family has been substantially eroded. Much of modern society thus relies on specialists in therapy and self-transformation to attain good mental health. Although sound mental health was integral to traditional Indian society and therapy as a specialized field dealing with mental disorders was virtually non-existent, still within the scope of yogi knowledge there is a wealth of in-depth information on the workings of the mind, including knowledge applicable to restoring mental health. Some of that knowledge was alluded to in the beginning of this article when the basic principles of yoga psychology were described, especially the three factors by which the mind is swayed—our karma, the environment, and our actions. Each of these will now be discussed in more depth:

KARMA AND THE MIND

Karma is a powerful factor in influencing the mind. What comes to us in our daily lives by destiny is often disconcerting. Powerful mental states may also suddenly arise as a result of past actions. Due to karma we are also born with a set mental nature, which conditions the mind. Our response to these three manifestations of destiny is the main factor in forming our mental state.

Practically all classical Indian schools of thought accept destiny as an eternal moral order, a force to help us grow provided we comprehend the message it bears and respond properly. *Sastra*, to a large degree, is a compendium of archetypal stories of destiny with lessons on how to understand and respond to various circumstances. That all tribulations of destiny are filled with messages of self-transformation is attested to by the fact that most individuals would not trade the difficulties they underwent if they had to also relinquish the valuable lessons they learned from them. According to yoga psychology, optimum mental health cannot be achieved without some connection to a tradition of knowledge that teaches one to understand and respond to each situation in life in a way that molds one's mind towards goodness.

Although we can substantially change our nature by guidance and self-discipline, we are still born with a certain basic karmic nature. Part of that nature includes inborn occupational proclivities, for instance the longing to be creative, make money, or become learned. Another part of our psyche carries innate social tendencies such as the degree of our detachment or attachment to worldly life. If unhealthy attachments are pronounced, they cannot be transcended by will power alone, nor is it healthy to do so.

Repression causes frustration and anger, which molds the mind towards ignorance, making one susceptible to the result of that mode: inactivity and depression. *Sastra* thus helps identify one's occupational and social proclivity and prescribes suitable duties based on those inclinations, such as recommendations for career and marriage. Only by the regulation of strong attachments, and not by the unrestricted indulgence or thoughtless repression of them, both which degrade the mind, can one be elevated to a higher state of mental well-being.

Optimal mental health is thus very hard to achieve without carefully understanding one's nature and engaging it properly.

ENVIRONMENT AND THE MIND

Bhagavad-gita confirms the importance of the environment in molding the mind towards goodness when it deems the knowledge found in the fourteenth chapter, where the modes of nature are comprehensively analyzed, best of all. Traditional Indian culture, ideally ordered in goodness, was itself influenced by this knowledge. Thus just living in such a society, where many aspects of life were carefully guided by this knowledge, from the objects of sound (music) and sight (art) to moral behavior, was therapeutic.

Although today one has little access to such an environment, still everyone has at least some control over his or her immediate surroundings. For example, the parts of the day that are in different modes, are usually within one's rule. Thus if we simply wake early, just before and around sunrise which is the time of the day substantially in the form of *sattva guna* (goodness), the mind will be given a significant boost towards goodness. Of course, the factors that influence the mind are numerous, but even such a simple adjustment of taking avail of the early morning hours will substantially engender peacefulness and clarity of mind.

All five objects of the senses (sight, sound, touch, smell, and taste) can manifest in different modes and thus everything from our diet to the people we associate with, from the places we frequent to our level of cleanliness can be molded in a way to influence the mind to a higher state of well-being. Those concerned with strong inner well-being, whether to make an unhealthy mind healthy for the purpose of general contentment, or to make the healthy mind more fit to facilitate meditation, must know the science of how the environment affects the consciousness.

ACTIONS AND THE MIND

There are three groups of action geared for positive transformation: actions with an innate spirit of attachment, but restrained by regulation (*karma-yoga*), restrained actions (*jnana*), and dedicated actions (*bhakti*). For the sake of discussing action in terms of how it affects the supple mind, I have divided action into four categories. The three groups of action above will be explored within those categories

1. Dharma

2. Programming
3. Spiritual practice in general
4. The path of devotion (Bhakti)

HOW ACTIONS AFFECT THE MIND

Before discussing the four categories of action in relation to the mind, it is helpful to review the mechanics of how information from the senses and one's response to it create the general tenor of one's mind:

Information entering the mind through the senses makes latent impressions called *samskaras* that form one's basic psychological make-up. *Samskaras* are imprints in the subconscious that push to be filled or not filled with the same experiences that caused them. They can also be called attachments, latent desires, or memories of pleasures. Based on those *samskaras*, one responds to future data by ascribing some feeling (like or dislike) towards it. As a result one is impelled to once again act, to have new experiences and thus either create additional *samskaras*, or strengthen old ones. In either case, the tenor of the mind is altered.

For example, if one drinks alcohol and becomes gladdened, a memory of that particular pleasure, a *samskara*, is imbedded in the psyche. The desire for intoxication thus becomes part of one's psychology. Although that imprint may remain latent (in that one may not always feel like drinking) when that *samskara* is activated by some circumstance, for example going to a party where alcohol is served, one is impelled to drink. In this way, a further imprint for drinking is imbedded in the psyche, increasing one's desire for alcohol and also the likelihood of drinking in the future. In other words, a single act and the accompanying experience can entangle the soul in a continual cycle of the creation and fulfillment of impulses. Within this karmic circle the *samskara* at the root of the initial action is then perpetually strengthened so that a predominant psychological nature is formed.

It can't be stressed enough how important properly translating the information we receive through the senses is, as the *samskara* made by sense data is ultimately determined by one's interpretation of it. In other words, the very same information can produce imprints that foster either enlightening or degrading thoughts (and consequent actions) depending on how such data is computed.

Pertaining to this subject, the role of *buddhi*, or intelligence, as the function of the mind with the capacity to properly digest or comprehend information has already been discussed. Properly comprehended or digested sense data means understanding the true nature of things. This correlation between understanding reality and mental health and the parallel between ignorance and suffering is at the core of yoga psychology. This connection is also not foreign to most schools of psychological therapy where most fears, phobias, anxieties, and mood swings are not considered fundamental conditions of reality, but mistaken conceptions of it, the only difference being the differing methods stressed to bring one to a higher level of cognition. Most schools also recognize the transforming or therapeutic affect of bringing one to a stage appropriate action based on higher cognition and the positive affect that has on the mind.

In conclusion, actions have a very influential affect on the condition of the mind, and inspire positive mental transformation when they are in response to a solid understanding of the world. All four categories of action are thus based on producing healthy imprints related to an understanding of the true nature of objects and situations.

PSYCHOLOGICAL KNOWLEDGE OF BHAGWAT GEETA

Spoken and written commentary on Bhagavad Gita, the distilled spiritual essence of Vedas and Upanishads, is aplenty. Mahatma Gandhi was quoted as saying that whenever he had a problem Bhagavad Gita offered an answer and the solution. For a student of psychology Bhagavad Gita offers a valuable case study for lessons in psychotherapy – resolution of conflict and successful resumption of action from a state of acute anxiety and guilt laden depression that precipitated inaction.

This presentation makes a humble attempt to discuss the therapy process involved in Bhagavad Gita in which Lord Krishna helped the grief-stricken Arjuna through dialogue and discussion. The focus would be on the conflict and diagnosis of patient, the background setting of the situation, personality of patient, technique of therapy, underlying psychological concepts/ principles/theories, the Guru - Sishya concept, etc.

Bhagavad Gita is part of the great epic Mahabharatha, a widely popular mythological story in Hindu philosophy; part of Bhishma Parva, Gita is almost in its entirety the dialogue between two individuals, Lord Krishna (considered as incarnation of Bhagawa. Vishnu, Narayana) and Arjuna (the Pandava prince, Nara) in the battle field (war between the Pandavas and the Kauravas, the cousins, for control of the kingdom of Hasthinapura) of Kurukshetra. It has 18 yogas (chapters), with about 701 slokas (short poems), the first one being "Arjuna Vishada Yoga" (Sorrow of Arjuna) and the last one "Moksha Sanyasa Yoga" (Nirvana and Renunciation).

I would urge the reader to understand the Bhagavad Gita in whatever which way and wisdom he/she would like depending on their belief systems and cultural-religious background. A fiction story or a piece of history dating back to about 4000-5000 B.C. or part of mythology dictated by Sage Veda-Vyasa and written by Lord Ganesh! What is more important and relevant is.

NOT WHAT IT IS BUT WHAT TRANSPIRED

in those 18 chapters of Bhagavad Gita; the process and content of the dialogue; its usefulness as a model of counseling and possible contemporary application value to current day psychological therapies, specially, but need not be limited to, in the Indian context.

The fact of interest for the student of Psychology psychology lies embedded in the dialogue between these two slokas:

- Sishya the Aham Sadhi Mam Tvam Prapannam (I am your disciple, Guide me, Help me) [1] II chapter....3]rd Sloka
- Nasto mohah Smrtir labdha Tvat Prasadan mayachyuta Sthithosmi gata-Sandehaha Karishye Vachanam tava

XVIII chapter....73 ("Clouds" have cleared; my senses are back, all your gift with my doubts vanished, Ready to act as you direct) rd Slok The 3rd sloka of 2nd chapter is depiction of the helpless state of Arjuna praying Lord Krishna for help. The 73rd Sloka of 18th chapter is reflection of dissolution of anxiety, worry, depression and guilt and preparedness for action with confidence and vigor. Whatever transpired between the 3rd sloka of 2nd chapter and the 73rd sloka of the 18th chapter is the matter of scientific curiosity for every student of psychology as it resulted in the total relief from the distress.

NOW THE SCIENTIFIC QUESTIONS CAN BE:

- Do we have any lessons from this?
- Can we develop a model of therapy from these lessons?
- ? Relevance of this model to current day practice
- How useful this approach can be and in which problem?
- What could be the limitations of this approach?

Counseling/psychotherapy is essential and an integral component of psychiatric interventions in the management of a patient with psychological distress/disease. The psychotherapeutic models available are developed and imported from the western literature. The applicability and usefulness of these models in the Indian context was discussed with some skepticism keeping in mind the varying cultural, religious, spiritual, societal attitudes (broadly described as eastern/oriental culture) by psychiatrists in the past.[24] The Guru-Chela concept, as a model in psychotherapy, popularized by Dr. Neki gets widely debated in the Indian context. Eminent Indian psychiatrists and psychologists discussed and proposed Bhagavad Gita as a source and model to develop psychotherapeutic concepts suitable to Indian context. (Of course the eastern/oriental/Indianness of the 21st century Indian can be a matter of speculation and debate).

I. DHARMA

As discussed, knowledge of the true nature of things and responding to the world based on that understanding creates the best disposition of mind. The science of doing this is called *dharma*. In the introduction *dharma* was defined as: “The correct choice in any circumstances to ensure the healthiest affect on the mind is called *dharma*. This very subtle science of prescribed action (*dharma*) is elaborately described in *sastra*.” *Dharma* is subtle because it is prescribed according to one’s individual nature, which varies from person to person. In fact, it varies right from birth where a fraction of an almost unlimited stock of a person’s past karma, including strong *samskaras*, is funneled into one’s particular field of activities (the gross and subtle bodies).

Dharma is thus always done in careful consideration of one’s individual nature, although certain actions are obviously more universal prescriptions, such as *The Ten Commandments* or the *yamas* (moral restraints) of the *Yoga Sutras*. An example of this principle of *dharma* being prescribed according to one’s nature, and not universally applied, is the appropriate response to the objects of sex desire. Like all potential responses to pleasure, the first consideration is the degree of one’s attachment towards the object of that pleasure.

Thus if sexual attraction is at a depth where it cannot be transcended, then *dharma* is to act on that desire, but under careful regulation, in this case limiting the fulfillment of sex desire at the least to the sphere of marriage, if not solely for procreation. If the depth of one’s attachment is minimal, however, *dharma* is the opposite, renunciation of those desires. The same paradigm is applicable to all prescriptions of *dharma*—attachments that cannot be transcended have to be carefully worked through according to prescribed regulation. The result is also the same—the mind is favorably transformed by carefully doing one’s duty.

An especially important application of this model of action is the choice of suitable work.

Occupation is an activity that occupies most of our day and thus a key element in how the mind forms itself.

When our work is lined up with our inborn nature and done in the proper way, when it is *dharma*, the mind is positively transformed. When it is not, one is frustrated. Day after day tolerating boredom or frustration due to occupational work against one's nature can easily activate either a strong desire for unwarranted indulgence in sense pleasure or excessive inactivity. Unfortunately, such desires must be carried home for fulfillment often crimping in mode and time our ability to put our mind towards direct spiritual practice.

Positive mental transformation, for most, cannot be separated from a socio-occupational system designed to provide both meaningful work (*varna*) and an appropriate and supportive social status (*ashram*). Such a system, such as the social structure that was an ideal for Classical Indian society, was also best supported by a simple agrarian based economy. Its purpose was not only to supply suitable psychophysical occupational and social engagement, but to free one's time and energy for spiritual practices geared for direct mental transformation.

Although modern society is not particularly structured to support mental health or spiritual growth, and one often finds oneself in stressful occupational and social situations, one seeking to maximize mental and spiritual development cannot neglect a holistic approach, one that seeks, as far as possible, to align one's social and occupational life with one's psychophysical nature. In summary, there are two choices for incorrect action (*adharma*) and two choices for correct action (*dharma*):
Incorrect action 1: To impulsively indulge one's unhealthy attachments. Such action is in the mode of ignorance and molds the mind accordingly.

Incorrect action 2: To repress one's desires whimsically. By doing so one's mind is occupied further by those attachments leading to frustration, anger, and bewilderment. Repression thus also eventually molds the mind towards ignorance, the worst mode.
Correct action 1: To satisfy one's attachments by prescribed regulation. Regulation affords one the advantage of both the satisfaction and renunciation of desire. By prescribing conditions to fulfill desire, one not only thinks less of those desires, but avoids the foibles of repression. Regulation also means that beyond the limited prescription for enjoyment, one is renouncing passions, thus ruling them by goodness and gradually moving the mind towards that mode.

Correct action 2: To renounce the object of the senses by one qualified to do so. By renunciation at the level of true indifference, one attains the platform of dispassion, and quickly brings the mind to its most purified state. Suitable mentors must thus not only clearly know that one is not the body, but they must help people understand what the body is. If one is not able to reasonably assess a person's level of attachment, but is only able to highlight the duality between mind and body, action cannot be prescribed in a way that fosters a peaceful and functional mind, either for living in the world or for pursuing transcendence. Such guides must also be qualified to inspire and teach renunciation to gradually move people towards that goal.

II. PROGRAMMING

Regardless of one's level of renunciation, one can learn to program or condition the mind to give up bad habits and to develop good ones. This is described in the *Yoga Sutras* as consciously supplanting bad *samskaras* with good ones. To understand how programming works, one should first understand the duality between pleasure and happiness, that *samskaras* that may give momentary

pleasure, such as intoxication and fault-finding, also simultaneously mold the mind towards distress. Understanding this duality, one can then program the mind to supplant the *samskaras* impelling one to indulge in a bad habit by associating it with ones that highlight the suffering it causes. For example, one may give up smoking by regularly visualizing the distress caused by it, such as lung disease and the lack of charactersuch addictions reflect, so that eventually a healthy *samskara* of aversion (smoking is bad) supersedes the unhealthy imprint of attachment (smoking is good). As one can displace the root of a bad habit by creating a distressful imprint in the mind, one can also uproot a bad habit by nurturing another attachment that gives one more pleasure, but sits in opposition to that tendency. For instance, one can be attached to being truthful and then vow to never smoke. Every time one then desires to smoke, the desire for truthfulness is activated, overpowering the craving to smoke. Of course, this is provided that the *samskara* for honesty is deeper than the *samskara* for smoking, or whatever bad habit one is trying to overcome.

These are just simple examples to illustrate how the mind can be programmed or conditioned to change one's nature. They also illustrate the importance of integrity. Integrity means to make one's thoughts and actions one or integral with one's principles. A strong taste for honesty makes it so much easier to undergo the discipline required for transformation.

Without such integrity, our commitment to overcome bad habits will often be rationalized away. Yoga psychology is thus always accompanied by a culture that diligently programs honesty, by the values it stresses, the exemplars it promotes and the literature it recommends.

Again, although we may be at a disadvantage in the modern world where good *samskaras*, such as integrity, are generally not sufficiently cultured, it doesn't mean that we can't find practical means to program the mind to be true to our principles. For example, one can still consciously seek exemplars in character. Exemplars in character, those who have strong attachment to principles, are one of the most powerful ways to instill impressions of character, especially if one can develop a relationship of respect and service to such persons. We naturally try to give up habits that are antithetical to the lives of those we admire. One can also hear about such people, especially if they are saints of the past. Of course, the ability to subdue passions is also affected by the strength of the habit we are trying to control. When such imprints have become extremely deep by repeated reinforcement, they are recalled addictions. At that level they forcibly supersede good judgment and take a more concerted effort to overcome.

In that regard, the 12-step program is an apparently successful method of overcoming addictions. An interesting study would be an analysis of exactly how that is accomplished in terms of yoga psychology, especially in terms of programming. From those I have known in the midst of such programs, it is clear to me that it is an ingenuous way of superseding very deep, bad *samskaras* by strongly reinforcing and creating good ones, such as humility, integrity, the distress of bad habits, the pleasure of good habits, and respect for exemplars of non-addiction. I am especially intrigued by the spiritual aspect of the program. By admitting one's helplessness (the first step) and petitioning a higher power (the second step) one creates or reinforces the good *samskaras* of humility and dependence. Such qualities allow one to experience affection, which strikes against the root of all addiction—the lack of memory in the subconscious of nurturing that fosters depression and impels one to mistakenly fill that void of happiness with repeated sensual stimulation. To transform the mind it must be reconditioned. Yoga psychology, by describing how the mind works, offers a working model of how to positively program the mind.

III. SPIRITUAL PRACTICE (SADHANA)

The objective of yoga psychology is not just to stabilize the mind, but to perfect it. This was described in the introduction. "Yoga psychology deals with the transformation and stabilization of the mind, not as an end in itself, but as means to attain a higher state of consciousness beyond the mind where the *purusa*, or soul, imbibes in its own pure nature." To attain that state, however, the support of the mind is necessary. The mind is called *antar-karanam*, the internal instrument. Like all instruments, the mind requires tuning or sharpening to function best. To succeed in spiritual life, one must therefore gradually mold the mind to higher forms of cognition.

In terms of transforming the mind, we have already discussed the importance of properly structuring our environment and adhering to moral actions within our day to day lives. To achieve optimum transformation and ultimate transcendence, however, it is of utmost importance to reserve a time and place to exclusively engage with the mind for the purpose of transforming it. Such a prescribed exercise is called *sadhana*, or spiritual practice. The foundation of *sadhana* is meditation.

To understand how meditation transforms the mind, one first has to understand its goal – to bring the mind to its pure state. This state can be compared to the original condition of a perfectly tuned instrument where its maximum potential is realized. The mind thus functions best in *sattva*, the most wholesome state of matter. In other words, in *sattva* the discriminating ability of the mind is sharpened to the degree where the soul can perfectly distinguish itself from its encasement, the mind and body. In terms of this ability to foster true perception, this optimum state can also be compared to a properly formed and thoroughly cleansed lens.

Spiritual practice is thus the process of cleansing the mirror of the mind of its distortions, called *vrattis* or thoughts, especially those born of passion and ignorance, which like a distorted lens skew the soul's vision. Meditation accomplishes this by the practice of undeviating concentration on a single object of focus. By such focus for an uninterrupted and prolonged time, all other fluctuations of the mind, which distort the natural lucidity of *sattva*, are neglected and thus quelled, especially when that practice is accompanied by *vairagya*, a rigorous cultivation of dispassion towards those impulses.

IV. BHAKTI

So far we have discussed transformation based on individual effort. The path of *bhakti* adds the aspect of grace to our discussion, help beyond individual effort. Grace thus implies the conviction in a unique supremely potent and omniscient soul, a being with total power to direct the laws of nature and thus cleanse one's mind simply by grace. *Bhakti* as a process of transformation is thus the act of giving oneself to God in devotion and petitioning that grace.

Patanjali Muni indirectly alludes to the path of grace in the *Yoga Sūtras*. In the first chapter, he describes *isvara pranidhana* (surrender to the Lord) as an optional method of meditation and also outlines its main practice—chanting mantras such as *aum*, which are not only signifiers of the Lord, but non-different from Him and full of spiritual potency. In the chapter that follows, he outlines "surrender to the Lord" in a somewhat different context, as one of the six mandatory moral observances that are prerequisite for meditation. Also listed there are the different benefits of adhering to each of the six classic moral observances including *samadhi*, the benefit of perfectly practicing *isvara pranidhana*. *Samadhi*, full spiritual trance, is the goal of meditation. As "surrender to the Lord" is the lone moral observance paired with a spiritual result, and also the only object of meditation that is an active transformative agent, it is also logically the inferred choice for meditation. Commenting

on *isvara pranidhana*, Vyasa, the main commentator on the *Yoga Sutras*, directly confirms why “simply by the yogi’s longing, God bestows His grace upon the yogi. When this happens the fruit’s of samadhi becomes quickly available.”

Bhakti as a process of transformation in relation to grace as described in the *Yoga Sutras* thus works something as follows:

By repetition of the Lord’s names and thinking of their meaning, which is a call to surrender, devotion naturally arises in the heart. Imbued with devotion, the presence of the Lord is then naturally felt everywhere until thoughts of devotion pervade the mind. The Lord, in reciprocation, naturally bestows His grace upon such a devoted soul by awarding him or her *samadhi*, but without the same effort usually required to attain such a wholesome state. In this sense, the process of *bhakti* works through the transformation of the material mind as other processes do. Sri Caitanya, certainly one of the most prominent proponents of the *Bhakti* tradition, thus declares in the first verse of His seminal composition *Siksastakam*, “*ceto darapana marjanam*” –that chanting cleanses (*marjanam*) the mind (*ceto*), which is like a mirror (*darpanam*). In ways, this is a classical yogic description of attaining samadhi, where the material mind of the embodied soul regains its pure condition where the soul can be reflected on it without distortion, the stage before one transcends the corporeal sphere altogether.

Of course, how the mind recovers its pure condition on the path of *bhakti*, and how it does so in other processes, is also quite different. On the path of *bhakti*, real devotion, selfless devotion, is not just a mental or physical activity, but an expression of the soul. Thus unlike other paths, which work, so to speak, from the outside in, that is they deal directly with the transformation of mind as a way to achieve pure inner awareness, *bhakti* is the opposite. *Bhakti* is first a rousing of the soul with devotion that then purifies the mind. In other words, as consciousness flows through the sheaths of the conditioned soul to animate it, including the mind, when that consciousness is awakened to its true nature of selfless devotion, the mind is gradually transformed to more and more conducive states for higher realization. This transformation thus happens simultaneously as *bhakti* imbues the soul with devotion:

“Devotion, direct experience of the Supreme Lord, and detachment from other things—these three occur simultaneously for one who has taken shelter of the Supreme Personality of Godhead, in the same way that pleasure, nourishment, and relief from hunger comes simultaneously and increasingly, with each bite, for a person engaged in eating.” (*Bhag* 11.1.42). Obviously, the degree to which *bhakti* inspires the soul and transforms the mind depends on the purity of our practice and our level of devotion. Real transformative devotion is thus *rag bhakti*, where attachment (*rag*) to the Lord, not just obligation and duty, is the motivating force for our action.

Bhakti, action done with pure love for God, is thus a powerful transformative agent as it invokes grace, stirs the soul, and flows naturally away from egoism and exploitation, the core obstacles to yoga. In *Bhagavad-gita* it is thus deemed the best of transformative paths.

Summar Yoga psychology gives a practical, workable, and holistic paradigm for transformation, which thoroughly explains the effect of one’s nature, actions, environment and heartfelt devotion on the development of a healthy mind.

The prime source for my study of yoga psychology was the recently published “*The Yoga Sutras of Patanjali*” by Dr. Edwin Bryant, NorthPoint Press, which is not only a translation of the *Yoga Sutras*, but is a translation and commentary on all the major commentators on the *Yoga Sutras* as well. I

began this paper before the book was officially published, so I would like to personally thank Professor Bryant for sharing with me, in advance, some excerpts of his work. The author is not only an established academic, but a long time student and practitioner of yoga as well, which makes for an especially insightful and readable translation and commentary.

ii. Bhagavad-gita, 6.5

iii. Yoga Sutras 1.5

iv. Inherent in most systems of Indian yogic thought, and most methods of mental health, is the concept that distress lies not in reality, but in our perception of it, and thus mentors by carefully freeing us from ignorance also make us more mentally healthy.

v. An example would be a young child who has had experiences with his parents and thus develops a bad impression towards all authority and who then distrust all elders, even kind ones.

vi. Problems of restoring mental health were also dealt with in the social structure, including family and priests. Extremely serious mental problems were also dealt with by certain types of tantrics. *Bhagavad-gita*, 14.

vii. In Indian time there are 36 48-minute divisions called *muhurtas*. The *brahma muhurta*, the 48 minutes before sunrise, was considered the most conducive for spiritual life.

viii. Cleanliness is the object of sight in the mode of goodness and will naturally make one more peaceful and clear minded.

ix. Yoga is generally considered part of the path of *jnana*.

PSYCHOLOGICAL KNOWLEDGE OF BUDDHISM

Buddhist psychology is primarily about self-knowledge- finding out more about who you are, understanding your decisions, actions, thoughts, feelings, etc. It is an expression of the Delphic dictum *Know Thyself* and the injunction that transformative spiritual paths throughout time and geography have demanded as the central ingredient in authentic happiness. Buddhist psychology is 'radical,' as it aims to challenge your worldview (as all authentic spirituality and psychology does). It is radical in that it addresses the basis or foundation of our psychological functioning, our sense of who we are, and our relationships with others and with the world. As a result, the fruit of applying the psychological insights of the Buddha requires diligence, perseverance and discernment as they will naturally encounter the resistances and obstacles inherent in our conditioned nature.

It is not a coincidence that Buddhism finds itself so welcome in the western world since the last decades of the preceding century. While the appeal certainly includes those who have converted to Buddhism as a faith and have adopted the practices, liturgies and meditations of whatever form of Buddhism speaks to them, the more unique and far-reaching impact of Buddhism, as a psychology has taken place in academia and among clinical researchers, who have observed that the Buddhist understanding of consciousness, mind, behavior, motivation, personality and psychopathology bear a close resemblance to perspectives held in western psychology and psychotherapy.

While the Buddha was not a psychiatrist or psychologist in the formal sense of the word, the vast majority of his recorded teachings, are explicitly concerned with the sources of emotional suffering and their amelioration. No doubt there is much, much more to Buddhism than the psychology he

elucidates. Yet, an argument will be made that these more 'religious' elements, for the want of a better word, or possibly 'experience-far' aspects, are of appeal to those who seek a religious Buddhism, a Buddhism that provides for a level of faith and understanding that speaks to the needs of their heart, but which can be separated out, and set aside, for those who do not seek such a religious experience (possibly content with their own existing faith, or with none at all) but who rather wish to deepen their self-knowledge and happiness.

It is these experience-near or psychological Buddhism that speaks loudly in the West and which may be anticipated to be the legacy of the Buddhist encounter with the West.

Let's examine some of the confluences of Western and Buddhist psychology. There is certainly a high degree of overlap in goals and content areas of both disciplines that focus directly on understanding human behavior, the source or conditions for unhappiness and ways to reduce, attenuate or even eliminate such unhappiness. Indeed the Buddhist corpus has extensive psychological writings- very explicit and detailed- and not found in other religious traditions. Thus it is not surprising that some aspect of Buddhist psychology has been of interest to those professions in the west dedicated to alleviating human suffering: medicine, psychiatry, psychology, nursing, social work.

The professional journals for each of these disciplines have published so much scientific research (especially related to mindfulness practice) that to fully describe the studies would require a book in itself. The Dalai Lama has explicitly encouraged interaction between western disciplines to further establish links with science and clinical practice. The Mind and Life Institute is an expression of this venture of cooperation. Elements of Buddhist psychology have been integrated into psychotherapeutic practices for a variety of psychopathological conditions, including depression, anxiety, addiction and stress. Scientific writers from the entire range of clinical psychology and psychiatry, ranging from psychoanalysis to cognitive to behavioral to humanistic theory, have all addressed aspects of Buddhist psychology. Not surprising, the Buddhist traditions that have been of greatest appeal to western science and psychology have been those that appear to contain a higher proportion of experience-near aspects (Theravadin, Zen) because they carry much less religious baggage and more easily translated into Western concepts. Less impactful has been the teachings of Mahayana and Tibetan or tantric Buddhism which include a strong element of experience-far teachings and thus are more difficult to translate into concepts that are digestible by the western mind. Nevertheless, even these traditions reflect a more esoteric psychology that does find resonance in the West and which full certainly continue to attract significant interest.

Buddha was primarily an ethical teacher and reformer, not a metaphysician. He disliked metaphysical discussions devoid of practical utility. Instead of discussing metaphysical questions, which are ethically useless and intellectually uncertain, Buddha always tried to enlighten persons on the most important questions of sorrow, its origin, its cessation and the path leading to its cessation. The answers to these four questions constitute the essence of the Buddha's enlightenment. These have come to be known as four noble truths. They are:

- (a) Life is full of suffering (*Duhkha*),
- (b) There is a cause of this suffering (*Duhkha-samudaya*),
- (c) It is possible to stop suffering (*Duhkha-nirodha*),
- (d) There is a way to extinguish suffering (*Duhkha-nirodha-marga*).

The first noble truth is life full of suffering. The very essential conditions of life appeared to be fraught with suffering-birth, old age, disease, death, sorrow, grief, wish, despair, in short, all that is born of attachment, is suffering. The second noble truth is that there is a cause of this suffering. Suffering is due to attachment. Attachment is one translation of the word *trishna*, which can also be translated as thirst, desire, lust, craving, or clinging. Another aspect of attachment is *dvesha*, which means avoidance or hatred. A third aspect of attachment is *avidya*, meaning ignorance.

Buddha preaches about the chain of 12 links in the cause and maintenance of suffering. These chain of causes and effects lead to sufferings in the world. The suffering in life is due to birth, which is due to the will to be born, which again is due to our mental clinging to objects. Clinging again is due to thirst or desire for objects. This again is due to sense-experience, which is due to sense-object contact, which again is due to the six organs of cognition. These organs are dependent on the embryonic organism (composed of mind and body), which again could not develop without some initial consciousness, which again hails from the impressions of the experience of past life, which lastly are due to ignorance of truth. These constitute the wheel of existence (*bhava-chakra*): Birth and rebirth.

The third noble truth about suffering is that suffering can be extinguished. Nirvana is the state of being wherein all clinging, and so all suffering, can be eliminated here, in this very life. Buddha pointed out that work without attachment, hatred and infatuation (*rāga, dveṣa, moha*) does not cause bondage. The fourth noble truth about suffering is that there is a path (*marga*)-which Buddha followed and others can similarly follow-to reach to a state free from misery. He called it the Eightfold Path to liberation.

Eightfold Path (*astangika-marga*): This gives, in a nutshell, the essentials of 'Buddha Ethics'. This Path is open to all, monks as well as laymen. The first two segments of the path are referred to as *prajñā*, meaning wisdom: Right views-understanding the Four Noble Truths, especially the nature of all things as imperfect, impermanent, and insubstantial and our self-inflicted suffering as founded in clinging, hate, and ignorance. Right resolve/aspiration- having the true desire/determination to free oneself from attachment, hatefulness, and ignorance.

The next three segments of the path provide more detailed guidance in the form of moral precepts, called '*sila*': Right speech-Abstaining from lying, gossiping, and hurtful speech generally. Speech is often our ignorance made manifest, and is the most common way in which we harm others. Right action/conduct. Right conduct includes the '*Pancha-Sila*', the five vows for desisting from killing, stealing, sensuality, lying and intoxication. Right livelihood-Making one's living in an honest, non-hurtful way.

The last three segments of the path are the ones Buddhism is most famous for, and concern *samadhi* or meditation. Despite the popular conception, without wisdom and morality, meditation is worthless, and may even be dangerous. Right effort - Taking control of your mind and the contents thereof, effort to develop good mental habits. When bad thoughts and impulses arise, they should be abandoned. This is done by watching the thought without attachment, recognizing it for what it is and letting it dissipate. Good thoughts and impulses, on the other hand, should be nurtured and enacted. Right mindfulness - Mindfulness refers to a kind of meditation (*vipassana*) involving an acceptance of thoughts and perceptions, a "bare attention" to these events without attachment.

This mindfulness is to be extended to daily life as well. It becomes a way of developing a fuller, richer awareness of life. Right concentration - One who has successfully guided his life in the life of last seven rules and thereby freed himself from all passions and evil thoughts is fit to enter into deeper stages of concentration that gradually take him to the goal of his long and arduous journey –

cessation of suffering.

Right concentration, through four stages, is the last step in the path that leads to the goal-nirvana.

- (i) The 1st stage of concentration is on reasoning and investigation regarding the truths. There is then a joy of pure thinking.
The 2nd stage is unruffled meditation even free from reasoning. There is then a joy of tranquillity
- (ii) The 3rd stage of concentration is detachment from even the joy of tranquillity. There is then indifference to even such joy but a feeling of a bodily case still persists.
- (iii) The 4th and final stage of concentration is detachment from this bodily case too. There are then perfect equanimity and indifference. This is the state of nirvana or perfect wisdom. This is the highest form of Buddhist meditation, and full practice of it is usually restricted to monks and nuns who have progressed considerably along the path.

BUDDHISM AND WESTERN PSYCHOLOGY

Assessment of Buddhism in terms of modern western psychology started when British Indologist Rhys Davids translated *Abhidhamma Pitaka* from Pali and Sanskrit texts in 1900. She published the book entitled it, "Buddhist Manual of Psychological Ethics". In 1914, she wrote another book "Buddhist psychology: An inquiry into the analysis and theory of mind".

The mid-twentieth century saw the collaborations between many psychoanalysts and Buddhist scholars as a meeting between "two of the most powerful forces" operating in the Western mind. A variety of renowned teachers, clinicians and writers in the west such as Carl Jung, Erich Fromm, Alan Watts, Tara Brach, Jack Kornfield, Joseph Goldstein, and Sharon Salzberg among others have attempted to bridge and integrate psychology and Buddhism, from time to time, in a manner that offers meaning, inspiration and healing to the common man's suffering.

Buddhism and Western Psychology overlap in theory and in practice. Over the last century, experts have written on many commonalities between Buddhism and the various branches modern western psychology like phenomenological psychology, psychoanalytical psychotherapy, humanistic psychology, cognitive psychology and existential psychology.

BUDDHISM AND PHENOMENOLOGICAL PSYCHOLOGY

Any assessment of Buddhism in terms of psychology is necessarily a modern western invention. Western and Buddhist scholars have found in Buddhist teachings a detailed introspective phenomenological psychology. Rhys Davids in her book "Buddhist Manual of Psychological Ethics" wrote, "Buddhist philosophy is ethical first and last. Buddhism set itself to analyze and classify mental processes with remarkable insight and sagacity". Buddhism's psychological orientation is a theme Rhys Davids pursued for decades as evidenced by her other writings.

Abhidhamma Pitaka articulates a philosophy, a psychology, and ethics as well; all integrated into the framework of a program for liberation. The primary concern of the *Abhidhamma* (or *Abhidharma* in Sanskrit), is to understand the nature of experience, and thus the reality on which it focuses is conscious reality. For this reason, the philosophical enterprise of the *Abhidhamma* shades off into a phenomenological psychology.

Later on long-term efforts to integrate Abhidhammic psychology with Western empirical sciences have been carried out by other leaders such as Chogyam Trungpa Rinpoche and the 14th Dalai Lama.

In introduction to his 1975 book, *Glimpses of the Abhidharma*, Chogyam Trungpa Rinpoche wrote: "Many modern psychologists have found that the discoveries and explanations of the abhidharma coincide with their own recent discoveries and new ideas; as though the abhidharma, which was taught 2,500 years ago, had been redeveloped in the modern idiom".

Every two years, since 1987, the Dalai Lama has convened "Mind and Life" gatherings of Buddhists and scientists. Reflecting on one Mind and Life session in March 2000, psychologist Daniel Goleman, the author of the best-selling "Emotional Intelligence" and "Destructive Emotions: A Scientific Dialogue with the Dalai Lama" noted; "since the time of Gautama Buddha in the 5th century BC, an analysis of the mind and its workings has been central to the practices of his followers. This analysis was codified during the first millennium, after his death within the system called *Abhidhamma* (or Abhidharma in Sanskrit), which means ultimate doctrine".

BUDDHISM AND EXISTENTIAL PSYCHOLOGY

Buddha said that life is suffering. Existential psychology speaks of *ontological anxiety* (dread, angst). Buddha said that suffering is due to attachment. Existential psychology also has some similar concepts. We cling to things in the hope that they will provide us with a certain benefit. Buddha said that suffering can be extinguished. The Buddhist concept of nirvana is quite similar to the existentialists' freedom. Freedom has, in fact, been used in Buddhism in the context of freedom from rebirth or freedom from the effects of karma. For the existentialist, freedom is a fact of our being, one which we often ignore. Finally, Buddha says that there is a way to extinguish suffering. For the existential psychologist, the therapist must take an assertive role in helping the client become aware of the reality of his or her suffering and its roots. Likewise, the client must take an assertive role in working towards improvement— even though it means facing the fears they've been working so hard to avoid, and especially facing the fear that they will "lose" themselves in the process.

PSYCHOLOGICAL KNOWLEDGE OF SUFISM

The mystics drew their vocabulary largely from the Qur'ān, which for Muslims contains all divine wisdom and has to be interpreted with ever-increasing insight. In the Qur'ān, mystics found the threat of the Last Judgment, but they also found the statement that God "loves them and they love him," which became the basis for love-mysticism. Strict obedience to the religious law and imitation of the Prophet were basic for the mystics. By rigid introspection and mental struggle, the mystic tried to purify his baser self from even the smallest signs of selfishness, thus attaining *ikhlaṣ*, absolute purity of intention and act. *Tawakkul* (trust in God) was sometimes practiced to such an extent that every thought of tomorrow was considered irreligious. "Little sleep, little talk, little food" were fundamental; fasting became one of the most important preparations for the spiritual life.

The central concern of the Sufis, as of every Muslim, was *tawḥīd* the witness that "there is no deity but God." This truth had to be realized in the existence of each individual, and so the expressions differ: early Sufism postulated the approach to God through love and voluntary suffering until a unity of will was reached; Junayd spoke of "recognizing God as He was before creation"; God is seen as the One and only actor; He alone "has the right to say 'I'." Later, *tawḥīd* came to mean the knowledge that there is nothing existent but God, or the ability to see God and creation as two aspects of one reality, reflecting each other and depending upon each other (*waḥdat al-wujūd*). The mystics realized that beyond the knowledge of outward sciences intuitive knowledge was required in order to receive that illumination to which reason has no access. *Dhawq*, direct "tasting" of experience, was essential for them. But the inspirations and "unveilings" that God grants such mystics by special grace must

never contradict the Qur'ān and tradition and are valid only for the person concerned.

Even the Malāmātīs, who attracted public contempt upon themselves by outwardly acting against the law, in private life strictly followed the divine commands. Mystics who expressed in their poetry their disinterest in, and even contempt of, the traditional formal religions never forgot that Islam is the highest manifestation of divine wisdom.

Sufism is considered the inner dimension of Islam and is based on the teachings of the Prophet Mohammad (pbuh) and the holy Qur'an. Sufi psychology is the application of Sufism. Expressions of the basic concepts vary, sometimes radically, between Sunni and Shi'a Muslims and between the various Sufi orders (See Fadiman and Frager 1997; Geoffroy 2010; Grisell 1983; Lings 1993).

The goal of Sufism and Sufi psychology is unified oneness, in whichever aspect of one's being is unified in harmony. It is based on the concept *La ilaha illa Allah*, which means there is only one God. The Prophet taught through his actions that whatever exists in one individual has to come to one point and present itself. When this occurs, the absolute knowledge of oneness with Existence is attained. Called Irfan, derived from the word ma'rifa meaning cognition (Angha 2002b), Sufism is considered the science of the soul.

Beginning in 1945, Yusuf Murad, an academic psychologist and purveyor of the Freudian and psychoanalytic tradition, published a dictionary of terms that provided the Arabic equivalents to English, French and German terms in the fields of psychology and psychoanalysis.

Freud's concept of the 'unconscious' merited special attention. The Arabic term became Ibn Arabi's redolent *al-la-shu'ur*, discussed in his classic, *The Bezels of Wisdom*. Ibn Arabi's poetic and elliptical work had fascinated readers for centuries, just as it fascinated 20th-century Arab Freudians. In the *Bezels*, Ibn Arabi relates the parable of Abraham, whom God visits in a dream and tells to sacrifice his son. According to Ibn Arabi, sleep and dreams occur in the plane of the imagination (*hadrat al-khayal*) and must be subject to interpretation.

his conception of reality as being at once an unreality, while at the same time *not* an illusion at all, brings to light another concept intimately connected to psychoanalysis, the concept of the Imaginary. The Imaginary is greatly elaborated in the later psychoanalytic tradition, most notably by Jacques Lacan – Lacan had read about Ibn Arabi by way of Corbin.

As the religious studies scholar William Chittick elaborates, Ibn Arabi perceived the Imaginal world as an intermediate realm, a world in between the spiritual and the corporeal. As Lacan would later do, Ibn Arabi theorised the example of one's own reflection in the mirror. Is my image in the mirror real or unreal? In one sense it is, and in another sense it is not. This clarifies the nature of the Imaginary as both existent and non-existent. The affinities between mystical Islam and Freudian thought are clear, and deep. But did Islamic thinkers make these connections?

between psychoanalysis and Islam? They did, often pointing to the shared traditions of dream interpretation, as well as the shared technique of understanding texts and dreams through the relationship between the latent and manifest meaning of religious knowledge.

Islamic thinkers also recognised the uncanny resemblance between the analyst-analysand and the *shaykh* (or spiritual master)-disciple relation in Sufism. The mid-20th-century Egyptian Abu al-Wafa al-Ghunaymi al-Taftazani, a *shaykh* of a Sufi order and later a professor of Islamic philosophy and Sufism at Cairo University, began writing about Sufism in the 1950s. He was widely read in Egypt and beyond, and he often compared Sufism and the psychoanalytic tradition.

In particular, al-Taftazani noted that both Sufism and psychoanalysis relied upon an introspective method; both engaged not with the manifest content of the psyche or soul (*nafs*), but with its latent content, a domain often marked by sexual desires. Most importantly, both exhibited a concern for the *batin* or the realm of hidden meaning, as well as for the inner reaches of the unconscious (*al-la-shu'ur*).

The Sufi *shaykh*, much like the analyst, he observed, must ascertain unconscious thoughts and desires from his disciple, in order to facilitate a transformation of the self. Sufism and Freudianism were obviously closely related. Abd-al-Halim Mahmud, a scholar of Sufism who would eventually become Grand Imam of Al-Azhar, noted that 'every Sufi master is a "psychotherapist", so to speak'. The relationship between the Sufi *shaykh* and his disciple is, then, one of attunement with potential for psychotherapeutic transformation.

Sufi practitioners understood their struggle to be part of a larger battle between the noble and ignoble tendencies of man. Al-Taftazani emphasised that Sufis aimed to attain direct knowledge and love of God. They sought a mystical union with God, annihilating the ego-self, in which God remains as a sublime excess.

It was not, al-Taftazani pointed out, a subjective and individual self-exploration; it was a union with the divine. Freud would likely have seen Sufism as 'nothing but psychology projected into the external world', but to al-Taftazani and others it was as an ethical path toward the divine.

PSYCHOLOGICAL KNOWLEDGE OF INTEGRAL YOGA

All spiritual seeking moves towards an object of Knowledge to which ordinary man in his humdrum of life does not turn his eye. A state of knowledge where we can touch, enter, know by identity the Ineffable, Infinite, Indescribable Eternal. As mental beings we have to start from our ordinary instruments and objects mostly but thereafter suprasensuous and supramental means and faculties are needed, as what we are seeking is that 'where the eyes cannot reach, nor speech, not even mind,...' In traditional systems, all cosmic existence is termed as ignorance. Absolute can only inhibit transcendental and non-cosmic existence. Thus, there is negation of individual and cosmic. The aim of traditional object of knowledge is Nirvana, annihilation of ego; there actions are only those required for rites as per scriptures, and that too in early stages only. In severe *Jnanayoga* all actions are abandoned. Even worship and devotion are not required as for that you need some 'other' and with the rise of knowledge there is no other, there is only One. It relies exclusively on Intellect and separates itself from all the rest, i.e. heart, body, life, senses. Undoubtedly thought is the faculty nearest to the Self, thought can regard all the activities and yet stand back from them all, it is less outward tended and more capable of quiescence, it is most constant, normal and effective means for enlightening his ignorance. Its functions of gathering and reflection, meditation, fixed contemplation, absorbed dwelling of the mind on the objects are all most tested and reliable ways of lessening the thick and heavy wall of ignorance.

In reality, thought only is a scout and pioneer, it can guide but not command or effectuate. The leader of the journey is the Will, *Tapas*, *Shakti*, and *Shraddha*, which sovereignly determine our orientation and of which the intellect and the heart are more or less blind and automatic servants and instruments. All activities proceed from this supreme Self and are determined by it. In these activities is expressed the conscious Will or *Shakti* of the spirit moved to manifest its being in infinite ways. This Will is more profound and nearer to the Absolute than our surface thought power. To know that will in us and in the universe and follow it to its divine finalities, whatever these may be is the truest culmination for knowledge. Since thought is not the highest or strongest part of our

nature, its exclusive satisfaction is not necessary in the integral Yoga, it has to see due satisfaction of other faculties as well. The impulse towards Absolute is not just dry and abstract, not just straight line logical thinking, it is, in fact, more multi-sided, more complex, richly diverse and endless. An abstract logic can only reach infinite empty negation or equally infinite and vacant affirmation. Heart, will, life and even the body are no lesser forms of the Conscious Being and are having great significance.

PSYCHOLOGICAL KNOWLEDGE OF SCIENCE AND SPIRITUALITY

Scientific interest in religious spirituality and mental health has increased dramatically. However, many researchers have tended to ignore the historic incompatibility between spirituality and traditional science. A review of the spirituality research suggests that important themes of this historic incompatibility persist in contemporary theories of spirituality. Yet, many spirituality researchers have proceeded as if this incompatibility did not exist. Indeed, there is evidence that spiritual conceptions have been altered to "fit" the requirements of science. No alteration would seem necessary if scientific method were a neutral tool of investigation that did not affect the conceptions themselves.

However, if method itself has philosophical commitments, and if these commitments are incompatible with the conceptual foundations of many conceptions of spirituality, then spirituality researchers may be undermining their own conceptions in the service of science. We outline the philosophical commitments of traditional scientific methods and the philosophical commitments of many contemporary conceptions of spirituality to begin a conversation about this possibility.

EXAMINING THE RELATIONSHIP BETWEEN RELIGIOUS

Spirituality and Psychological Science There has long been an interest in the relationship between religious spirituality and mental health. However, this interest has recently extended to the use of traditional scientific methods for examining this relationship (cf. Clay, 1996; Donohue, 1989; Shafranske, 1996). This use of science to examine the spiritual is unprecedented, uniting two historically separate realms of knowledge and even methods.¹ This unity, however, has been effected without much critical discussion. Calls for such discussion have been issued (e.g., Dennis, 1995; Gorsuch, 1988; Tjeltveit, 1989; Williams and Faulconer, 1994), but with certain exceptions (e.g., Jones, 1996; Richards & Bergin, 1997), these calls have not been heeded in the spirituality and mental health literature.

Critical examination is nevertheless required, because the philosophical commitments of traditional scientific method may conflict with the theoretical assumptions of many conceptions of spirituality (cf. Bergin, 1980; Ellis, 1980; Walls, 1980). This conflict could lead to unintended and unfortunate consequences. There is evidence, for example, that some spirituality researchers alter, ignore, or fail to elaborate important conceptions of spirituality that are incompatible with the traditional philosophy of science (Slife, Nebeker, & Hope, 1996).

The present paper attempts to address these issues. The purpose of the paper is to begin laying the foundation for fertile theoretical discussion and productive empirical work in the important realm of spirituality. We feel that the first task in laying this foundation is one of clarification.

Therefore, we begin by describing the historical separation between science and spirituality. We focus our inquiry on religious spirituality to narrow the vast domain of spirituality to a manageable size. This focus also allows us to point to a more specific history and philosophy with which to compare the history and philosophy of science.

Our main point of departure for this comparison is modernism, both in its emphasis on method for evaluating truth claims and in its assumptions about the nature of the world. Interestingly, many contemporary spirituality researchers embrace modernist scientific methods but reject the naturalistic philosophical assumptions that underlie these methods in their conceptions of spirituality.

We characterize these researchers as antimodernists and attempt to begin a discussion of the appropriateness of their approach to spirituality research. This discussion cannot occur in any productive manner without considering alternative approaches, so relevant postmodernist assumptions are also outlined. First, however, historical context is needed.

A Brief History of the Separation of Science and Spirituality Historically, both spiritual and scientific knowledge have revolved around the issue of authority: Who or what has the authority to decide the truth? In the Middle Ages, the authority for knowledge was primarily considered to be a "who"—God—with the priest or some other "instrument" as a sometimes fallible conduit for God's authority. This authority involved not only what we would consider today to be "religious" or "spiritual" issues, but also what we would consider today to be "scientific" or "secular" issues. To give God authority especially over the latter types of knowledge, such as medicine, sounds strange to many today, but this strangeness is due to the intellectual movements that followed the Middle Ages—the Renaissance and the Enlightenment. These latter movements saw the church gradually lose its authority over general knowledge to two philosophical movements involving rigorous logic and systematic observation.

The first philosophical movement, known as Rationalism, held that the primary authority for truth is rationality or logic. If knowledge, including religious knowledge, did not stand up to the test of rigorous reasoning, then it was suspect. Most religions, however, were not founded upon totally rational systems of thought.

THIS HISTORIC CONFLICT

This historic conflict has not been ignored by contemporary psychological researchers of spirituality (cf. Dennis, 1995; Jones, 1996). Still, a review of the relevant literature reveals that it has rarely been addressed or discussed in the light of present research practices. Jones (1996) and Dennis (1995) correctly note that a growing consensus of scholars has rejected this traditional philosophy of science (sometimes known as "positivism"). However, this rejection is rarely reflected in the research practices of mainstream researchers (cf.

Harmon, 1993, 1995; Slife & Williams, 1995; Slife & Williams, 1997), including, we contend, those researchers investigating spirituality.⁸ Indeed, it appears that most spirituality researchers have proceeded as if the assumptions and practices of traditional, positivistic science—including such practices as replication, reduction, and operationalization—do not conflict with the assumptions they make about spirituality. Many researchers seem to have presumed that scientific method qua practice is a neutral or objective tool of inquiry into spirituality. However, relatively recent advancements in the philosophy of science cast doubt on this neutrality (Bohman, 1993; Dennis, 1995; Gadamer, 1993; Harmon, 1993; Jones, 1996; Polkinghorne, 1983; Robinson, 1985; cf. Slife & Williams, 1995).

PSYCHOLOGICAL KNOWLEDGE OF AVIDYA AND VIDYA

Lauren, a Los Angeles yoga teacher, slipped in a lunge while teaching and injured her ankle. Because she's a practice-through-the-pain kind of yogi, she didn't even stop to assess the injury before continuing her class. When she finally got to the doctor, she discovered she would have to stay off the

ankle for at least a month.

For Lauren, this triggered a deep identity crisis. Since her teens, her strong body has been the source of her well-being, her self-esteem, and, in adulthood, her income. She can still teach, and her injury may even turn out to be an incentive to deepen her understanding of alignment. But because the "me" she has always felt herself to be is so tied to her physicality, the accident has left her deeply disoriented. Of course, she tells me impatiently, she knows she's not her body. But knowing that doesn't seem to cure her feelings of self-doubt and fear.

George has a different issue. His wife has told him she's involved with another man and wants to have an open marriage. George feels shocked, abandoned, and insecure, which leads him to thoughts like "I'm not good at relationships" and "I'm not lovable." Essentially, he feels the same disorientation that Lauren does. "I don't know who I am when the person I love doesn't want me," he says.

AVIDYA: AN IDENTITY CRISIS

Deeper than the trauma itself, deeper even than the memories that may be contributing to their feeling of personal derailment, Lauren and George are both suffering from the core misunderstanding that the yogic texts call *avidya*—a basic ignorance of who we are and the underlying reality that connects everything in the universe. Their current situation is an opportunity for each of them to recognize this fundamental misperception—to look into the nature of identity itself. When everything you have relied on seems to dissolve, you get not only a glimpse of the cracks in your psychological infrastructure but also a chance to examine the source of the problem, which gives you a better shot at getting free of it.

The Sanskrit word *vidya* means wisdom or knowledge—the wisdom earned through deep practice and experience. The prefix *a* indicates a lack or an absence. In the yogic sense, *avidya* means something that goes far beyond ordinary ignorance. *Avidya* is a fundamental blindness about reality. The core ignorance we call *avidya* isn't a lack of information, but the inability to experience your deep connection to others, to the source of being, and to your true Self. *Avidya* has many layers and levels, which operate in different ways. We see it threaded through every aspect of our lives—in our survival strategies, our relationships, our cultural prejudices, the things we hunger for and fear. All forms of cluelessness and fogged perception are forms of *avidya*. But behind each of *avidya*'s manifestations is the failure to recognize that essentially you are spirit, and that you share this with every atom of the universe.

For instance, one common way you can see *avidya* in action is in the habit of thinking that other people should treat you better or that you need someone's approval to feel good about yourself. You might "know" that this isn't true—that people often act without regard for the welfare of others and that making your self-esteem contingent on how others feel about you is a bit like trying to buy zucchini at the Gap.

If someone points out to you that you are responsible for your own inner state, you might think, "I know!" But knowing that truth intellectually doesn't change your feelings or behavior. It doesn't stop you from trying to cajole or manipulate your friends and partners and children into acting the way you think you "need" them to act—perhaps demanding continual reassurances of love from a partner, or looking for constant evidence of being needed. Intellectual knowledge alone doesn't have the practical power to help you. For that knowledge to become *vidya*, or true wisdom, you need to understand it on a visceral level. Until you do, you are suffering from *avidya* on the level of

relationships, with all of the attendant discomfort and pain. And the same goes for every other type of avidya.

IDENTIFYING AVIDYA

In Patanjali's Yoga Sutra II.5, we are given four useful clues for identifying when we have slipped into avidya. Each clue points to a particular way in which we take surface perceptions for reality. It cautions us to look deeper—to inquire beneath what our physical senses or cultural prejudices or egoic belief structures tell us. "Avidya," the sutra says, "is to mistake the impermanent for the eternal, the impure for the pure, sorrow for happiness, and the not-Self for the true Self." If you explore this sutra, it can lead you to a profound reflection on the illusory nature of perception. Even a casual look at history reveals that each advance in science and culture has called into question beliefs that our ancestors took for granted—everything from the idea that Earth is the center of the solar system to the notion that matter is solid. The primary purpose of the sutra is question our notions of identity. But, at the same time, it offers a window into some of our garden-variety forms of cluelessness. Notice how Patanjali's definition applies to so many levels of ignorance. Mistaking the perishable for the imperishable? That's the everyday denial that keeps people believing they can depend on fossil fuels indefinitely, or jog on asphalt without damaging their cartilage. It's that hopeful belief that your romantic passion will last forever, or that another person's love will give you security. On a deeper level, it's what keeps you from seeing that your conception of "me"—"my personality," "my self"—is not stable and is certainly not permanent, that just as your body is an ever-shifting configuration of atoms, so your internal sense of self consists of thoughts about who you are (as in "I'm pretty" or "I'm confused"), feelings like happiness or restlessness, and moods such as depression or hopefulness—all of which are subject to change.

PRACTICING AWARENESS OF AVIDYA

Taken together, these flavors of avidya cause you to live in a kind of trance state—aware of what's obvious on the surface but unable to recognize the underlying reality. Since this personal trance is fully supported by the beliefs and perceptions of the culture around you, it's difficult for most of us even to recognize the existence of the veil. To fully dismantle avidya is the deep goal of yoga, and it demands a radical shift of consciousness. But the good news is that just recognizing that you're entranced is to begin to wake up from the dream. And you can begin to free yourself from its more egregious manifestations by simply being willing to question the validity of your ideas and feelings about who you are.

Avidya makes you believe that the way you think or feel things are is the way they actually are. You can step past this misperception by looking at what your mind habitually tells you and questioning its conclusions about reality. Then, go a step further and notice how feelings create thoughts, and thoughts create feelings—and how the reality they construct for you is exactly that: a construct! One of the great moments for catching your own avidya is to tune into the first conscious feeling that surfaces as you wake up in the morning. Then, notice where it takes you. For several days recently, I woke up feeling lonely and slightly sad. This is not usual for me, so it caught my attention. I would emerge from the prewaking state and open my eyes to a gray sky (we were having a lot of morning fog on the California coast that week). I'd feel a dull, sinking energy in my body. Within seconds, something would grab hold of that feeling, identify with it ("I'm sad"), and expand it into a dulled, gray inner landscape.

This automatic process is the action of what in yoga is called the "I-maker," or *ahamkara*—the

mechanical tendency to construct a "me" out of the separate components of inner experience. The inner dialogue ran something like this: "Oh, no, another gray day. Gray skies make me feel depressed. I need to get out of this climate. No, I shouldn't blame the weather. It's me. I have these depressed family genes. It's hopeless!" Before I even got out of bed, I had written off my entire day.

HOW TO FREE YOURSELF FROM AVIDYA

Dismantling avidya is a multilayered process, which is why one breakthrough is usually not enough. Since different types of practice unpick different aspects of avidya, the Indian tradition prescribes different types of yoga for each one—devotional practice for the ignorance of the heart, selfless action for the tendency to attach outcomes, meditation for a wandering mind. The good news is that any level you choose to work with is going to make a difference.

You free yourself from a piece of your avidya every time you increase your ability to be conscious, or hold presence during a challenging event. You can do this in dozens of ways. For instance, you can increase your consciousness about your connection and responsibility to the planet by sensitizing yourself to the energy in the natural world, in wind and water and trees. You can increase your awareness of your connections to others by listening better and by practicing kindness—but also by sinking your awareness into the heart center and trying to tune in to others from that interior place. You increase your consciousness of yourself by noticing your blind spots, or by noticing your emotions and their effect in the body.

MEDITATIONS TO DISMANTLE AVIDYA

Meditations that tune you into pure Being will begin to remove the deeper ignorance that makes you automatically identify "me" with the body, personality, and ideas. On a day-to-day, moment-to-moment level, you burn off a few layers of avidya every time you turn your awareness inward and reflect on the subtle meaning of a feeling or a physical reaction.

These types of interventions are not just key spiritual practices. They are also practical self-help techniques. When George asks himself, "Is it really true that my wife's involvement with another man damages my sense of self?" he has a chance to recognize that his wife's choices are not statements about who he is. This calms his anxiety, which gives him some leverage for moving forward. Noticing where the sadness and disorientation sit in his body, feeling his way into the sensations around the sadness, might lead him to look for the root feeling behind the fear and disorientation.

He might notice that he has a hidden belief about himself, like "I'm unlovable," and recognize that it comes from childhood and is not really related to the current situation. He could then practice with the sad feeling, maybe breathe it out, or substitute a positive thought for the painful belief, and notice how either practice changes his mood. In this way, his self-inquiry practice gives him support and clarity as he decides how to handle his wife's request for an open relationship.

SELF-KNOWLEDGE IN INDIAN PSYCHOLOGY

Within the normal routine of science these fundamental questions are seldom raised. Each scientific discipline has its own framework within which more immediately practical questions are selected, answers searched and, in due time, generally found. As long as we remain within the boundaries of our discipline, the deep questions do not really arise.

They do come up, however, when we get involved in interdisciplinary work. Then we get confronted

with the significant differences in approach to knowledge and its acquisition that exist between the different scientific disciplines. The issue comes up still more trenchantly, when we try to study a subject that simply does not fit within the parameters of our particular discipline. Consciousness is one such subject that challenges the most basic assumptions of the disciplines that are at present trying to tackle it. When consciousness was studied in the 19th century there was plenty of confusion, no doubt, but no essential, epistemological difficulty, for it was approached mainly from within the confines of a metaphysical and clinical psychology in which subjective, introspective forms of enquiry were still accepted as a legitimate source of knowledge. When psychology in the early years of the 20th century, attempted to become an objective science, like physics, it redefined itself as behaviorism, and the subject of consciousness disappeared more or less completely from scientific enquiry (Guzaldere, 1995).

Only at the very end of the 20th century, did consciousness force itself again on the scientific agenda. This time around, however, it was taken up by an objective psychology, "evidence-based" medicine, and hard sciences like neurophysiology, computer science and physics. And here the epistemological difficulties arose. There can be no doubt that the objective sciences have made tremendous progress during recent times regarding the functional and physical correlates of consciousness, but it is hard to believe that this will make us much wiser about consciousness itself.

If it is confirmed, for example, that our human consciousness is not located in any one specific center of the human brain but that it goes together with 40Hz electromagnetic waves that move from the front to the back over the frontal lobes, then this is extremely interesting in its own right, but it is not very clear how much this adds to what we know about consciousness itself (as distinct from its material correlates). That the essence of consciousness escapes scientific study as presently understood is perhaps not so surprising. Modern science has put all its energy into arriving at knowledge that is objective and independent of the observer, and consciousness might quite well be quintessentially subjective.

From where then do we get knowledge about consciousness itself? An answer might be found in the fact that modern science is not the only systematic effort to arrive at knowledge that humanity has made so far. There are in fact many other knowledge systems, but for our purpose the most promising is that of the spiritual traditions of India, which have specialized for thousands of years in the exploration of the inner worlds and on the acquisition of valid and reliable knowledge of consciousness. That the Indic traditions could play a major role in the further development of consciousness studies is widely acknowledged (Baruss, 1998).

What is less clearly seen, is that this contribution consists of a unique combination of two elements: on the one hand a highly sophisticated theoretical framework for the study of consciousness and on the other a welter of practical techniques to change consciousness. How crucial this latter ability to modify consciousness could be for the effective study of consciousness has as yet hardly been recognized. This is surprising given the immense role physical technology has played in the advancement of the physical sciences: technology has not only provided the apparatus needed for more detailed observations, but it also has been the spur for further theoretical work and the final test for the practical applicability of theoretical advances. Similar roles have been played by Yoga in the development of the Indic theories of consciousness. An effective "technology of consciousness" is absolutely critical for the development of more powerful and reliable methods to arrive at subjective knowledge.

Integrating Eastern and Western knowledge systems is however not easy. It is still comparatively simple, for example, to study the physiological effects of meditation techniques from within

science. Such decontextualised phenomena don't conflict with the standard scientific paradigm and have been extensively studied in literally thousands of scientific research projects.

But more subtle aspects of the Indian understanding of consciousness cannot be fully grasped without challenging the materialistic, reductionist premises that are, according to many, still the bedrock of modern science. Such not physically reducible aspects of reality cannot be fully understood without adopting at least some essential elements of the Vedic, or Buddhist, ontology, which are incompatible with a materialistic view of reality.

If one studies the materialist and the spiritual systems dispassionately, it becomes clear that the results of Yoga cannot be explained losslessly by the materialistic worldview, while, as we will see later, it is comparatively easy to fit the entire scientific enterprise within one or two specific niches of the more comprehensive Indian ontology. But before we can work this out, we must have a look at what the two different traditions actually mean by knowledge, consciousness and reality.

MEANT BY KNOWLEDGE

The words "knowledge" and "consciousness" are used in many different ways by different people, so before proceeding I'll try to clarify how I will use these terms. I don't think it is possible, or for that matter, very useful, to give exhaustive definitions of either. These concepts are too complex and comprehensive for such an attempt. So the following is meant only as a first indication of the direction in which we will move. For our limited purpose it is sufficient to observe that the knowledge aimed at by science is not of the same type as the knowledge aimed at by the Vedic tradition. Scientific knowledge consists of explicit statements about things and processes and the relationships between them. One of the most generic descriptions of a valid statement of scientific knowledge is probably "If you do action *a*, under conditions *c*, you will get result *r*". (Velmans, 2001) This pragmatic formula holds even for much of yogic knowledge, but it does not hold for all of it: it presumes, for example, the existence of an independent agent, which doesn't apply to the higher ranges of mystical experience. There are other differences as well. In the Vedantic worldview, where truth is not seen primarily as a property of sentences, but as something inherent in the observer as well as the observed, the knowledge aimed at doesn't consist of independently existing, external descriptions of such truth.

The aim rather consists of the very act of seeing, realising or even becoming that truth. In ordinary science explicit statements about reality are complete in themselves; in Yoga statements about reality are rarely more than hints or aids, meant to arrive at a direct perception of a deeper truth, which itself remains concealed behind the outer formula.

As Forman (1990, p.41) says with respect to "Pure Consciousness Events", "linguistic systems are afloat, not pinned down to the terms in which the mystic undergoes the event". While scientific knowledge can indicate avenues for outer action, Vedic knowledge indicates rather a different way to be and experience. Even the role of reason is not the same in both systems.

In the early, Vedic and Upanishadic tradition rational thinking is not used as a means to arrive at truth, but rather as a means to express as faithfully as possible a truth already seen or lived on a "higher" level of consciousness, so that the expression, by the quality of the consciousness inherent in it, can help others to experience that truth directly for themselves.

WITHIN THE CONTEXT OF YOGA, SRI AUROBINDO DESCRIBES VEDIC KNOWLEDGE AS FOLLOWS:

[T]he knowledge we have to arrive at is not truth of the intellect; it is not right belief, right opinions, right information about oneself and things, that is only the surface mind's idea of knowledge. To arrive at some mental conception about God and ourselves and the world is an object good for the intellect but not large enough for the Spirit; it will not make us the conscious sons of Infinity. Ancient Indian thought meant by knowledge a consciousness which possesses the highest Truth in a direct perception and in self-experience; to become, to be the Highest that we know is the sign that we really have the knowledge.

For the individual to arrive at the divine universality and supreme infinity, live in it, possess it, to be, know, feel and express that one in all his being, consciousness, energy, delight of being is what the ancient seers of the Veda meant by the Knowledge; (Sri Aurobindo, 1972a, p.686-87) It may be clear that this Vedic concept of knowledge is something entirely different from the scientific concept of knowledge. Of course the ancients were aware of the more mundane type of knowledge, but they were less exclusively interested in it than modern science. Avidya, or "ignorance", as they called it somewhat disdainfully, denotes all knowledge that is not knowledge of the Absolute and the word is specifically used for knowledge of the world, in other words, for science. According to Sri Aurobindo's interpretation of the Ish Upanishad, both *vidya* (Knowledge of the One) and *avidya* (knowledge of the multiplicity) are needed for a complete understanding of reality: Into a blind darkness they enter who follow after the Ignorance, they as if into a greater darkness who devote themselves to the Knowledge alone.

He who knows That as both in one, the Knowledge and the Ignorance, by the Ignorance crosses beyond death and by the Knowledge enjoys Immortality.

(Sri Aurobindo's translation, 1996, pp. 21-22) In the acquisition of the Vedic type of Knowledge four clearly demarcated stages are distinguished, of which only the first is a part of ordinary science: information, experience, realization and transformation.

These four stages of understanding are most typically used to describe different levels of understanding the ultimate reality, but they also occur in other types of knowledge. Information can be gained by listening to others, by reading or by conducting objective experiments. It is the level of knowledge science deals with. Unless it is related to something emotionally loaded, information generally does not directly affect a person. Only through the second stage of direct experience, knowledge becomes really one's own. Still, experience does not yet make any deep change to whom one is in one's essence.

It is still something one *has* and is still separate from who one thinks one *is*. Direct personal involvement comes with the third step realisation. Realisation involves a true reversal of consciousness. After realisation, there is no coming back. It changes who you feel you are. But even then, even though one has changed one's basic position and outlook on reality, one's nature remains still largely what it was.

The whole nature changes only during the last stage, through the process of transformation. Experience and realisation can come by themselves, or after much effort, but they are things that happen at once. One can afterwards remember the exact date and time. Transformation however is a gradual and laborious process.

Before we can explore how the Vedic, inner knowledge relates to scientific knowledge, we have to have a look at what consciousness is, for human knowledge is typically a combination of information with consciousness, or at least potential consciousness. Recent years have seen an

enormous interest in information, largely spawned by the communications industry with its need to store and transfer information electronically. We will not get into this information aspect but focus rather on the aspect of consciousness.

CONSCIOUSNESS WHAT IS REALITY?

In most scientific literature, consciousness is equated with the ordinary mental awareness of one's surrounding and one's internal movements. Sri Aurobindo uses the word "consciousness", in line with the Vedic tradition, in a much wider sense, for something that is pervasive throughout existence. As such it can take many forms. In man consciousness manifests most typically as mind, but in pure inorganic matter, for example, it manifests as not more than an obscure habit of form and movement. Consciousness in Sri Aurobindo's terminology is thus a much wider concept than mind. It exists in many grades or types that together form a hierarchy ranging from matter to the pure spirit, with the mind somewhere in the middle.

SRI AUROBINDO FORMULATES HIS VIEW OF THIS WIDER RANGE OF CONSCIOUSNESS AS FOLLOWS:

Consciousness is usually identified with mind, but mental consciousness is only the human range which no more exhausts all the possible ranges of consciousness than human sight exhausts all the gradations of colour or human hearing all the gradations of sound – for there is much above or below that is to man invisible and inaudible. So there are ranges of consciousness above and below the human range, with which the normal human [consciousness] has no contact and they seem to it unconscious...(Sri Aurobindo, 1972b, p.234).

This extended use of the term may in first instance be confusing for those who are used to the way the term is used in most of western scientific literature. Consciousness and mind are there often equated and in psychology mind is even used as a wider concept than consciousness (for example when a distinction is made between conscious and unconscious mental processes). Such a restricted conceptualization of consciousness makes of consciousness a freak phenomenon that suddenly appears at a certain level of physical complexity and that as such defies explanation. Much of the confusion that presently reigns in the field of consciousness studies seems to be due to an unworkable delineation of both matter and consciousness. Chalmers' "hard problem"[REF] for example, is hard only because it contains implicit assumptions about the relationship between matter and consciousness that are quite unwarranted.

If we take consciousness in line with the Vedic tradition as all-pervasive and existing not only within individuals, but also, independently, on a cosmic scale, then the individual consciousnesses can be seen as instances, portions or representatives of these different types of cosmic consciousness. The gradedness of consciousness and its cosmicity taken together have led to a conception of reality as a complex scheme involving interpenetrating but experientially distinct worlds, each consisting of a different type of consciousness and being.

Sri Aurobindo sees these different worlds as different *relations* between conscious existence as observer and the same conscious existence as the observed. Human mentality, that is our mental awareness of the physical world, is just one type of consciousness somewhere in the middle of a long scale. At the upper limit of the scale there is the consciousness the Divine has of himself. At the bottom end of the hierarchy we have the completely involved consciousness of inorganic matter. In the latter, self-oblivion is almost complete with the elemental particles of physics moving

about in a seemingly unconscious, but still lawful organisation: "the force acting automatically and with an apparent blindness as in a trance, but still with the inevitability and power of truth of the Infinite" (Sri Aurobindo, 1972a, p. 344). The grades of conscious existence in between the two extremes of Spirit and Matter have been described in many ways. Sri Aurobindo use generally the Vedic "sevenfold chord of being": Sat, Chit, Ananda, Supramental, Mental, Vital and Physical, with several subdivisions within each of these seven major planes.

We mean [by planes of consciousness, planes of existence] a general settled poise or world of relations between Purusha and Prakriti, between the Soul and Nature. For anything that we can call world is and can be nothing else than the working out of a general relation which a universal existence has created or established between itself, or let us say its eternal fact or potentiality and the powers of its becoming. That existence in its relations with and its experience of the becoming is what we call soul or Purusha, individual soul in the individual, universal soul in the cosmos; the principle and the powers of the becoming are what we call Nature or Prakriti (Aurobindo 1972c, p. 429).

In this view there exists neither a purely objective world "out there", nor a purely subjective experience "in here". Reality consists of the different *relationships* between consciousness-existence as observer and the *same* consciousness-existence as observed. Conscious existence is all there is at any level. When consciousness-existence identifies itself with the ordinary physical mind, it experiences a separation between itself as subject and itself as object and senses itself as a separate subject in the midst of what appears to it as an "objectively", independently existing matter. There can be no doubt that this is the most common experience of reality amongst humans, but otherwise it is not privileged in any manner.

Matter as we see it and our ordinary mental consciousness are not real primitives, but rather intermediate points on a long continuum of conscious-existence, which ranges from what appears to us as an unconscious matter to what appears to us as superconscious spirit. Of course in our ordinary mental awareness we don't see reality like this, we see the world as existing independently "out there", and we experience our own consciousness as existing "inside" and as looking out at that "objective reality". This is quite sufficient for most practical purposes, but will not do as a full description of reality.

It grants much too concrete a sense of reality to the world as we see it. It should be clear that not only acknowledged subjective phenomena like colour and hardness but even supposedly objective phenomena like space and time are constructs of our mental level of consciousness. *All* our descriptions of reality, whether stemming from a naive common sense or from the most sophisticated mathematical models of science, can, in principle, never be more than the outcome of the interaction between our observing conscious existence with whatever ineffable conscious existence presents itself to it as object. Even the very distinction between subject and object exists only on the intermediate levels: at the bottom consciousness is totally involved in its own separate existence, at the top it is all encompassing.

These different worlds of Veda and Vedanta are not closed systems that are completely sufficient within themselves. But it is not correct to speak of interactions between essentially different types of substances or forces either (e.g. of interactions between mind and matter). The different worlds are interwoven in a different manner, based on an underlying identity. In terms of the observing self, Vedanta holds that there is actually only one observing Self (the *paramatman*).

The many selves of the Sankhyas only appear separate and different from each other by a process of self-variation an "exclusive concentration" that takes place in portions of the original Self that in essence remains One. Similarly, as the Sankhyas acknowledge, there is only one objective reality, which is ineffable, or, in the more descriptive Sanskrit phrase, *anantaguna*, "of infinite quality".

So there is actually only one world of which we are portions and see aspects. When our individual consciousness expands and begins to merge with the cosmic consciousness, we begin to realise that there is only one conscious existence that separates itself, for the joy of manifestation, into an infinite number of relations between itself as observing consciousness and itself as observed Nature. At any given time, the only thing we can know about the reality is the interaction between the center, and thus the type, of consciousness we identify with and this ineffable Nature. The scientific, objective, relationship is just one amongst many such relationships.

FOUR TYPES OF KNOWLEDGE

On the basis of this broad philosophical conceptualisation of knowledge, consciousness and reality, we can now attempt to build a more pragmatic bridge between scientific and Vedic knowledge. Though the scientific and the Vedic ways of knowing seem so different as to be incompatible, they may actually be complimentary and prove to be equally needed to arrive at a complete picture of ourselves and of the world in which we live. While scientific knowledge has proven to be extremely effective within the limited range of the mental understanding of the physical world, the Vedic type of Knowledge has provided a comprehensive map of the whole field.

Just like science has spawned a technology to explore the material level of reality in an objective way, the Vedic tradition has developed yoga as an effective technology to study the inner and higher levels of reality in a subjective way. It does this largely by enabling the observer to change the type and center of his or her consciousness. This is not only relevant for those interested in metaphysics and spiritual growth. What happens on the higher and lower levels of consciousness has an enormous influence on our ordinary waking state, and their study is thus of the utmost importance for humanity. The systematic study of consciousness will have to begin, however, on the level of the ordinary waking mind. Even in our ordinary waking state, there is not only one type of knowledge, but several. In one place, Sri Aurobindo distinguishes four different types of knowledge that are routinely used in the ordinary waking state. Together they form a gradient between the external knowledge that Science works with and the inner knowledge that according to the Vedic tradition is the essence of all other forms of knowledge. The four types of knowledge are called as follows:

1. Knowledge by indirect separative contact (= scientific knowledge of the outer reality)
2. Knowledge by direct separative contact (= objective introspection of inner processes)
3. Knowledge by direct intimate contact (= experiential knowledge of inner processes)

4. KNOWLEDGE BY IDENTITY (= VEDIC KNOWLEDGE)

The first type of knowledge, *knowledge by indirect separative contact*, consists of explicit, objective information about what we see as the external world. Sri Aurobindo describes it as *indirect* because it is mediated by the external sense organs, and as *separative* because it goes together with a sense of clear separation between the self, who is the knower, and the object, which is the known. This type of knowledge has been developed and expanded impressively by the physical sciences over the last couple of centuries and is perhaps too well-known to need much further comment.

The last type, *knowledge by identity*, is the very different type of knowledge that we have of our own existence. For this type of knowledge the senses are not required as it is a knowledge that arises "from inside out." It is the knowledge we have of ourselves simply because we are. There is no difference here between subject and object and, in a way, not even a process: knowing and being are one. In our ordinary waking consciousness, knowledge by identity is hardly developed and almost point-like in character: it is undifferentiated and has no other content than the bare fact of its own existence. But according to the Vedic tradition, it is possible, through extensive spiritual practice, to develop this type of knowing further and then there is no theoretical limit to its scope. It is through this type of knowledge that the individual is considered capable of realising his or her identity with the Cosmic or the Transcendent Divine. It is also this type of knowledge the Upanishad speaks about when it says: "When That is known, all is known." The logic behind this amazingly bold statement is that knowledge by identity is in essence the knowledge of the Self, and as all individual Selves are ultimately one, it is considered possible to have an intimate self-knowledge of other selves.

This claim is in principle open for experimental testing, but it may be clear that it requires a rather radical change in many aspects of one's cognitive functioning to make knowledge by identity operational to a substantial degree. It should not be surprising, however, if smaller manifestations of the basic principle would be found to be fairly common, for example in occurrences of telepathic communication. As interest in consciousness studies increases and our insight in the processes and techniques of change in consciousness deepens, one can expect more and more interesting work in this direction.

In between these two extremes there are two more types of knowledge, both used for our internal states and processes. The first is knowledge about internal, psychological and physiological states and processes obtained by looking "objectively" at what is happening inside oneself. If one focuses on one's physical state, one could say for example, "My hands feel cold."

The cold sensation is then felt as pertaining to a part of myself, even though I'm neither fully identified with the cold sensation nor with the hands. The same separation between the inner observer and the inner observed can be experienced with feelings or thoughts. I can say for example, "I like this approach to Epistemology," or "I think that he is right." In this type of knowledge there is a small gap between the observer and the inner process that is being observed. This type of knowledge is thus called knowledge by separative direct contact, *separative* because there is this sense of distance between the knower and the known, *direct* because the outer senses are not required. This type of knowledge was, under the name of "introspection", used extensively in Psychology till the second decade of the twentieth century when it was discarded in favour of a purely external study of behaviour. In a later section we will discuss some of the difficulties with introspection and the solutions Indian psychology has found for them.

In the third type of knowledge one identifies with some inner psychological state or process. One is conscious, but one does not *observe* what is going on inside because one is fully involved in what one is doing. This type of identification is experienced for example, when one is fully engulfed in a feeling, say a feeling of happiness. If one expresses what one feels in such a state of engrossing happiness, one does not say anymore explicitly and self-referentially, "Today I'm really happy," which would imply a certain distance, but one's happiness shows implicitly in the manner in which one expresses oneself, e.g. "What a beautiful day it is today!" Similarly, when one is completely engrossed in one's own thinking one can express what one is thinking, but the expression does not involve a reflexive reference to the fact that one is thinking. One could say, for example, "You are right." Even in this case there must be some implicit awareness that one is thinking this, but one is

not aware of it by looking at one's own thinking process from the outside.

One is aware of it from within the thinking itself, or perhaps one should say, by *being* the thought. This third type is thus called knowledge by intimate direct contact, intimate because the observer is united with the observed, and direct because there are no intermediary sense organs involved. Knowledge by intimate direct contact is hardly used in the development of science but, under the name of "experiential knowledge", it is an essential element of all forms of "learning by doing" and the training of skills. It is also used extensively in psychotherapy, whether psychodynamic, cognitive behavioral, or humanistic / transpersonal. It can be trained to extraordinary levels of intensity and refinement by spiritual practice and it plays an important role in most mystical traditions.

Though it is useful to distinguish these four types of knowledge conceptually, in daily life they often go together, in quick succession or even simultaneously. The most fascinating aspect of this is, that the last, the knowledge by identity, is always present in the other three, be it often as a hidden, implicit presence. This is clear for the middle two: one simply *knows* that the hand one feels as cold is "one's own", one *knows* that it is oneself who is happy. But knowledge by identity is there in a diminished form even in our sense-based knowledge of the outside world: one recognises what one sees *as part of one's world*.

This may look like a rather minimal level of identification, but the suffering caused by its absence in some of the most serious and "unlivable" forms of schizophrenia, makes clear how essential this basic sense of belonging is for a healthy existence. There is another form in which knowledge by identity presents itself within our knowledge of the outside world, and that is in all we know about the structure of the world that we cannot derive from the raw data our senses provide. There are certain basic knowledge structures that are needed to make sense of what comes from the senses. The fundamental rules of logic and mathematics are one interesting example of such innate or intuitive knowledge, but it occurs also in the less formalized knowledge individuals have of their surrounding. Sri Aurobindo holds that a lot of this "built-in," instinctive knowledge is required to make anything at all out of the extremely incomplete and imperfect information that our sense-organs provide.

The necessity or otherwise of this type of pre-experiential knowledge has been discussed for centuries, but it appears the tide is slowly turning again in its favour. For example, Sir Karl Popper (1994, p.15) has given some of the most convincing arguments against a *tabula rasa* image of the newborn child and recent psychological research seems to provide experimental evidence corroborating the idea that we do have extensive innate knowledge about the structure of the world.

How such innate knowledge relates to intuitive knowledge remains however a complex issue. In Sri Aurobindo's description of the manifold reality, logic and mathematics both belong to the pure mental plane and not to the physical plane, and they are derived from knowledge by identity rather than from knowledge by separative indirect contact.

THE HONING OF SUBJECTIVE KNOWLEDGE

As a whole, science has concentrated almost exclusively on the acquisition of sense-based knowledge of the outer world. This is understandable in terms of the historical division of territories between science and religion at the time of Descartes. It can also be explained as a universal human trait: the windows of the senses look outwards, as the Upanishads say, and that is where we are inclined to look for truth in the first place. But there are also a number of pragmatic reasons that

have maintained this strong external focus. The main one is the lack of reliability of untrained introspection and other forms of subjective knowledge. All human perception is prone to error, but perceptions of inner states are particularly inconsistent and unreliable. There are many reasons for this. One of them is that human beings are aware of only a tiny fraction of what is going on inside.

We have access only to the surface and miss out on the forces and processes that take place below, behind and above the surface, and these surface appearances can be misleading. As Freud discovered in the early twentieth century and the Indian tradition in a completely different (and much more comprehensive) fashion several millennia earlier, it is from these deeper (and higher) layers of consciousness that our outer nature is determined. As long as one doesn't open the deeper recesses of one's nature to the inner sight, it is not possible to achieve a reliable form of introspection.

A second distorting factor is that we have an interest in the outcomes. In introspection one typically looks with one part of oneself at another part of oneself. It is extremely difficult to watch oneself objectively without any bias, fear or expectation. The mind has its preferences, the vital nature its desires and needs, the body its physical limitations.

All these interfere with a "clean" observation. This is of course true for external observations as well, but the outer reality does not so easily change because of one's moods or desires. The inner states, on the other hand, change easily under such influences and even due to the observing process itself. Taking all this together it is quite understandable that introspection was discarded in the beginning of the twentieth century as too unreliable a source of information for scientific use.

But none of these problems with introspection is irremediable. Each one of them can by systematic effort be eliminated. The different paths of Yoga have in fact all developed techniques that are supposed to achieve exactly this. They all aim to arrive at a direct perception and finally a merger of one's individual consciousness and being with the consciousness and being of the Divine. To make this possible, a considerable purification of one's inner instrument, or *antahkarana* is essential.

The different yogic traditions thus all have their methods to improve the range, the "resolution" and the reliability of inner perception. These techniques can be grouped into those that aim at greater concentration, at freedom from the sense-mind leading to an ability to penetrate the deeper and higher layers of consciousness, and at freedom from partial identifications, that is from the body, from the vital drives and emotions, from one's thoughts and finally from the ego-sense.

These techniques are within their tradition considered to lead to a free consciousness, capable of watching the movements of Prakriti, nature, as a completely independent witness, making it possible to observe inner events not only with a greater precision but also with a perfect "objectivity" and thus reliability. The inner disciplines of Yoga can thus play exactly the same role for a science of the inner realities as modern technology is playing for the material sciences.

CONCLUSION

If we presume that the essential nature, the *svadharma*, of science is to look for truth, then there should be all reason for science to expand its field and take up the methods of Yoga to achieve reliable and detailed knowledge of the inner realities.

This is, however, an entirely new territory for science. Modern science is a child of the European Enlightenment and systematic methods to train consciousness have, at least in recent times, not been part of the mainstream western tradition. Besides new methodologies, it would involve new attitudes towards personal involvement and, perhaps most difficult of all, the acceptance of Indic ontologies, which are more comprehensive than the materialistic and idealistic philosophies with which the West is familiar.

It will even involve new scientific hierarchies, based less on intellectual acumen and vital assertiveness, and more on inner wisdom. Given the political and economical dominance of the West at present, one can expect considerable resistance to this acceptance of Eastern techniques, philosophies and attitudes.

There are, however, precedents of cultural influence moving in the opposite direction of political conquest. In classical Rome, for example, Greek art and science were widely, and we would now say rightly, valued above their Roman counterparts: after Athens had been defeated militarily and politically, slaves from Greece were used extensively as teachers for the Roman elite.

Eugene Taylor predicts, on the basis of a detailed study of the history of spirituality in the United States, that a similar cultural counter stream will take place in the coming years.

He sees that as a result of a "cross-cultural exchange of ideas between East and West unprecedented in the history of Western thought" there will be a "historical change in the very context in which reality is defined" (Taylor 1999, p. 290). One can only hope that Taylor's prediction will come true. At present spiritual development is left entirely to the subculture and remains outside the compass of science.

As a result, mainstream society is in a state that has much in common with multiple personality disorder. Public life -- the media, government, business, and education -- is entirely governed by the materialist and reductionist ideas of the physical sciences.

Private life, after five and in the weekends, follows often a completely different set of values and truths. Like all such internal divisions this split is leaving both sides diminished. Science is providing more and more power without the wisdom to use it. Religion and spirituality abound in uncritically accepted creeds and dogmas, and miss the best that the progressive intellect of humanity could have given them. If science and spirituality can come together we can expect an unprecedented collective progress in the inner realm, and it is hard to deny that this is sorely needed.

All really serious problems facing humanity at the present stage are not material in nature but psychological. Imagine the joy and fulfillment if the ancient yogic techniques for attaining inner peace, freedom and wisdom could again become an organic part of our collective life and could be developed further for the benefit of all present and future generations!.

Emergence of Psychology MCQs

1. Phrenologists tried to find out about personality by:
 - a. reading a person's horoscope
 - b. feeling a person's skull
 - c. looking at a person's hands
 - d. asking people questionsAnswer: d

2. A limitation of selective breeding studies is that they cannot:
 - a. tell us anything about the role of genes
 - b. be used to study human beings
 - c. provide information relevant to the nature/nurture debate
 - d. tell us anything about the role of the environmentAnswer: d

3. Which neo-Freudian challenged his ideas about penis envy?
 - a. Adler
 - b. Fromm
 - c. Jung
 - d. HorneyAnswer: d

4. Someone who feels as though they are not living up to expectations would be described by Adler as having:
 - a. low self-realization
 - b. an Adlerian complex
 - c. an inferiority complex
 - d. low actualizationAnswer: d

5. According to Freud, the mind's three components are:
 - a. ego, id, superego
 - b. unconscious, moral, immoral
 - c. oral, anal, phallic
 - d. primary, secondary, tertiaryAnswer: d

6. The idea that you can assess someone's personality by studying their face is called:
 - a. phrenology
 - b. physiology
 - c. somatology
 - d. physiognomyAnswer: d

7. The complex is to girls as the complex is to boys.
- Electra, Oedipus
 - Oedipus, Electra
 - oral, phallic
 - phallic, oral
- Answer: a
8. The discovery that the heritability of the Big Five personality traits is around 40% – 50% suggests that:
- the environment plays no role in personality
 - genes play no role in personality
 - the environment plays an important role in personality
 - the Big Five traits account for about half of our personality
- Answer: c
9. Humanistic psychologists embraced the idea of:
- repression
 - free will
 - unconscious drives
 - the id
- Answer: b
10. According to Eysenck, extraverts seek to their arousal while introverts seek to their arousal.
- decrease, increase
 - hide, reveal
 - increase, decrease
 - reveal, hide
- Answer: c
11. Allport believed that traits could be organized into three levels:
- primary, secondary, tertiary
 - cognitive, emotional, physiological
 - id, ego, superego
 - cardinal, central, secondary
- Answer: d
12. The MMPI is used to measure:
- unconscious drives
 - the Big Five traits
 - personality and psychological disorders
 - leadership potential
- Answer: c

- 13.** Which of the following is NOT one of the Big Five traits?
- a. sense of humour
 - b. openness to experience
 - c. conscientiousness
 - d. extraversion
- Answer: a
- 14.** Freud founded the _____ approach to understanding human behaviour.
- a. palliative
 - b. psychodynamic
 - c. patronymic
 - d. psychedelic
- Answer: b
- 15.** The influence of parents on the personality of their children is:
- a. non-existent
 - b. weakest in early childhood
 - c. strongest in early childhood
 - d. consistent across the lifespan
- Answer: c
- 16.** What is special about “knockout” mice?
- a. they are very attractive
 - b. their DNA has been modified
 - c. they are easy to knock out
 - d. they are unusually aggressive
- Answer: b
- 17.** The aim of behavioural genetics is to learn about:
- a. the extent to which geneticists can modify people’s behaviour
 - b. the possibility of eradicating behavioural problems in children
 - c. the genetic and environmental influences on human behaviour
 - d. the ability of animals to learn language
- Answer: c
- 18.** Monozygotic is to _____ twins as dizygotic is to ___ twins.
- a. male, female,
 - b. female, male
 - c. fraternal, identical
 - d. identical, fraternal
- Answer: d
- 19.** Which of the following characteristics describe someone who, according to Maslow, is self-actualized?
- a. creativity

- b. confidence
 - c. spontaneity
 - d. all of the above Answer: d
20. According to Freud, children pass through 4 stages of psychosexual development. Which of the following shows the stages in the correct developmental order?
- a. oral, anal, phallic, latency
 - b. latency, oral, anal, phallic
 - c. phallic, anal, oral, latency
 - d. oral, phallic, latency, anal Answer: a
21. Projective tests claim to reveal information about:
- a. career aptitude
 - b. intellectual attainment
 - c. unconscious processes
 - d. parenting style Answer: c
22. Traits are defined as:
- a. physical characteristics that distinguish us from other people
 - b. relatively enduring characteristics that influence our behaviour across many situations
 - c. unconscious tendencies to act in different ways according to the situation
 - d. permanent personality tendencies that determine our behaviour in any situation Answer: b
23. Sheldon's theory that people with different body types have different personalities has been:
- a. supported by research
 - b. discredited
 - c. shown to be accurate for thin people but not overweight people
 - d. shown to be accurate for women but not for men Answer: b
24. Which of the following is not a defence mechanism?
- a. projection
 - b. regression
 - c. ingratiation
 - d. sublimation Answer: c
25. Rohan is self-disciplined, focused on achievement and keen to do his duty. He would be expected to score highly on:
- a. neuroticism
 - b. agreeableness
 - c. extraversion

- d. conscientiousness
Answer: d
26. The Barnum effect helps to explain people's belief in:
- fortune-telling
 - astrology
 - horoscopes
 - all the above
Answer: d
27. ___ are the basic biological units that transmit characteristics from one generation to the next:
- genes
 - neurons
 - glia
 - instincts
Answer: a
28. Which of the following would NOT be useful to a behavioural geneticist?
- family studies
 - case studies
 - adoption studies
 - twin studies
Answer: d
29. According to Freud, the id is to the ___ principle as the ego is to the _____ principle.
- aggressive, sexual
 - sexual, aggressive
 - pleasure, reality
 - reality, pleasure
Answer: c
30. Lana is friendly, always willing to help others and compassionate. We would expect Lana to score highly on:
- extraversion
 - agreeableness
 - neuroticism
 - openness to experience
Answer: b
31. Consider the following statement (s) is related to the features of Sufism
- They recognize the value of repetition of God's name and sometimes resort to music of a loving devotional character as an aid to concentration.
 - Instead of depriving God of form and attributes they impute to him the qualities of effulgence, love, mercy, generosity and immanence.
 - Instead of inculcating fear of the wrath of God, they put forward the ideal of securing union with Him by pursuing the path of perfect love.
- Which of the following statement (s) is/are correct?

- A. Only I
 B. Only II
 C. I, II & III
 D. None of the above
 Ans: C
32. Which of the following was the first Sufi Order in Indian Subcontinent?
 A. Chishti
 B. Qadiriyya
 C. Suhrawardiyya
 D. Naqshbandi
 Ans: A
33. Which was/were not the basic devotional practices of Chisti order of Sufi?
 A. Reciting the names of Allāh loudly, sitting in the prescribed posture at prescribed times (dhikr-i dzahir)
 B. Reciting the names of Allāh silently (dhikr-i khafī)
 C. Regulating the breath (pās-ianfās)
 D. Lifelong of spiritual confinement in a lonely corner or cell for prayer and contemplation (čilla)
 Ans: D
34. Which is/are the correct principles of Chisti Order?
 I. Unselfish service to mankind
 II. Living for Allah alone
 III. Maintaining complete trust in Him
 IV. Inexhaustible generosity and forgiveness
 Code:
 A. Both I & II
 B. Both I & III
 C. Both III & IV
 D. I, II, III & IV
 Ans: D
35. Which of the following is/are correct reasons for the extensive development of the Chishti order in India?
 A. The strong disapproval of mixing with the Sultans, princes or nobles by the Chishti Shaikhs together with establishing close contacts with the poor and the downtrodden.
 B. Their uncompromising attitude towards all forms of political oppression and social injustice.
 C. Their bold stand in favour of Sama, which has been vehemently, criticized by the orthodox Ulama and upholders of some other orders.
 D. All of the above
 Ans: D

- 36.** What do you mean by Wahdat al-Wujud?
- Unity of Being
 - Unity of Humanity
 - Unity of God
 - Unity of Thought
- Ans: A
- 37.** Which of the following was/were the doctrine of Sufism?
- Meditation & Good action
 - Repentance of sins
 - Performance of prayers
 - Charity & Suppression of passions by ascetic practices
- Code:
- Only I
 - Only II
 - I, II & III
 - I, II, III & IV
- Ans: D
- 38.** Who translated Chintamani Bhatt's Suka Saptati into Persian from Sanskrit and gave it the title Tuti-nama?
- Khwaja Qutbuddin Bakhtiyar Kaki
 - Baba Farid
 - Khwaja Ziauddin Nahkashabi
 - None of the above
- Ans: C
- 39.** Who among the following Sufi Saint popularly known as Makhdum-i-Jahaniyan (Lord of the world's people)?
- Sufi Sayyid Jalaluddin Bukhari
 - Shaikh Fakhruddin Ibrahim Iraqhi
 - Shaikh Sharufuddin Ahmad Yaha Munyari
 - Mir Sayyid Ali Hamadani
- Ans: A
- 40.** Who was the composer of treatise called Hamat (Flashes) which constitutes a very impressive commentary on the Unity of Being (Wahdat-al- Wujud)?
- Sufi Sayyid Jalaluddin Bukhari
 - Shaikh Fakhruddin Ibrahim Iraqhi
 - Shaikh Sharufuddin Ahmad Yaha Munyari
 - Mir Sayyid Ali Hamadani
- Ans: B

- 41.** Postcolonialism refers to
- a historical phase undergone by Third World countries after the decline of colonialism
 - a slave mindset
 - an important tenet of structuralism
 - the deconstructive "différance" Answer: a
- 42.** Which sub-specialty in postcolonial criticism analyzes the importance of human constructions of physical with mental spaces, especially in political contexts?
- spatial/geographical studies
 - psycho-mythic studies
 - ecofeminism
 - both a and b Answer: a
- 43.** Homi Bhabha's most significant concept is
- postcolonial interpellation
 - the objective correlative
 - hybridity
 - orientalism Answer: c
- 44.** The claim of Robert C. J. Young is that postcolonialism
- looks "at the world from the other side of the photograph"
 - is historically inaccurate
 - is the product of leftist propaganda
 - all of the above Answer: a
- 45.** Postcolonial critics speak primarily of
- slavery in ancient cultures
 - the conquests of Spain
 - Euro-American imperialism
 - African-African slavery Answer: c
- 46.** Chinua Achebe attacks for its racism
- Adventures of Huckleberry Finn
 - Frankenstein
 - Heart of Darkness
 - The "Nigger" of the Narcissus Answer: c

- 47.** The departure from a homeland by a people is called by postcolonial critics
- diaspora
 - emigration
 - inundation
 - interpellation
- Answer: a
- 48.** Postcolonial criticism has been important to
- Third-World feminism
 - deconstruction
 - structuralism
 - psychological approaches
- Answer: a
- 49.** According to Gayatri Chakravorty Spivak, a "subaltern" is
- usually a woman
 - a Third-World denizen
 - multiply oppressed
 - all of the above
- Answer: d
- 50.** The motif of a "City Upon a Hill" has been used by
- the author of the Gospel of Matthew
 - John Winthrop in "A Model for Christian Charity"
 - John F. Kennedy in his Inaugural Address
 - all of the above
- Answer: d
- 51.** According to the text, the lower level of explanation corresponds to _____ processes.
- social
 - cultural
 - biological
 - interpersonal
- Answer: c
A psychologist exploring the impact of a new drug on activity in the brain is working on the Answer: c level of explanation.
- 52.** Psychology is defined as the scientific study of:
- people and things
 - emotions and beliefs
 - perception and religion

- d. mind and behavior
Answer: d
53. The scientific approach is more useful at answering questions about _____ than questions about ____.
- a. lower
 - b. middle
 - c. upper
 - d. all of the above
Answer: a
54. A psychologist studying what makes people laugh in different countries around the world is working on the _____ level of explanation.
- a. lower
 - b. middle
 - c. higher
 - d. none of the above
Answer: c
55. Different people react differently to the same situation. This is referred to as:
- a. multiple determinants
 - b. nativism
 - c. the Simpson effect
 - d. individual differences
Answer: d
56. ____ is to nature as _____ is to nurture.
- a. environment, genes
 - b. conscious, unconscious
 - c. inaccuracy, accuracy
 - d. biology, experience
Answer: d
57. The term "tabula rasa" highlights the importance of ____ in shaping behaviour.
- a. genes
 - b. experience
 - c. nature
 - d. predestination
Answer: b
58. The Greek philosopher _____ believed that knowledge is acquired through experience and learning.
- a. Archimedes
 - b. Rousseau
 - c. Plato
 - d. Aristotle
Answer: d
59. ____ is to nature as _____ is to nurture.
- a. Plato, Aristotle

- b. Aristotle, Plato
 - c. Pliny, Archimedes
 - d. Stavros, PlinyAnswer: a
- 60 __is the belief that the mind is fundamentally differentfrom the body.
- a. mindism
 - b. dualism
 - c. centralism
 - d. specialismAnswer: b
- 61 The school of psychology whosegoal was to identify the basic elements of experience was called:
- a. experientialism
 - b. dualism
 - c. functionalism
 - d. structuralism Answer: d
- 62 Which of the following was mostclosely associated with the structuralist school of psychol-ogy?
- a. Titchener
 - b. James
 - c. Descartes
 - d. WatsonAnswer: a
- 63 Darwin's theory of_____arguedthat physiological characteristics evolve because they are useful tothe organism.
- a. extreme usefulness
 - b. natural endowment
 - c. natural selection
 - d. natural wellbeingAnswer: c
- 64 __was to structuralism as___was to functionalism.
- a. Wundt, Titchener
 - b. Wundt, James
 - c. James, Titchener
 - d. Milner, ThompsonAnswer: b
- 65 Freud championed _____ psychology.
- a. psychodynamic
 - b. cultural
 - c. conscious
 - d. biodynamicAnswer: a

- 66** Which school of psychology believes that it is impossible to objectively study the mind?
- functionalism
 - behaviorism
 - humanism
 - socialism
- Answer: b
- 67** Receiving an electric shock would be an example of a _____ whereas being frightened would be an example of a _____.
- stimulus, response
 - punishment, reward
 - reaction, emotion
 - reinforcement, stimulus
- Answer: a
- 68** Dr Pula wants to explore differences in child-rearing practices between British and Chinese parents. She is most likely a:
- cognitive psychologist
 - physiological psychologist
 - cognitive-ergonomic psychologist
 - social-cultural psychologist
- Answer: d
- 69** Nature is to _____ as nurture is to _____.
- environment/genes
 - conscious/unconscious
 - genes/environment
 - unconscious/conscious
- Answer: c
- 70** Freud emphasized the role of _____ in shaping people's personality.
- free will
 - unconscious desires
 - hormones
 - group influence
- Answer: b
- 71** Evolutionary psychology has its roots in:
- behaviourism
 - collectivism
 - functionalism
 - structuralism
- Answer: c
- 72** Most human behaviour:
- can be easily explained
 - has multiple causes
 - stems from unconscious desires
 - depends on social influence
- Answer: b

74. forensic psychologist would be most likely to study:
- the accuracy of eyewitness memory
 - the impact of advertising on shopping behaviour
 - the effect of hormones on decision making
 - gender differences in learning styles
- Answer: a
75. The behaviourists rejected introspection because:
- it was too slow
 - it invaded people's privacy
 - it yielded too much data
 - it was too subjective
- Answer: d
76. Another term for reinforcement is:
- stimulus
 - reward
 - response
 - condition
- Answer: b
77. East Asian cultures tend to be more oriented toward ___ while Western cultures tend to be more oriented toward__.
- individualism/collectivism
 - collectivism/individualism
 - cultural norms/social norms
 - social norms/cultural norms
- Answer: b
78. Watson and Skinner both contributed to which school of psychology?
- functionalism
 - cognitive
 - social-cultural
 - behaviourism
- Answer: d
79. Which field of psychology would be most likely to study the influence of over-crowding on conformity?
- personality
 - cognitive
 - clinical
 - social
- Answer: d
80. The child having the difficulty in picking up objects is suspected to have
- Lower level of intellectual function
 - Sight impairment
 - Speech impairment
 - Locomotor impairment
- Answer: D

81. Which philosophy developed the monitorial system in classrooms?

- a. Vedic
 - b. Vedant
 - c. Islam
 - d. Buddhism
- Answer: C

82. Match the following :

List – I (Thinker)	List – II (Type of Education)
I. Gandhi	1. Shantiniketan
II. Tagore	2. Integral Yoga
III. Aurobindo	3. Gurukul
IV. Vivekananda	4. Man making education
5. Wardha Scheme	

Code :

I III III IV(A) 5 1 2 4

(B) 5 1 4 2

(C) 3 4 2 5

(D) 4 2 3 5

Answer: A

83. If Ram is taller than Mohan and Mohan is taller than Sohan, Ram is the tallest. This statement comes under which type of reasoning ?

- a. Inductive Reasoning
 - b. Deductive Reasoning
 - c. Linear Reasoning
 - d. Conditioned Reasoning
- Answer: C

84. When a poor rural girl hailing from a socially disadvantaged family gets scholarship for higher studies and then lands in a high paid job in city it is not an instance of education becoming

- a. a vehicle for social mobility
 - b. a tool for gender justice
 - c. a vehicle for geographical mobility
 - d. an instrument for social stratification
- Answer: D

85. The policy of reservation of seats in higher education and in Government employment is an example for.

- a. Sponsored mobility
 - b. Contest mobility
 - c. Cultural mobility
 - d. Geographical mobility
- Answer: A

86. What does the Counsellor do in "Observation for Recording" and "Observation for Rating"?

- I. In Observation for Recording, the Counsellor acts like a versatile camera.
- II. In Observation for Recording, the Counsellor records everything unmindful of the distraction

caused to the client.

- III. In Observation for Rating, the Counsellor does not observe the client while indulged in rating.
- IV. In Observation for Rating, the Counsellor judges and rates the brain, while still observing the client.

Choose the correct answers from the code given below:

- a. I and IV
 - b. II and III
 - c. I and III
 - d. III and IV
- Answer: A

87. A face to face, informal interaction is considered the best technique for collecting information about the client and his/her problem. How?

- a. It helps to get first hand information about the client and his/her problem.
 - b. It is very easy to organise and conduct an interview with the client.
 - c. The interview can be videographed.
 - d. It is flexible and makes the client feel comfortable.
- Answer: A

88. What is meant by the term "curriculum"?

- a. The subject of study offered by an educational institution.
 - b. Theory and Practical courses to be completed to qualify for a level of education.
 - c. Organised whole of learning and other experiences provided by educational institutions, to realize set goals.
 - d. The prescribed syllabi in the various subjects, plus practical courses and project/ dissertation.
- Answer: C

89. What are the uses of System Analysis, when applied to classroom instruction as a sub system of the curriculum?

- I. It helps to design classroom instruction differently.
- II. It helps to assess the effectiveness of the existing instructional design.
- III. It helps the teacher to verify results and get feedback.
- IV. It helps as a novel method of reviewing classroom instruction.

Choose the correct answers from the code given below:

- a. III, IV and I
 - b. I, II and III
 - c. IV, I and II
 - d. II, III and IV
- Answer: B

90. Tests that do not require the use of language of the subjects but responses are in the form of activities are called as

- a. Verbal tests
 - b. Non-verbal tests
 - c. Performance tests
 - d. None of the above
- Answer: C

91. Identity versus role confusion is a characteristic of

- a. Childhood stage

- b. Adolescence stage
 - c. Infancy stage
 - d. Early childhood stage Answer: B
92. Who is a famous psycholinguistic?
- a. Gardner
 - b. Alan Newell
 - c. A. Simon
 - d. Noam Chomsky Answer: d
93. The effectiveness of a multi-media approach in teaching can be answered through
- a. Experimentation
 - b. Survey
 - c. Case-studies
 - d. Longitudinal studies Answer: A
94. Who is the author of book Principle of Psychology?
- a. Willhelm Wundt
 - b. Charles Darwin
 - c. Sigmund Freud
 - d. William James Answer: d
95. In which year Sigmund Freud published the book 'The Ego' and 'The Id'?
- a. 1927
 - b. 1972
 - c. 1980
 - d. 1908 Answer a
96. First issue of cognitive neuroscience appears in the year.
- a. 1967
 - b. 1989
 - c. 1997
 - d. 1978 Answer b
97. Psychology is a _____.
- a. A natural science
 - b. A physical science
 - c. A biological science
 - d. A social science Answer: D
98. Psychology as a 'Science of Mind', defined by _____ school of psychology.
- a. Psychoanalysts
 - b. Behaviourists
 - c. Functionalists

d. Ancient Greek Philosophers Answer: D

99. In the year _____ the Scientific Psychology was first accepted.

a. 1779

b. 1679

c. 1879

d. 1889 Answer: C

100. Who is the father of Experimental Psychology.

a. Wilhelm Wundt

b. Sigmund Freud

c. C.G. Jung

d. E.B. Titchener Answer: A

101. Psychology can be literally defined as the__.

(a) Science of mind

(b) Science of behaviour

(c) Science of soul

(d) Science of consciousness Answer: C

102. J.B. Watson, the founder and father of behaviouristic school of psychology defined 'Psychology' as the science of _____.

(a) Soul

(b) Consciousness

(c) Mind

(d) Behaviour Answer: D

103. E.B. Titchener (1867-1927) defined 'Psychology' as the science of _____.

(a) Conscious Experience

(b) Science of Mind

(c) Science of Experience

(d) Science of Soul Answer: A

104. Who defined 'Psychology' as the scientific study of activities of organism in relation to its environment?

(a) J.B Watson

(b) Sigmund Freud

(c) Wood worth

(d) William James Answer: C

105. "S-R" concept was first established by _____.

(a) J.B Watson

- (b) Wilhelm Wundt
- (c) William James
- (d) I.P. PavlovAnswer: A

106. Rejecting the concept of “S-R” connectionism, further “S-O-R” concept was developed by _____.

- (a) Woodworth
- (b) C.G. Jung
- (c) E.B. Titchener

107. Who defined “Psychology as the science of immediate experience with consciousness being the main subject matter”?

- (a) E.B. Titchener
- (b) William James
- (c) Sigmund Freud
- (d) Wilhelm WundtAnswer: a&d

108. Who is the founder and principal proponent of psychoanalysis__.

- (a) Sigmund Freud
- (b) E.B Titchener
- (c) C.G. Jung
- (d) Alfred AdlerAnswer: A

109. Who is the psychologist who constructed the first intelligence test?

- (a) William James
- (b) J. B. Watson
- (c) William Mc Dougall
- (d) Alfred BinetAnswer: D

110. The occurrence of ‘O’ in ‘S-O-R’ concept is responsible in regulating the behavior of the organism and making psychological activity

- (a) Complex
- (b) Dynamic
- (c) Fixed
- (d) PuzzledAnswer: B

111. Anything which evokes a response in the Organism is called.

- (a) Stimulus
- (b) Thing

- (c) Situation
- (d) IncidenceAnswer: A

112. The method of 'Field Observation' is always considered as_____.

- (a) Subjective
- (b) Complex
- (c) Neutral
- (d) ObjectiveAnswer: D

113. To study Abnormal Psychology means, to study mainly the nature of_.

- (a) Normality of mind
- (b) Unconscious level of mind
- (c) Subconscious level of mind
- (d) Abnormality of mindAnswer: B

114. Clinical Psychology deals withthe practical aspect of_____.

- (a) Abnormal Psychology
- (b) Educational Psychology
- (c) Child Psychology
- (d) Experimental PsychologyAnswer: A

115. Sigmund Freud is regarded asthe father of,in psychology. (a) Gestalt school

- (b) Behaviouristic school
- (c) Functionalistic school
- (d) Psychoanalytic schoolAnswer: D

116. Ebbinghuas, had done thepioneering experiments on

- (a) Perception
- (b) Emotion
- (c) Memory
- (d) ThinkingAnswer: C

117. Science is invariably characterised by_____.

- (a) Its methodology
- (b) Its theory
- (c) Its fact
- (d) Its hypothesisAnswer: A

118. General psychology deals with_____.

- (a) Personality
- (b) Development
- (c) Intelligent
- (d) Fundamentals of all branches of psychology Answer: D

119. Industrial Psychology is_____.

- (a) Theoretical Psychology
- (b) Applied Psychology
- (c) Educational Psychology
- (d) Abnormal Psychology Answer: B

120. Developmental Psychology studies_.

- (a) Personality
- (b) Motivation
- (c) Intelligence
- (d) Various stages of development of man Answer: D

121. Abnormal Psychology is concerned with_____.

- (a) Developmental stages of individual
- (b) Diagnosis of abnormal behaviour
- (c) Abnormal behaviour and its causes
- (d) Treatment of abnormal behaviour Answer: C

- (a) Behaviour of an individual at work
- (b) Behaviour and experience in social situations
- (c) Behaviour of ethnic groups
- (d) Abnormal Behaviour of people Answer: B

123. Psychology is the science studying the behaviour of_____.

- (a) Mankind
- (b) Living Organism
- (c) Animals
- (d) Plants Answer: B

124. Some of the most useful knowledge of human perception has borrowed from_____.

- (a) Chemistry
- (b) Physics
- (c) Sociology

(d) ZoologyAnswer: B

125. A major part of developmental psychology is devoted to the understanding of behaviour of _____.

- (a)** Children
- (b)** Adolescents
- (c)** Women
- (d)** Old peopleAnswer: A

126. Who is the founder of 'Individual Psychology'?

- (a)** David Hull
- (b)** Thorndike
- (c)** Alfred Binet
- (d)** Alfred AdlerAnswer: D

127. From the following pioneered psychologist who is associated with Behaviourism?

- (a)** B.F. Skinner
- (b)** William James
- (c)** Megde Arnold
- (d)** David HullAnswer: A

128. Who is recognised as the father of psychoanalysis?

- (a)** Sigmund Freud
- (b)** Tolman
- (c)** Alfred Adler
- (d)** William JamesAnswer: A

129. Wolf Gang Kohler was associated with _____ school of psychology.

- (a)** Social Psychology
- (b)** Gestalt Psychology
- (c)** Industrial Psychology
- (d)** Educational PsychologyAnswer: B

130. The "Law of effect" was coined by _____.

- (a)** Skinner
- (b)** Pavlov
- (c)** Kohler
- (d)** ThorndikeAnswer: C

131. Archetype is a terminology associated with _____.

- (a) Jung
 - (b) Freud
 - (c) Adler
 - (d) Skinner
- Answer: C

132. Who established the first experimental psychological laboratory?

- (a) Sigmund Freud
 - (b) B.F. Skinner
 - (c) Evan Pavlov
 - (d) Wilhelm Wundt
- Answer: D

133. Who is the valuable contributor in insightful learning?

- (a) Thordike
 - (b) B.F. Skinner
 - (c) Evan Pavlov
 - (d) Kohler
- Answer: D

134. The most pioneered contributor to Behavioural school of psychology is_____.

- (a) Freud
 - (b) Allport
 - (c) Watson
 - (d) Fechner
- Answer: C

135. Wilhelm Wundt established the first laboratory of experimental psychology at_____.

- (a) Greenwich
 - (b) Zurich
 - (c) Leipzig
 - (d) Munich
- Answer: C

136. From the following psychologist, who rejected introspection as a method of psychology__.

- (a) B.F. Skinner
 - (a) Fulton
 - (b) Cattell
 - (c) J.B. Watson
- Answer: D

137. In which method of study of psychology, independent and dependent variable are important elements.

- (a) Introspection Method
- (b) Experimental Method
- (c) Observational Method

(d) Case History Method
Answer: B

138. In _____ method of study in psychology, passive study and analysis of human behaviour is usually done.

(a) Introspection Method

(b) Experimental Method

(c) Observational Method

(d) Genetic Method
Answer: C

139. In the simplest experimental method, 'E' manipulates ____.

(a) One Variable

(b) Two Variables

(c) Three Variables

(d) Four Variables
Answer: A

140. What it is called, when more than one independent variable works in an experimental situation.

(a) Situational Crisis

(b) Interaction

(c) Multisituational Effect

(d) Variable Crisis
Answer: B

141. Who has been considered as the father of psychoanalysis method of study__?

(a) Sigmund Freud

(b) E.B Titchener

(c) C.G. Jung

(d) Alfred Adler
Answer: A

142. Who has been credited as the first developer of first intelligence test and made important contributions to our understanding of the thought process?

(a) William James

(b) Alfred Binet

(c) William McDougall

(d) J.B. Watson
Answer: B

143. The concepts like "Introspection" and "Conscious Experience" are associated with__.

(a) Functionalism

(b) Behaviourism

(c) Structuralism

(d) Gestalt Psychology
Answer: C

- 144.** A Provisional theory to explain observed facts is known as_____.
- (a) Construct
 - (b) Theory
 - (c) Hypothesis
 - (d) Event Answer: C
- 145.** ___ is the least noticeable value of stimulus.
- (a) Stimulus Threshold
 - (b) Response Threshold
 - (c) Hypothesis
 - (d) Problem Answer: A
- 146.** ___ approach emphasizes the role of instinctual processes and their modification in the course of interaction with the society.
- (a) Dynamic and Psychoanalytic Approach
 - (b) Cognitive Approach
 - (c) Holistic Approach
 - (d) Stimulus-Response Behaviouristic Approach Answer: A
- 147.** The system which still survives very nearly in its rigid forms is
- (a) Dynamic and Psychoanalytic
 - (b) Approach
 - (c) Stimulus-Response Behaviouristic Approach
 - (d) Existential Approach Answer: C
- 148.** _ approach is popularly rooted in Gestalt psychology.
- (a) Wholistic Approach
 - (b) Cognitive Approach
 - (c) Dynamic and Psychoanalytic Approach Holistic Approach
 - (d) Existential Approach Answer: B
- 149.** The perspective which is concerned with characteristic changes that occur in people as they mature is known as_____.
- (a) Developmental Perspective
 - (b) Biological Perspective
 - (c) Humanistic Perspective
 - (d) Psychoanalytic Perspective Answer: A
- 150.** For the first time, the word 'Psychology' is introduced by__.
- (a) Rudolf Goekle
 - (b) William James

- (c) Sigmund Freud
- (d) C. G. JungAnswer: A

151. Rudolf Goekle used the word 'Psychology' for the first time in theyear_.

- (a) 1590 AD
- (b) 1095 AD
- (c) 1950 AD
- (d) 1509 ADAAnswer: A

152. Which branch of psychologydeals with the study of animal behaviour?

- (a) Social Psychology
- (b) Comparative Psychology
- (c) Abnormal Psychology
- (d) Differential PsychologyAnswer: B

153. Woodworth's approach todefine Psychology is_____.

- (a) Dynamic
- (b) Constant
- (c) Fluctuating
- (d) simpleAnswer: A

154. Who is the Founder of GestaltPsychology_?

- (a) Kurt Koffka
- (b) Max wertheimer
- (c) Kurt Lewin
- (d) Wolfgang KohkerAnswer: B

155. ___ field of psychologyfocuses on the potential role of evolution in behaviour.

- (a) Developmental Psychology
- (b) Physiological Psychology
- (c) Evolutional Psychology
- (d) Cognitive PsychologyAnswer: C

156. Which perspective of psychology emphasizes the overtbehaviour of the individual?

- (a) Developmental Perspective
- (b) Behaviouristic Perspective
- (c) Humanistic Perspective
- (d) Psychoanalytic PerspectiveAnswer: B

157. Thought process is the maincomponent of _____ perspective.

- (a) Gestalt Perspective
 - (b) Biological Perspective
 - (c) Humanistic Perspective
 - (d) Cognitive Perspective
- Answer: D

158. ___ perspective focuses on changes in behaviour and cognitive processes over the life span.

- (a) Developmental Perspective
 - (b) Biological Perspective
 - (c) Humanistic Perspective
 - (d) Psychoanalytic Perspective
- Answer: A

159. 'Behaviour can be influenced by social and cultural factors', the ___ perspective of psychology emphasizes it.

- (a) Developmental Perspective
 - (b) Biological Perspective
 - (c) Humanistic Perspective
- Answer: D

160. The frameworks for explaining various events or processes in science is known as ____.

- (a) Facts
 - (b) Theories
 - (c) Models
 - (d) Hypothesis
- Answer: B

161. Emphasizing what comes to mind first or most readily/quickly is known as ____.

- (a) Heuristic
 - (b) Critical Thinking
 - (c) Intuitive Thought
 - (d) Confirmation Bias
- Answer: A

162. A systematic study of facts according to a reliable and correct method of study is called a ____.

- (a) Scientific Study
 - (b) Biological Study
 - (c) Social Technique

- (a) Genes
 - (b) Culture and environment
 - (c) Past life
 - (d) God or almighty
- Answer: A

178. The role of brain, body chemical, central nervous system, neural mechanism, etc., are considered the__ branch of psychology.

- (a) Cognitive psychology
 - (b) Positive psychology
 - (c) Neuropsychology
 - (d) Evolutionary psychology
- Answer: C

179. Who proposed the famous PASS theory on psychology?

- (a) Binet-Simon
 - (b) Cattell
 - (c) J. P Das
 - (d) Thurstone
- Answer: C

180. The first psychological laboratory was established in India at__.

- (a) Delhi University
 - (b) Bombay University
 - (c) Calcutta University
 - (d) Banaras Hindu University
- Answer: C

181. First Psychology department started in the department of philosophy at Calcutta University in the year_____.

- (a) 1905
 - (b) 1916
 - (c) 1890
 - (d) 1780
- Answer: B

182. First psychology Department in India established by the headship of.

- (a) Prof. K. D. Brata
 - (b) Prof. N. N. Sengupta
 - (c) Prof. G. Gupta
 - (d) Prof. Ganguli
- Answer: B

183. The famous book 'Principles of Psychology' was authored by__.

- (a) Wilhelm Wundt
 - (b) E. B. Titchner
 - (c) J. B. Watson
 - (d) William James
- Answer: D

184. According to J. B. Watson, 'Psychology is a Science of ____'.

- (a) Soul
 - (b) Mind
 - (c) Behaviour
 - (d) Brain
- Answer: C

185. Some of our most useful knowledge of human perception borrowed from__.

- (a) Physics
 - (b) Chemistry
 - (c) Sociology
 - (d) Mathematics
- Answer: A

186. The structuralist intended to identify the building blocks of__.

- (a) Consciousness
 - (b) Subconsciousness
 - (c) Unconsciousness
 - (d) None of the above
- Answer: A

187. Who discovered that all mental processes are not accompanied by mental imagery?

- (a) Wilhelm Wundt
 - (b) E. B. Titchner
 - (c) J. B. Watson
 - (d) Oswald Kulpe
- Answer: D

188. The functionalist strongly influenced by__.

- (a) Wilhelm Wundt
- (b) Charles Darwin

- (c) J. B. Watson
- (d) William James Answer: B

189. Who is credited for setting up the first psychological laboratory in United States?

- (a) Willhelm Wundt
- (b) Charles Darwin
- (c) J. B. Watson
- (d) William James Answer: D

190. What is the meaning of 'Flock' according to Gestalt psychology?

- (a) The whole
- (b) Perceptual unit
- (c) Perception
- (d) Closure Answer: B

191. Who is the father of psychodynamic theory?

- (a) Willhelm Wundt
- (b) Charles Darwin
- (c) Sigmund Freud
- (d) William James Answer: C

192. Self actualisation is proposed by _____.

- (a) Carl Roser
- (b) Abraham Mashlow
- (c) Sigmund Freud
- (d) William James Answer: B

193. Computer provided a new way to conceptualise mental processes and to develop detail theories which is known as _____.

- (a) Cognitive Approach
- (b) Behavioural Approach
- (c) Gestalt Approach
- (d) Information Processing Approach Answer: D

194. The belief that complex behaviours can be understood as the sum of several simpler one's is called:

- a. reductionism
- b. functionalism
- c. introspection
- d. animism Answer: A

195. Wundt's primary method of research was:

- a. experimentation
 - b. autoethnography
 - c. introspection
 - d. lesioning
- Answer: C

196. Jung stated that humans possess both a _unconscious and a__unconscious:

- a. shadow/manifest
 - b. personal/collective
 - c. introvert/extravert
 - d. phenomenal/latent
- Answer: B

197. Remembering that the capital of Canada is Ottawa requires:

- a. sensory memory
 - b. semantic memory
 - c. episodic memory
 - d. procedural memory
- Answer: B

198. Which of the following psychologists was NOT a behaviourist?

- a. Watson
 - b. Thorndike
 - c. Skinner
 - d. Maslow
- Answer: D

199. Positive reinforcement involves___something to increase a response whereas negative reinforcement involves__something.

- a. repeating/increasing
 - b. adding/removing
 - c. removing/adding
 - d. increasing/repeating
- Answer: B

200. Two kinds of learning studied by behaviourists are:

- a. classical conditioning and operant conditioning
 - b. manifest learning and latent learning
 - c. conscious learning and unconscious learning
 - d. operant conditioning and instrumental conditioning
- Answer: A

201. Which of the following is NOT a theory of dreaming?

- a. expectation fulfillment
 - b. activation-synthesis
 - c. threat-simulation
 - d. elucidatory consciousness
- Answer: D

202. The brain has four lobes: occipital, frontal, and ____.

- a. sympathetic, parasympathetic
- b. autonomic, somatic
- c. temporal, parietal
- d. visual, auditory

Answer: C

203. A psychologist who practices Gestalt Therapy would most likely be a(n):

- a. humanist
- b. behaviourist
- c. evolutionist
- d. cognitivist

Answer: A

204. A psychologist primarily interested in mental processes such as memory and perception would most likely be a(n):

- a. humanist
- b. behaviourist
- c. evolutionist
- d. cognitivist

Answer: D

205. Which of the following topics would be of least interest to a biological psychologist?

- a. hunger
- b. thirst
- c. free will
- d. sleep

Answer: C

206. William James worked during the:

- a. late 20th century
- b. late 19th century
- c. middle ages
- d. the 1700s

Answer: B

207. Freud argued that dreams have both _____ content and _____ content.

- a. Freudian, Jungian
- b. conditioned, unconditioned
- c. latent, manifest
- d. somatic, autonomic

Answer: C

208. In Pavlov's work dogs salivated naturally in response to being given meat powder.

In this situation, salivation is the while the meatpowder is the.

- a. UCR, UCS
 - b. UCS, UCR
 - c. CS, CR
 - d. CR, CSA
- Answer: A

209. Which of the following was a humanistic psychologist?

- a. Freud
 - b. Watson
 - c. Wernicke
 - d. Rogers
- Answer: D

210. What are the two parts of the autonomic nervous system?

- a. somatic, autonomic
 - b. reflexive, responsive
 - c. sympathetic, parasympathetic
 - d. frontal, occipital
- Answer: C

211. MBTI stands for:

- a. Manifold Barometric Temperature Indicator
 - b. Multiple Behavioural Theories Instrument
 - c. Myers Briggs Type Indicator
 - d. Maslow Bosun Trend Indicator
- Answer: C

212. Which lobe of the brain is also known as the auditory cortex?

- a. frontal
 - b. temporal
 - c. occipital
 - d. parietal
- Answer: B

213. Which of the following is NOT associated with Freud?

- a. id
 - b. ego
 - c. shadow
 - d. super-ego
- Answer: C

214. In Seligman's ABCDE model of learned optimism, B stands for:

- a. belief
 - b. behaviour
 - c. brain
 - d. blessing
- Answer: A

215. __ needs were at the bottom of Maslow's pyramid/hierarchy.

- a. safety

 - c. adulthood
 - d. old age
- Answer: B

237. Frotteurism is:

- a. a type of schizophrenia
 - b. an eating disorder
 - c. a paraphilia
 - d. a somatoform disorder
- Answer: C

238. Gender identity disorder is a controversial diagnosis because:

- a. it seems to occur only in North America
 - b. only people who have undergone psychoanalysis are ever diagnosed with it
 - c. people who "suffer" from it do not regard their feelings or behaviours as a disorder
 - d. it has a prevalence rate of zero
- Answer: C

239. Which of the following is NOT a characteristic of borderline personality disorder?

- a. mood swings
 - b. hallucinations
 - c. impulsivity
 - d. identity problems
- Answer: B

240. Which category/cluster of personality disorder does borderline personality disorder come under?

- a. dramatic/erratic
 - b. odd/eccentric
 - c. avoidant/dependent
 - d. anxious/inhibited
- Answer: A

141. person suffering from hypoactive sexual desire disorder has:

- a. too little interest in sex
 - b. too much interest in sex
 - c. an obsessive need to expose their genitals in public
 - d. a desire to witness suffering in other people
- Answer: A

242. Acrophobia is to _____ as arachnophobia is to ____.

- a. open spaces, spiders
 - b. spiders, open spaces
 - c. heights, spiders
 - d. spiders, heights
- Answer: C

243. Which of the following has NOT been classified as a sexual disorder?

- a. dyspareunia

- b. vaginismus
- c. premature ejaculation
- d. creatinuria

Answer: D

244. person who worries excessively about having a serious illness is most likely to be diagnosed as suffering from:

- a. borderline personality disorder
- b. conversion disorder
- c. hypochondria
- d. mitochondria

Answer: C

245. In the context of psychological disorders, APD stands for:

- a. anxious personality disorder
- b. arousal paraphilia disorder
- c. antisocial personality disorder
- d. antagonistic performance disorder

Answer: C

246. BPD is more common in ____; APD is more common in _____.

- a. uneducated people, educated people
- b. children, adolescents
- c. extraverts, introverts
- d. women, men

Answer: D

247. Hallucinations are classed as a ____ symptom of schizophrenia.

- a. positive
- b. cognitive
- c. negative
- d. transitive

Answer: A

248. Dysthymia appears to be a milder form of:

- a. bipolar disorder
- b. clinical depression
- c. schizophrenia
- d. Munchausen syndrome

Answer: B

249. To understand anxiety disorders we need to take account of:

- a. only biological factors
- b. only environmental factors
- c. both biological and environmental factors
- d. neither biological nor environmental factors

Answer: C

250. APD is a type of _____ disorder.

- a. internalizing
 - b. mood
 - c. somatoform
 - d. externalizing
- Answer: D

251. The difference between somatoform disorders and factitious disorders is that:

- a. somatoform disorders only happen to men, factitious disorders only happen to women
 - b. somatoform disorders involve cognition, factitious disorders involve emotion
 - c. in somatoform disorders the physical symptoms are real, in factitious disorders the physical symptoms are not real
 - d. somatoform disorders are caused by environmental factors, factitious disorders are caused by genetic factors
- Answer: C

252. Which of the following would be classified as a social-cultural influence in the bio-psycho-social model of illness?

- a. neurotransmitters
 - b. homelessness
 - c. patterns of negative thinking
 - d. genetic makeup of the individual
- Answer: B

253. criticism of the DSM is that it:

- a. hasn't changed since the 1950s
 - b. is not actually used by therapists, insurers etc
 - c. only includes a handful of disorders
 - d. is primarily focused on Western illness
- Answer: D

254. Physically attractive people are usually perceived as:

- a. more intelligent than unattractive people
 - b. more dominant than unattractive people
 - c. more socially skilled than unattractive people
 - d. all of the above
- Answer: D

255. Research has shown a positive correlation between aggression and the level of:

- a. acetylcholine
 - b. testosterone
 - c. estrogen
 - d. GABA
- Answer: B

256. In Milgram's original study on obedience, what percentage of participants were willing to administer the maximum level of shock:

- a. 5%
- b. 30%

- c. 65%
- d. 95%Answer: C

257. People are more likely to help others if:

- a. they are in a bad mood
- b. they feel guilty about something
- c. someone else is already helping
- d. they are in a hurryAnswer: B

258. Punching a wall or kicking a chair when you are angry at a co-worker are examples of:

- a. displaced aggression
- b. inanimate hostility
- c. repression
- d. avoidant attachmentAnswer: A

259. An advertiser who seeks to associate their product with something people already like (for example, a celebrity or a popular song) is making use of:

- a. classical conditioning principles
- b. pseudoscience
- c. operant conditioning principles
- d. sublimationAnswer: A

260. According to Moreland and Beach, the more frequently we see a person the:

- a. less likely we are to recognize them
- b. less likely we are to trust them
- c. more likely we are to dislike them
- d. more likely we are to like themAnswer: D

261. Having an audience typically ___ us if we are doing an easy task and ___ us if we are doing a difficult task.

- a. hinders, hinders
- b. helps, helps
- c. helps, hinders
- d. hinders, helpsAnswer: C

262. Groupthink is most likely when:

- a. there is time pressure
- b. group members feel no sense of group identity
- c. there is a weak leader
- d. group members are in frequent contact with people outside the groupAnswer: A

263. Stimulation of the amygdala is most likely to increase feelings of:

- a. happiness
- b. guilt

- c. shyness
- d. aggression Answer: D

264. Evolutionary theory predicts that we will be most likely to help:

- a. old people
- b. family members
- c. poor people
- d. strangers Answer: B

265. Research has shown that people are LESS willing to administer severe shocks in the Milgram paradigm if:

- a. they choose the level of shock themselves
- b. the person telling them to administer the shock is in another room
- c. they knew that other people had refused to administer severe shocks
- d. all of the above Answer: D

266. In terms of interpersonal attraction, research suggests that:

- a. opposites attract
- b. similarity breeds contempt
- c. birds of a feather flock together
- d. a stitch in time saves nine Answer: C

267. We tend to stereotype people on the basis of their:

- a. physical appearance
- b. age
- c. race
- d. all of the above Answer: D

268. People who are high in self-monitoring are _____ likely to act in ways consistent with their attitudes than people who are low in self-monitoring.

- a. more
- b. less
- c. neither more nor less
- d. more if they are angry, less if they are sad Answer: B

269. To be classed as "intimate", a relationship must be based on:

- a. passion
- b. acceptance
- c. social support
- d. all of the above Answer: D

270. Prejudice is to _____ as discrimination is to _____.

- a. thought, action
- b. race, age

- c. stereotype, categorization
- d. negative, positive Answer: A

271. The tendency to underestimate the role of situational factors when deciding why a stranger behaved in a particular way is known as the:

- a. self-serving bias
- b. fundamental attribution error
- c. situational exploitation bias
- d. causal explanation error Answer: B

272. If you want someone to be attracted to you, research suggests that you should:

- a. ask them about themselves
- b. argue with them
- c. talk only about yourself
- d. all of the above Answer: A

273. The fact that as group size are:

- a. passionate
- b. interdependent
- c. self-serving
- d. all of the above Answer: B

274. Groups that set _____ and increases, group productivity _____ goals are more likely tends to decrease is most likely explained by:

- a. groupthink
- b. stereotyping
- c. social loafing
- d. social facilitation Answer: C

275. According to the "foot in the door" technique, you are more likely to be able to change someone's attitude if you:

- a. visit them in their home
- b. start by complimenting them on their choice of footwear
- c. tell them how many celebrities hold the attitude you want them to adopt
- d. get them to make a small change in attitude to start with Answer: D

276. Jill and John have been married for many years and rely on each other to meet important goals. This reliance reveals that they to be effective than groups that don't set these kind of goals.

- a. easy, vague
- b. vague, unreachable
- c. specific, attainable
- d. difficult, unattainable Answer: C

277. Which of the following best illustrates the concept of minority influence?

- a. a union is successful in negotiating an improved benefits package for its members

- b. three teenagers manage to persuade their school to adopt a new anti-litter policy
 - c. Shari is able to persuade her friend Ivy to give up smoking
 - d. the government passes a law requiring cyclists to wear helmets
- Answer: B

- 278.** According to cognitive dissonance theory, we may be motivated to change our attitudes to:
- a. reduce negative feelings
 - b. conform to the attitudes of high-status individuals
 - c. force others to do the same
 - d. increase our level of anxiety
- Answer: A

- 279.** Another term for the fundamental attribution error is:
- a. commitment
 - b. correspondence bias
 - c. cognitive dissonance
 - d. stereotype threat
- Answer: B

- 280.** We are likely to make a _____ attribution to explain our success, and a ____ attribution to explain our failure.
- a. causal, correlational
 - b. correlational, causal
 - c. person, situation
 - d. situation, person
- Answer: C

- 281.** Benjamin thinks that if he kicks his car and swears at his computer he will release his anger and be less aggressive with his co-workers. Benjamin believes in:
- a. the fundamental attribution error
 - b. social loafing
 - c. social facilitation
 - d. catharsis
- Answer: D

- 282.** One likely explanation for why so many people ignored Kitty Genovese's situation is:
- a. social facilitation
 - b. the social responsibility norm
 - c. diffusion of responsibility
 - d. groupthink
- Answer: C

- 283.** The Implicit Association Test is designed to measure:
- a. verbal ability
 - b. unconscious stereotyping
 - c. hidden mathematical ability
 - d. dream content
- Answer: B

- 284.** Phrenologists tried to find out about personality by:
- a. reading a person's horoscope
 - b. feeling a person's skull

- c. looking at a person's hands
- d. asking people questions Answer: A

285. limitation of selective breeding studies is that they cannot:

- a. tell us anything about the role of genes
- b. be used to study human beings
- c. provide information relevant to the nature/nurture debate
- d. tell us anything about the role of the environment Answer: B

286. Which neo-Freudian challenged his ideas about penis envy?

- a. Adler
- b. Fromm
- c. Jung
- d. Horney Answer: D

287. Someone who feels as though they are not living up to expectations would be described by Adler as having:

- a. low self-realization
- b. an Adlerian complex
- c. an inferiority complex
- d. low actualization Answer: A

288. According to Freud, the mind's three components are:

- a. ego, id, superego
- b. unconscious, moral, immoral
- c. oral, anal, phallic
- d. primary, secondary, tertiary Answer: D

289. The idea that you can assess someone's personality by studying their face is called:

- a. phrenology
- b. physiology
- c. somatology
- d. physiognomy Answer: A

290. The ___ complex is to girls as the _____ complex is to boys.

- a. Electra, Oedipus
- b. Oedipus, Electra
- c. oral, phallic
- d. phallic, oral Answer: C

291. The discovery that the heritability of the Big Five personality traits is around 40%– 50% suggests that:

- a. the environment plays no role in personality
- b. genes play no role in personality
- c. the environment plays an important role in personality

d. the Big Five traits account for about half of our personality Answer: B

292. Humanistic psychologists embraced the idea of:

- a. repression
- b. free will
- c. unconscious drives
- d. the id Answer: B

293. According to Eysenck, extraverts seek to ___ their arousal while introverts seek to ___ their arousal.

- a. decrease, increase
- b. hide, reveal
- c. increase, decrease
- d. reveal, hide Answer: C

294. Allport believed that traits could be organized into three levels:

- a. primary, secondary, tertiary
- b. cognitive, emotional, physiological
- c. id, ego, superego
- d. cardinal, central, secondary Answer: D

295. The MMPI is used to measure:

- a. unconscious drives
- b. the Big Five traits
- c. personality and psychological disorders
- d. leadership potential Answer: C

296. Which of the following is NOT one of the Big Five traits?

- a. sense of humour
- b. openness to experience
- c. conscientiousness
- d. extraversion Answer: A

297. Freud founded the _____ approach to understanding human behaviour.

- a. palliative
- b. psychodynamic
- c. patronymic
- d. psychedelic Answer: B

298. The influence of parents on the personality of their children is:

- a. non-existent
- b. weakest in early childhood
- c. strongest in early childhood
- d. consistent across the lifespan Answer: C

299. What is special about "knockout" mice?

- a. they are very attractive
 - b. their DNA has been modified
 - c. they are easy to knock out
 - d. they are unusually aggressive
- Answer: B

- 300.** The aim of behavioural genetics is to learn about:
- a. the extent to which geneticists can modify people's behaviour
 - b. the possibility of eradicating behavioural problems in children
 - c. the genetic and environmental influences on human behaviour
 - d. the ability of animals to learn language
- Answer: C

- 301.** Monozygotic is to twins as dizygotic is to _____ twins.
- a. male, female,
 - b. female, male
 - c. fraternal, identical
 - d. identical, fraternal
- Answer: D

- 302.** Which of the following characteristics describe someone who, according to Maslow, is self-actualized?
- a. creativity
 - b. confidence
 - c. spontaneity
 - d. all of the above
- Answer: D

- 303.** According to Freud, children pass through 4 stages of psychosexual development. Which of the following shows the stages in the correct developmental order?
- a. oral, anal, phallic, latency
 - b. latency, oral, anal, phallic
 - c. phallic, anal, oral, latency
 - d. oral, phallic, latency, anal
- Answer: A

- 304.** Projective tests claim to reveal information about:
- a. career aptitude
 - b. intellectual attainment
 - c. unconscious processes
 - d. parenting style
- Answer: C

- 305.** Traits are defined as:
- a. physical characteristics that distinguish us from other people
 - b. relatively enduring characteristics that influence our behaviour across many situations
 - c. unconscious tendencies to act in different ways according to the situation
 - d. permanent personality tendencies that determine our behaviour in any situation
- Answer: B

- 306.** Sheldon's theory that people with different body types have different personalities has been:
- a. supported by research
 - b. discredited

- c. shown to be accurate for thin people but not overweight people
 - d. shown to be accurate for women but not for men
- Answer: B

307. Which of the following is not a defence mechanism?

- a. projection
 - b. regression
 - c. ingratiation
 - d. sublimation
- Answer: C

308. Rohan is self-disciplined, focused on achievement and keen to do his duty. He would be expected to score highly on:

- a. neuroticism
 - b. agreeableness
 - c. extraversion
 - d. conscientiousness
- Answer: D

309. The Barnum effect helps to explain people's belief in:

- a. fortune-telling
 - b. astrology
 - c. horoscopes
 - d. all the above
- Answer: D

310. ___ are the basic biological units that transmit characteristics from one generation to the next:

- a. genes
 - b. neurons
 - c. glia
 - d. instincts
- Answer: A

311. Which of the following would NOT be useful to a behavioural geneticist?

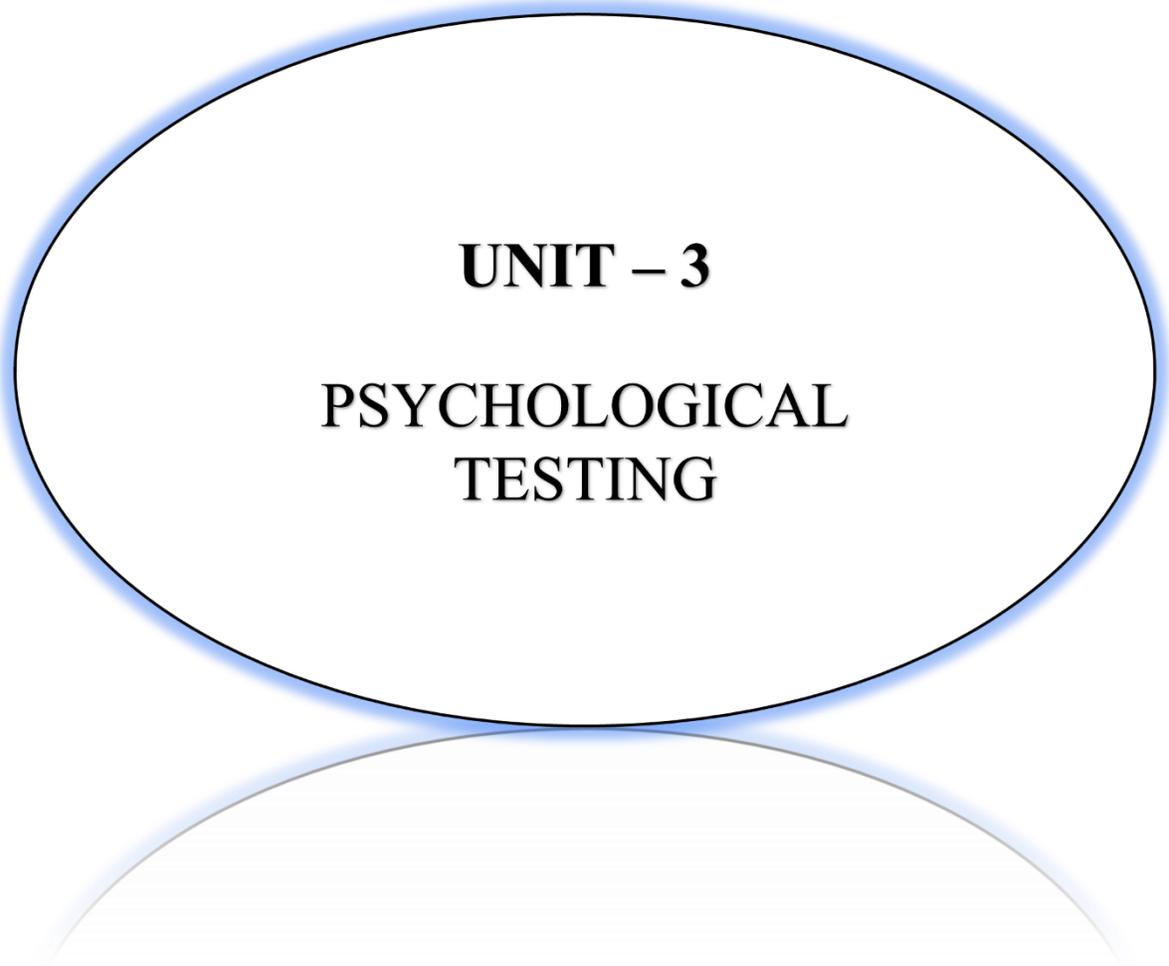

- a. family studies
 - b. case studies
 - c. adoption studies
 - d. twin studies
- Answer: B

312. According to Freud, the id is to the ___ principle as the ego is to the ___ principle.

- a. aggressive, sexual
 - b. sexual, aggressive
 - c. pleasure, reality
 - d. reality, pleasure
- Answer: C

313. Lana is friendly, always willing to help others and compassionate. We would expect Lana to score highly on:

- a. extraversion
 - b. agreeableness
 - c. neuroticism
 - d. openness to experience
- Answer: B

UNIT – 3

**PSYCHOLOGICAL
TESTING**

PSYCHOLOGY

WHAT ARE TYPES OF TEST CONSTRUCTION: ITEM WRITING, ITEM ANALYSIS?

TYPES OF TESTS TEST CONSTRUCTION: ITEM WRITING, ITEM ANALYSIS

Test Psychological testing – also called psychological assessment– is the foundation of how psychologists better understand a person and their behavior. It is a process of problem solving for many professionals – to try and determine the core components of a person’s psychological or mental health problems, personality, IQ, or some other component. It is also a process that helps identify not just weaknesses of a person, but also their strengths.

Psychological testing measures an individual’s performance at a specific point in time – right now. Psychologists talk about a person’s “present functioning” in terms of their test data. Therefore, psychological tests can’t predict future or innate potential.

Psychological testing is not a single test or even a single type of test. It encompasses a whole body of dozens of research-backed tests and procedures of assessing specific aspects of a person’s psychological makeup. Some tests are used to determine IQ, others are used for personality, and still others for something else. Since so many different tests are available, it’s important to note that not all of them share the same research evidence for their use – some tests have a strong evidence base while others do not.

Psychological assessment is something that’s typically done in a formal manner only by a licensed psychologist (the actual testing may sometimes be administered by a psychology intern or trainee studying to become a psychologist). Depending upon what kind of testing is being done; it can last anywhere from 1 1/2 hours to a full day.

Testing is usually done in a psychologist’s office and consists largely of paper-and-pencil tests (nowadays often administered on a computer for ease-of-use).

Psychological testing is divided into four primary types:

- Clinical Interview
- Assessment of Intellectual Functioning (IQ)
- Personality Assessment
- Behavioral Assessment

In addition to these primary types of psychological assessment, other kinds of psychological tests are available for specific areas, such as aptitude or achievement in school, career or work counseling, management skills, and career planning.

Within the field of test development, the tasks and/or questions that are used to construct tests and examinations are referred to as ‘items’, and the range techniques involved in preparing those items are collectively referred to as ‘item writing’. Is item writing an art or science?

The best item development techniques combine elements of both these intellectual activities. On the one hand, there is a fair amount of experimental method, which we might recognize as

scientific, incorporated within the whole set of procedures for developing a good item, or the sets of such things we call 'tests. However, as this document will make clear, writing a good item is also a highly creative act. By the end of the process something new, powerful, and useful has emerged – a test instrument which has used words, symbols or other materials from a curriculum or a syllabus in a new way, often to serve a variety of educational purposes. In doing so, the item developer needs imagination and ingenuity as well as knowledge: form, structure and balance become important, as they are to a sculptor or a musician. Why are these building-blocks of tests called 'items', anyway? Is it merely educational jargon? Why not call them 'questions'?

The choice of the word 'item', in preference to 'question', draws attention to two matters. One is that items are often not in question format – the test-taker is required to perform a specific task, or reveal specific knowledge, which is implied in the words given on the test paper, rather than explicitly offered as a direct question.

The other matter concerns the independence of items in a test. Like the items on a shopping list, they are discrete, or they should be. If you can't get one right, that should not stop you from having a fair chance of obtaining success on all the others. The term 'item writing', used in the title of this document, draws attention to this essential independence – the separate skills, abilities or pieces of knowledge which make up human learning are considered individually in the test. This is the prime focus.

However, the discussion (and the test development process) begins and ends with consideration of a second focus. It considers what happens when these items achieve additional significance or importance by having been grouped or combined with other items to form a test instrument. We must continually remember that our building blocks are part of a larger whole. Several times in the paragraphs above, the word 'development' has been used. This is not mere jargon either.

It draws attention to the fact that items do not spring to life ready-made in an item writer's brain. A thorough developmental process often in a defined and specialized sequence, occurs. Like the student knowledge to be tested, it occurs gradually – sometimes with false starts, and often with much wastage on the way, as the test writers clarify their initial ideas, add to them, try them out, and finally decide what will serve their purposes best. Note also the use of the plural 'writers. Item writing is best done using a team approach at various stages of the exercise.

learning difficulties, and so on. However, the real objectives for any test come directly from considering two things in conjunction. The first is the actual educational context in which the results of the testing will be used. The second is the knowledge and understanding the test-taker will be expected (or able) to bring into the test-room.

The objectives which are determined will therefore be local and specific, and determining what they are is the starting point for determining what the test and its items ought to look like. Much of the material in this paper concerns one particular branch of item writing which is perhaps the most difficult to master – the development of multiple-choice items and tests. However this emphasis should not obscure the fact that all items, from simple short-answer formats to extended response essays, need the same careful and methodical processes during their development if the final tests are to be reliable and valid measures of learning outcomes.

The suggestions made as to process can (and should) be applied whether the user is a teacher in a school preparing a semester test or an administrator setting up a large national assessment program.

One more element remains to be added to the matrix used in this example – the formats which have been chosen for the test item themselves. In the UNESCO study being used as an example in this section, only a small space of time was available for each of the cells of the matrix. Hence the solution to the format problem could not involve vast amounts of reading or writing by the test takers, or large numbers of computational exercises to test their basic numeracy. For policy reasons, equal amounts of time had to be given to testing in English and testing in the student's vernacular language, and this suggested selection of formats which were similarly parallel.

The time allocations were suggestive. Thirteen minutes for computations suggested 25 exercises at about two a minute. Eight minutes for reading comprehension suggested 8 short-answer questions (one a minute), and the free writing exercise suggested a sentence every two minutes.

So long as the test-takers were given a few minutes to read through the paper before the test actually began, the stimulus material for the reading and writing exercises could be fully informative but not particularly extensive. More reading comprehension questions could perhaps have been asked if a multiple-choice format had been chosen, but this format was decided against – additional information about a student's writing skills would be elicited if they prepared their own sentences as responses to the comprehension questions.

PROBLEMS FOR SOLUTION

The problems which test-writers set for solution by candidates actually represent a sub-category of constructed responses but seem important and common enough to be discussed separately. In a sense, setting an essay task for extended response has a problem element built into it, especially if the candidate is required to read a large amount of informative stimulus and choose some sort of personal response to be developed during the test. For example, we might look again at an example (given earlier under the heading 'Extended Responses') with this in mind: Read the material presented opposite and prepare a balanced and detailed critical response to the ideas about education presented by the various writers and cartoonists.

Your piece of writing should be between 600 and 1000 words. Other problems may not require words as a response, but quantitative reasoning and expressions for their solution. Or perhaps it is manipulation of materials that is required, as in a test conducted in a laboratory or workshop or art studio.

Mathematical problems are probably the most common kind, from simple primary examples to more complex ones at higher levels of schooling. As in the first example, they too might involve manipulation of objects as an aid to their solution.

ITEM ANALYSIS

There is not room in a paper of this size to canvass and describe all the different options which exist for the analysis of item data. Papers for other modules will explore the matter in some detail. School-based tests will use simple rather than complex strategies to obtain (and indices to express) this information.

Larger test programs will probably have the resources to engage in quite lengthy and complex processing. Broadly speaking, for multiple-choice items in large programs, the analysis consists of statistics which show the facility of each item:

the percentage of the whole test-taking population which got it right

- the discrimination index of each item: how well the keyed answer distinguishes between students of high ability and those less able;
- the response level for each item: how many actually attempted it, right or wrong;
- the criterion score on each item: the mean score of all those who did attempt it;
- whether any distractors did not function well: attracted too few candidates, or a preponderance of those of high ability

However, from the item-editor's point of view, it should be noted that at least five other things are under analysis during this vital stage of the whole development process. Information is obtained about:

1. the parts of an item, especially in multiple-choice format with its stems, keyed answers and distractors;
2. the integrity or worthwhileness of the item as a whole;
3. the performance of the item as a discrete test element;
4. the performance of an item with regard to other items in the same set or test;
5. the integrity or worthwhileness of the test as a whole.

The distinctions between 2, 3, and 4 (which seem on the surface to be saying much the same thing) are important, especially for a multiple-choice test. Each, for the item editor, might offer a slightly different reason for rejecting or retaining an item in the final test. An item might be worthwhile as a measure of a particular higher order skill

(2) It might operate well as a discrete test element, discriminating satisfactorily between the most able and the less able (3). But it might be simply far too hard by comparison with all the other items in the test (4) and deserve exclusion on that ground.

STAGE TWO – EDITING FOR PUBLICATION

When the test has been taken into the field and tried out, and the item analysis has been completed, a second stage of editing then occurs. Using the analysis results, each item is scrutinized and decisions made about rejection or retention.

There may be a little judicious re-writing, but this should be limited to minor changes to distractors only. If the stem and keyed answer need change, then a new item has resulted, and this would require further trial testing: it would be better to reject the item and use one that did work. Once every item is clean, making up the final form actually begins.

As in so many matters to do with test development, there is a sequence of activity which should be followed, in order to ensure that new bugs don't appear and the test as completely as possible meets the original specification. Figure 16 suggests an appropriate sequence.

EDITING FOR PUBLICATION – A CHECKLIST OF ACTIVITIES

1. Read the item analysis and sort the items (or groups of items) into three piles:

- a) ready to go;
- b) needing editing;
- possible rejects

2. Edit items and establish a final pool of items for the test. Check the omit rate to establish optimum test length.

3. Check the specification against this pool for the number and qualities of the items available. Reinstate any usable 'rejects' if all the objectives are not satisfactorily covered.

4. Assign the items to a tentative order for the whole test and enter the scoring scheme at the end of each section of the test.

5. Check this order for: a) order of difficulty (for example, in a set of multiple-choice items, make sure some easy ones occur early, to give the candidate some confidence);

b) keyed answer order and distribution;

c) balance and variety of item type.

6. Write or insert appropriate instructions for candidates. Include suggestions for time to be spent on each section.

7. Assign the items to a preliminary paging of the test-paper: some may have to be moved to allow a more satisfactory layout. Allow sufficient space for answering if there is to be no separate answer sheet.

WHAT IS NORMING, RELIABILITY AND VALIDITY OF PSYCHOMETRIC TESTS?

Norming, Reliability and Validity of Psychometric Test

Evaluation of human qualities – such as attitude, competency, proficiency, accomplishment, and belief, among other constructs- is routinely conducted by administering tests fairly, which are precisely formulated and applied using standardized protocols. Test takers are usually concerned with the results from a test administered to them; they don't have a proclivity to look into the technical aspects or characteristics of the tool itself. Despite this, many people take the tests internal components into account because they realize that the relevance and usefulness of test result interpretation are dependent on its core features. In technical terms, these internal test attributes are termed as psychometric properties.

The psychometric properties of a test are associated with the data that has been garnered from the assessment to find out how well it evaluates the interest construct. The development of a valid test is conditional on the fact that it has been subjected to statistical analyses, which ascertains that it has adequate psychometric properties.

A good psychometric test must have three fundamental properties- reliability, validity, and norming. Be it hiring or developing employees, choosing the correct set of assessments is pivotal in making or breaking a business.

Besides the reliability and validity of tests, the standardization of the assessments normed for various aspects, such as age, gender, education, profession, employability, etc. also determines the properties of tests.

Psychometric properties, usually, provide insights into a test's meaningfulness, appropriateness, and usefulness (or rather say, its validity). Let's say a test is publicized as a measure important for diagnosing a mental disorder such as bipolar disorder. The psychometric properties of a test present the test creators and users with satisfactory evidence of whether the tool performs as portrayed.

The psychometric property of a test focuses on its feature. Some psychometric properties speak volumes about the quality of the whole test, while others give weight to its constituent parts, sections, and even individual items. For instance, when considered in totality, a psychometric property could reveal whether the test assesses a single construct or multiple constructs.

The characteristic of a test analyzing only one dimension or multiple dimensions is the psychometric property of the whole instrument. Another psychometric property of the test could point out whether the instrument evaluates the target construct reasonably well for both men and women. We can call this a psychometric property of gender equality. Yet other psychometric properties furnish evidence whether a test assesses a construct consistently (reliability).

Psychometric properties are most often expressed quantitatively. Numerical quantities such as a coefficient or an index are used to represent the property. For example, the reliability coefficient is a numerical value that most students and professionals are familiar with. Even though reliability is mentioned as the psychometric feature for a test, it is expressible in the form of quantitative value.

Likewise, many other psychometric properties are expressed numerically. Meanwhile, a quantifiable value is not often the best way to convey a specific psychometric property. For example, validity, being a hard fact, cannot be suggestively reduced to a single value or index. It is an encompassing psychometric property, but an exhaustive discussion that synthesizes a substantial body of evidence is required to explain test validity. One must explore and learn about the psychometric properties of tests for two key reasons. First, this knowledge enables makers to create useful tests. Psychometricians and other experts who create tests must analyze and describe the functionality of tests to build them to a predefined level of quality.

Second, the awareness about the psychometric properties of a test ensures that the information gained using the instrument could provide a firm foundation for making the right decisions. It stands to reason those counselors, psychologists, policy personnel, educators, and many other professionals often formulate their decisions on the data collected from the tests.

PSYCHOMETRIC PROPERTIES: RELIABILITY, VALIDITY, AND NORMING

In definition, a standardized test is administered and scored in a consistent or "standard" manner. They are designed in a way that stabilizes questions, conditions for administering, scoring procedures, and interpretations as consistent.

Standardized testing could be composed of true-false, multiple-choice, authentic assessments, or essays. It's possible to shape any form of assessment into standardized tests. When it comes to the creation of psychometric evaluations, questions are measured in scales. And these too are often most valid with standardization post-creation.

We should look for these three factors when creating/standardizing psychometric tests:

- Nature of Reliability
- Understanding Validity
- Importance of Norms

NATURE OF RELIABILITY IN PSYCHOMETRIC TESTS

Psychometric Test Reliability refers to the level to which test scores are accurate and free of measurement mistakes. In other words, does the test measure what it is supposed to measure? It is the consistency in the measurement tool to produce scores by which interpolations can be made.

For instance, a test measuring intelligence should yield the same score for the same person after he or she has completed the test each time within a short period in between (provided the test taker has not changed regarding his/her intelligence over the period).

A test is reliable as long as it produces similar results over time, repeated administration, or under similar circumstances.

If you were to use a professional dart player as an example, his or her ability to hit the designated target consistently, but not the bullseyes under specified conditions, would classify them as an excellent and reliable dart player. However, this does fail on account of validity. When compared to psychometric assessments, a reliable test is better known for its ability to produce stable results over time.

Over the years, scholars and researchers uncovered multiple ways to check for reliability. Some include testing the same participants at different points of time or presenting the participants with varying versions of the same test to see how consistent the results are. Suffice it to say that an assessment has to show demonstrably excellent reliability to qualify for validity.

TYPES OF PSYCHOMETRIC TEST RELIABILITY

Parallel Forms Reliability

In this type, the two tests that are different use the same content but separate procedures or equipment, and yield results that are the same for each test taker.

- **INTERNAL CONSISTENCY RELIABILITY:**

Items within the test are examined to see if they appear to measure what the test measures. Internal reliability between test items is referred to as internal consistency.

- **INTER-RATER RELIABILITY:**

When two raters score the psychometric test in the same way, inter-scorer consistency is high.

- **TEST-RETEST RELIABILITY:**

This is when the same test is conducted over time, and the test taker displays consistency in scores over multiple administrations of the same test.

FACTORS INFLUENCING PSYCHOMETRIC TEST RELIABILITY

There are always minor discrepancies in psychometric test reliability. Moreover, individuals taking the same psychometric test may have different thoughts, feelings, or ideas at various points in the time, leading to variance in scores. A lot of factors (both stable traits and momentary issues) can result in variation in test scores.

Stable traits include weight, height, and other such characteristics. Momentary inconsistency is attributed to different things such as the health of test-takers, an understanding of a particular test item, and so forth.

Why Psychometric Test Reliability Counts

Reliability is essential for psychometric tests. After all, what is the point of having the same test yield different results each time, especially if scores can affect employee selection, retention, and promotion?

ERRORS IN RELIABILITY

Psychometricians identify two different categories of errors:

- **Systematic errors:** These are factors that impact test construction and are inbuilt in the test.
- **Unsystematic errors:** These are errors resulting from random factors such as how the test is given or taken.

Numerous factors influence test reliability. The timing between two test sessions affects test-retest and alternate/parallel forms reliability. The similarity of content and expectations of subjects regarding different elements of testing affects only the latter type of reliability along with split half and internal consistency.

Changes in subjects over time, such as their environment, physical state, emotional and mental well-being, also need to be considered while assessing the reliability of psychometric tests. Test-based factors such as inadequate testing instructions, biased scoring lacking in objectivity, and guessing on the part of the test-taker also influence the reliability of tests. Tests can generate reliable estimates sometimes and not so stable results other times (Geisinger, 2013).

So, just how reliable is your test? Well, it all depends on these factors:

Construction of Items/ Question

Test designers construct questions on the psychometric test to assess mental quality (for example, motivation). The test questions difficulty level or the confusion they create through ambiguity can negatively influence reliability. Biases in interpreting the items as well as errors in question construction can only be corrected if test instructions are properly implemented, and the redesign and research process is active and ongoing.

- **ADMINISTRATION**

Administration of the test is another area where systemic errors can creep in. Instructions accompanying the analysis should be clear cut and well defined. Errors in the guidance provided to

test takers or administrators can have multiple adverse effects on the reliability of the test. Guidelines that affect accurate interpretation could lower test reliability.

- **SCORING**

Reliability also means that the test has a particular scoring system, by which interpretation of results is possible. All tests comprise instructions on scoring. Errors such as conclusions without basis or substantial proof can lower the reliability of the test. Test construction is associated with research to provide evidence for the conclusions drawn. If there is a systematic error in the test design phase, this can impact reliability too.

- **ENVIRONMENTAL FACTORS**

Excessive extremes in temperature or distractions of an audio-visual nature can influence test scores regarding reliability. Errors made in administering the psychometric test can also impact the reliability of scores obtained. Human error is possible too, an interpretation or scoring can be influenced by the examiner's attitude towards the test taker.

- **TEST-TAKER**

The person being examined may suffer from social desirability concerns and give answers that are not reflective of actual choices. Other factors that influence test takers include anxiety, bias, physical factors like illness, or lack of sleep.

OVERCOME PSYCHOMETRIC TEST RELIABILITY ISSUES?

- **Test Length:**

Increasing test length can be a way to improve reliability. The longer the test, the more reliable it is considered.

- **SPEED TEST:**

Speed versus power in psychometric testing is an age-old debate. Speed tests are designed to ensure all students cannot complete the items. Power tests provide items of average difficulty and ensure that students have ample opportunity to complete the psychometric test. Test takers can be evaluated with reliability if a test has items that can be completed. Speed tests cannot be measured using internal consistency, parallel form, or test-retest method.

- **GROUP HOMOGENEITY:**

This is another factor whereby the more heterogeneous the scores of the test, the more reliable its measures will be.

Item Difficulty When there is low variability among test scores, reliability decreases. If the test is so easy that every test taker can easily complete it, how will it serve as a measure of individual differences?

UNDERSTANDING VALIDITY IN PSYCHOMETRIC TESTS

Validity is qualitatively defined as the test's efficacy to measure what it claims to measure. Suffice

to say, a test with high validity ensures the test items (questions) remain closely linked with the test's intended focus.

It is understandable to expect a test used in organizations to shed light on how a candidate would perform in a particular job. With this in mind, it is essential to reiterate the difference between reliability and validity, with the former being a prerequisite to the latter.

Let's consider the same dart player. In repeated trials, he or she continues to miss the mark consistently by about two inches. Of course, this implies a reliable aim. Each shot hits the board in a region two inches from the target. It's difficult to not question his validity as a professional – considering he or she doesn't hit the bull's eye as is the aim of all professional dart players – in comparison to his or her peers.

Reliability and validity go hand in hand, but reliability by no means indicates validity. As our example showed, having the first without the second hints at high consistency, but also inaccurate consistency.

THERE ARE TESTS FOR VALIDITY

IMPORTANCE OF NORMING IN PSYCHOMETRIC TESTS

What are the Psychometric Properties?

Evaluation of human qualities – such as attitude, competency, proficiency, accomplishment, and belief, among other constructs- is routinely conducted by administering tests fairly, which are precisely formulated and applied using standardized protocols. Test takers are usually concerned with the results from a test administered to them; they don't have a proclivity to look into the technical aspects or characteristics of the tool itself. Despite this, many people take the tests internal components into account because they realize that the relevance and usefulness of test result interpretation are dependent on its core features. In technical terms, these internal test attributes are termed as psychometric properties.

The psychometric properties of a test are associated with the data that has been garnered from the assessment to find out how well it evaluates the interest construct. The development of a valid test is conditional on the fact that it has been subjected to statistical analyses, which ascertains that it has adequate psychometric properties.

A good psychometric test must have three fundamental properties- reliability, validity, and norming. Be it hiring or developing employees, choosing the correct set of assessments is pivotal in making or breaking a business.

Besides the reliability and validity of tests, the standardization of the assessments normed for various aspects, such as age, gender, education, profession, employability, etc. also determines the properties of tests

Psychometric properties, usually, provide insights into a test's meaningfulness, appropriateness,

and usefulness (or rather say, its validity). Let's say a test is publicized as a measure important for diagnosing a mental disorder such as bipolar disorder. The psychometric properties of a test present the test creators and users with satisfactory evidence of whether the tool performs as portrayed.

The psychometric property of a test focuses on its particular feature. Some psychometric properties speak volumes about the quality of the whole test, while others give weight to its constituent parts, sections, and even individual items. For instance, when considered in totality, a psychometric property could reveal whether the test assesses a single construct or multiple constructs.

The characteristic of a test analyzing only one dimension or multiple dimensions is the psychometric property of the whole instrument. Another psychometric property of the test could point out whether the instrument evaluates the target construct reasonably well for both men and women. We can call this a psychometric property of gender equality. Yet other psychometric properties furnish evidence whether a test assesses a construct consistently (reliability).

Psychometric properties are most often expressed quantitatively. Numerical quantities such as a coefficient or an index are used to represent the property. For example, the reliability coefficient is a numerical value that most students and professionals are familiar with. Even though reliability is mentioned as the psychometric feature for a test, it is expressible in the form of quantitative value.

Likewise, many other psychometric properties are expressed numerically. Meanwhile, a quantifiable value is not often the best way to convey a specific psychometric property. For example

validity, being a hard fact, cannot be suggestively reduced to a single value or index. It is an encompassing psychometric property, but an exhaustive discussion that synthesizes a substantial body of evidence is required to explain test validity.

One must explore and learn about the psychometric properties of tests for two key reasons. First, this knowledge enables makers to create useful tests. Psychometricians and other experts who create tests must analyze and describe the functionality of tests to build them to a predefined level of quality. Second, the awareness about the psychometric properties of a test ensures that the information gained using the instrument could provide a firm foundation for making the right decisions. It stands to reason that counselors, psychologists, policy personnel, educators, and many other professionals often formulate their decisions on the data collected from the tests.

FACTORS INFLUENCING PSYCHOMETRIC TEST RELIABILITY

There are always minor discrepancies in psychometric test reliability. Moreover, individuals taking the same psychometric test may have different thoughts, feelings, or ideas at various points in the time, leading to variance in scores.

A lot of factors (both stable traits and momentary issues) can result in variation in test scores. Stable traits include weight, height, and other such characteristics. Momentary inconsistency is attributed to different things such as the health of test-takers, an understanding of a particular test item, and so forth.

WHY PSYCHOMETRIC TEST RELIABILITY COUNTS?

Reliability is essential for psychometric tests. After all, what is the point of having the same test yield different results each time, especially if scores can affect employee selection, retention, and promotion?

ERRORS IN RELIABILITY

Psychometricians identify two different categories of errors:

- **Systematic errors:** These are factors that impact test construction and are inbuilt in the test.
- **Unsystematic errors:** These are errors resulting from random factors such as how the test is given or taken.

Numerous factors influence test reliability. The timing between two test sessions affects test-retest and alternate/parallel forms reliability. The similarity of content and expectations of subjects regarding different elements of testing affects only the latter type of reliability along with split half and internal consistency.

Changes in subjects over time, such as their environment, physical state, emotional and mental well-being, also need to be considered while assessing the reliability of psychometric tests. Test-based factors such as inadequate testing instructions, biased scoring lacking in objectivity, and guessing on the part of the test-taker also influence the reliability of tests. Tests can generate reliable

estimates sometimes and not so stable results other times (Geisinger, 2013).

So, just how reliable is your test? Well, it all depends on these factors:

• CONSTRUCTION OF ITEMS/ QUESTIONS

Test designers construct questions on the psychometric test to assess mental quality (for example, motivation). The test questions difficulty level or the confusion they create through ambiguity can negatively influence reliability.

Biases in interpreting the items as well as errors in question construction can only be corrected if test instructions are properly implemented, and the redesign and research process is active and ongoing.

- **ADMINISTRATION**

Administration of the test is another area where systemic errors can creep in. Instructions accompanying the analysis should be clear cut and well defined. Errors in the guidance provided to test takers or administrators can have multiple adverse effects on the reliability of the test. Guidelines that affect accurate interpretation could lower test reliability.

- **SCORING**

Reliability also means that the test has a particular scoring system, by which interpretation of results is possible. All tests comprise instructions on scoring. Errors such as conclusions without basis or substantial proof can lower the reliability of the test. Test construction is associated with research to provide evidence for the conclusions drawn. If there is a systematic error in the test design phase, this can impact reliability too

- **ENVIRONMENTAL FACTORS**

Excessive extremes in temperature or distractions of an audio-visual nature can influence test scores regarding reliability. Errors made in administering the psychometric test can also impact the reliability of scores obtained. Human error is possible too, and interpretation or scoring can be influenced by the examiner's attitude towards the test taker.

- **TEST-TAKER**

The person being examined may suffer from social desirability concerns and give answers that are not reflective of actual choices. Other factors that influence test takers include anxiety, bias, physical factors like illness, or lack of sleep.

HOW TO OVERCOME PSYCHOMETRIC TEST RELIABILITY ISSUES?

- **Test Length:**

Increasing test length can be a way to improve reliability. The longer the test, the more reliable it is considered.

- **SPEED TEST:**

Speed versus power in psychometric testing is an age-old debate. Speed tests are designed to ensure all students cannot complete the items. Power tests provide items of average difficulty and ensure that students have ample opportunity to complete the psychometric test. Test takers can be evaluated with reliability if a test has items that can be completed. Speed tests cannot be measured using internal consistency, parallel form, or test-retest method.

Group Homogeneity

This is another factor whereby the more heterogeneous the scores of the test, the more reliable its measures will be.

- **ITEM DIFFICULTY:**

When there is low variability among test scores, reliability decreases. If the test is so easy that

every test taker can easily complete it, how will it serve as a measure of individual differences?

UNDERSTANDING VALIDITY IN PSYCHOMETRIC TESTS

Validity is qualitatively defined as the test's efficacy to measure what it claims to measure. Suffice to say, a test with high validity ensures the test items (questions) remain closely linked with the test's intended focus.

It is understandable to expect a test used in organizations to shed light on how a candidate would perform in a particular job. With this in mind, it is essential to reiterate the difference between reliability and validity, with the former being a prerequisite to the latter.

Let's consider the same dart player. In repeated trials, he or she continues to miss the mark consistently by about two inches. Of course, this implies a reliable aim. Each shot hits the board in a region two inches from the target. It's difficult to not question his validity as a professional – considering he or she doesn't hit the bull's eye as is the aim of all professional dart players – in comparison to his or her peers.

Reliability and validity go hand in hand, but reliability by no means indicates validity. As our example showed, having the first without the second hints at high consistency, but also inaccurate consistency.

There are tests for validate

Even with a test that is both reliable and valid, there exists a question about results. An assessment fails without quantifiable results, but as often stated – human beings are far from measurable.

Validity is subjectively defined as the test's capacity to measure what it claims to measure. It's imperative to say that a psychometric test with high validity guarantees the items remain firmly connected with the test's intended core interest.

IMPORTANCE OF NORMING IN PSYCHOMETRIC TESTS

Psychometric tests are often normed against groups for comparison. It also avoids looking at individual items or questions and instead observes the total score of an individual as compared to a representative sample for the same.

A representative sample means using a group of children when developing a test for children and an adult group when developing a test for adults. Also, based on the population, samples are generally made representative based on demographic factors like age, gender, education, religion, etc.

This is primarily a standard practice because a psychometric test score of say 30 correct out of 40 is meaningless unless compared to the performance of others at a similar level on the same test. The practice of using relative scores becomes all the more important when interpreting ability test results.

When you get the 94th percentile on a trait like extraversion, you know that you are simply more extraverted than 94% of the sample group from whom the test makers derived the normal distribution. On the other hand, if you scored 94% on a math test, it implies that you marked about

94 in every 100 questions correctly

It's important to note, however, that every test has its appropriate norm group. Data is better developed when the psychometrics is within the context of the role also. For example, if the role possessed numerical work but without the time pressure in real-world scenarios, someone with below average results on numerical reasoning tests may be given the benefit of the doubt.

Where possible, it also makes sense to take the candidate's response style in interpreting percentile scores. It has something to do with both speed and accuracy, meaning some people may prefer a slower approach through ability tests – which are a part of psychometrics – with emphasis on precision. Others may cover ground on several items with lowered accuracy.

Psychological constructs such as personality have no right or wrong answers associated with them, and can thereby not be marked using percentages. Therefore academics and researchers alike resort to norming, among other methods, to make sense of scores on personality assessments.

With growing concerns over costs, conveniences, and other logistical challenges, technology-enabled assessments have become popular over time as well. Simply because they serve to streamline the process, reduce costs, increase efficiencies, allow employers to assess, and analyze more data points than previously deemed possible.

Know-how about the creation or standardization of psychometric tests aside, it's also imperative to understand how best one can determine the quality of a psychometric test

WHAT IS AREAS OF TESTING: INTELLIGENCE, CREATIVITY, NEURO PSYCHOLOGICAL TESTS, APTITUDE, PERSONALITY ASSESSMENT, INTEREST INVENTORIES ?

AREAS OF TESTING: INTELLIGENCE, CREATIVITY, NEUROPSYCHOLOGICAL TESTS, APTITUDE, PERSONALITY ASSESSMENT, INTEREST INVENTORIES

Intelligence test Psychology

Intelligence test, series of tasks designed to measure the capacity to make abstractions, to learn, and to deal with novel situations.

The most widely used intelligence tests include the Stanford-Binet Intelligence Scale and the Wechsler scales. The Stanford-Binet is the American adaptation of the original French Binet-Simon intelligence test; it was first introduced in 1916 by Lewis Terman, a psychologist at Stanford University. The individually administered test—revised in 1937, 1960, 1973, 1986, and 2003—evaluates persons two years of age and older and is designed for use primarily with children. It consists of an age-graded series of problems whose solution involves arithmetical, memory, and vocabulary skills.

The test is scored in terms of intelligence quotient, or IQ, a concept first suggested by German psychologist William Stern and adopted by Lewis Terman in the Stanford-Binet Scale. The IQ was originally computed as the ratio of a person's mental age to his chronological (physical) age, multiplied by 100. Thus, if a child of 10 had a mental age of 12 (that is, performed on the test at the level of an average 12-year-old), then the child was assigned an IQ of $(12/10) \times 100$, or 120.

A score of 100, for which the mental age equaled the chronological age, was average; scores above 100 were above average, scores below 100 were below average. The concept of mental age has fallen into disrepute, however, and few tests now involve the computation of mental ages.

Yet many tests still yield an IQ; this figure is now computed on the basis of the statistical percentage of people who are expected to have a certain IQ. Intelligence test scores follow an approximately "normal" distribution, with most people scoring near the middle of the distribution curve and scores dropping off fairly rapidly in frequency away from the curve's centre.

For example, on the IQ scale about 2 out of 3 scores fall between 85 and 115 and about 19 out of 20 scores fall between 70 and 130. A score of about 130 or above is considered gifted, while a score below about 70 is considered mentally deficient or intellectually disabled.

Intelligence tests have provoked a great deal of controversy about what kinds of mental abilities constitute intelligence and whether the IQ adequately represents these abilities, with debate centring on cultural bias in test construction and standardization procedures. Critics have charged that intelligence tests favour groups from more affluent backgrounds and discriminate against less privileged racial, ethnic, or social groups. Consequently, psychologists have attempted to develop culture-free tests that would more accurately reflect an individual's native ability.

One such test, the Johns Hopkins Perceptual Test, developed by Leon Rosenberg in the early 1960s to measure the intelligence of preschool children, has a child try to match random form (ordinary geometric forms, such as circles, squares, and triangles, are avoided because some children may be more familiar with the forms than are others).

Another attempted solution to the problem was to use test material pertinent to a child's living environment; for example, for inner-city children, urban and not pastoral scenes are appropriate.

CREATIVITY TESTS

Tests designed to measure creativity in children or adults.

Creativity tests, mostly devised during the past 30 years, are aimed at assessing the qualities and abilities that constitute **creativity**. These tests evaluate mental abilities in ways that are different from—and even diametrically opposed to—conventional **intelligence** tests. Because the kinds of abilities measured by creativity tests differ from those measured by **intelligence quotient (IQ)** tests, persons with the highest scores on creativity tests do not necessarily have the highest IQs. Creative people tend to have IQs that are at least average if not above average, but beyond a score of 120 there is little correlation between performance on intelligence and creativity tests.

Most creativity tests in use today are based at least partially on the theory of creativity evolved by J.P. Guilford in the 1950s. Guilford posited that the **ability** to envision multiple solutions to a problem lay at the core of creativity.

He called this process **divergent thinking** and its opposite—the tendency to narrow all options to a single solution—**convergent thinking**. Guilford identified three components of divergent thinking: fluency (the ability to quickly find multiple solutions to a problem); flexibility (being able to simultaneously consider a variety of alternatives); and originality (referring to ideas that differ from those of other people). Early tests designed to assess an individual's aptitude for divergent

thinking included the Torrance (1962) and Meeker (1969) tests.

The most extensive work on divergent thinking was done under Guilford's direction at the University of Southern California by the Aptitudes Research Project (ARP), whose findings between the 1950s and 1970s produced a broad structure-of-intellect (SI) model which encompassed all intellectual functions, including divergent thinking. A number of the ARP divergent thinking tests, which were originally devised as research instruments for the study of creativity, have been adapted by a variety of testing companies for use by educators in placing gifted students and evaluating gifted and talented programs. The ARP tests are divided into verbal and figural categories. Those that measure verbal ability include:

- Word fluency : writing words containing a given letter
- Ideational fluency: naming things that belong to a given class(i.e., fluids that will burn)
- Associational fluency: writing synonyms for a specified word
- Expressional fluency: writing four-word sentences in which each word begins with a specified letter
- Alternate uses: listing as many uses as possible for a given object
- Plot titles: writing titles for short-story plot
- Consequences: listing consequences for a hypothetical event ("What if no one needed to sleep?")
- Possible jobs: list all jobs that might be symbolized by a given emblem.
- The figural ARP tests, which measure spatial aptitude, include the following:
 - Making objects: drawing specified objects using only a given set of shapes, such as a circle, square, etc.
 - Sketches: elaborating on a given figure to produce sketches of recognizable items
 - Match problems: removing a specified number of matchsticks from a diagram to produce a specified number of geometric shapes
 - Decorations: using as many different designs as possible to outline drawings of common objects.
- Divergent thinking tests are generally evaluated based on the number and variety of answers provided; the originality of the answers; and the amount of detail they contain (a characteristic referred to as elaboration). A number of creativity tests currently in use include sections that measure divergent thinking.

Rather than ways of thinking, some creativity tests evaluate attitudes, behavior, creative **perception**, or creative activity. Some creativity tests specifically address the problem of assessing creativity in minority populations, who are at a disadvantage in tests that place a strong emphasis on verbal and semantic ability. The Eby Gifted Behavior Index reflects the growing view of creativity as specific to different domains. It is divided into six talent fields

verbal, social/leadership, visual/spatial, math/science problem- solving, mechanical/technical, and musical. The Watson-Glaser Critical Thinking Appraisal is a more analytical assessment of **giftedness** based on five components of critical thinking: inference, deduction, interpretation, awareness of assumptions, and evaluation of arguments.

Creativity tests have been found reliable in the sense that one person's scores tend to remain similar across a variety of tests. However, their validity has been questioned in terms of their ability to predict the true creative potential of those who take them. In one study, there was little

correlation between the scores of both elementary and secondary students on divergent thinking tests and their actual achievements in high school in such creative fields as art, drama, and science.

Creativity tests have also been criticized for unclear instructions, lack of suitability for different populations, and excessive narrowness in terms of what they measure. In addition, it may be impossible for any test to measure certain personal **traits** that are necessary for success in creative endeavors, such as initiative, self-confidence, tolerance of ambiguity, **motivation**, and perseverance. Tests also tend to create an anxiety-producing situation that may distort the scores of some test takers.

USEFUL CREATIVITY TESTS TO KNOW IF YOU ARE CREATIVE

I find creativity tests a fascinating subject to study. Whether you use creativity in your hobby or at work, I think it is a characteristic worth nurturing. A friend of mine once asked “how do you rate or measure a creative corporate culture?”. I told him there are two ways. The first is to set key performance indicators on the innovations or the ideas your company develop (I’m talking about qualitative ideas within the company or for your stakeholders). The second way is to share creativity tests to the people you are working with.

Many people believe that creativity is subjective and is uniquely innate to us. What we do not know is that several researches have been conducted to document the measurement of creativity. These creativity tests have been used by several researchers, educators and psychologists to gauge a person’s creative quotient (CQ) and determine which aspect of our creativity needs more nurturing. I think it can be useful for an organisation to have a clear view of his creative corporate culture landscape.

1 – GUILFORD’S TEST OF DIVERGENT THINKING – ALTERNATIVE USES TASK

This test is used to measure how respondents are able to come up with alternative uses for a certain product (a chair, paperclip, cup etc.) based on four factors: originality, fluency, flexibility and elaboration. It aims to derive multiple answers to the question and categorize the answers into:

- Originality – the novelty of the alternative use
 - Fluency – the number of uses the respondent was able to come up with
 - Flexibility – the categories with which the alternative uses fall into
 - Elaboration – the amount of detail the respondent provided with regards to the alternative use of the item.
- Remote Associate

This is one of the creativity tests that fall into convergent thinking – that is finding the “one-right” answer to the problem. This test gives the respondents three words which are in one way or the other related. The respondents’ task is to find what links or associates these words together.

Example: What links: Elephant–Lapse–Vivid Answer: check at the end of this article

2 – TORRANCE TEST OF CREATIVE THINKING – INCOMPLETE FIGURES

Ellis Paul Torrance was one of the forerunners of the creativity tests we use until today. One of the most notable tests he ever came up with was the Incomplete Figures. This test is favoured by many

because it is easy to administer and can be finished in a short period of time. The test begins with giving the respondents and incomplete figure which they must draw and build an object upon.

Possible solutions at the end of this document.

For those that don't trust creativity tests here is an interesting article of the Creativity Research Journal Can We Trust Creativity Tests? A Review of the Torrance Tests of Creative Thinking (TTCT)

ARTISTIC-ASSESSMENT TESTS

These creativity tests are administered in special domains or areas. It is the equivalent of Pulitzer Prize for the best well-written work or the Nobel Prize for an outstanding individual in a specific field. Artistic assessment tests are often used to measure the creativity of an artwork, dance, design and similar fields.

5 – Self-Assessment Test

Self-assessment tests allow respondents to assess their creative intelligence by answering questions. The questions usually ask how they feel about a certain situation and whether you have that certain creative trait. Several self-assessment tests have been developed over the years, two of which was created by one of Torrance's colleague, Joe Khatena. The test is called the Khatena-Torrance Creative Perception Inventory which contains two sub-categories:

1. Something About Myself (SAM)- gauging the respondents artistic abilities, self-strength and individuality.
2. What Kind of Person Are You? (WKOPAY)- measures imagination, self-confidence and inquisitiveness.
- 3.

There are still so many creativity tests available today, several of them are built upon the principles created by Torrance, Guilford and other forerunners. I think the ongoing interest in measuring creativity is a wonderful development, considering that several factors in this day and age influence one's creative skills.

NEUROPSYCHOLOGICAL TESTS

If you're having trouble concentrating or making decisions, some simple tests might be helpful in figuring out what's wrong. They're called neuropsychological tests.

Neuropsychology looks at how the health of your brain affects your thinking skills and behavior.

These tests are usually done with a pencil and paper in a doctor's office. They may also be done on a computer. Or, a neuropsychologist may just ask you a series of questions that you answer orally

These tests help your doctors look at your attention span and how well you concentrate on things. Other areas covered by neuropsychological testing include:

- Your ability to think, understand, learn, and remember (cognition)
- Memory
- Motor function (walking, coordination, etc.)

- Perception (how well you take in what you see or read)
- Problem-solving and decision-making
- Verbal ability

You may be given different types of test, including:

Memory test: Repeat a list of words, sentences, or numbers.

Cognition test: Explain how two items are like. For instance, if you see a picture of a dog and a cat, you might answer that they're both animals or that they are both pets.

Verbal communication test: Name some items as the person giving the test points at them. You might also be given a letter of the alphabet and told to list words that start with that letter.

Motor tests: These might include tasks such as inserting pegs into a pegboard using one hand and then the other.

You might also be given tests to see how your hearing and vision affect your thinking and memory.

Neuropsychological Test Use

You usually take a neurological test when you have a noticeable change in your thinking or memory. They help doctors figure out whether your problems are caused by any of the following:

- Disease, such as Alzheimer's
- Brain injury
- Emotional disorders, such as depression or anxiety
- Normal brain changes related to getting older

It is especially important for doctors to find out about thinking problems in cases where the patient has a movement disorder, such as Parkinson's disease. This is a condition that affects the brain cells that control movement and coordination.

People with Parkinson's eventually can have trouble with their memory or with communication. If you have Parkinson's, you might get a neuropsychological test soon after diagnosis. Results from future tests can then be compared with that first test to see if the disease is changing your thinking skills.

NEUROPSYCHOLOGICAL TEST PREPARATION

No matter what type of neurological test you take, you won't need to study for it. There are a few things you should do before the test, however:

- Get a good night's sleep, since being tired affects how you think.
- Eat a good breakfast.
 - Don't drink anything with alcohol in it the night before the test
- Ask your doctor about whether you can take any medications, including sleep medicine, the night before.
- Tell the psychologist about any previous psychological tests you've taken.

- Relax and don't worry about the results.

You or a loved one should bring a list of all your medications. If you have trouble answering questions about your medical history or symptoms, bring someone along who can.

NEUROPSYCHOLOGICAL TEST PROCEDURE

Part of the testing will include a review of your medical history. If you've had a stroke, for instance, you may have a harder time thinking or talking. It will help the neuropsychologist to better understand your challenges if they know that you've had a stroke. Your neuropsychologist will also interview you or someone close to you to learn more about your symptoms. They will then decide what tests will be given.

A technician who works with the neuropsychologist will typically give you the tests. This person is usually a "psychometrist," a person who is trained to give and score these tests. Or the person may be a student working on a doctoral degree in psychology.

HOW LONG WILL THE TEST TAKE?

The testing may take 3 to 6 hours. It depends on how at ease you are and how quickly you and the technician can go through all the questions. You'll get breaks during the session. In some cases, you might need to make more than one visit.

Neuropsychological Test Results and Follow U

Once the tests are done, the neuropsychologist will go over the results and write a report. It will include a diagnosis and suggestions for treatment, if any is needed.

The treatment plan could include more medical tests, such as a CT or MRI scan of your brain. This is helpful in looking for tumors or other diseases.

Treatment might also include counseling if the diagnosis is depression. Medications to help manage symptoms may also be recommended.

Whatever the results are, they will become part of your permanent medical history. They will be helpful in understanding your current health picture and your future medical needs, too.

If you're ever told you should undergo neuropsychological testing, understand that the tests are meant to get a picture of your brain health at this moment. Your thinking skills may get worse, or they may improve.

When you and your doctor get more information about your brain now, you'll both be able to make smarter decisions about your mental and physical health later.

SPECIFIC AREAS OF APTITUDE TEST MECHANICAL APTITUDE TEST:

This test is designed to measure fundamental aptitudes of tool usage, press visualization and sub arithmetic in the area of mechanical ability. Mechanical aptitude is a combination of various factors. It is very difficult to give any clear-cut list of the various traits comprising mechanical ability.

CLERICAL APTITUDE TEST:

General intelligence, speed, appropriateness of vocabulary, accuracy in checking and measure business arithmetic is required in clerical services. Abilities in regard to official language usage, spelling, vocabulary, hand writing etc. are tested in clerical aptitude tests. Clerical aptitude like the mechanical aptitude is a combination of several traits. Super thinks that, "In routine clerical work one would expect speed and accuracy in checking numerical and verbal symbols to be a characteristic of the successful worker.

There is some justification for referring to this ability as clerical aptitude." According to Bigham "Clerical work is based on perceptual ability, intellectual ability, command over the basic educational skills and motor ability. Bill is of the opinion that clerical duties, "include the gathering, classification and presentation of data of all sorts and the analysis and use of these data in planning, executing and determining the results of operation."

A. PERCEPTUAL:

"The ability to observe words and numbers to see instantly and correctly what is on the paper."

B. INTELLECTUAL:

"Ability to grasp the meaning of words and symbols."

CLERICAL APTITUDE CAN BE MEASURED THROUGH THE FOLLOWING WAYS:

Grade in academic Subjects

Here subjects usually considered for this purpose are English, type writing, book keeping etc.

1. SOCIAL ABILITY:

The social ability of a person can be measured through his participation in curricular activities.

2. APTITUDE TEST:

Standardized tests have also been found to be useful in indicating success in clerical jobs. It has been found that factors like general intelligence, speed and accuracy in checking and measuring business arithmetic determine the suitability of an individual for a clerical job. Abilities with regard to English and Hindi usage, spelling, vocabulary, hand writing, etc. are also important. More than 30 years ago, Muscio and Sowton made an effort to measure aptitude for typing in London.

FIVE TYPES OF QUESTIONS WERE INCLUDED IN THIS TYPE OF QUESTION:

- (1) Reproduction of sentences immediately after they are read
- (2) Carrying out directions,
- (3) Calculating products of numbers,
- (4) Completion of sentences, and
- (5) Spelling test.

THE MINNESOTA CLERICAL TEST:

This test is designed to select persons for accountancy and book-keeping. Super recommends that it can be used with adolescents but very cautiously. Besides there is Johnson O'cannon's clerical test

ART APTITUDE TESTS:

Seashore and Meier devised an Art Judgment Test. It consists of 125 pairs of pictures. Each pair consists of two pictures painted by some famous artists, one picture being of a superior quality and the other of inferior type. The person taking the test is shown these pictures and asked to select from each pair the one that is the "More pleasing, more artistic, more satisfying." After counting the score, we find the aptitude of the subject for art. Another test that may be mentioned in this category is of McAdory Art Test.

SEASHORE MUSICAL TESTS:

These tests are designed to measure pitch, intensity, time timber, tonal memory and rhythm – the factors which determine the suitability of a man in music. Seashore established a clinic at the University of Law in 1916 for testing musical capacity.

THE ASSESSMENT IS MADE ON THE FOLLOWING BASES:

I. Musical Sensitivity which takes note of:

Simple form of impression, which includes

- (i) Sense of pitch,
- (ii) Sense of intensity,
- (iii) Sense of time,
- (iv) Sense of extensity.

(4) TESTS OF SCIENTIFIC APTITUDE:

"This two-hour test for students in college and senior high school has been shown to reveal at least as much about the relative scientific aptitude of college students as science teachers discover after a semester or more of contact with them. It provides an indication of aptitude for the various branches of engineering, chemistry, physics, biology and other work in which success depends in part upon the ability to profit by training in scientific method.

Performance is relatively independent of acquired knowledge. Whatever specific information is needed is furnished in the test. Since, it makes no attempt to ascertain whether a person actually knows enough about mathematics for example, to enable him to profit by engineering studies, such information must be sought from the school record or from standard achievement test." – Bingham

CONSTRUCTION INVOLVES THESE PROCESSES:

- (a) A careful analysis of the occupation into its elements,
- (b) Determination of the psychological qualities important in respect of each element,
- (c) Testing of individuals for these qualities,
- (d) Finding out the correlation between performance in the test and performance in the occupation.

EDUCATIONAL APTITUDE TEST:

Yele has developed a battery of educational aptitude test to measure a person's relative aptitude in:

- i. Linguistic ability
- ii. Verbal reasoning
- iii. Quantitative reasoning
Verbal ability
- iv. Mathematical aptitude
- v. Teaching aptitude and
- vi. Spatial visualizing

(5) TEACHING APTITUDE TEST:

Teaching aptitude test may broadly contain three types of test items:

- (1) Test items relating to knowledge in the areas of aptitude test, teachers trait test, teaching efficiency inventories, teaching attitude test, and tests of intelligence and general mental ability.
- (2) Test items relating to the application of principles in various areas related to teaching.
- (3) Test items relating to education and allied areas of a miscellaneous nature.

BROAD AREAS RELATING TO TEACHING APTITUDE:

Teaching aptitude, would to a large extent, be determined by the candidate's knowledge in the following areas:

- 1. Educational thought-the contribution of great educators.
- 2. Standard work on education
- 3. Pupil-teacher relations.
- 4. Special needs of backward and gifted students.
- 5. Educational practices in general.
- 6. Teaching techniques for special subjects.
Evaluation and measurement
- 7. Institutional planning.
- 8. Planning individual lesson.
- 9. Role of mass media in education.

CONSTRUCTION AND STANDARDISATION OF THE APTITUDE TEST FOR SECONDARY SCHOOL TEACHERS:

B.M. Upadhyaya, Ph. D. Psychology, Saurashtra University, 1976. The test included 125 items.

It was found that sex and socio-economic backgrounds were not related to aptitude for teaching, whereas academic discipline and previous experiences of teaching were found to be significantly related to aptitude for teaching.

7. Construction and Standardisation of an Aptitude Test for Primary School Teachers in Gujarat State. D.P. Patel, Ph.D. Education, South Gujarat University, 1980.

THE TEST COVERED THE FOLLOWING TEN TEACHER TRAITS:

1. Interest in the profession.
 2. Attitude towards community.
 3. Mental ability.
 4. Professional information.
 5. Attitude towards children.
- Personality assessment Psychology

Personality	assessment,	the measurement of	personal
characteristics.	Assessment is	an end result of	gathering

information intended to advance psychological theory and research and to increase the probability that wise decisions will be made in applied settings (e.g., in selecting the most promising people from a group of job applicants).

The approach taken by the specialist in personality assessment is based on the assumption that much of the observable variability in behaviour from one person to another results from differences in the extent to which individuals possess particular underlying personal characteristics (traits). The assessment specialist seeks to define these traits, to measure them objectively, and to relate them to socially significant aspects of behaviour.

A distinctive feature of the scientific approach to personality measurement is the effort, wherever possible, to describe human characteristics in quantitative terms. How much of a trait manifests itself in an individual? How many traits are present? Quantitative personality measurement is especially useful in comparing groups of people as well as individuals.

Do groups of people from different cultural and economic backgrounds differ when considered in the light of their particular personality attributes or traits? How large are the group differences?

Overt behaviour is a reflection of interactions among a wide range of underlying factors, including the bodily state of the individual and the effects of that person's past personal experiences. Hence, a narrowly focused approach is inadequate to do justice to the complex human behaviour that occurs under the constantly changing set of challenges, pleasures, demands, and stresses of everyday life. The sophisticated measurement of human personalit

inescapably depends on the use of a variety of concepts to provide trait definitions and entails the application of various methods of observation and evaluation. Personality theorists and researchers seek to define and to understand the diversity of human traits, the many ways people have of thinking and perceiving and learning and emoting.

Such nonmaterial human dimensions, types, and attributes are constructs—in this case, inferences drawn from observed behaviour. Widely studied personality constructs include anxiety, hostility, emotionality, motivation, and introversion-extroversion. Anxiety, for example, is a concept, or construct, inferred in people from what they say, their facial expressions, and their body movements.

Personality is interactional in two senses. As indicated above, personal characteristics can be thought of as products of interactions among underlying psychological factors; for example, an individual may experience tension because he or she is both shy and desirous of social success. These products, in turn, interact with the types of situations people confront in their daily lives. A person who is anxious about being evaluated might show debilitated performance in evaluative situations (for example, taking tests), but function well in other situations in which an evaluative emphasis is not present. Personality makeup can be either an asset or a liability depending on the situation. For example, some people approach evaluative situations with fear and foreboding, while others seem to be motivated in a desirable direction by competitive pressures associated with performance.

MEASURING CONSTRUCTS

Efforts to measure personality constructs stem from a variety of sources. Frequently they grow out of theories of personality; anxiety and repression (the forgetting of unpleasant experiences), for example, are among the central concepts of the theory of psychoanalysis. It is understandable that efforts would be made to quantify one's degree of anxiety, for example, and to use the score thus obtained in the assessment of and in the prediction of future behaviour. Among the major issues in the study of personality measurement is the question of which of the many personality constructs that have been quantified are basic or fundamental and which can be expected to involve wasted effort in their measurement because they represent poorly defined combinations of more elemental constructs; which measurement techniques are most effective and convenient for the purpose of assessment; and whether it is better to interview people in measuring personality, or to ask them to say, for example, what an inkblot or a cloud in the sky reminds them of.

ASSESSMENT METHODS

Personality tests provide measures of such characteristics as feelings and emotional states, preoccupations, motivations, attitudes, and approaches to interpersonal relations. There is a diversity of approaches to personality assessment, and controversy surrounds many aspects of the widely used methods and techniques. These include such assessments as the interview, rating scales, self-reports, personality inventories, projective techniques, and behavioral observation

INTEREST INVENTORIES PERSONALITY INVENTORIES

Among the most common of self-report tests are personality

inventories. Their origins lie in the early history of personality measurement, when most tests were constructed on the basis of so-called face validity; that is, they simply appeared to be valid. Items were included simply because, in the fallible judgment of the person who constructed or devised the test, they were indicative of certain personality attributes. In other words, face validity need not be defined by careful, quantitative study; rather, it typically reflects one's more-or-less imprecise, possibly erroneous, impressions. Personal judgment, even that of an expert, is no guarantee that a particular collection of test items will prove to be reliable and meaningful in actual practice.

A widely used early self-report inventory, the so-called Woodworth Personal Data Sheet, was developed during World War I to detect soldiers who were emotionally unfit for combat. Among its ostensibly face-valid items were these: Does the sight of blood make you sick or dizzy? Are you happy most of the time? Do you sometimes wish you had never been born? Recruits who answered these kinds of questions in a way that could be taken to mean that they suffered psychiatric disturbance were detained for further questioning and evaluation. Clearly, however, symptoms revealed by such answers are exhibited by many people who are relatively free of emotional disorder.

Rather than testing general knowledge or specific skills, personality inventories ask people questions about themselves. These questions may take a variety of forms. When taking such a test, the subject might have to decide whether each of a series of statements is accurate as a self-description or respond to a series of true-false questions about personal beliefs.

Several inventories require that each of a series of statements be placed on a rating scale in terms of the frequency or adequacy with which the statements are judged by the individual to reflect his tendencies and attitudes. Regardless of the way in which the subject responds, most inventories yield several scores, each intended to identify a distinctive aspect of personality.

One of these, the Minnesota Multiphasic Personality Inventory (MMPI), is probably the personality inventory in widest use in the English-speaking world. Also available in other languages, it consists in one version of 550 items (e.g., "I like tall women") to which subjects are to respond "true," "false," or "cannot say." Work on this inventory began in the 1930s, when its construction was motivated by the need for a practical, economical means of describing and predicting the behaviour of psychiatric patients. In its development efforts were made to achieve convenience in administration and scoring and to overcome many of the known defects of earlier personality inventories.

Varied types of items were included and emphasis was placed on making these printed statements (presented either on small cards or in a booklet) intelligible even to persons with limited reading ability.

Most earlier inventories lacked subtlety; many people were able to fake or bias their answers since the items presented were easily seen to reflect gross disturbances; indeed, in many of these inventories maladaptive tendencies would be reflected in either all true or all false answers. Perhaps the most significant methodological advance to be found in the MMPI was the attempt

on the part of its developers to measure tendencies to respond, rather than actual behaviour, and to rely but little on assumptions of face validity.

The true-false item "I hear strange voices all the time" has face validity for most people in that to answer "true" to it seems to provide a strong indication of abnormal hallucinatory experiences. But some psychiatric patients who "hear strange voices" can still appreciate the socially undesirable implications of a "true" answer and may therefore try to conceal their abnormality by answering "false."

A major difficulty in placing great reliance on face validity in test construction is that the subject may be as aware of the significance of certain responses as is the test constructor and thus may be able to mislead the tester.

Nevertheless, the person who hears strange voices and yet answers the item "false" clearly is responding to something—the answer still is a reflection of personality, even though it may not be the aspect of personality to which the item seems to refer; thus, careful study of responses beyond their mere face validity often proves to be profitable.

Much study has been given to the ways in which response sets and test-taking attitudes influence behaviour on the MMPI and other personality measures.

The response set called acquiescence, for example, refers to one's tendency to respond with "true" or "yes" answers to questionnaire items regardless of what the item content is. It is conceivable that two people might be quite similar in all respects except for the tendency toward acquiescence. This difference in response set can lead to misleadingly different scores on personality tests.

One person might be a "yea-sayer" (someone who tends to answer true to test items); another might be a "nay-sayer"; a third individual might not have a pronounced acquiescence tendency in either direction.

Acquiescence is not the only response set; there are other test-taking attitudes that are capable of influencing personality profiles. One of these, already suggested by the example of the person who hears strange voices, is social desirability. A person who has convulsions might say "false" to the item "I have convulsions" because he believes that others will think less of him if they know he has convulsions.

The intrusive potentially deceiving effects of the subjects' response sets and test-taking attitudes on scores derived from personality measures can sometimes be circumvented by varying the content and wording of test items. Nevertheless, users of questionnaires have not yet completely solved problems of bias such as those arising from response sets. Indeed, many of these problems first received widespread attention in research on the MMPI, and research on this and similar inventories has significantly advanced understanding of the whole discipline of personality testing.

ATTRIBUTES OF THE MMPI

The MMPI as originally published consists of nine clinical scales (or sets of items), each scale having been found in practice to discriminate a particular clinical group, such as people suffering from schizophrenia, depression, or paranoia (see mental disorder). Each of these scales (or others produced later) was developed b

determining patterns of response to the inventory that were observed to be distinctive of groups of individuals who had been psychiatrically classified by other means (e.g., by long-term observation).

The responses of apparently normal subjects were compared with those of hospital patients with a particular psychiatric diagnosis—forexample, with symptoms of schizophrenia. Items to which the greatest percentage of “normals” gave answers that differed from those more typically given by patients came to constitute each clinical scale.

In addition to the nine clinical scales and many specially developed scales, there are four so-called control scales on the inventory. One of these is simply the number of items placed by the subject in the “cannot say” category.

The L (or lie) scale was devised to measure the tendency of the testtaker to attribute socially desirable attributes to himself. In response to “I get angry sometimes” he should tend to mark false; extreme L scorers in the other direction appear to be too good, too virtuous. Another so-called F scale was included to provide a reflection of the subjects’ carelessness and confusion in taking the inventory (e.g., “Everything tastes the same” tends to be answered true by careless or confused people).

More subtle than either the L or F scales is what is called the K scale. Its construction was based on the observation that some persons tend to exaggerate their symptoms because of excessive openness and frankness and may obtain high scores on the clinical scales; others may exhibit unusually low scores because of defensiveness. On the K-scale item “I think nearly anyone would tell a lie to keep out of trouble,” the defensive person is apt to answer false, giving the same response to “I certainly feel useless at times.”

The K scale was designed to reduce these biasing factors; by weighting clinical-scale scores with K scores, the distorting effect of test-taking defensiveness may be reduced.

In general, it has been found that the greater the number and magnitude of one’s unusually high scores on the MMPI, the more likely it is that one is in need of psychiatric attention.

Most professionals who use the device refuse to make assumptions about the factualness of the subject’s answers and about his personal interpretations of the meanings of the items. Their approach does not depend heavily on theoretical predilections and hypotheses. For this reason the inventory has proved particularly popular with those who have strong doubts about the eventual validity that many theoretical formulations will show in connection with personality measurement after they have been tested through painstaking research.

The MMPI also appeals to those who demand firm experimental evidence that any personality assessment method can make valid discriminations among individuals.

COMPARISON OF THE MMPI AND CPI

The MMPI has been considered in some detail here because of its wide usage and because it illustrates a number of important problems confronting those who attempt to assess personality characteristics. Many other omnibus personality inventories are also used in applied settings and in research. The California Psychological Inventory (CPI), for example, is keyed for severe personality variables that include sociability, self-control, flexibility, and tolerance. Unlike the

MMPI, it was developed specifically for use with “normal” groups of people.

Whereas the judgments of experts (usually psychiatric workers) were used in categorizing subjects given the MMPI during the early item-writing phase of its development, nominations by peers (such as respondents or friends) of the subjects were relied upon in work with the CPI. Its technical development has been evaluated by test authorities to be of high order, in part because its developers profited from lessons learned in the construction and use of the MMPI. It also provides measures of response sets and has been subjected to considerable research study.

OTHER SELF-REPORT TECHNIQUES

Beyond personality inventories, there are other self-report approaches to personality measurement available for research and applied purposes. Mention was made earlier of the use of rating scales. The rating-scale technique permits quantification of an individual’s reactions to himself, to others, and, in fact, to any object or concept in terms of a standard set of semantic (word) polarities such as “hot-cold” or “good-bad.” It is a general method for assessing the meanings of these semantic concepts to individuals.

Another method of self-report called the Q-sort is devised for problems similar to those for which rating scales are used. In a Q-sort a person is given a set of sentences, phrases, or words (usually presented individually on cards) and is asked to use them to describe himself (as he thinks he is or as he would like to be) or someone else. This description is carried out by having the subject sort the items on the cards in terms of their degree of relevance so that they can be distributed along what amounts to a rating scale. Examples of descriptive items that might be included in a Q-sort are “worries a lot,” “works hard,” and “is cheerful.”

Typical paper-and-pencil instruments such as personality inventories involve verbal stimuli (words) intended to call forth designated types of responses from the individual. There are clearly stated ground rules under which he makes his responses. Paper- and-pencil devices are relatively easy and economical to administer and can be scored accurately and reliably by relatively inexperienced clerical workers.

They are generally regarded by professional personality evaluators as especially valuable assessment tools in screening large numbers of people, as in military or industrial personnel selection.

Assessment specialists do not assume that self-reports are accurate indicators of personality traits. They are accepted, rather, as samples of behaviour for which validity in predicting one’s everyday activities or traits must be established empirically (i.e., by direct observation or experiment). Paper-and-pencil techniques have moved from their early stage of assumed (face) validity to more advanced notions in which improvements in conceptualization and methodology are clearly recognized as basic to the determination of empirical validity

WHAT IS ATTITUDE SCALES – SEMANTIC DIFFERENTIAL, STAPLES, LIKERT SCALE
COMPUTER-BASED PSYCHOLOGICAL TESTING ?

**ATTITUDE SCALES – SEMANTIC DIFFERENTIAL, STAPLES, LIKERT SCALE
COMPUTER-BASED PSYCHOLOGICAL TESTING**

Direct Attitude Measures

Perhaps the most straightforward way of finding out about someone's attitudes would be to ask them. However, attitudes are related to self-image and social acceptance.

In order to preserve a positive self-image, people's responses may be affected by social desirability. They may not well tell about their true attitudes, but answer in a way that they feel socially acceptable.

Given this problem, various methods of measuring attitudes have been developed. However, all of them have limitations. In particular the different measures focus on different components of attitudes – cognitive, affective and behavioral – and as we know, these components do not necessarily coincide.

Attitude measurement can be divided into two basic categories

SEMANTIC DIFFERENTIAL

The semantic differential technique of Osgood et al. (1957) asks a person to rate an issue or topic on a standard set of bipolar

adjectives (i.e. with opposite meanings), each representing a seven point scale.

To prepare a semantic differential scale, you must first think of a number of words with opposite meanings that are applicable to describing the subject of the test.

For example, participants are given a word, for example 'car', and presented with a variety of adjectives to describe it. Respondents tick to indicate how they feel about what is being measured.

In the picture (above), you can find Osgood's map of people's ratings for the word 'polite'. The image shows ten of the scales used by Osgood. The image maps the average responses of two groups of 20 people to the word 'polite'.

The semantic differential technique reveals information on three basic dimensions of attitudes: evaluation, potency (i.e. strength) and activity.

- **Evaluation** is concerned with whether a person thinks positively or negatively about the attitude topic (e.g. dirty – clean, and ugly - beautiful).
- **Potency** is concerned with how powerful the topic is for the person (e.g. cruel – kind, and strong - weak).
- **Activity** is concerned with whether the topic is seen as active or passive (e.g. active – passive).

Using this information we can see if a person's feeling (evaluation) towards an object is consistent with their behavior. For example, a place might like the taste of chocolate (evaluative) but not eat it often (activity)

The evaluation dimension has been most used by social psychologists as a measure of a person's attitude because this dimension reflects the affective aspect of an attitude.

Evaluation of Direct Methods

An attitude scale is designed to provide a valid, or accurate, measure of an individual's social attitude. However, as anyone who has every "faked" an attitude scales knows there are shortcomings in these self-report scales of attitudes.

There are various problems that affect the validity of attitude scales. However, the most common problem is that of social desirability.

Socially desirability refers to the tendency for people to give "socially desirable" to the questionnaire items. People are often motivated to give replies that make them appear "well adjusted", unprejudiced, open minded and democratic. Self-report scales that measure attitudes towards race, religion, sex etc. are heavily affected by socially desirability bias.

Respondents who harbor a negative attitude towards a particular group may not wish be admit to the experimenter (or to themselves) that they have these feelings. Consequently, responses on attitude scales are not always 100% valid.

HIGH-DIMENSIONAL CONTEXT SPACES

Osgood et al.'s semantic differential can also be seen as a predecessor of contemporary corpus-derived measures of semantics and semantic similarity. For example, Burgess and Lund's (1997) hyperspace analogue to language model (HAL) learns a high-dimensional context from large-scale linguistic corpora

that encompass many millions of words of speech or text. The model tracks lexical co-occurrences throughout the corpus and from these derives a high-dimensional representational space. The meaning of a word is conceived of as a vector. Each element of this vector corresponds to another word in the model, with the value of an element representing the number of times that the two words co-occurred within the discourse samples that constitute the corpus. For example, the vector for dog will contain an element reflecting the number of times that the word 'bone' was found within a given range of words in the corpus. These vectors can be viewed as the coordinates of points (individual words) in a high-dimensional semantic space. Semantic similarity is then a matter of distance between points in this space.

Several other such usage-based models have been proposed to date; similar in spirit to HAL, for example, is Lindauer and Dumas's (1997) latent semantic analysis (see also Semantic Processing: Statistical Approaches). The basic approach might be seen to be taking to its logical consequence Wittgenstein's famous adage of 'meaning as use.'

Its prime advantage over related approaches such as spatial models of similarity and the semantic differential lies in the ability to derive semantics and thus measures of semantic similarity for arbitrarily large numbers of words without the need for any especially collected behavioral data. The ability of these models to capture a wide variety of phenomena, such as results in semantic priming and effects of semantic context on syntactic processing, has been impressive.

Staple scale

Staple scale is defined as a rating scale that is close-ended with a single adjective (unipolar), developed to gather respondent insights about a particular subject or event. The survey question

is comprised of an even number of response options without a neutral point.

For example, these options can range from any scales like +2 to -2 or +5 to -5 or even +10 to -10 and they are purely dependent on the nature of the study and the required outcome, all without a neutral point. The stapel scale can be indicated as standalone questions or even as a matrix question type where each line item is one unique adjective.

This scale was named after its developer, Jan Staple. Since this is a non-comparative and categorical scale, it makes it very similar to a semantic differential scale with the sole difference being the presence of only adjective in between a positive and negative category rather than having two opposing adjectives. Respondents must indicate the relevance of each characteristic to an object in the question.

An example of the use of staple scale question in a survey is understanding the competency level of a respondent's supervisor on the basis of some basic skills. This question helps the surveyor understand if the top management of the company is fit to be in the role or not or if they could get to a certain level with training.

CHARACTERISTICS OF STAPEL SCALE

The scale can be depicted either as vertical or a horizontal scale with one single adjective in the middle of the range of values and the respondent has to choose a numerical value that best defines the validity of the adjective

- **Agreement and Disagreement:** A positive score accurately describes the object, and a negative score is the exact opposite; the statement is incorrect. Higher up the rating scale indicates a higher acceptance with the single adjective and a lower negative score indicates the disagreement with the adjective. This directly equates to the + rating being a strong agreement and the – rating being strong disagreement.
- **Data Analysis:** The data collected in a stapel scale survey is treated as an interval and it can be analyzed in the same way as the data collected by using a semantic differential survey type. The results in both question types are similar.
- **No Need of Bipolarity:** Due to the nature of the question, one adjective and the subsequent rating is adequate to collect feedback about a certain adjective. This question type is used when there is difficulty in finding out bipolar adjectives or there is difficulty in pre-testing of adjectives to ensure their true bipolarity.

STAPEL SCALE SURVEY USED

A staple scale survey is used to conduct an in-depth data analysis about each metric in a question and that is done by having to select from that a numerical value is assigned to each metric or adjective. Staple scale questions allow flexibility to tweak a survey in a way that suits the research objective. The survey respondent can be asked questions in a way that they offer maximum value about each metric.

Stapel scale surveys are generally used in customer-satisfaction surveys due to the nature of the questions asked and the numerical data collected. The researcher or the organization conducting

survey uses staple scale questions to rate each parameter of their product or service individually. This provides a complete snapshot of aspects and is important in understanding if their business is doing well and what is not.

USE STAPEL SCALE QUESTIONS IN YOUR SURVEY RESEARCH

- **Easy to administer:** Stapel scale questions are very easy to administer due to the nature of how they are set-up. They are used effectively due to the rating nature of the responses which makes it easier for a survey respondent to answer the question correctly.
- **Reduce survey drop off rate:** The options provided in a question are administered separately with each adjective forming one option and one question can have multiple options. This makes it easier for a survey respondent to answer each option on the basis of each objective rather than be forced to select between two or more objectives. This reduces the drop-off rate in a survey.
- **Collect actionable insights:** Each objective is provided a numerical value and each adjective forces a respondent to respond rather than leaving it blank. This helps collect a higher level of actionable insights.

THE DIFFERENCE BETWEEN STAPEL SCALE AND SEMANTIC DIFFERENTIAL QUESTIONS IN A SURVEY:

Although the data collected in both, stapel scale surveys and semantic differential scales are similar, there are some other stark differences between them. Some of the major differences are:

UNIT-3 Psychological testing

-Stapel Scale Questions-Semantic Differential Questions

In a stapel scale survey, the options are **unipolar**. The rating given to each question is on the basis of one objective

In a semantic differential question, the options are **bipolar**. The rating provided in a question is on the basis of two polar opposite objectives.

There is **no neutral point** in a staple scale question which means each option can describe the objective. -The semantic differential **allows for a neutral** which means that a survey respondent can question unanswered if the bipolar objectives do not appropriately define the experience.

-There is no capped number of responses as long as the number of **responses are even**. -There are generally **seven responses** from highly unlikely to highly likely.

-Each stapel scale survey question has **forced responses** due to the lack -Semantic differential survey questions provide the

UNIT-3 Psychological testing -

-of a neutral zero option. -flexibility for **unforced responses** due to the presence of a neutral option.-

-The options are represented **numerically**. -
The options are represented **textually**. -

Advantages of using a Stapel Scale

The stapel scale survey has many advantages. Some of them are:

- **Easy to understand and respond to:** A stapel scale question is easy to understand and respond to as there is a + and – rating system for each adjective in the stapel scale survey. This makes it very easy for each survey respondent to understand and to reply to.
- **Numerical labels:** Numerical labels reduce all possible ambiguity in the mind of a respondent about their feeling towards an objective or metric. This ensures that the option selected by the survey respondent numerically represents their emotions towards that object.
- **Forces a response as there is no neutral or zero:** A stapel scale survey helps collect the ideal or most ideal response to a question as it eliminates the possibility of a neutral answer leaving each objective to be aptly selected.

Measures both the direction and the intensity of attitudes simultaneously: Since the stapel scale question looks to measure each objective separately, there is a deeper rooted clarity on the direction and intensity of each objective separately. The “how positive” or “how negative” throws light on the degree of each objective in the mind of the respondent.

LIKERT SCALE DEFINITION, EXAMPLES AND ANALYSIS

Various kinds of rating scales have been developed to measure attitudes directly (i.e. the person knows their attitude is being studied). The most widely used is the Likert scale (1932).

In its final form, the Likert scale is a five (or seven) point scale which is used to allow the individual to express how much they agree or disagree with a particular statement.

For example:

I believe that ecological questions are the most important issues facing human beings today.

A Likert scale assumes that the strength/intensity of an attitude is linear, i.e. on a continuum from strongly agree to strongly disagree, and makes the assumption that attitudes can be measured.

For example, each of the five (or seven) responses would have a numerical value which would be used to measure the attitude under investigation.

Likert Scale Examples for Survey

In addition to measuring statements of agreement, Likert scales can measure other variations such as frequency, quality, importance, and likelihood, etc.

How can you analyze data from a Likert scale?

The response categories in Likert scales have a rank order, but the intervals between values cannot be presumed equal.

Therefore, the mean (and standard deviation) are inappropriate for ordinal data (Jamieson, 2004)

Statistics you can use are:

- Summarize using a median or a mode (not a mean as it is ordinal scale data); the mode is probably the most suitable for easy interpretation.
- Display the distribution of observations in a bar chart (it can't be a histogram, because the data is not continuous).

CRITICAL EVALUATION

Strengths

Likert Scales have the advantage that they do not expect a simple yes / no answer from the respondent, but rather allow for degrees of opinion, and even no opinion at all.

Therefore quantitative data is obtained, which means that the data can be analyzed with relative ease.

Offering anonymity on self-administered questionnaires should further reduce social pressure, and thus may likewise reduce social desirability bias Paulus (1984) found that more desirable personality characteristics were reported when people were asked to write their names, addresses and telephone numbers on their questionnaire than when they told not to put identifying information on the questionnaire.

Limitations

However, like all surveys, the validity of the Likert scale attitude measurement can be compromised due to social desirability.

This means that individuals may lie to put themselves in a positive light.

COMPUTER-BASED TEST INTERPRETATION IN PSYCHOLOGICAL ASSESSMENT

Computers are playing an ever increasing role in the administration and scoring of psychological tests, and in the generation of interpretative reports of test results. As a result of concerns that this enhanced role of the computer has not always been applied with the same ethical, professional, and technical standards that govern the traditional means of testing and test interpretation, the American Psychological Association has put forth the Guidelines for Computer-Based Tests and Interpretations. Of the 31 CBTI Guidelines, nine describe user responsibilities in two areas, administration and interpretation. These user guidelines emphasize standardization of administrative procedures and the need for professional judgment in conjunction with the use of computer-generated interpretative reports.

The guidelines for developers are more numerous and complex as a result of the multitude of steps required in the design of system that either administer/score or interpret test results. In

the case of systems to administer/score tests, there are human factor and psychometric issues. With respect to interpretation, the areas of concern are classification and validity. The final section contains one guideline specifying reasonable access to computer-based test systems by qualified professionals for purposes of scholarly review. The CBTI Guidelines are designed to address the problems that already exist with computer testing and interpretation while at the same time keeping in mind the promise of this new technology.

As the educational applications of computing have continued to evolve, more complex and interactive computer learning environments have emerged. Generally, these environments focus on providing students with experiences testing hypothesis, organizing and interpreting data, and performing other problem-solving activities within a particular content area. In this article, the complexity of educating teachers so that they can effectively

utilize this software and integrate it into the curriculum is discussed. It is suggested that teachers are accustomed to delivering and evaluating curriculum in the framework of behavioral psychology and that the more cognitive orientation of computer learning environments will be difficult for teachers to implement.

The article suggests that experiences for teachers must include the opportunity to experience learning and problem-solving with tool software and simulations and examination of these approaches with respect to views of the learner, goals, roles of the teacher, and evaluation of outcomes. A sample experience for teachers using the Logo language is described

APPLICATIONS OF PSYCHOLOGICAL TESTING IN VARIOUS SETTINGS: CLINICAL

Psychological tests enable mental health professionals to make diagnoses more reliably, validly, and quickly than they can from personal observation alone. Tests can uncover problems that a mental health professional may not detect until much later. This allows the clinician to focus on the appropriate treatment more quickly, thereby saving time and money for the patient or client. Once a course of treatment has begun, tests can help the clinician monitor the effectiveness of the treatment as it proceeds.

Tests are not designed to label people. In fact, responsible test manuals discourage any such linkage between results and labels. These manuals help users interpret the test results in a way that respects each individual's uniqueness. They also recommend that the test user base diagnoses or clinical decisions on several sources of information rather than on just a single test result.

However, some public groups such as insurance companies, legislatures, school boards, and human service agencies do attach labels to people. This happens when programs and treatments are standardized by categories. Thus, an individual seeking treatment or a child with learning problems often has to be diagnosed and labeled to fit into one of the categories in order to receive funding for the special help they need.

DO CLINICAL PSYCHOLOGISTS USE DIFFERENT TESTS FROM THOSE USED IN BUSINESSES OR IN SCHOOLS?

Sometimes. But most psychological tests, especially those measuring motor skills and mental aptitudes, can be useful in more than one field. A test for cognitive ability, for example, may be used in a school or at an employment office as well as by a mental health clinician. Also, some

tests require high levels of training and expertise of test users for proper administration and interpretation.

CAN A TEST PROVE THAT SOMEBODY IS MENTALLY DISTURBED?

Tests alone cannot diagnose a person. They are tools used only by qualified and competent professionals, just as a physician may combine information from X-rays, blood tests, and personal examination of the patient in reaching a physical diagnosis.

WHAT GOOD ARE TESTS WHEN SOMEBODY HAS ALREADY BEEN DIAGNOSED WITH A PSYCHIATRIC DISORDER?

Psychological tests are often used to monitor a person's response to medications, which are used increasingly in treating a number of disorders, including depression, schizophrenia, and attention deficit disorder in children. The tests can help to track progress during a course of treatment to determine if a person is receiving the correct dosage, or is responding correctly to the medication. In a similar manner, tests can help monitor a person's response to other therapeutic treatments such as psychotherapy. Tests can also serve to confirm or reject potential diagnoses.

SINCE WE NOW HAVE MODERN MEDICAL PROCEDURES, SUCH AS MAGNETIC RESONANCE IMAGING (MRI), WHY DO WE NEED NEUROPSYCHOLOGICAL TESTS?

It's true that medical imaging techniques are now widely used to help physicians diagnose neurological illnesses. However, neuropsychological tests are useful for screening patients for signs of neurological disorder. They are also helpful, and far less expensive than computerized tomography (CT) scans and MRIs, for monitoring patients over long periods of recovery or rehabilitation. Through neuropsychological testing, a physician can measure the progress of stroke victims, for example, and determine whether a particular treatment is working properly.

Psychological assessment contributes important information to the understanding of individual characteristics and capabilities, through the collection, integration, and interpretation of information about an individual (Groth-Marnat, 2009; Weiner, 2003). Such information is obtained through a variety of methods and measures, with relevant sources determined by the specific purposes of the evaluation. Sources of information may include

- Records (e.g., medical, educational, occupational, legal) obtained from the referral source;
- Records obtained from other organizations and agencies that have been identified as potentially relevant;
- Interviews conducted with the person being examined;
- Behavioral observations;
- Interviews with corroborative sources such as family members, friends, teachers, and others; and
- Formal psychological or neuropsychological testing.

Agreements across multiple measures and sources, as well as discrepant information, enable the creation of a more comprehensive understanding of the individual being assessed, ultimately leading to more accurate and appropriate clinical conclusions (e.g., diagnosis, recommendations for treatment planning)

The clinical interview remains the foundation of many psychological and neuropsychological

assessments. Interviewing may be structured, semi structured, or open in nature, but the goal of the interview remains consistent—to identify the nature of the client's presenting issues, to obtain direct historical information from the examinee regarding such concerns, and to explore historical variables that may be related to the complaints being presented. In addition, the interview element of the assessment process allows for behavioral observations that may be useful in describing the client, as well as discerning the convergence with known diagnoses.

Based on the information and observations gained in the interview, assessment instruments may be selected, corroborative informants identified, and other historical records recognized that may aid the clinician in reaching a diagnosis. Conceptually, clinical interviewing explores the presenting complaint(s) (i.e., referral question), informs the understanding of the case history, aids in the development of hypotheses to be examined in the assessment process, and assists in determination of methods to address the hypotheses through formal testing.

INDUSTRIAL AND ORGANIZATIONAL PSYCHOLOGY

Industrial and organizational psychology, also known as I/O psychology, is the study of the workplace.

According to the American Psychological Association, I/O psychology pulls from ideas about decision theory, small group theory, and criterion theory. It applies them to real-world workplace situations.

This field focuses on analyzing employee engagement, company culture, retention, productivity, morale, and team building

Industrial and organizational psychologists can work with individual employees, groups, management teams, and consultants on improving the above processes.

For Dr. Jeremy Nicholson, a TCSP professor of behavioral economics, I/O psychology is “a standardized skillset” that includes personnel selection, workplace training, business development, human resources, and consulting.

Are you interested in pursuing an industrial and organizational psychology degree? Whether you're looking for an online program or an on-campus degree program near you, The Chicago School offers a certificate and a variety of M.A. programs in this field.

business psychology?

While I/O psychology focuses on more individual and personal workplace issues such as engagement and morale, business psychology applies psychological practices to big-picture areas.

These areas include corporate strategy, stakeholder relationships, market performance, and broader business operations. Professionals who are knowledgeable of this intersection between psychology and business use assessment and intervention skills to analyze high-level issues and provide recommendations to a business leadership team.

This career field includes consultants, program directors, and organizational development specialists. Oftentimes, business psychologists work with senior leadership teams, business

owners, and board members.

The Chicago School offers various I/O and business psychology degrees and certificates including

- Certificate in I/O psychology (online)
- B.A. in psychology with a business psychology minor (online)
- M.A. in I/O psychology (online and various campuses)
- Ph.D. in business psychology (online and various campuses)
- M.A. and Ph.D. in Organizational Leadership (online and various campuses)

Two intertwined fields

Of course, I/O psychology and business psychology are clearly linked. Both work to improve the overall function, performance, and efficiency of businesses.

The merging of these two disciplines creates the possibility for professionals to establish themselves as authorities with multiple psychological foundations that are rooted in business-minded practices. Professionals in I/O and business psychology are not only able to navigate business fields but also understand and describe the psychological nuance that drives individual behavior—and this, makes them more versatile.

According to Dr. Jay Finkelman, a TCSPP professor of I/O business psychology and the department chair of the Southern California campuses, “they all fit under the same umbrella.”

This overlap is clear even in The Chicago School’s degree tracks. For example, you can pursue a business psychology degree with an industrial and organizational focus.

Finally, many I/O psychologists cover corporate strategy, and business psychologists analyze issues such as employee retention and productivity. All aspects of a business are intertwined, so it’s inevitable that two psychology fields that specialize in helping businesses succeed are intertwined.

EDUCATION, COUNSELING, MILITARY. CAREER GUIDANCE

Career Counseling This section summarizes the development of career counseling, the most widely used career counseling interventions, the typical settings in which career counseling occurs, important differences among clients who seek career counseling services, the focal issues examined in career counseling, and the career counseling process. The articles appearing in this section describe these topics in greater detail (see the sidebar for links).

DEVELOPMENT OF CAREER COUNSELING

The theoretical underpinnings of career counseling were first recorded around 360 B.C. when Plato observed in *The Republic* that different jobs require different types of workers for optimal performance. Today we regard this as obvious; the jobs of elementary school teacher, truck driver, opera singer, and accountant each require a different set of skills and interests.

Frank Parsons formalized this theory of the relation between people and jobs in the late 19th century. He wrote that effective career placement requires knowledge of the special talents of

the worker, the requirements of various occupations, and the relations between these sets of knowledge. Over time Parsons's ideas have been codified into the person-environment fit model and trait and factor counseling. The overlapping disciplines of counseling psychology, vocational psychology, and career counseling emerged from this beginning. Three crises, World Wars I and II and the Great Depression, helped shape career counseling. Prior to World War I, French scholars Alfred Binet and Theodore Simon developed a test to measure cognitive ability. Their work paved the way for modern intelligence tests. Entry into World War I suddenly confronted the United States with the need to place hundreds of thousands of workers into suitable jobs.

Using the Binet-Simon approach as a starting point, the U.S. Army developed a series of tests (e.g., the Army Alpha and Army Beta) to measure cognitive aptitudes. Scores of these tests were used to place military recruits into suitable jobs. This work developed and validated a model of vocational placement that has been a key component of career counseling for over 90 years.

The Great Depression focused attention on the nation's workforce and provided another stimulus to the development of career counseling. Under the leadership of Donald G. Paterson at the University of Minnesota, the Minnesota Employment Stabilization Research Institute (MESRI) undertook a decade of research on the optimal relation of workers to jobs. MESRI research demonstrated that workers perform better and are less likely to quit or be terminated when placed in occupations that match their interests and aptitudes. The MESRI also developed an extensive library of aptitude tests for use in job placement. MESRI research demonstrated unequivocally that skilled career counseling using a trait-and-factor approach produces beneficial results.

The entry of the United States into World War II again created a need to assign millions of workers to jobs in an efficient manner. The career counseling procedures and instruments developed and validated by the MESRI were applied in the most massive application of career counseling in history.

Following the war, the GI Bill enabled veterans to enter colleges and universities in unprecedented numbers. This created a strong need for career counseling services in those institutions. An even larger number of veterans sought civilian jobs. This created a demand for career counseling services for civilians and stimulated the development of the United States Employment Service.

Clinical psychology was a well-established specialty for treating the mentally ill by the end of World War II. Insightful leaders such as University of Minnesota psychologist John G. Darley recognized that normal individuals sometimes need assistance in dealing with problems confronting them in daily life. Clinical psychologists were ill prepared to provide this assistance, but that is the type of assistance career counseling personnel had been providing. The contemporary specialty of counseling psychology is an outgrowth of the MESRI research, military experience in vocational placement, and Darley's recognition of healthy individuals' needs for developmentally oriented services.

As the United States became more affluent during the 1950s and 1960s, two social movements furthered the development of career counseling. Early 20th-century generations experienced the strife and deprivation of two world wars and the Great Depression, but the baby boom generation experienced a time of relative affluence and tranquility. The earlier generations' survival concerns were replaced by the baby boomers' desire for an occupation that would enhance their quality of life and contribute to a better world. Established workers also began to consider a midlife career change to a more meaningful occupation.

Workers who in earlier times would have unquestioningly followed in their parents' footsteps or taken a job that satisfied their basic survival needs now turned to career counseling for assistance in achieving these goals.

Group Counseling

Group counseling differs from individual counseling in one important respect; group members learn from each other in addition to learning from their interactions with the counselor. This can be particularly valuable to individuals who are early in their career exploration and lack career-related experience and information.

Group career counseling takes a variety of forms. Career development groups include most of the components found in individual career counseling, and they have similar objectives. Group participants typically take tests and participate in a group discussion of their test results. In addition, they may be assigned to complete a computer-based activity, prepare a resume, complete a homework assignment, or interview a potential employer or a person employed in a career of interest. Clients complete these activities outside the group and discuss their experiences during a group meeting.

Structured group interventions are more narrowly focused on a specific issue. The goals of structured groups are limited only by the needs of clients and the imagination of psychologists. For example, structured groups are commonly offered to teach assertiveness skills, resume preparation, time management, study skills, and interviewing skills. Sensitivity groups focus on interpersonal topics such as sexism, racism, and other workplace behaviors.

ORGANIZATIONS

Among the earliest organizations to provide career counseling services were the corporations that emerged with the industrial

revolution. Until recent years the primary focus of these organizations was employee selection and individual career advancement (often referred to as career management).

Corporations began to offer a wider range of services in the late 1980s, and many now offer a program of career counseling services.

Government agencies such as the military, rehabilitation agencies, and correctional facilities also provide career counseling services. Career counseling on military bases tends to emphasize the transition from a military specialty to a civilian occupation. Rehabilitation counseling helps people identify suitable training and employment options so that they can become self-supporting. The focus in correctional and mental health facilities is on helping clients develop work attitudes, behaviors, and marketable skills that will permit them to secure and maintain employment following their discharge.

Many organizations employ staff members (often in their human resources department) to provide career services. Specialists employed as independent contractors may supplement the routine services by providing specialized services such as psychological assessment and work evaluations. Other organizations contract with independent professionals or corporations (e.g., an employee assistance firm) for career counseling services.

Private Practice

Until recently there was little opportunity for career counselors to work exclusively in private practices. Free career counseling is available to most individuals through schools, colleges and universities, services organizations (e.g., B'nai Brith and Bi Brothers and Big Sisters of America) and government agencies (e.g., the United States Employment Service, the Rehabilitation Services Administration, and the military).

However, expansion of the range of career services offered by corporations in the late 1980s increased the opportunities for psychologists in private practice to specialize in career counseling. Organizations often find that contracting with private practitioners is cost-effective because career services can be purchased on an as-needed basis.

CAREER GUIDANCE AND COUNSELING PROGRAMS

What is a Career Guidance and Counseling Program?

It is a comprehensive, developmental program designed to assist individuals in making and implementing informed educational and occupational choices. A career guidance and counseling program develops an individual's competencies in self-knowledge, educational and occupational exploration, and career planning.

WHY IS CAREER GUIDANCE AND COUNSELING KEY TO THE DELIVERY OF VOCATIONAL-TECHNICAL EDUCATION?

Career guidance and counseling programs help individuals acquire the knowledge, skills, and experience necessary to identify options, explore alternatives and succeed in society. These programs better prepare individuals for the changing workplace of the 21st century by:

- teaching labor market changes and complexity of the workplace
- broadening knowledge, skills, and abilities
- improving decision making skill
- increasing self-esteem and motivation
- building interpersonal effectiveness
- maximizing career opportunities
- improving employment marketability and opportunities
- promoting effective job placement
- strengthening employer relations

BENEFITS FROM CAREER GUIDANCE AND COUNSELING PROGRAMS?

Everyone benefits--youth and adults, male and female, disabled, disadvantaged, minorities, limited English proficient, incarcerated, dropouts, single parents, displaced homemakers, teachers, administrators, parents and employers.

WHERE ARE CAREER GUIDANCE AND COUNSELING PROGRAMS OFFERED?

Everywhere--elementary, junior and senior high schools, community colleges, technical institutes, universities, career resource centers, correctional facilities, community-based organizations, human services agencies, community and business organizations, skill clinics, employment and

placement services.

WHERE IS CAREER GUIDANCE AND COUNSELING WORKING?

During 1997-1998, four career guidance programs were selected as exemplary in the following sites:

- Dorchester District Two Career Development Initiatives, Summerville, SC
- La Crosse Central High School Guidance/Career Center, LaCrosse, W
- Lewis and Clark Community College: Career and Employment Services, Godfrey, IL
- Rich South High School: Horizon Program, Richton Park, IL
- Additionally, States implementing the National Career Development Guidelines have many success stories.

WHAT ARE THE KEY COMPONENTS OF SUCCESSFUL CAREER GUIDANCE AND COUNSELING PROGRAMS?

- A planned sequence of activities and experiences to achieve specific competencies such as self-appraisal, decision making, goal setting, and career planning
 - Accountability (outcome oriented) and program improvement (based on results of process/outcome evaluations)
 - Qualified leadership
 - Effective management needed to support comprehensive career guidance programs
 - A team approach where certified counselors are central to the program
 - Adequate facilities, materials, resources
 - Strong professional development activities so counselors can regularly update their professional knowledge and skills
- Different approaches to deliver the program such as outreach, assessment, counseling, curriculum, program and jobplacement, follow-up, consultation, referral

CONCLUSION

Career counseling theory and practice is an effective psychological specialty that has benefited from over 90 years of innovation and experimentation. Meta-analyses of decades of research reveal that career interventions produce measurable benefits. Individual career counseling, structured career counseling groups, career workshops, and career education are all effective interventions that are useful for helping clients explore options and make career decisions. Nevertheless, efforts continue to identify even more effective career counseling interventions that can be used to assist an increasingly diverse clientel.

Psychological testing MCQs

1. The validity of a test refers to:
 - A. ? how norms for the test were developed
 - B. ? whether a test is precise as a tool of measurement
 - C. ? whether the test measures what it purports to measure

D. ? whether a test is consistent in its measurement

Ans:- C

2. Interviews are a primary method of information gathering in:

A. ? clinical and counseling assessment

B. ? all are correct

C. ? forensic assessment

D. ? personnel assessment

Ans:- B

3. Who are the authors of your textbook?

A. ? Eric Cartman and Stan Marsh

B. ? Cohen and Swerdlik

C. ? Davis and Palladino

D. ? Beavis and Butt-head

Ans:- B

4. Which of the following describes a "good" test? A good test

A. ? is valid

B. ? is reliable

C. ? has norms

D. ? all are correct

E. Ans:- D

5. The most significant growth of psychological testing occurred in the:

A. ? 1950s and 1960s

B. ? 1920s and 1930s

C. ? 1910s and 1920s

D. ? 1930s and 1940s

Ans:- A

6. What was the importance of Binet's test of intelligence?

A. ? served as a catalyst for the early growth of psychological measurement

B. ? none are correct

C. ? served as a catalyst for subjective psychological tests (e.g., Rorschach Inkblot test)

D. ? served as a catalyst for personality test development

Ans:- A

7. In personnel assessment, psychological tests are used primarily for the benefit of the:

A. ? examiner

B. ? consumer

C. ? employee

D. ? employer

Ans:- D

8. Which of the following is true of tests used in clinical settings? They are:

A. ? used to choose the best person for the job

B. ? used to measure consumer attitudes

C. ? used as a measure of corporate culture

D. ? used with one individual at a time

Ans:- D

9. By federal law, which of the following types of tests may not be used in schools?

A. ? minimal competency exams

B. ? all may be used in schools

C. ? IQ tests

D. ? Achievement tests

Ans:- B

10. Where should you be able to find detailed information on the development of a particular test, its normative sample, and specific details regarding the studies presented in support of its psychometric soundness?

A. ? in the Standards for Educational and Psychological Tests

B. ? in published reviews of the test

C. ? in test catalogues distributed by the test publisher

D. ? in the test manual

Ans:- D

11. Tests may differ with respect to:

A. ? content

B. ? administration

C. ? all are correct

D. ? format

Ans:- C

12. According to the APA, about how many tests are developed each year?

A. ? 15,000

B. ? 50,000

C. ? 20,000

D. ? 1,000

Ans: C

13. In business and industry, engineering psychologists tend to be most involved with:

A. ? the selection of the most qualified employees for positions

B. ? the prediction of public receptivity to new products

C. ? creating and testing instrumentation for trains

D. ? the design of products that can be used with optimal safety and efficiency

Ans:- A

14. According to the authors of your textbook, which of the following is the most controversial of the 12 assumptions of psychological assessment?

A. ? tests and measurement benefit society

B. ? testing and assessment can be conducted in a fair and unbiased manner

C. ? present day behavior sampling predicts future behavior

D. ? various sources of error are part of the assessment process

Ans:- B

15. During which decade did public concern regarding psychological testing reach its height, resulting in formal investigations of the psychological testing enterprise?

A. ? 1970s

B. ? 1990s

C. ? 1960s

D. ? 1980s

Ans:- C

16. The Standards for Psychological and Educational Tests are most useful for all of the following EXCEPT:

A. ? test publishers

B. ? test-takers

C. ? test users

D. ? test developers

Ans:- B

17. The Thirteenth Mental Measurements Yearbook contains:

A. ? sample personality tests

B. ? sample intelligence tests

C. ? annual reviews of test development

D. ? reviews of psychological tests

Ans:- D

18. Biofeedback equipment has been used in psychological measurement to assess:

A. ? all are correct

B. ? changes in blood level in the brain

C. ? changes in muscular tension

D. ? changes in saliva flow

Ans:- C

19. The field of ergonomics is concerned with the study of:

A. ? the relationship between people and work

B. ? the abuse of ergs in industry and organizations

C. ? aberrant behavior in a recessionary economy

D.? the receptivity of people to new products and services

Ans:- A

20. The factors that influence social behavior and thoughts in certain ways are called–

- A. ?** Independent variables
- B. ?** Confounding variables
- C. ?** Dependent variables
- D. ?** Mediating variables

Ans: d

21. Feeling touchy or hypersensitive following an upsetting experience is a form of–

- A. ?** Imprinting
- B. ?** Habituation
- C. ?** Sensitization
- D. ?** Reflexive Behaviour

Ans : c

22. Because it has the external features associated with the concept of dog, a wolf is perceived as a dog. This is an example of–

- A.** Centration
- B.** Equilibration
- C.** Object Permanence
- D.** Prototype

Ans : d

23. Which of the following is the final destination for much of the brain's information about emotion before action is taken?

- A.** Amygdala
- B.** Anterior cingulate cortex
- C.** Pre-frontal cortex
- D.** Hypothalamus

Ans : c

24. Research shows that the following does not contribute to teacher effectiveness–

- A.** Communication skills
- B.** Use of ICT
- C.** Years of experience
- D.** Use of student feedback

Answer:c

25. Phonemic restoration as we perceive speech in a noisy party is an example of–

- A.** Top-down processing
- B.** Bottom-up processing

- C. Subliminal Perception
- D. Supraliminal perception

Ans : a

26. Cattell Propounded gf-gc theory of intelligence mainly based on—

- A. First order factors of abilities
- B. Second order factors of abilities
- C. Third order factors of abilities
- D. Higher order factors of abilities

Ans : b

27. Which one of the following statements is true?

- A. The 'Global Five' factors in personality refer to the second-order factors of 16 PF, latest edition.
- B. The 'Global Five' factors refer to the factors assessed by the NEO-Five Factor Inventory, latest edition.
- C. The 'Global Five' factors refer to the factors assessed by Goldberg's bipolar adjectives.
- D. The 'Global Five' factors are derived from Eysenck Personality Profiler, latest edition.

Ans : a

28. Which of the following statement best defines maturation?

- A. It is directly based on Social-Cognitive learning.
- B. It is an automatic biological development of the body that naturally unfolds overtime
- C. It does not take place in human beings.
- D. It is the basis of all physical and psychological developments.

Ans : b

29. Brief stress enhances the activity of immune system as evidenced by the action of—

- A. macrophages
- B. T cells
- C. B cells
- D. All these

Ans : d

30. Torrance Tests of Creative Thinking (TTCT) are mainly indexing—

- A. Creative Products
- B. Creative Processes
- C. Creative Personality
- D. Creative Persuasion

Ans : b

31. Which one the scaling method is more likely to yield multidimensional attitude scale?

- A. Guttman Scalogram analysis
- B. Paired comparison method

- C. Equal appearing intervals method
- D. Method of summated rating

Ans : d

32. When is aspiration a method of choice to make a lesion?

- A. in a deeper brain area
- B. in an area of cerebral cortex
- C. and irreversible lesion
- D. in underlying white matter

Ans : b

33. A psychologist was administering a projective test which involved a word association task. She tended to nod and smile every time a plural word was given by the respondent. The following testing bias was seen—

- A. favouritism
- B. test wiseness
- C. selective reinforcement
- D. gender of assessor

Ans : c

34. Four important elements in the theory of signal detection are—

- A. errors, hits, speed and accuracy
- B. speed, accuracy, power and false alarm
- C. hit, miss, correct rejection and false alarm
- D. acuity, efficacy, speed and power

Ans : c

35. Jia had written a list to do her week and work, but incidently left it home while going out for her first activity. Trying to remember the list, Jia remembers what was at the beginning of the list and what was at the end but not those things in the middle. This is an example of—

- A. Encoding specificity effects
- B. Flash bulb memory
- C. Serial position effect
- D. Tip-of-the tongue effect

Ans : c

36. The underlying motivation for acts of aggression is—

- A. intent to harm
- B. anger
- C. retaliation
- D. need to exert control

Ans : d

37. Which of the following is a characteristic of Chomsky's theory?

- A. Development of language is between three and five years of age

- B.** Language development is dependent on the reinforcements received by the child
- C.** Children acquire mistakes in language by observing their parents and others around them
- D.** Children have an innate mental grammar

Ans : d

38. Failure to develop consistent identity results in—

- A.** Inferiority
- B.** Role confusion
- C.** Stagnation
- D.** Social isolation

Ans : b

39. Helpers respond to the needs of a victim because they want to accomplish something rewarding; this may be referred as—

- A.** Negative state – relief model
- B.** Empathic – joy hypothesis
- C.** Empathy – altruism hypothesis
- D.** Pluralistic empathy

Ans : b

40. Which is the correct order of the emergence of following Psycho-Social strengths?

- A.** Love, Fidelity, Wisdom, Care
- B.** Care, Fidelity, Love, Wisdom
- C.** Fidelity, Love, Care, Wisdom
- D.** Care, Fidelity, Wisdom, Love

Ans : c

41. From the following list of tools used by the career guidance counselor, choose the odd one out—

- A.** DAT
- B.** GATB
- C.** DBDA
- D.** SVIB

Ans : d

42. Detecting movement in spite of camouflage is easier for people who are—

- A.** field dependent
- B.** field independent
- C.** both field dependent and field independent
- D.** neither field dependent nor field independent

Ans : b

43. Read the following statement and decide—“If a rat that had previously learned to traverse a maze or a runway to obtain food is placed directly into a non-empty goal box, it will stop traversing the maze or runway on

subsequent trials". What is exemplified?

- A. Latent Learning
- B. Place learning
- C. Response Extinction
- D. Latent Extinction

Ans : d

44. Self is conceptualized in Western and Eastern perspectives on personality, respectively as—

- A. free and deterministic
- B. instinctive and learned
- C. ideal and real
- D. independent and interdependent

Ans : d

45. The centre-surround organization of ganglion cells that enhance contrast at edges in a visual environment are well illustrated by—

- A. Craik bands
- B. Mach bands
- C. Luminance bands
- D. Optic bands

Ans : a

46. The growth needs of ERG theory are represented by various needs in Maslow's model—

- A. Physiological and social needs
- B. Safety needs and esteem needs
- C. Social needs and esteem needs
- D. Esteem needs and self-actualization needs

Ans : d

47. When a Background Interference Procedure was used experimentally, the following findings became apparent?

- A. Field independent persons did better than field dependent persons
- B. Field dependent persons did better than field independent persons
- C. Both field dependent and field independent persons did equally well
- D. BIP enhanced the performance of all subjects

Ans : a

48. People with moderate mental retardation would have an IQ in the range of—

- A. 10 to 19
- B. 35 to 54
- C. 55 to 70
- D. 20 to 34

Ans : b

49. The following is not typically found in a school in a school guidance counsellor's office—

- A. Sand pit
- B. Lie detec
- C. Psychometric tests
- D. Puppets and play dough

Ans : b

50. Emotional intelligence is different from other intelligences in that ...

- A. it is a set of skills
- B. it can be measured using testseasily
- C. the focus is on emotionalreasoning, ability and knowledge
- D. it is a new type of intelligence

Answer:c. the focus is on emotional reasoning, ability and knowledge

51. Emotional intelligence can bestudied through ...

- A. the abilities-focussedapproach
- B. the integrative modelapproach
- C. the mixed model approach
- D. all of the above

Answer:d. all of the above

52. Which of the following describeshow Ability Emotional Intelligence and Trait Emotional Intelligence are different?

- A. The way they are measured
- B. The way they areconceptualized
- C. The way they correlate withother constructs
- D. All of the above

Answer:d. all of the above

53. Incremental validity refers to ...

- A. the additional contribution a new psychological idea makesto existing knowledge
- B. the additional evidence provided by new research
- C. the way research findings arereinterpreted
- D. the way statements arewritten in new tests

Answer:a. the additional contribution a newpsychological idea makes to existingknowledge

54. When predicting intellectual academic performance in medicalstudents, EI showed ...

- A. it is essentially social skills
- B. large incremental validity
- C. no incremental validity
- D. a deterioration in its display

Answer: c. no incremental validity

55. Which of the following is thebest predictor of academic performance?

- A. Trait EI
- B. IQ

- C. Personality
- D. None of these

Answer: b. IQ

56. Mixed Emotional Intelligence models have ...

- A. significant overlap with conscientiousness, extraversion, and self-efficacy
- B. no significant overlap with conscientiousness, extraversion, and self-efficacy
- C. non-significant overlap with conscientiousness, extraversion, and self-efficacy
- D. little overlap with conscientiousness, extraversion, and self-efficacy

Answer: a. significant overlap with conscientiousness, extraversion, and self-efficacy

57. The higher the Trait EI ...

- A. the higher the likelihood of personality disorder
- B. the lower the likelihood of personality disorder
- C. the higher the likelihood of self-harm
- D. the higher the likelihood of harm to others

Answer: b. the lower the likelihood of personality disorder

58. EI is linked to romantic relationship satisfaction because EI may be linked to ...

- A. having better understanding of the partner's emotions
- B. giving the person higher self-esteem
- C. agreeing with the partner all the time
- D. getting what one wants out of the relationship

Answer: a. having better understanding of the partner's emotions

59. Lower EI is likely linked to more aggressive behavior because ...

- A. taking action is more important than expressing emotions
- B. people with lower EI often think of themselves as victims
- C. that is the only way the person knows how to express their displeasure
- D. other's emotions and behaviors are misinterpreted as hostile, and an aggressive response is therefore exhibited

Answer: d. other's emotions and behaviors are misinterpreted as hostile and an aggressive response is therefore exhibited

60. Demonstrating incremental validity of which of the following is tricky?

- A. Intelligence
- B. Ability EI
- C. Trait EI
- D. All of the above

Answer: c. Trait EI

61. Which of the following makes measuring EI challenging?

- A. Whether the scenarios presented should be authentic or hypothetical

- B. Whether conscious, effortful processing or spontaneous processing of emotional materials should be measured
- C. How happy the person is feeling
- D. a and b only

Answer: d. a and b only

62. Ability EI tests are more objective than Trait EI tests because...

- A. they are easier to demonstrate one's own strength
- B. participants tended to rate their own Trait EI as higher than they actually are
- C. they are made up of multiple-choice questions
- D. they cost money

Answer: b. participants tended to rate their own Trait EI as higher than they actually are

63. Dunning-Kruger effect in EI states that ...

- A. a person with low EI is unaware of his or her own low EI
- B. a person with high EI is aware that others have low EI
- C. a person is the best person to estimate his or her own EI
- D. a person's EI is best evaluated by others

Answer: a. a person with low EI is unaware of his or her own low EI

64. Having high EI may not always be adaptive. Why?

- A. Others will likely ignore them
- B. They will have high opinion of themselves
- C. These people are more sensitive to mood manipulation
- D. All of above

Answer: c. These people are more sensitive to mood manipulation

65. Psychology may best be described as the scientific study of _____ and ____.

- A. A Mental state, physical states
- B. B Thoughts, emotions
- C. C Behavior, mental processes
- D. D Mental health, mental illness

Answer: Option [C]

66. Freud believed that adult problems usually:

- A. A Result in Freudian slip
- B. B Result in bad dreams
- C. C Can be traced back to critical stages during childhood
- D. D Are the result of poor behavior

Answer: Option [C]

67. Gestalt theory emphasizes:

- A. A flow of consciousness
- B. B The atoms of thought
- C. C Environmental stimuli
- D. D Our tendency to see pattern

Answer: Option [D]

68. Whereas the _____ asked what happens when an organism does something; the ____ asked how and why.

- A. A functionalist, behaviorist
- B. B structuralist, introspections
- C. C structuralist, functionalist
- D. D functionalist, structuralist

Answer: Option [D]

69. The ____ lobe is to hearing as the occipital lobe is to vision.

- A. Cerebellar
- B. Parietal
- C. Temporal
- D. Frontal

Answer: Option [C]

70. Reflexes are usually controlled by the:

- A. Hypothalamus
- B. Spinal cord
- C. Frontal lobe
- D. Medulla

Answer: Option [B]

71. A part of the brain that sends signals "alert" to higher centers of the brain in response to incoming messages is:

- A. amygdala
- B. Hippocampus
- C. Limbic system
- D. Reticular formation

Answer: Option [D]

72. Perception of the brightness of a color is affected mainly by:

- A. The saturation of light waves
- B. The wavelength of light waves
- C. The purity of light waves
- D. The amplitude of light waves

Answer: Option [A]

73. Which of the following is not a clue for depth perception?

- A. Orientation
- B. Interposition
- C. Reduced clarity
- D. Linear perspective

Answer: Option [A]

74. According to Michel's 'situationist' critique of personality, which of the following statements is true?

- A. Behaviors that express a trait in different settings only correlate weakly
- B. Different measures of the same trait only correlate weakly
- C. Behavior is highly specific to particular situations
- D. All of the above

Answered: D. All of the above

75. Psychophysics is the study of:

- A. Depth perception
- B. Perceptual illness
- C. Movement perception
- D. The psychological perception of physical stimuli

Answer: Option [D]

76. Perceptual constancies are

- A. Likely inborn and not subject to leaning
- B. An aid in perceiving a stable and consistent world
- C. Confusing to an individual rather than helping him determine what really exists
- D. Illusion in which we perceive something that does not correspond to the sensory information

Answer: Option [B]

77. Which of the following is a subdivision of the autonomic nervous system?

- A. Brain and spinal cord
- B. Only sympathetic nervous system
- C. Only the parasympathetic nervous system
- D. Both the sympathetic and Para-sympathetic nervous system

Answer: Option [D]

78. Which of the following approaches to personality is least deterministic?

- A. The humanistic approach
- B. The behavioral approach
- C. The psychoanalytic approach
- D. The social learning approaches

Answer: Option [A]

79. In Freud's theory of personality

- A. The id operates by secondary process
- B. The superego obeys the pleasure principle
- C. The ego obeys the reality principle
- D. The ego operates by primary process thinking

Answer: Option [C]

80. The frustration-aggression hypothesis;

- A. Was developed by social learning theorist
- B. Assumes that frustration produces aggression
- C. Assume that aggression is basic instinct
- D. Claims that frustration and aggression are both instinctive

Answer: Option [B]

81. The James-Lange or body reaction theory of emotion says

- A. You feel emotion then a bodily reaction
- B. Emotions and visceral reactions are simultaneous
- C. The somatic nervous system is the seat of emotion
- D. You react with your body first then you feel emotion

Answer: Option [D]

82. Analysis of avoidance learning suggests that many phobias are acquired through ____ conditioning.

- A. Classical
- B. Operant
- C. Intermittent
- D. Reinforcement

Answer: Option [A]

83. The ability to learn by observing a model or receiving instructions, without reinforcement, is called ____

- A. Contingency
- B. Social learning
- C. Cognitive learning
- D. Instrumental learning

Answer: Option [B]

84. Illnesses that seem to result from an interaction of physical and psychological factors are called:

- A. Somatic
- B. Hysterical
- C. Psychosomatic
- D. Conversion disorder

Answer: Option [C]

85. Which of the following clinical procedures are based, in part on classical conditioning?

- A. Transference
- B. Token economy
- C. Two chair technique
- D. Systematic desensitization

Answer: Option [D]

86. When people are _____ they have lost touch with reality.

- A. Manic
- B. Neurotic Psychotic
- C. Psychopathic

Answer: Option [C]

87. Intelligence can be defined as:

- A. Knowledge of a great many facts
- B. The ability to get good grades in school
- C. All the factors that make one person different from another
- D. The ability to think abstractly and learn from experience

Answer: Option [D]

88. According to Piaget the process of building mental representation of the world through direct interaction with it is:

- A. Adaptation
- B. Conservation
- C. Metacognition
- D. Egocentrism

Answer: Option [A]

89. People who consistently come up with _____ explanations of events are more prone to depression.

- A. dysthemic
- B. Delusional
- C. Pessimistic
- D. Overly optimistic

Answer: Option [C]

90. The leading cause of mental retardation is believed to be:

- A. Inherited traits
- B. Environmental factors
- C. Organic brain syndrome
- D. Fetal alcohol syndrome

Answer: Option [B]

91. An affective disorder in which a person swings from one mood extreme to another is

classified as:

- A. Bipolar
- B. Unipolar
- C. Manic
- D. Depressive

Answer: Option [A]

92. Albert Ellis and Aron Beck are names associated with the _____ therapy approach.

- A. Gestalt
- B. Cognitive
- C. Behavioral
- D. Phenomenological

Answer: Option [B]

93. The process by which a trained professional uses psychological methods to help people with psychological problem is known as:

- A. Psychiatry
- B. Psychoanalysis
- C. Psychosurgery
- D. Psychotherapy

Answer: Option [D]

94. Basic characteristics of tasks that result in social loafing is that they are:

- A. Additive
- B. Negative
- C. Subtractive
- D. Multiplicative

Answer: Option [A]

95. Backward Conditioning occurs when :

- A. CS and US are presented simultaneously
- B. CS is presented first and US is presented before the termination of CS
- C. CS is presented first and US is presented after the termination of CS
- D. US is presented first and CS is presented after the termination of US

Answer: Option [D]

96. The James-Lange theory and the cognitive theory of emotion disagree on whether:

- A. specific brain centers are involved in specific emotions.
- B. bodily feedback determines which emotion is felt.
- C. individuals can judge their emotions accurately.
- D. there is no any biological involvement in human emotions.

Answer: Option [B]

97. Biologically based emotional and behavioral tendencies that are evident in early childhood represent:

- A. Trait
- B. Type

C. Temperament

D. Style

Answer: Option [C]

98. In Jungian theory, the idea that energy is automatically redistributed in the psyche in order to achieve equilibrium or balance depicts:

A. Principle of Equivalence

B. Principle of Synchronicity

C. Principle of Entropy

D. Principle of Opposites

Answer: Option [C]

99. After the recent terrorist attacks in France, a psychologist proposed a study wherein he would interview two hundred French citizens to find whether their attitude towards fate as a consequence of the attack. This study can best be labelled as:

A. attitude change experiment

B. field experiment

C. ex post facto study

D. psychometric study

Answer: Option [C]

100. Which of the following is correct while comparing classical and operant conditioning ?

A. Operant conditioning takes place before reinforcement while classical conditioning takes place after reinforcement.

B. Operant conditioning takes place as a result of some voluntary action while classical conditioning takes place without choice.

C. In operant conditioning, response is elicited while in classical conditioning it is emitted.

D. In operant conditioning magnitude of the response is the index of conditioning while in classical conditioning it is the rate of response.

Answer: Option [B]

101. Words learned under water are recalled:

A Better on land than under water

B Better above land (sky) than on land

C Better above land (sky) than underwater

D Better under water than on land

Answer: Option [D]

102 Which of the following sequence is correct ?

A. Oral phase ® Anal phase ® Latency ® Phallic ® Genital

B. Anal ® Oral ® Phallic ® Latency ® Genital

C. Oral ® Anal ® Phallic ® Latency ® Genital

D. Oral ® Phallic ® Anal ® Genital ® Latency

Answer: Option [C]

103. Which memory is the result of instrumental/motor learning processes ?

A. Semantic memory

B. Episodic memory

- C. Sensory memory
- D. Procedural memory

Answer: Option [D]

103 In which lobe of the cerebral cortex, the primary olfactory cortex lies ?

- A. Frontal lobe
- B. Temporal lobe
- C. Occipital lobe
- D. Parietal lobe

Answer: Option [B]

104 "Factor Analysis is used as a means of confirming a structured model than as a means of discovering a structural model". This is true of which theory of intelligence ?

- A. Spearman
- B. Thurstone
- C. Jensen
- D. Guilford

Answer: Option [D]

105 What is the role of positive and negative reinforcement ?

- A. To increase the likelihood that responses preceding both will be repeated.
- B. To decrease the likelihood that responses preceding negative reinforcement will be repeated.
- C. To increase the likelihood that responses preceding only positive reinforcement will be repeated.
- D. To ensure that there are no negative consequences following the behaviour.

Answer: Option [A]

106 While forming a concept one chooses to take one hypothesis and selects many of its features to quickly form the concept at once :

- A. Successive scanning
- B. Conservative focusing
- C. Focus gambling
- D. Simultaneous scanning

Answer: Option [C]

107 What is the correct sequence an auditory stimulus takes to reach the primary auditory cortex ?

- A. Cochlear nuclei - Superior olive - Inferior colliculus - Medial geniculate nucleus
- B. Cochlear nuclei - Inferior colliculus - Superior olive - Medial geniculate nucleus
- C. Superior olive - Cochlear nuclei - Inferior colliculus - Medial geniculate nucleus
- D. Medial geniculate nucleus - Inferior colliculus - Superior olive - Cochlear nucleus

Answer: Option [A]

108 In the above context, which one of the following correlation should be computed to obtain item-remainder correlations?

- A. Point biserial correlation
- B. Phi-coefficient

- C. Rank difference correlation
- D. Tetrachoric correlation

Answer: Option [A]

109 Which one of the following statement would be true in the above context?

- A. Kuder - Richardson reliability coefficient would also be .90, but the split-half reliability coefficient may differ from .90.
- B. Split-half reliability coefficient would also be .90, but the Kuder - Richardson reliability coefficient may differ from .90.
- C. Both Kuder - Richardson reliability coefficient and split-half reliability coefficient would be .90.
- D. The correlation between odd and even parts of the test would be .90.

Answer: Option [A]

110. To obtain inter-item correlations, which one of the following correlation coefficient should be used in the above analysis?

- A. Biserial correlation
- B. Point biserial correlation
- C. Phi-coefficient
- D. Rank difference correlation

Answer: Option [C]

110 What is the expected Cronbach alpha for the short versions, referred to in the paragraph?

- A. 0.45
- B. 0.67
- C. 0.82
- D. 0.90

Answer: Option [C]

111. Which one of the following conclusions can be drawn from the data provided above? The new Abstract Thinking Test has:

- A. Satisfactory convergent validity
- B. Satisfactory divergent validity
- C. Satisfactory concurrent validity
- D. Unsatisfactory concurrent validity

Answer: Option [D]

112. The factors that influence social behavior and thoughts in certain ways are called:

- A. Independent variables
- B. Confounding variables
- C. Dependent variables
- D. Mediating variables

Answer: Option [D]

113. Phonemic restoration as we perceive speech in a noisy party is an example of :

- A. Top-down processing
- B. Bottom-up processing
- C. Subliminal perception

D. Supraliminal perception

Answer: Option [A]

114. Feeling touchy or hypersensitive following an upsetting experience is a form of :

- A. Imprinting**
- B. Habituation**
- C. Sensitization**
- D. Reflexive Behavior**

Answer: Option [C]

115. Because it has the external features associated with the concept of dog, a wolf is perceived as a dog. This is an example of:

- A. Centration**
- B. Equilibration**
- C. Object permanence**
- D. Prototype**

Answer: Option [D]

116. Which of the following is the final destination for much of the brain's information about emotion before action is taken?

- A. Amygdala**
- B. Anterior cingulate cortex**
- C. Pre-frontal cortex**
- D. Hypothalamus**

Answer: Option [C]

117. Cattell propounded gf-gc theory of intelligence mainly based on :

- A. First order factors of abilities**
- B. Second order factors of abilities**
- C. Third order factors of abilities**
- D. Higher order factors of abilities**

Answer: Option [B]

118. Which one of the following statements is true?

- A. The 'Global Five' factors in personality refer to the second-order factors of 16 PF, latest edition.**
- B. The 'Global Five' factors refer to the factors assessed by the NEO-Five Factor Inventory, latest edition.**
- C. The 'Global Five' factors refer to the factors assessed by Goldberg's bipolar adjectives.**
- D. The 'Global Five' factors are derived from Eysenck Personality Profiler, latest edition.**

Answer: Option [A]

119. Which of the following statements best defines maturation?

- A. It is directly based on social-cognitive learning**
- B. It is an automatic biological development of the body that naturally unfolds over time**
- C. It does not take place in human beings**
- D. It is the basis of all physical and psychological developments**

Answer: Option [B]

120.Four important elements in the theory of signal detection are:

- A.** errors, hits, speed and accuracy
- B.** speed, accuracy, power and false alarm
- C.** hit, miss, correct rejection and false alarm
- D.** acuity, efficacy, speed and power

Answer: Option [C]

121.Jia had written a list to do her week end work, but incidentally left it home while going out for her first activity. Trying to remember the list, Jia remembers what was at the beginning of the list and what was at the end but not those things in the middle. This is an example of:

- A.** Encoding specificity effect
- B.** Flash bulb memory
- C.** Serial position effect
- D.** Tip-of-the tongue effect

Answer: Option [C]

122.Torrance Tests of Creative Thinking (TTCT) are mainly indexing:

- A.** Creative Products
- B.** Creative Processes
- C.** Creative Personality
- D.** Creative Persuasion

Answer: Option [B]

123.Which one of the scaling methods is more likely to yield multidimensional attitude scale?

- A.** Guttman scalogram analysis
- B.** Paired comparison method
- C.** Equal appearing intervals method
- D.** Method of summated rating

Answer: Option [D]

124.When is aspiration a method of choice to make a lesion?

- A.** in a deeper brain area
- B.** in an area of cerebral cortex
- C.** an irreversible lesion
- D.** in underlying white matter

Answer: Option [B]

125.A psychologist was administering a projective test which involved a word association task. She tended to nod and smile every time a plural word was given by the respondent. The following testing bias was seen:

- A.** favoritism
- B.** test wiseness
- C.** selective reinforcement
- D.** gender of assessor

Answer: Option [C]

126.Which of the following is a characteristic of Chomsky's theory?

- A.** Development of language is between three and five years of age

- B. Language development is dependent on the reinforcements received by the child
- C. Children acquire mistakes in language by observing their parents and others around them
- D. Children have an innate mental grammar

Answer: Option [D]

127. The Centre-surround organization of ganglion cells that enhance contrast at edges in a visual environment is well illustrated by:

- A. Craik bands
- B. Mach bands
- C. Luminance bands
- D. Optic bands

Answer: Option [A]

128. The growth needs of ERG theory are represented by various needs in Maslow's model:

- A. Physiological and social needs
- B. Safety needs and esteem needs
- C. Social needs and esteem needs
- D. Esteem needs and self-actualization needs

Answer: Option [D]

129. In Bloom's taxonomy of educational objectives, the following appear in ascending order :

- A. Remember ® Understand ® Apply ® Analyze
- B. Apply ® Analyze ® Understand ® Remember
- C. Understand ® Apply ® Remember ® Analyze
- D. Analyze ® Remember ® Apply ® Understand

Answer: Option [A]

130. Helpers respond to the needs of a victim because they want to accomplish something rewarding; this may be referred to as:

- A. Negative state-relief model
- B. Empathic-joy hypothesis
- C. Empathy-altruism hypothesis
- D. Pluralistic empathy

Answer: Option [B]

131. Which is the correct order of the emergence of the following Psycho-Social strengths ?

- A. Love, Fidelity, Wisdom, Care
- B. Care, Fidelity, Love, Wisdom
- C. Fidelity, Love, Care, Wisdom
- D. Care, Fidelity, Wisdom, Love

Answer: Option [C]

132. Detecting movement in spite of camouflage is easier for people who are :

- A. field dependent
- B. field independent
- C. both field dependent and field independent

D. neither field dependent nor field independent

Answer: Option [B]

133. Self is conceptualized in Western and Eastern perspectives on personality, respectively, as:

A. free and deterministic

B. instinctive and learned

C. ideal and real

D. independent and interdependent

Answer: Option [D]

134. When a Background Interference Procedure was used experimentally, the following findings became apparent?

A. Field independent person did better than field dependent persons

B. Field dependent persons did better than field independent persons

C. Both field dependent and field independent persons did equally well

D. BIP enhanced the performance of all subjects

Answer: Option [A]

135. People with moderate mental retardation would have an IQ in the range of :

A. 10 to 19

B. 35 to 54

C. 55 to 70

D. 20 to 34

Answer: Option [B]

136. The following is not typically found in a school guidance counsellor's office :

A. Sand pit

B. Lie detector

C. Psychometric tests

D. Puppets and play dough

Answer: Option [B]

137. According to Piaget the children are able to grasp the concept of object permanence and conservation in:

A. Sensory motor stage

B. Pre-operational stage

C. Concrete operational stage

D. Formal operations stage

Answer: Option []

138. Which one of the following design is used in the above research ?

A. Multigroup design with single I.V.

B. 2³ factorial design

C. 2³ mixed factorial design

D. Repeated measures design

Answer: Option [B]

139. Which one of the following statements is true in the context of the above study?

- A. The assumption of homogeneity of variance was satisfied.
- B. The assumption of homogeneity of variance was not satisfied.
- C. The correction for heterogeneity of variance was required.
- D. The data are insufficient to evaluate the assumption of homogeneity of variance.

Answer: Option [A]

140. On the basis of the information provided about the main effect of A, it can be concluded that:

- A. Interpolated learning had no effect on the recall of A.
- B. Interpolated learning caused retroactive interference.
- C. Interpolated learning caused retroactive facilitation.
- D. Either retroactive interference or retroactive facilitation has occurred.

Answer: Option [D]

141. What would be the degrees of freedom for the numerator and denominator of the F-ratio defined as MSA_{3B}/MSE ?

- A. 1 and 96 respectively
- B. 1 and 98 respectively
- C. 2 and 97 respectively
- D. 3 and 96 respectively

Answer: Option [A]

142. A procedure that establishes a sequence of responses which lead to a reward following the final response and then working backwards is called

- A. Shaping
- B. Stimulus control
- C. Chaining
- D. Stimulus generalization

Answer: Option [C]

143. In a study on scaling of attitude items, eleven statements were included. What would be the number of pairs of attitude statements?

- A. 21
- B. 55
- C. 110
- D. 121

Answer: Option [B]

144. Who first attempted to describe personality traits in terms of Lexicon descriptors?

- A. Ross Stagner
- B. Allport and Osbert
- C. R.B. Cattell
- D. Costa and McCrae

Answer: Option [B]

145. Which of the following is incorrectly arranged?

- A. Encoding – retrieval – storage
- B. Encoding – storage – retrieval
- C. Storage – encoding – retrieval
- D. Retrieval – encoding – storage

Answer: Option [B]

146. Which one of the following does not contribute to memory?

- A. Interesting / disinteresting learning material
- B. Goal behind learning
- C. Gender
- D. Some rest after learning

Answer: Option [C]

147. In terms of efficiency in scanning information, which one of the following strategies is considered to be the best?

- A. Conservative focusing
- B. Focus gambling
- C. Simultaneous scanning
- D. Successive scanning

Answer: Option [C]

148. According to Master and Johnson following is the correct sequence of human sexual response:

- A. Excitement → Orgasm → Plateau → Resolution
- B. Excitement → Plateau → Orgasm → Resolution
- C. Excitement → Arousal → Orgasm → Resolution
- D. Arousal → Excitement → Orgasm → Resolution

Answer: Option [B]

149. In graphical representations showing stress levels on X axis and performance on Y axis, best performance can be expected at

- A. Lower end of X axis
- B. Middle portion of X axis
- C. Higher end of X axis
- D. None of the above

Answer: Option [B]

150. Lesions of the ventromedial nuclei in the hypothalamus produce

- A. Anorexia
- B. Obesity
- C. Low level of Leptin
- D. Hyperinsulinemia

Answer: Option [B]

151. When the action potential reaches the end of the axon terminals, it causes the release of

- A. An electric spark that sets off the next neuron
- B. Positively charged ions that excite the next cell

- C. Negatively charged ions that inhibit the next cell.
- D. Neurotransmitters that excite or inhibit the next cell.

Answer: Option [D]

152. AIDS attack a number of very different population; young gay men, intravenous drug users, hemophiliacs, Haitians, infants and recipients of blood transfusion, but commonly among them is the decrease in T lymphocytes, so it is an example of

- A. Inductive reasoning
- B. Deductive reasoning
- C. Analogical reasoning
- D. Syllogism

Answer: Option [A]

153. Muller-Lyer illusion is likely to occur more in cultures characterized by

- A. People living in rectangular and square buildings
- B. People living in buildings which are round and have few corners
- C. People living in open spaces
- D. People living in caves

Answer: Option [A]

154. One prominent class of theorists of deductive reasoning believe that deduction depends on _____ of inference akin to those of _____.

- A. informal rules; logical calculus
- B. formal rules; analytical calculus
- C. procedural rules; logical calculus
- D. formal rules; logical calculus

Answer: Option [D]

155. What is the correct sequence of products in Guilford's Struct of Intellect Model (SOI) ?

- A. Unit → Class → System → Relations → Implication → Transformation
- B. Class → Unit → Systems → Relation → Transformation → Implication
- C. Unit → Class → Relation → System → Transformation → Implication
- D. Unit → Relation → Class → System → Transformation → Implication

Answer: Option [C]

156. The light passes through the eye in which of the following sequence ?

- A. Cornea, Pupil, Lens, Retina
- B. Cornea, Lens, Pupil, Retina
- C. Lens, Cornea, Pupil, Retina
- D. Pupil, Cornea, Lens, Retina

Answer: Option [A]

157. Which one of the following statement is true in the context of item analysis?

- A. Item-total correlation = Item-remainder correlation
- B. Item-total correlation is greater than or equal to item-remainder correlation.
- C. Item-total correlation is smaller than or equal to item-remainder correlation.
- D. Item-total correlation cannot be negative.

Answer: Option [B]

159. The difference in images in the two eyes is greater for objects that are close and smaller for distant objects is an example of

- A.** Binocular Disparity
- B.** Convergence
- C.** Accommodation
- D.** Relative Size

Answer: Option [A]

160. Shaping in instrumental conditioning means

- A.** Teaching a complex sequence of behaviors by first shaping the final response in the sequence and then working backwards
- B.** A continuous reinforcement schedule is used for establishing new behaviors.
- C.** It involves reinforcing successive approximations of the final desired behavior.
- D.** Consistent occurrence of a behaviour in the presence of discriminative stimulus.

Answer: Option [C]

161. According to Trichromatic theory of colour vision, which of the following are the three types of cones ?

- A.** Red, Yellow and Blue
- B.** Red, Blue and Green
- C.** Yellow, Blue and Green
- D.** Yellow, Red and Blue

Answer: Option [B]

162. Which one of the following conclusion can be drawn on the basis of the above study ?

- A.** The researcher's hypothesis has been accepted.
- B.** The researcher's hypothesis has been rejected.
- C.** The researcher's hypothesis has been partially accepted.
- D.** Inadequate data to evaluate researcher's hypothesis.

Answer: Option [B]

163. Amit met with an accident and later turned into impulsive, irresponsible and less concerned with the consequences of his actions. He must have suffered damage in

- A.** Parietal lobe
- B.** Frontal lobe
- C.** Occipital lobe
- D.** Temporal lobe

Answer: Option [B]

164. Effective teaching may include conceptual scaffolding, which is best described by the following statement:

- A.** introducing practice sessions after every module.
- B.** gradually fading support as student proficiency increases.
- C.** punishing student for incorrect answers.
- D.** encouraging brighter students to help weaker students.

Answer: Option [B]

165. A social worker, appointed to assist the psychiatrist, used to administer and interpret Rorschach test. This is an

- A. ethically incorrect practice
- B. ethically correct practice
- C. ethically correct practice provided the results are used only for diagnostic purpose.
- D. ethically correct practice provided the results are kept confidential and are used only for diagnostic purpose.

Answer: Option [A]

166. The following instrument can not be utilized in the measurement of emotions:

- A. Sphygmomanometer meter
- B. Galvanic skin response
- C. Digital thermometer
- D. Pupillary measurement camera

Answer: Option [C]

167. Arrange in sequence the stage of personality development according to Rollo May

- A. Innocence → ordinary consciousness of self → rebellion → creative consciousness of self
- B. Innocence → rebellion → ordinary consciousness of self → creative consciousness of self
- C. Ordinary consciousness of self → innocence → rebellion → creative consciousness of self
- D. Rebellion → innocence → ordinary consciousness of self → creative consciousness of self

Answer: Option [B]

168. The rapid change in performance as the size of reinforcement is varied is called

- A. Crispi effect
- B. Disequilibrium hypothesis
- C. Premack principal
- D. Programmed learning

Answer: Option [A]

169. In Solomon Asch's study on conformity, subjects conformed to the Group approximately what percent of time

- A. 25%
- B. 35%
- C. 45%
- D. over 50%

Answer: Option [B]

170. Perceived fairness of the amount and rewards among individuals refers to __ while perceived fairness of the ways used for rewards and pays refers to _____.

- A. Organizational justice, Distributive justice
- B. Equity, Organizational justice
- C. Distributive justice; Procedural justice
- D. Procedural justice; Distributive justice

Answer: Option [C]

171. The concept of _____ is vital in the understanding of fractional anticipated goal response

- A. Drive stimulus reduction
- B. Reactive Inhibition
- C. Secondary Reinforcement
- D. Conditioned Inhibition

Answer: Option [C]

172. Which of the following identity status describes the individual who has been exploring but not yet committed to self-chosen values and goals?

- A. Identity achievement
- B. Identity foreclosure
- C. Identity diffusion
- D. Identity moratorium

Answer: Option [D]

173. Scientific study of Creativity is considered to be started by

- A. Galton
- B. Guilford
- C. Torrance
- D. Mednick

Answer: Option [B]

174. Culture exerts strong effect on memory through the operation of cultural schema. One's memory is influenced by learning in

- A. Own culture effect
- B. Culture effect due to enculturation
- C. Acculturation effect
- D. Socialization effect

Answer: Option [A]

175. Evolutionary Social Psychology Research seeks to investigate :

- A. Changes in human behavior
- B. Seeks to investigate the potential role of genetic factors on social behavior
- C. Interrelationships between people of two groups of different social environment
- D. Focuses on individual's behavior.

Answer: Option [B]

176. Which one of the following is the right explanation of flash bulb memory?

- A. New, important, helpful social events
- B. Unspecific, important, common events
- C. Specific, surprising, unimportant events
- D. Unspecific, important, common events

Answer: Option [A]

178. Which of the following sequences is correct with respect to effective teaching ?

A. Match student's level → specify learning goals → emphasize self comparison → suggest improvements and model problem solving.

B. Specify learning goals → emphasize self-comparison → suggest improvements and model

problem solving → match student's level.

C. Suggest improvements and model problem solving → match student's level → specify learning goals → emphasize self-comparison

D. Emphasize self-comparison → match student's level → specify learning goals → suggest improvements and model problem solving.

Answer: Option [A]

179. Sleep disorders can be categorized as

A. Paraphilias and Dysfunctions

B. Insomnia and Hypersomnia

C. Parasomnias and Dyssomnias

D. Serotonergic and Dopaminergic

Answer: Option [C]

180. Which is the correct sequence of the stages involved in creative thinking ?

A. Preparation; orientation; illumination; incubation; verification

B. Preparation; incubation; illumination; orientation; verification

C. Orientation; preparation; incubation; illumination; verification

D. Orientation; preparation; illumination; incubation; verification

Answer: Option [C]

181. Selective attention in vision and audition respectively have been dubbed as

A. 'optic' and 'haptic'

B. 'spotlight' and 'gateway'

C. 'spatial' and 'acoustic'

D. 'central' and 'peripheral'

Answer: Option [B]

182. Which is not the part of "on the job training" ?

A. Orientation training

B. Job instruction training

C. Role playing

D. Apprentice training

Answer: Option [C]

183. "Pygmalion effect" in educational settings suggests :

A. exceptional progress by student as a result of high teacher expectations.

B. biases creeping into summative assessment

C. authenticity factors in classroom assessment.

D. influences on curricular structure.

Answer: Option [A]

184. Which of the following is not a diagnosable sleep disorder :

A. Somnambulism

B. Somniloquy

C. Sleep terror

D. Insomnia

Answer: Option [B]

185. field experiment at the Bronx Zoo illustrated the potential importance of ____ indicating that an individual has legitimate authority. Fill in the blank from given below.

- A. Gender
- B. Uniforms
- C. Age
- D. An authoritarian personality

Answer: Option [D]

189. Thinking is a complex set of collaborations between _____ and ____ representations and processes.

- A. Linguistic; semantic
- B. Linguistic; verbal
- C. Semantic; non-linguistic
- D. Linguistic; non-linguistic

Answer: Option [D]

190. Signal detection depends upon

- A. motivation and expectations
- B. signal intensity and noise
- C. sensitivity and response criterion
- D. absolute and relative thresholds

Answer: Option [C]

191. Which of the following does not present with symptoms of mental retardation ?

- A. Cri du chat syndrome
- B. Down's syndrome
- C. Fugue
- D. Trisomy-21

Answer: Option [C]

192. Therapist suggested to Sunil that while trying to give up the habit of washing hands unnecessarily, he should wear a rubber band around his wrist and snap it everytime he feels like washing his hands. What therapy he is using?

- A. Systematic desensitization
- B. Aversion therapy
- C. Flooding
- D. Modelling

Answer: Option [B]

193. The need for _____ produces active, controlling social behavior while need for ____ produces more passive, less controlling social behavior.

- A. affiliation; self-esteem
- B. confidence; intimacy
- C. affiliation; intimacy
- D. intimacy; affiliation

Answer: Option [C]

194. According to Triarchic Theory of Intelligence, arrange the correct functional sequence of meta components

- A.** Identification of problem → defining the givens, goals & obstacles → choosing appropriate strategy → selection of lower order processes → selection of mental representation → allocation of mental resources → monitoring → evaluation.
- B.** Identification of problem → defining the givens, goals & obstacles → selection of lower order processes → choosing appropriate strategy → selecting a mental representation → allocating mental resources → monitoring → evaluation.
- C.** Identification of problem → choosing appropriate strategy → defining givens, goals and obstacles → allocating mental resources → monitoring → selecting mental representation → evaluation
- D.** Defining the givens, goals and obstacles → identification of problem → selection of lower order processes → choosing appropriate strategy → selecting a mental representation → allocating mental resources → monitoring → evaluation

Answer: Option [B]

195. Which is the correct sequence of the stages involved in creative thinking ?

- A.** Preparation; orientation; illumination; incubation; verification
- B.** Preparation; incubation; illumination; orientation; verification
- C.** Orientation; preparation; incubation; illumination; verification
- D.** Orientation; preparation; illumination; incubation; verification

Answer: Option [C]

196. In which one of the following scaling methods, Law of Comparative Judgement is used clearly while computing scale values?

- A.** Summated ratings
- B.** Equal appearing intervals
- C.** JND scales
- D.** Paired Comparison

Answer: Option [D]

197. The model of memory most frequently cited consists of Short Term Memory (STM) which serve(s) as gateway to Long Term Memory (LTM). This model was propounded by

- A.** Ebbinghaus
- B.** Craik and Lockhart
- C.** Tulving
- D.** Atkinson and Shiffring

Answer: Option [D]

198. The phenomenon of clinging to one's initial conceptions after the basis on which they were formed and had been discredited refers to :

- A.** Belief bias
- B.** Belief perseverance
- C.** Over confidence
- D.** Framing decisions

Answer: Option [B]

199. Mechanistic and Cognitive approaches to motivation differ in the extent to which ___ are

invoked to account for the initiation, direction, intensity and persistence of goal directed behaviour.

- A. Dynamic traits
- B. Higher mental processes
- C. Drives
- D. Instincts

Answer: Option [B]

200. Which of the following is the term for describing a child's one word utterances ?

- A. Over extensions
- B. Under extensions
- C. Holophrases
- D. Telegraphic speech

Answer: Option [C]

201. What would be the multiple correlation between the job efficiency and the three predictors (M.B.A. marks, selection test scores, and the evaluations scores at the end of inhouse training) ?

- A. 0.50
- B. 0.65
- C. 0.75
- D. Inadequate data

Answer: Option [C]

202. The b coefficient obtained in multiple regression is

- A. Partial correlation coefficient
- B. Correlation coefficient
- C. Regression coefficient
- D. Partial regression coefficient

Answer: Option [D]

203. Which one of the following conclusion can be drawn on the basis of above paragraph ?

- A. All the four predictors (M.B.A. marks, selection test scores, evaluation scores at the end of inhouse training and communications skills) are uncorrelated with each other.
- B. Out of the four predictors, at least some are correlated with each other
- C. Communication skills scores are uncorrelated with other predictors.
- D. The four predictors theoretically appear to be correlated, but we cannot infer about their intercorrelations from the data provided.

Answer: Option [B]

204. Words learned under water are recalled :

- A. Better on land than under water
- B. Better above land (sky) than on land
- C. Better above land (sky) than underwater
- D. Better under water than on land

Answer: Option [D]

205. Amit met with an accident and later turned into impulsive, irresponsible and less concerned with the consequences of his actions. He must have suffered damage in

- A. Parietal lobe

- B. Frontal lobe
 - C. Occipital lobe
 - D. Temporal lobe
- Answer: Option [B]

206.Effective teaching may include conceptual scaffolding, which is best described by the following statement :

- A. introducing practice sessions after every module.
- B. gradually fading support as student proficiency increases.
- C. punishing student for incorrect answers.
- D. encouraging brighter students to help weaker students.

Answer: Option [B]

207.A social worker, appointed to assist the psychiatrist, used to administer and interpret Rorschach test. This is an

- A. ethically incorrect practice
- B. ethically correct practice
- C. ethically correct practice provided the results are used only for diagnostic purpose.
- D. ethically correct practice provided the results are kept confidential and are used only for diagnostic purpose.

Answer: Option [A]

208.Arrange in sequence the stage of personality development according to Rollo May

- A. Innocence → ordinary consciousness of self → rebellion → creative consciousness of self
- B. Innocence → rebellion → ordinary consciousness of self → creative consciousness of self
- C. Ordinary consciousness of self → _____ .innocence → rebellion → creative consciousness of self
- D. Rebellion → innocence → ordinary consciousness of self → creative consciousness of self

Answer: Option [B]

209.The rapid change in performance as the size of reinforcement is varied is called

- A. Crispi effect
- B. Disequilibrium hypothesis
- C. Premack principal
- D. Programmed learning

Answer: Option [A]

210.In Solomon Asch's study on conformity, subjects conformed to the Group approximately what percent of time

- A. 25%
- B. 35%
- C. 45%
- D. over 50%

Answer: Option [B]

211.Which of the following identity status describes the individual who has been exploring but not yet committed to self chosen values and goals ?

- A. Identity achievement

- B. Identity foreclosure
- C. Identity diffusion
- D. Identity moratorium

Answer: Option [D]

212.Scientific study of Creativity is considered to be started by

- A. Galton
- B. Guilford
- C. Torrance
- D. Mednick

Answer: Option [B]

213.Sleep disorders can be categorized as

- A. Paraphilias and Dysfunctions
- B. Insomnia and Hypersomnia
- C. Parasomnias and Dyssomnias
- D. Serotonergic and Dopaminergic

Answer: Option [C]

214.Which is the correct sequence of the stages involved in creative thinking ?

- A. Preparation; orientation; illumination; incubation; verification
- B. Preparation; incubation; illumination; orientation; verification
- C. Orientation; preparation; incubation; illumination; verification
- D. Orientation; preparation; illumination; incubation; verification

Answer: Option [C]

215.Selective attention in vision and audition respectively have been dubbed as

- A. 'optic' and 'haptic'
- B. 'spotlight' and 'gateway'
- C. 'spatial' and 'acoustic'
- D. 'central' and 'peripheral'

Answer: Option [B]

216.Job satisfaction is enhanced by tasks that are:

- A. Very easy to accomplish
- B. Overwhelming and rewarding
- C. Unrelated to one's personal needs
- D. Challenging but not overwhelming

Answer: Option [D]

217.Piaget's stage for infancy is:

- A. Formal operation
- B. Preoperational thought
- C. Sensory motor thoughts
- D. Concrete operations

Answer: Option [C]

218.When a researcher tests several groups of people at the same time each group at a different

age, he is conducting a(n) _____ study.

- A. Sequential
- B. Cross-sectional
- C. Longitudinal
- D. Observational

Answer: Option [B]

219. An individual becomes a member of social group through the process of:

- A. Aging
- B. Learning
- C. Maturation
- D. Socialization

Answer: Option [D]

220. The first two weeks of life are referred to as:

- A. Early childhood
- B. The neonatal period
- C. The period of infancy
- D. The preoperational stage

Answer: Option [B]

221. It would be more accurate to say that maturation:

- A. Can be delayed by illness or poor nutrition
- B. Is dramatically accelerated by good nutrition
- C. Is not affected by any environmental factors because it is genetic
- D. Is greatly accelerated by good health care and delayed by illness

Answer: Option [D]

222. Which of the following is part of the psychosocial domain?

- A. Memory
- B. Judgment
- C. Motor skills
- D. Style of behaving

Answer: Option [D]

223. The stage of prenatal development during which the developing organism is most vulnerable to injury is the:

- A. Embryonic stage
- B. Fetal stage
- C. Germinal stage
- D. Zygotic stage

Answer: Option [A]

224. The current Stanford-Binet Intelligence Test is descended from the test developed by Binet and Simon:

- A. In early 1600s
- B. In early 1800s

- C. In early 1900s
 - D. None of the above
- Answer: In early 1900s

225.The capacity to learn and adapt to the requirements for survival in one's culture is called:

- A. Learning
- B. Emotion
- C. Intelligence
- D. Abstraction

Answer: Intelligence

226.Who told that mental functioning involves two types of abilities – an associative ability and a cognitive ability?

- A. A. R. Jensen
- B. E. B. Titchener
- C. J. B. Watson
- D. Wilhelm Wundt

Answer: A. R. Jensen

227.Who viewed intelligence as an attribute of the person like any other attribute such as blood pressure and temperature etc?

- A. A. R. Jensen
- B. Carl Spearman
- C. R. B. Cattell
- D. None of the above

Answer: A. R. Jensen

228.According to Spearman, the capacity for activities like reading a novel, speaking fluently, planning the train route from a map etc. involve:

- A. Primary mental ability
- B. The manifestation of specific intelligence in greater degree
- C. Abstract level of intelligence
- D. The manifestation of general intelligence in greater degree

Answer: The manifestation of general intelligence in greater degree

229.Who introduced the term "Intelligence Quotient" (I.Q.)?

- A. William Stern
- B. R. B. Cattell
- C. A. R. Jensen
- D. E. L. Thorndike

Answer: William Stern

230.The term "intelligence" is derived from a Latin word, framed by Cicero to translate a Greek word used by Aristotle to include:

- A. Specific effective processes
- B. All effective processes
- C. Specific cognitive processes
- D. All cognitive processes

Answer: All cognitive processes

231. The simultaneous existence of two opposed emotions, motivations or attitudes e.g. love-hate, approach-avoidance is called:

- A. Rationalization
- B. Narcissism
- C. Instinct
- D. Ambivalence

Answer: Ambivalence

232. The proverbial story of milkmaid's daughter is an illustration of:

- A. Fantasy
- B. Creative Thinking
- C. Divergent Thinking
- D. Dream

Answer: Fantasy

233. If we start visualising that we will go to heaven and start experiencing all the pleasures therein, this would be:

- A. Imagination
- B. Daydreaming
- C. Dream
- D. None of the above

Answer: Day-dreaming

234. The difference between day-dreams and fantasy is that the former are much more organised and relate to the:

- A. Subconscious mental activity of the individual
- B. Unconscious mental activity of the individual
- C. Conscious mental activity of the individual
- D. Both conscious and unconscious activities of the individual

Answer: Conscious mental activity of the individual

235. Delusions can be classified into two types and these are:

- A. Transitory and permanent
- B. Direct and indirect
- C. Grandeur and persecution
- D. None of the above

Answer: Grandeur and persecution

236. Some delusions are there which are brief or fleeting. These are called:

- A. Delusion of Persecution
- B. Chronic Delusions
- C. Delusion of Grandeur
- D. Transient Delusions

Answer: Transient Delusions

237. Some delusions are there which are very elaborate and many completely engulf the individual.

These are called:

- A. Chronic or Systematic Delusions
- B. Transient Delusions
- C. Delusion of Grandeur
- D. Delusion of Persecution

Answer: Chronic or Systematic Delusions

238. "Sometimes an individual feels that he is being harassed, persecuted and plotted against by everyone. He is obsessed with the idea that everybody around is out to get him, harm him, kill him and he is a victim of domestic, national and international conspiracies". This is an example of:

- A. Delusion of Persecution
- B. Systematic Delusions
- C. Transient Delusions
- D. Delusion of Grandeur

Answer: Delusion of Persecution

239. The ideas which were interfering with the solution of the problem tend to fade in:

- A. Preparation Period
- B. Evaluation Period
- C. Incubation Period
- D. None of the above

Answer: Incubation Period

240. Hypochondriacal delusions are concerned with an excessive preoccupation with imaginary:

- A. Physical or Mental disease
- B. Psychoses
- C. Physical diseases
- D. Mental diseases

Answer: Physical or Mental disease

241. Self-condemnatory delusions generally reflect a need for:

- A. Affection
- B. Reward
- C. Punishment
- D. None of the above

Answer: Punishment

242. Hypochondriasis is usually interpreted as an escape from life difficulties:

- A. By a flight into coma stage
- B. By a flight into disease
- C. By a flight into unconscious stage
- D. By a flight into dream

Answer: By a flight into disease

243. Jean Piaget was a/an:

- A. Russian Psychologist
- B. English Psychologist
- C. Swiss Psychologist

D. German Psychologist
Answer: Swiss Psychologist

244. Jean Piaget used the term “Schemata” to refer to the cognitive structures underlying organized patterns of:

- A. Behavior**
- B. Experience**
- C. Temperament**
- D. None of the above**

Answer: Behavior

245. In which development stage, according to Piaget, “Object permanence” develops?

- A. Concrete operation period**
- B. Formal operation period**
- C. Preoperational Period**
- D. Sensorimotor Period**

Answer: Sensorimotor Period

246. Piaget speaks of the “plane of action” in the sensorimotor phase preceding and being essential for the later development of the:

- A. Plane of thought**
- B. Personality**
- C. Concept formation**
- D. Image**

Answer: Plane of thought

247. In which substage of Sensorimotor Period, the infant repeats and modifies actions which initially may have occurred by chance and which the child finds to be satisfying or pleasurable?

- A. Primary circular Reaction**
- B. Coordination of secondary schemata**
- C. Tertiary circular Reaction**
- D. None of the above**

Answer: Primary circular Reaction

248. Children actively use trial-and-error methods to learn more about the properties of objects in the developmental stage of:

- A. Coordination of secondary schemata**
- B. Primary circular Reactions**
- C. Tertiary circular Reactions**
- D. Secondary circular Reactions**

Answer: Tertiary circular Reactions

249. The major characteristic of the preoperational phase is the development of systems of representation, such as language, which Piaget calls the:

- A. Symbolic function**
- B. Explicit function**
- C. Communicative cues**
- D. Implicit function**

Answer: Symbolic function

250. The child's habit of attending to one salient aspect of a problem neglecting other ones, thus distorting reasoning is known as:

- A. Centration
- B. Syncretism
- C. Egocentrism
- D. Transductive reasoning

Answer: Centration

251. The child's cognitive structure reaches maturity during:

- A. The period of formal operations
 - B. Concrete operational period
 - C. Sensorimotor period
 - D. Preoperational period
- Answer: The period of formal operations

252. When we just start completely agreeing with some deduced results or principles and try to apply to particular cases, it is known as:

- A. Convergent Thinking
- B. Inductive Reasoning
- C. Divergent Thinking
- D. Deductive Reasoning

Answer: Deductive Reasoning

253. The concept of an automobile is:

- A. A haphazard concept
 - B. A disjunctive concept
 - C. An image
 - D. A conjunctive concept
- Answer: A conjunctive concept

254. The concepts which refer to relationship between two elements in a situation is known as:

- A. Relational Concepts
- B. Simple concepts
- C. Conjunctive Concepts
- D. None of the above

Answer: Relational Concepts

255. In which strategy in concept learning, the "S" immediately jumps to the conclusion?

- A. Gambler's approach
- B. Conservative approach
- C. Wholist approach
- D. Partist approach

Answer: Gambler's approach

256. In "Conservative Approach", in the strategies in concept formation, the "S" (Subject) proceeds very cautiously and systematically concentrating on:

- A. Three features of the card at a time
- B. Four features of the card at a time
- C. One feature of the card at a time
- D. None of the above

Answer: One feature of the card at a time

257. A German Psychologist, Karl Duncker, first proposed the concept of:

- A. Implicit Speech
- B. Subvocal talking
- C. Functional Fixity
- D. Realistic Thinking

Answer: Functional Fixity

258. "Functional Fixedness" is an important factor in:

- A. Day Dreaming
- B. Thinking
- C. Problem Solving
- D. None of the above

Answer: None of the above

259. Knowledge of 'phonemes' is essential for comprehending a language, but the phonemes themselves do not form a unit of perception of a language. The reason is that we never hear them one at a time. What we actually hear is two or three phonemes combined into a syllable called:

- A. A morpheme
- B. A phoneme
- C. A concept
- D. An image

Answer: A morpheme

260. The range between the loudest and the weakest sounds that an individual can make is called:

- A. Dynamic range
- B. Sensory range
- C. Pitch range
- D. None of the above

Answer: Dynamic range

261. The information processing theory emphasizes the contribution of the child rather than the role of reinforcement as emphasized by the:

- A. Operant model
- B. Insightful learning model
- C. Classical conditioning model
- D. Trial-and-Error model

Answer: Operant model

262. In 1860s, a French physician Paul Broca showed that a lower part of the frontal lobe, a short distance above and in the front of the left ear was mainly responsible for the:

- A. Creativity
- B. Formation and development of images

C. Control of spoken language

D. Concept formation

Answer: Control of spoken language

263.The language region in the lowerfrontal lobe is known as:

A. Broca's Area

B. Sherrington' Area

C. Wernicke's Area

D. None of the above

Answer: Broca's Area

264.The general term for speechdisorder due to brain damage is known as:

A. Aphasia

B. Paresthesia

C. Astasia-abasia

D. Aphonia

Answer: Aphasi

265. which of the following controlsthyroid gland?

A. metabolism

B. glucose absorption

C. emotions

D. a and b

E. b and c

F. none of these

Answer – A

266. --- is the process in whichdetecting ,translating and transmitting from external environment to brain...

A. adaptation

B. selective attention

C. sensation

D. perception

E. a and b both

F. none of these

Answer – C

267. Most common form of MoodDisorder...

A. Bipolar I

B. Bipolar II

C. Seasonal Affective Disorder

D. Major Depressive Disorder

E. a and c both

F. none of these

Answer – D

268. Which one option is not a compulsive behaviour with Obsessive-Compulsive Disorder?

- A.** Tapping
- B.** Hoarding
- C.** Washing
- D.** Checking
- E.** c and d both
- F.** none of these

Answer – A

269.— disorders is not more common in female populations...

- A.** AN
- B.** MDD
- C.** BPD
- D.** SP
- E.** a and d both
- F.** none of these

Answer – C

270.: Which one option is not commonly diagnosed in criminals?

- A.** Depersonalization Disorder
- B.** Narcissistic Personality Disorder
- C.** Schizophrenia
- D.** Anti-Social Personality Disorder
- E.** a and d both
- F.** none of these

Answer – C

271: Many celebrities said to have experienced which type of somatic disorder...

- A.** Disorder
- B.** Body Dysmorphic Dearealisation Disorder
- C.** Hyperchondriasis
- D.** Somatoform Disorder
- E.** all of these
- F.** noe of these

Answer – C

272: Many celebrities said to have experienced which type of somatic disorder...

- A.** Disorder
- B.** Body Dysmorphic Dearealisation Disorder
- C.** Hyperchondriasis
- D.** Somatoform Disorder
- E.** all of these
- F.** noe of these

Answer – C

273: Our general method for dealing with environment is...

- A.** perceptual style
- B.** cognitive style
- C.** personality perceptual style
- D.** intelligence
- E.** none of these
- F.** a and c both

Answer – B

274. The child's increasing skill at using his muscles is because of...

- A.** An opportunity to exercise
- B.** Pushing by parents
- C.** Learning
- D.** Maturation
- E.** a and b
- F.** None of these

Answer – D

275: psychological domain is...

- A.** Style of behaving
- B.** Memory
- C.** Motor skills
- D.** Judgment
- E.** b and c both
- F.** None of these

Answer – A

276. People lost touch with reality, when they are...

- A.** Manic
- B.** Neurotic
- C.** Psychotic
- D.** Psychopathic
- E.** c and d both
- F.** None of these

Answer – C

277. 'Importance' of intelligence can be judged according to which of the following?

- A.** The perception of its existence
- B.** The use of 'intelligence'
- C.** Its function in achieving social outcome that is valued by the society
- D.** All of the above

Answer: d. All of the above

278. Which of the following is NOT a situation for which an intelligence test is useful?

- A.** Assess weaknesses of a student in school
- B.** Help psychologists design rehabilitation programmes for neuropsychological patients
- C.** Find out the amount of future earning of a person
- D.** Help school psychologists plan an educational intervention programme for students who struggle

Answer: c. Find out the amount of future earning of a person

279. When examining criterion validity of IQ, which of the following is important?

- A.** The time of day when IQ was measured
- B.** The IQ test that was used
- C.** The psychologist who administers the test
- D.** Determining the direction of causality

Answer: d. Determining the direction of causality

280. Which of the following is least predicted by intelligence?

- A.** Academic success
- B.** Physical height
- C.** Occupational status
- D.** Family income

Answer: b. Physical height

281. In an educational setting, it has been found that ...

- A.** as grade level increases, intelligence becomes more important
- B.** intelligence is negatively correlated with diligence
- C.** high intelligence level leads to higher academic achievement
- D.** IQ is only relevant when non-verbal tests are used

Answer: a. as grade level increases, intelligence becomes more important

282. In a study of high school students, intelligence explained ...

- A.** as much variance in their academic achievement as their personality
- B.** less variance in their academic achievement than emotional intelligence
- C.** more variance in their academic achievement than either their personality or emotional intelligence
- D.** close to zero variance in their academic achievement

Answer: c. more variance in their academic achievement than either their personality or emotional intelligence

283. Intelligence can predict academic success ...

- A.** up until undergraduate degree qualification
- B.** beyond undergraduate degree qualification
- C.** in primary school only
- D.** in high school only

Answer: b. beyond undergraduate degree qualification

284. Which of the following can be predicted by intelligence?

- A.** Job level attained
- B.** Job-related training performance
- C.** Actual job performance
- D.** All of the above

Answer: d. All of the above

285. In non-Western countries, and excluding Australia and Japan, there is a vacuum of evidence for IQ predicting job performance. What does this suggest?

- A.** Non-Western countries do not measure job performance
- B.** IQ is an idea of the Western world
- C.** Researchers do not study non-Western countries
- D.** Job performance can only be measured through career advancement

Answer: b. IQ is an idea of the Western world

286. In terms of occupational types, high IQ scores are often found ...

- A.** among persons with physical jobs such as labourers
- B.** equally across all job types
- C.** among persons whose jobs require abstract thinking skills
- D.** among army recruits

Answer: c. among persons whose jobs require abstract thinking skills

287. A possible reason for why intelligence is predictive of job performance is that...

- A.** intelligence relates to the ability to handle complex information and learn
- B.** intelligence provides the person with a sense of confidence
- C.** intelligent individuals get along well with their supervisor who rates them favourably
- D.** all of the above

Answer: a. intelligence relates to the ability to handle complex information and learn

288. Which of the following statements is true of a study of US military personnel reported by Gottfredson (1997)?

- A.** There were many more high cognitive ability scorers who have trouble completing their military training compared to low scorers
- B.** There were as many high cognitive ability scorers as low scorers who have trouble completing their military training
- C.** Most of the high cognitive ability scorers completed their military training compared to the low scorers
- D.** Most high cognitive ability scorers completed their military training without complaining

Answer: c. Most of the high cognitive ability scorers completed their military training compared to the low scorers

289. The reason for why IQ would be related to income is ...

- A.** high intelligence leads the individual to seek further postgraduate training which in turn leads to highly valued and higher paid jobs.

- B.** knowledge equals to money
- C.** highly intelligent people are more likely to make themselves appear successful
- D.** employers are more likely to employ highly respected people

Answer: a. high intelligence leads the individual to seek further postgraduate training which in turn leads to highly valued and higher paid job.

290. Which of the following are explanations offered for why childhood IQs are negatively correlated with the risk of adult coronary heart disease?

- A.** Disease prevention mechanism is in operation such that higher intelligence is associated with healthier lifestyle
- B.** Disease management mechanism is in operation such that intelligent individuals can self-administer medication better
- C.** Intelligence leads individuals to avoid unhealthy environment and hazardous jobs which may damage health
- D.** All of the above

Answer: d. All of the above

291. Whilst cross-sectional studies may hint that obesity leads to low IQ, longitudinal studies where childhood IQ was measured before health indicators were measured later in adulthood showed that ...

- A.** obesity risks are not real
- B.** higher IQ increases the risk of obesity
- C.** lower IQ increases the risk of obesity
- D.** IQ and obesity are not related

Answer: c. lower IQ increases the risk of obesity

292. The child's increasing skill at using his muscles is due chiefly to:

- A.** Maturation
- B.** Learning
- C.** Pushing by parents
- D.** An opportunity to exercise

Answer: Option [B]

293. In three-factor models of personality a 'Constraint' factor is sometimes proposed. In Big Five terms, 'Constraint' is best understood as a combination of ...

- A.** low Extraversion and high Agreeableness
- B.** low Extraversion and low Agreeableness
- C.** high Conscientiousness and high Agreeableness
- D.** high Conscientiousness and low Agreeableness

Answer: c. high Conscientiousness and high Agreeableness

294. What combination of Big Five personality characteristics is associated with authoritarian tendencies?

- A.** Low Agreeableness and high Conscientiousness

- B.** Low Openness and high Conscientiousness
 - C.** High Neuroticism and low Agreeableness
 - D.** Low Openness and high Neuroticism
- Answer: b. Low Openness and high Conscientiousness

295. Which attachment style is associated with showing anger and upset during a discussion of a relationship problem with one's partner and reduced love and commitment toward them after it?

- A.** Secure
- B.** Insecure
- C.** Avoidant
- D.** Anxious/ambivalent

Answer: d. Anxious/ambivalent

296. Which of the following statements best describes the 'indigenous approach' to examining cultural variations in personality structure?

- A.** It employs indigenous people as research assistants
- B.** It translates Western personality measures into indigenous languages
- C.** It starts with the personality concepts and trait terms of the culture of interest
- D.** It addresses the personality structure of colonized peoples

Answer: c. It starts with the personality concepts and trait terms of the culture of interest

297. Which of the following statements best describes the current state of research on personality types?

- A.** Categorical personality types are very rare
- B.** Type A personality is an either-or personality type
- C.** Research shows that the Myers-Briggs Type Indicator identifies true personality types
- D.** Most personality variation between people is not well described by continuous dimensions

Answer: a. Categorical personality types are very rare

298. Conditioned response may be eliminated by withdrawing reinforcement. This is known as:

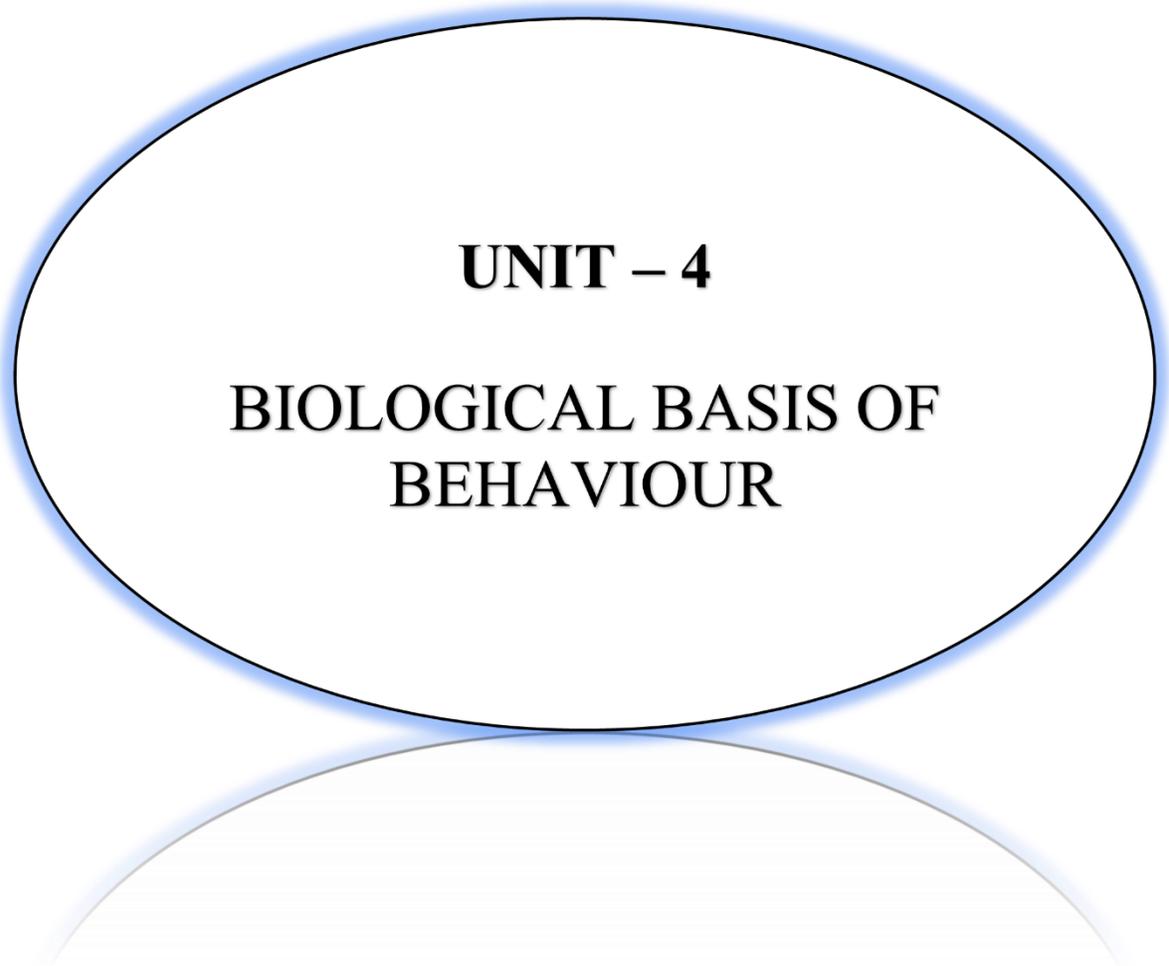

- A.** A Extinction
- B.** B Discrimination
- C.** C Spontaneous recovery
- D.** D Stimulus generalization

Answer: Option [A]

293. Any stimulus that follows a behavior and increases the likelihood that the behavior will be repeated is called a:

- A.** A Cue
- B.** B Punisher
- C.** C reinforcer
- D.** D Situational stimulus

Answer: Option [c]

UNIT - 4

**BIOLOGICAL BASIS OF
BEHAVIOUR**

Biological basis of behavior

What is Sensory systems: General and specific sensations, receptors and processes Neurons: Structure, functions, types, neural impulse, synaptic transmission. Neurotransmitters?

Sensory systems: General and specific sensations, receptors and processes Neurons: Structure, functions, types, neural impulse, synaptic transmission. Neurotransmitters

In more advanced animals, the senses are constantly at work, making the animal aware of stimuli, such as light or sound or the presence of a chemical substance in the external environment, while monitoring information about the organism's internal environment. All bilaterally symmetric animals have a sensory system.

The development of any species' sensory system has been driven by natural selection; thus, sensory systems differ among species according to the demands of their environments. For example, the shark, unlike most fish predators, is electro-sensitive (i.e., sensitive to electrical fields produced by other animals in its environment). While it is helpful to this underwater predator, electro-sensitivity is a sense not found in most land animals.

Senses provide information about the body and its environment. Humans have five special senses: olfaction (smell), gustation (taste), equilibrium (balance and body position), vision, and hearing. Additionally, we possess general senses, also called somatosensation, which respond to stimuli like temperature, pain, pressure, and vibration. Vestibular sensation, which is an organism's sense of spatial orientation and balance, proprioception (position of bones, joints, and muscles), and the sense of limb position that is used to track kinesthesia (limb movement) are part of somatosensation.

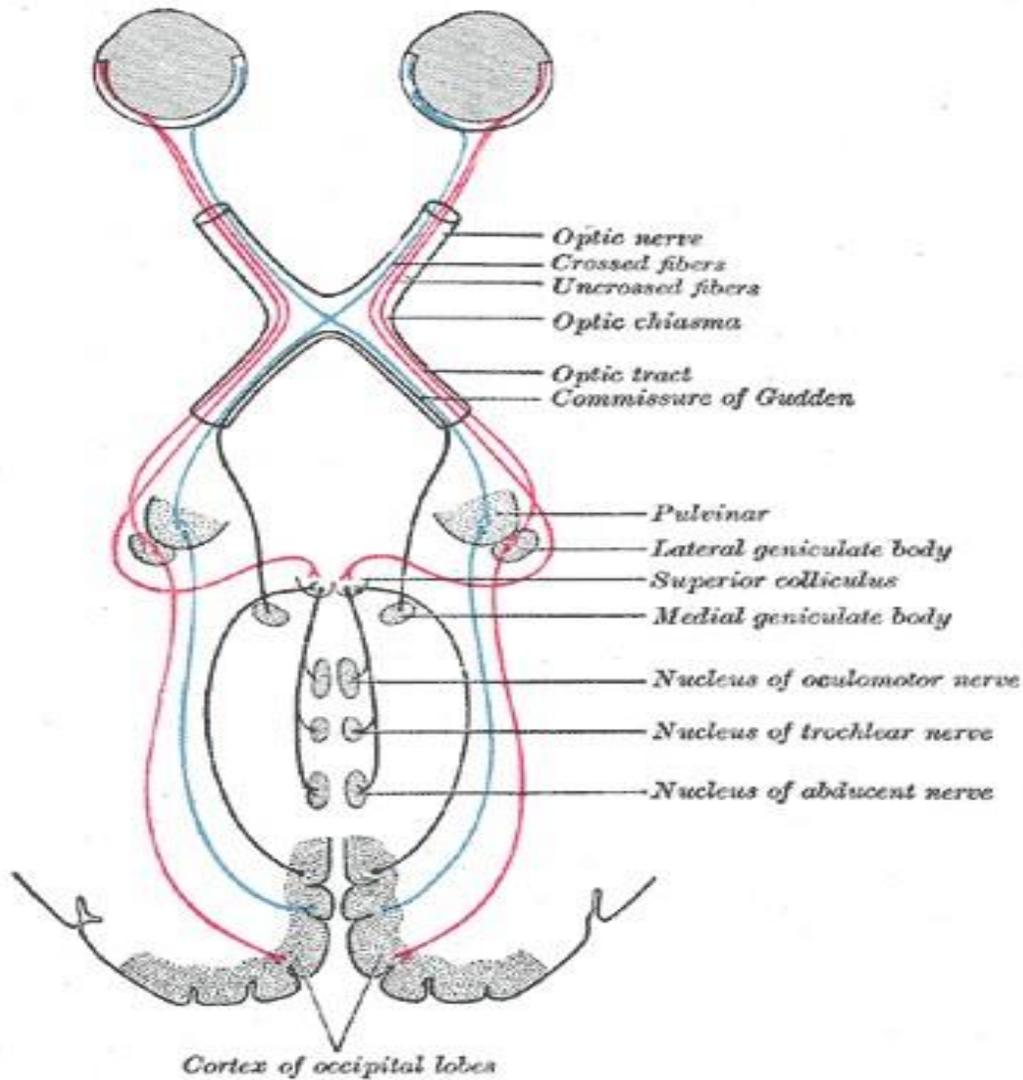

Although the sensory systems associated with these senses are very different, all share a common function: to convert a stimulus (light, sound, or the position of the body) into an electrical signal in the nervous system. This process is called sensory transduction. There are two broad types of cellular systems that perform sensory transduction. In one, a neuron works with a sensory receptor, a cell, or cell process that is specialized to engage with and detect a specific stimulus. Stimulation of the sensory receptor activates the associated afferent neuron, which carries information about the stimulus to the central nervous system. In the second type of sensory transduction, a sensory nerve ending responds to a stimulus in the internal or external environment; this neuron constitutes the sensory receptor.

Free nerve endings can be stimulated by several different stimuli, thus showing little receptor specificity. For example, pain receptors in your gums and teeth may be stimulated by temperature changes, chemical stimulation, or pressure.

Reception

The first step in sensation is reception: the activation of sensory receptors by stimuli such as mechanical stimuli (being bent or squished, for example), chemicals, or temperature. The receptor can then respond to the stimuli. The region in space in which a given sensory receptor can re-

spond to a stimulus, be it far away or in contact with the body, is that receptor's receptive field. Think for a moment about the differences in receptive fields for the different senses. For the sense of touch, a stimulus must come into contact with body. For the sense of hearing, a stimulus can be a moderate distance away. For vision, a stimulus can be very far away; for example, the visual system perceives light from stars at enormous distances.

Visual sensory System:

This scheme shows the flow of information from the eyes to the central connections of the optic nerves and optic tracts, to the visual cortex. Area V1 is the region of the brain which is engaged in vision.

Key Points

- Sensory signals are converted to electrical signals via depolarization of sensory neuron membranes upon stimulus of the receptor, which causes opening of gated ion channels that cause the membrane potential to reach its threshold.
- The receptor potentials are classified as graded potentials; the magnitude of these potentials

- is dependent on the strength of the stimulus.
- The sensory system shows receptor specificity; although stimuli can be combined in processing regions of the brain, a specific receptor will only be activated by its specific stimulus.
- The brain contains specific processing regions (such as the somatosensory, visual, and auditory regions) that are dedicated to processing the information which has previously passed through the thalamus, the 'clearinghouse and relay station' for both sensory and motor signals.
- The four major components of encoding and transmitting sensory information include: the type of stimulus, the stimulus location within the receptive field, the duration, and the intensity of the stimulus.

Key Terms

- **membrane potential:** the difference in electrical potential across the enclosing membrane of a cell
- **action potential:** a short term change in the electrical potential that travels along a cell
- **transduction:** the translation of a sensory signal in the sensory system to an electrical signal in the nervous system

Transduction

The most fundamental function of a sensory system is the translation of a sensory signal to an electrical signal in the nervous system. This takes place at the sensory receptor. The change in electrical potential that is produced is called the receptor potential. How is sensory input, such as pressure on the skin, changed to a receptor potential? As an example, a type of receptor called a mechanoreceptor possesses specialized membranes that respond to pressure. Disturbance of these dendrites by compressing them or bending them opens gated ion channels in the plasma membrane of the sensory neuron, changing its electrical potential. In the nervous system, a positive change of a neuron's electrical potential (also called the membrane potential), depolarizes the neuron. Receptor potentials are graded potentials: the magnitude of these graded (receptor) potentials varies with the strength of the stimulus. If the magnitude of depolarization is sufficient (that is, if membrane potential reaches a threshold), the neuron will fire an action potential. In most cases, the correct stimulus impinging on a sensory receptor will drive membrane potential in a positive direction, although for some receptors, such as those in the visual system, this is not always the case.

Sensory receptors for the various senses work differently from each other. They are specialized according to the type of stimulus they sense; thus, they have receptor specificity. For example, touch receptors, light receptors, and sound receptors are each activated by different stimuli. Touch receptors are not sensitive to light or sound; they are sensitive only to touch or pressure. However, stimuli may be combined at higher levels in the brain, as happens with olfaction, contributing to our sense of taste.

Encoding and Transmission of Sensory Information

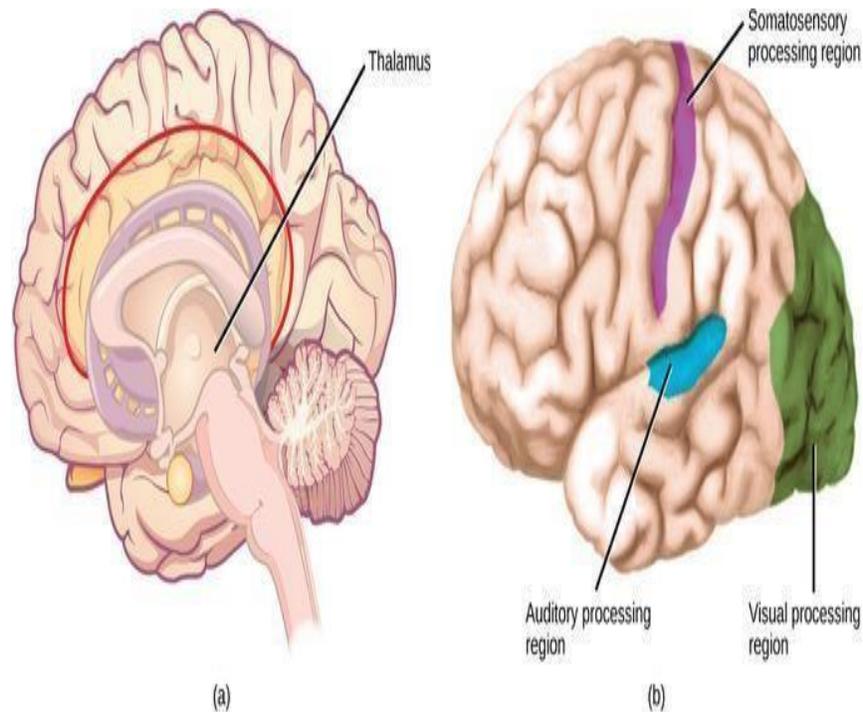

Four aspects of sensory information are encoded by sensory systems: the type of stimulus, the location of the stimulus in the receptive field, the duration of the stimulus, and the relative intensity of the stimulus. Thus, action potentials transmitted over a sensory receptor's afferent axons encode one type of stimulus. This segregation of the senses is preserved in other sensory circuits. For example, auditory receptors transmit signals over their own dedicated system. The electrical

activity in the axons of the auditory receptors will be interpreted by the brain as an auditory stimulus: a sound.

The intensity of a stimulus is often encoded in the rate of action potentials produced by the sensory receptor. Thus, an intense stimulus will produce a more rapid train of action potentials. Reducing the stimulus will likewise slow the rate of production of action potentials. A second way in which intensity is encoded is by the number of receptors activated. An intense stimulus might initiate action potentials in a large number of adjacent receptors, while a less intense stimulus might stimulate fewer receptors. Integration of sensory information begins as soon as the information is received in the central nervous system.

Perception

Perception is an individual's interpretation of a sensation. Although perception relies on the activation of sensory receptors, perception happens, not at the level of the sensory receptor, but at the brain level. The brain distinguishes sensory stimuli through a sensory pathway: action potentials from sensory receptors travel along neurons that are dedicated to a particular stimulus.

All sensory signals, except those from the olfactory system, are transmitted through the central nervous system: they are routed to the thalamus and to the appropriate region of the cortex. The thalamus is a structure in the forebrain that serves as a clearinghouse and relay station for sensory (as well as motor) signals. When the sensory signal exits the thalamus, it is conducted to the specific area of the cortex dedicated to processing that particular sense.

Function of senses

1. Detection of sensations allow the human body to be aware of changes (or stimuli) that occur in the environment or inside the body.
2. These senses permit the central nervous system to produce reactions for the stimuli and main-

tain body homeostasis.

3. Somatic senses ("soma" means body) detect touch, pain pressure, temperature, and tension on the skin and in internal organs.
4. Special senses detect the sensations of taste, smell, hearing, equilibrium, and sight, only in special sense organs in the head region (a phenomenon known as "cephalization").
5. All senses are detected by sensory receptors, and after integration and processing being done in the central nervous system, motor nerves produce a response.

6. Somatic Senses

1. sensory receptors in the skin, muscles, joints, and visceral organs detect external and internal stimuli of the body.
2. Three types of somatic senses:
 - a) Exteroceptive senses detect changes that occur at body surface, such as touch, pressure and temperature.
 - b) Proprioceptive senses detect changes that occur in muscles, tendons, ligaments and joint tissues.
 - c) Visceroceptive senses detect changes that occur in internal organs.

Special Senses

1. The senses of taste and smell (detected by chemoreceptors), hearing and equilibrium (detected by mechanoreceptors), and vision (detected by photoreceptors) are the five special senses.
2. Require specialized sensory receptors within large, complex sensory organs in the head region

Sense of Smell

- a) olfactory receptors located in "olfactory organs" are specialized chemoreceptors in the nasal cavity.
- b) olfactory receptors are bipolar neurons surrounded by ciliated columnar cells. These sensory cells, after being stimulated by olfactory sensations, send nerve impulses along the olfactory (cranial nerve I) to the cerebrum.
- c) gases in the air entering the nasal cavity are dissolved by nasal mucus (secreted by goblet cells in the columnar epithelium), and the resulting solution stimulates various olfactory receptors.

Sense of Taste

- a) about 10,000 taste buds occur in the oral cavity, mostly on the tongue. Each taste bud contains 40-60 taste receptors. These sensory cells, are stimulated by taste sensations.
- b) chemical substances from the food or beverage enter the mouth and are dissolved in the saliva (secreted by salivary glands and mucous membrane of oral cavity).
- c) dissolved chemical substances stimulate various taste buds in different regions of the tongue, and combinations of taste sensations produce hundreds of different taste senses.

Sense of Vision

- Accessory structures of the eye are those that are not directly related the sense of vision, but facilitate the physiology of the eyeballs.
- Eyebrows – to shade the eyes from sunlight and to prevent perspiration from reaching the eyes.

- Eyelids- to protect the eyes from foreign objects (e.g. dust particles) ,and to prevent desiccation (drying) of the eyes by lubricating fluid.
- Conjunctiva- a mucous membrane on the inner lining of eyelids, which produces lubricating and cleansing fluid for the surface of eye.
- Lacrimal gland- exocrine gland that secretes a dilute saline solution called tears for moistening the eyes. [Tears contain mucus, antibodies ,and antibacterial enzymes that protect the eye from infections. Emotional tears also contain enzymes that seem to help reduce stress levels].

Sense of Equilibrium

- a) detected by mechanoreceptors in the semicircular canals to help maintain body posture and body stability.
- b) nerve impulses generated by the receptors in semicircular canals are transmitted by the vestibular nerve to Nerve VIII, and the signals will be processed by the brain.

Sensory Modalities

Ask anyone what the senses are, and they are likely to list the five major senses—taste, smell, touch, hearing, and sight. However, these are not all of the senses. The most obvious omission from this list is balance. Also, what is referred to simply as touch can be further subdivided into pressure, vibration, stretch, and hair-follicle position, on the basis of the type of mechanoreceptors that perceive these touch sensations. Other overlooked senses include temperature perception by thermoreceptors and pain perception by nociceptors. Within the realm of physiology, senses can be classified as either general or specific. A **general sense** is one that is distributed throughout the body and has receptor cells within the structures of other organs. Mechanoreceptors in the skin, muscles, or the walls of blood vessels are examples of this type. General senses often contribute to the sense of touch, as described above, or to **proprioception** (body movement) and **kinesthesia** (body movement), or to a **visceral sense**, which is most important to autonomic functions. A **special sense** is one that has a specific organ devoted to it, namely the eye, inner ear, tongue, or nose. Each of the senses is referred to as a **sensory modality**. Modality refers to the way that information is encoded, which is similar to the idea of transduction.

Sensory Receptors

- **Structural Receptor Types**
- **Functional Receptor Types**

A major role of sensory receptors is to help us learn about the environment around us, or about the state of our internal environment. Stimuli from varying sources, and of different types, are received and changed into the electrochemical signals of the nervous system. This occurs when a stimulus changes the cell membrane potential of a sensory neuron. The stimulus causes the sensory cell to produce an action potential that is relayed into the central nervous system (CNS), where it is integrated with other sensory information—or sometimes higher cognitive functions—to become a conscious perception of that stimulus. The central integration may then lead to a motor response. Describing sensory function with the term sensation or perception is a deliberate distinction. **Sensation** is the activation of sensory receptor cells at the level of the stimulus. **Perception** is the central processing of sensory stimuli into a meaningful pattern. Perception is dependent on sensation, but not all sensations are perceived. Receptors are the cells or structures that detect sensations.

Sensory Receptors

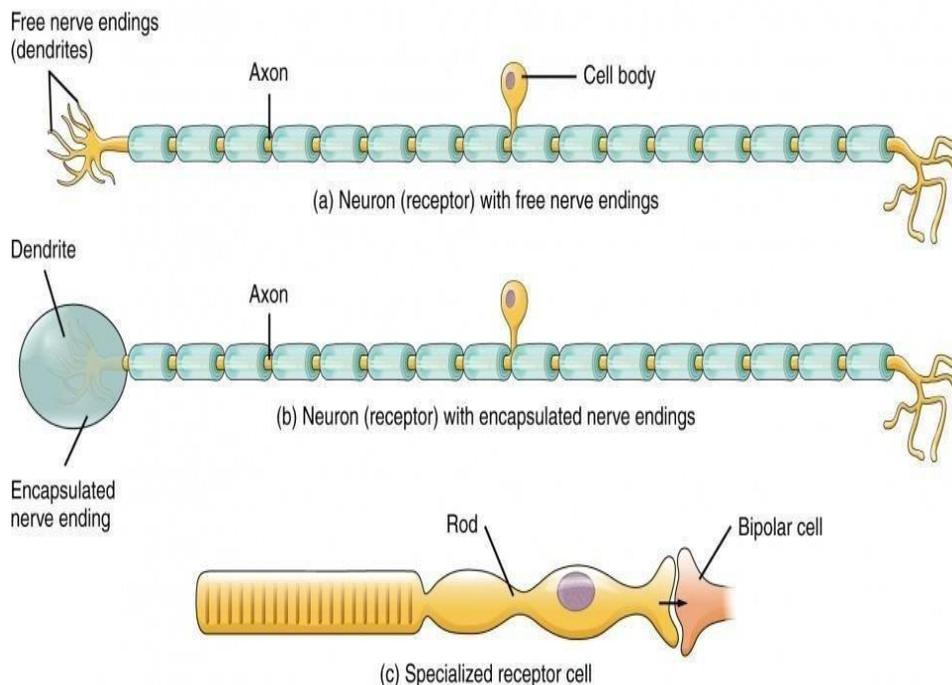

Stimuli in the environment activate specialized receptor cells in the peripheral nervous system. Different types of stimuli are sensed by different types of receptor cells. Receptor cells can be classified into types on the basis of three different criteria: cell type, position, and function. Receptors can be classified structurally on the basis of cell type and their position in relation to stimuli they sense. They can also be classified functionally on the basis of the **transduction** of stimuli, or how the mechanical stimulus, light, or chemical changed the cell membrane potential.

Structural Receptor Types

The cells that interpret information about the environment can be either

- (1) a neuron that has a **free nerve ending**, with dendrites embedded in tissue that would receive a sensation;
- (2) a neuron that has an **encapsulated ending** in which the sensory nerve endings are encapsulated in connective tissue that enhances their sensitivity; or
- (3) a specialized **receptor cell**, which has distinct structural components that interpret a specific type of stimulus (Figure 8.30). The pain and temperature receptors in the dermis of the skin are examples of neurons that have free nerve endings. Also located in the dermis of the skin are lamellated corpuscles, neurons with encapsulated nerve endings that respond to pressure and touch. The cells in the retina that respond to light stimuli are an example of a specialized receptor, a **photoreceptor**. Receptor cell types can be classified on the basis of their structure.

Sensory neurons can have either

- (a) free nerve endings or
- (b) encapsulated endings. Photoreceptors in the eyes, such as rod cells, are examples of
- (c) specialized receptor cells. These cells release neurotransmitters onto a bipolar cell, which then synapses with the optic nerve neurons.

Another way that receptors can be classified is based on their location relative to the stimuli. An **exteroceptor** is a receptor that is located near a stimulus in the external environment, such as the

receptors that are located in the skin. An **interoceptor** is one that interprets stimuli from internal organs and tissues, such as the receptors that sense the increase in blood pressure in the aorta or carotid sinus. Finally, a **proprioceptor** is a receptor located near a moving part of the body, such as a muscle, that interprets the positions of the tissues as they move.

Functional Receptor Types

A third classification of receptors is by the stimulus that is used to initiate the process of transduction. Chemical stimuli can be interpreted by a **chemoreceptor** that interprets chemical stimuli, such as an object's taste or smell. **Osmoreceptors** respond to solute concentrations of body fluids. Additionally, pain is primarily a chemical sense that interprets the presence of chemicals from tissue damage, or similar intense stimuli, through a **nociceptor**. Physical stimuli, such as pressure and vibration, as well as the sensation of sound and body position (balance), are interpreted through a **mechanoreceptor**. Light is detected by **photoreceptors** in the eyes. Another physical stimulus that has its own type of receptor is temperature, which is sensed through a **thermoreceptor** that is either sensitive to temperatures above (heat) or below (cold) normal body temperature.

Sensory Modalities

Ask anyone what the senses are, and they are likely to list the five major senses—taste, smell, touch, hearing, and sight. However, these are not all of the senses. The most obvious omission from this list is balance. Also, what is referred to simply as touch can be further subdivided into pressure, vibration, stretch, and hair-follicle position, on the basis of the type of mechanoreceptors that perceive these touch sensations. Other overlooked senses include temperature perception by thermoreceptors and pain perception by nociceptors.

Within the realm of physiology, senses can be classified as either general or special. A **general sense** is one that is distributed throughout the body and has receptor cells within the structures of other organs. Mechanoreceptors in the skin, muscles, or the walls of blood vessels are examples of this type. General senses often contribute to the sense of touch, as described above, or to **proprioception** (body position) and **kinesthesia** (body movement), or to a **visceral sense**, which is most important to autonomic functions. A **special sense** (discussed in Chapter 15) is one that has a specific organ devoted to it, namely the eye, inner ear, tongue, or nose.

Each of the senses is referred to as a **sensory modality**. Modality refers to the way that information is encoded into a perception. The main sensory modalities can be described on the basis of how each stimulus is transduced and perceived. The chemical senses include taste and smell. The general sense that is usually referred to as touch includes chemical sensation in the form of nociception, or pain. Pressure, vibration, muscle stretch, and the movement of hair by an external stimulus, are all sensed by mechanoreceptors and perceived as touch or proprioception. Hearing and balance are also sensed by mechanoreceptors. Finally, vision involves the activation of photoreceptors.

Listing all the different sensory modalities, which can number as many as 17, involves separating the five major senses into more specific categories, or **submodalities**, of the larger sense. An individual sensory modality represents the sensation of a specific type of stimulus. For example, the

general sense of touch, which is known as **somatosensation**, can be separated into light pressure, deep pressure, vibration, itch, pain, temperature, or hair movement. In this chapter we will discuss the general senses which include pain, temperature, touch, pressure, vibration and proprioception. We will discuss the special senses, which include smell, taste, vision, hearing and the vestibular system, in chapter 15.

Somatosensation (Touch)

Somatosensation is considered a general sense, as opposed to the submodalities discussed in this section. Somatosensation is the group of sensory modalities that are associated with touch and limb position. These modalities include pressure, vibration, light touch, tickle, itch, temperature, pain, proprioception, and kinesthesia. This means that its receptors are not associated with a specialized organ, but are instead spread throughout the body in a variety of organs. Many of the somatosensory receptors are located in the skin, but receptors are also found in muscles, tendons, joint capsules and ligaments.

Two types of somatosensory signals that are transduced by free nerve endings are pain and temperature. These two modalities use thermoreceptors and nociceptors to transduce temperature and pain stimuli, respectively. Temperature receptors are stimulated when local temperatures differ from body temperature. Some thermoreceptors are sensitive to just cold and others to just heat. Nociception is the sensation of potentially damaging stimuli. Mechanical, chemical, or thermal stimuli beyond a set threshold will elicit painful sensations. Stressed or damaged tissues release chemicals that activate receptor proteins in the nociceptors. For example, the sensation of pain or heat associated with spicy foods involves **capsaicin**, the active molecule in hot peppers. Capsaicin molecules bind to a transmembrane ion channel in nociceptors that is sensitive to temperatures above 37°C. The dynamics of capsaicin binding with this transmembrane ion channel is unusual in that the molecule remains bound for a long time. Because of this, it will decrease the ability of other stimuli to elicit pain sensations through the activated nociceptor. For this reason, capsaicin can be used as a topical analgesic, such as in products like Icy Hot™.

If you drag your finger across a textured surface, the skin of your finger will vibrate. Such low frequency vibrations are sensed by mechanoreceptors called Merkel cells, also known as type I cutaneous mechanoreceptors. Merkel cells are located in the stratum basale of the epidermis. Deep pressure and vibration is transduced by lamellated (Pacinian) corpuscles, which are receptors with encapsulated endings found deep in the dermis, or subcutaneous tissue. Light touch is transduced by the encapsulated endings known as tactile (Meissner's) corpuscles. Follicles are also wrapped in a plexus of nerve endings known as the hair follicle plexus. These nerve endings detect the movement of hair at the surface of the skin, such as when an insect may be walking along the skin. Stretching of the skin is transduced by stretch receptors known as bulbous corpuscles. Bulbous corpuscles are also known as Ruffini corpuscles, or type II cutaneous mechanoreceptors.

Other somatosensory receptors are found in the joints and muscles. Stretch receptors monitor the stretching of tendons, muscles, and the components of joints. For example, have you ever stretched your muscles before or after exercise and noticed that you can only stretch so far before your muscles spasm back to a less stretched state? This spasm is a reflex that is initiated by

stretch receptors to avoid muscle tearing. Such stretch receptors can also prevent over-contraction of a muscle. In skeletal muscle tissue, these stretch receptors are called muscle spindles. Golgi tendon organs similarly transduce the stretch levels of tendons. Bulbous corpuscles are also present in joint capsules, where they measure stretch in the components of the skeletal system within the joint. Additionally, lamellated corpuscles are found adjacent to joint capsules and detect vibrations associated with movement around joints. The types of nerve endings, their locations, and the stimuli they transduce are presented in the table below.

***No corresponding eponymous name.**

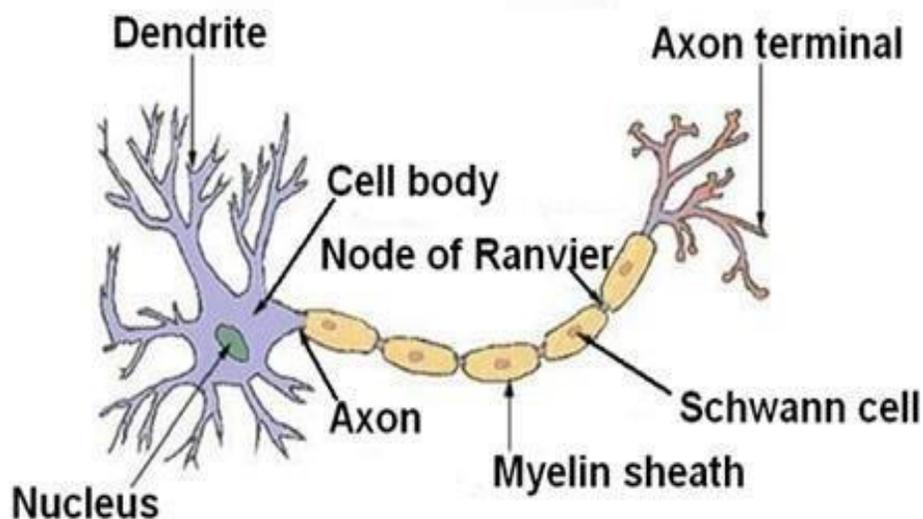

Mechanoreceptors of Somatosensation (Table 13.1)			
Name	Historical (eponymous) name	Location(s)	Stimuli
Mechanoreceptors of Somatosensation (Table 13.1)			
Name	Historical (eponymous) name	Location(s)	Stimuli
Free nerve endings	*	Dermis, cornea, tongue, joint capsules	Pain, temperature, mechanical deformation
Mechanoreceptors	Merkel's discs	Epidermal-dermal junction, mucosal membranes	Low frequency vibration (5-15Hz)
Bulbous corpuscle	Ruffini's corpuscle	Dermis, joint capsules	Stretch
Tactile corpuscle	Meissner's corpuscle	Papillary dermis, especially in the fingertips and lips	Light touch, vibrations below 50 Hz
Lamellated	Pacinian	Deep dermis, subcutaneous	Deep pressure, high-frequency
Mechanoreceptors of Somatosensation (Table 13.1)			
Name	Historical (eponymous) name	Location(s)	Stimuli
corpuscle	corpuscle	tissue, joint capsules	vibration (around 250 Hz)
Hair follicle plexus	*	Wrapped around hair follicles in the dermis	Movement of hair
Muscle spindle	*	In line with skeletal muscle fibers	Muscle contraction and stretch
Tendon stretch organ	Golgi tendon organ	In line with tendons	Stretch of tendons

Neurons: Structure, functions, types, neural impulse, synaptic transmission. Neurotransmitters.

Key Points

- Neurons are specialized cells that transmit chemical and electrical signals in the brain; they are the basic building blocks of the central nervous system.
- The primary components of the neuron are the soma (cell body), the axon (a long slender projection that conducts electrical impulses away from the cell body), dendrites (tree-like structures that receive messages from other neurons), and synapses (specialized junctions between neurons).
- Some axons are covered with myelin, a fatty material that acts as an insulator and conductor to speed up the process of communication.
- Sensory neurons are neurons responsible for converting external stimuli from the environment into corresponding internal stimuli.
- Motor neurons are neurons located in the central nervous system (CNS); they project their axons outside of the CNS to directly or indirectly control muscles.
- Interneurons act as the “middle men” between sensory and motor neurons, which convert external stimuli to internal stimuli and control muscle movement, respectively.

Structure of a Typical Neuron

The neuron is the basic building block of the brain and central nervous system. Neurons are specialized cells that transmit chemical and electrical signals. The brain is made up entirely of neurons and glial cells, which are non-neuronal cells that provide structure and support for the neurons. Nearly 86 billion neurons work together within the nervous system to communicate with the rest of the body. They are responsible for everything from consciousness and thought to pain and hunger. There are three primary types of neuron: sensory neurons, motor neurons, and interneurons.

Structures of a Neuron

In addition to having all the normal components of a cell (nucleus, organelles, etc.) neurons also contain unique structures for receiving and sending the electrical signals that make neuronal

communication possible.

The structure of a neuron: The above image shows the basic structural components of an average neuron, including the dendrite, cell body, nucleus, Node of Ranvier, myelin sheath, Schwann cell, and axon terminal.

Dendrite

Dendrites are branch-like structures extending away from the cell body, and their job is to receive messages from other neurons and allow those messages to travel to the cell body. Although some neurons do not have any dendrites, other types of neurons have multiple dendrites. Dendrites can have small protrusions called dendritic spines, which further increase surface area for possible connections with other neurons.

Cell Body

Like other cells, each neuron has a cell body (or soma) that contains a nucleus, smooth and rough endoplasmic reticulum, Golgi apparatus, mitochondria, and other cellular components.

Axon

An axon, at its most basic, is a tube-like structure that carries an electrical impulse from the cell body (or from another cell's dendrites) to the structures at opposite end of the neuron—axon terminals, which can then pass the impulse to another neuron. The cell body contains a specialized structure, the axon hillock, which serves as a junction between the cell body and the axon.

Synapse

The synapse is the chemical junction between the axon terminals of one neuron and the dendrites of the next. It is a gap where specialized chemical interactions can occur, rather than an actual structure.

Function of a Neuron

The specialized structure and organization of neurons allows them to transmit signals in the form of electric impulses from the brain to the body and back. Individually, neurons can pass a signal all the way from their own dendrites to their own axon terminals; but at a higher level neurons are organized in long chains, allowing them to pass signals very quickly from one to the other. One neuron's axon will connect chemically to another neuron's dendrite at the synapse between them. Electrically charged chemicals flow from the first neuron's axon to the second neuron's dendrite, and that signal will then flow from the second neuron's dendrite, down its axon, across a synapse, into a third neuron's dendrites, and so on.

This is the basic chain of neural signal transmission, which is how the brain sends signals to the muscles to make them move, and how sensory organs send signals to the brain. It is important that these signals can happen quickly, and they do. Think of how fast you drop a hot potato—before you even realize it is hot. This is because the sense organ (in this case, the skin) sends the signal “This is hot!” to neurons with very long axons that travel up the spine to the brain. If this didn't happen quickly, people would burn themselves.

Other Structures

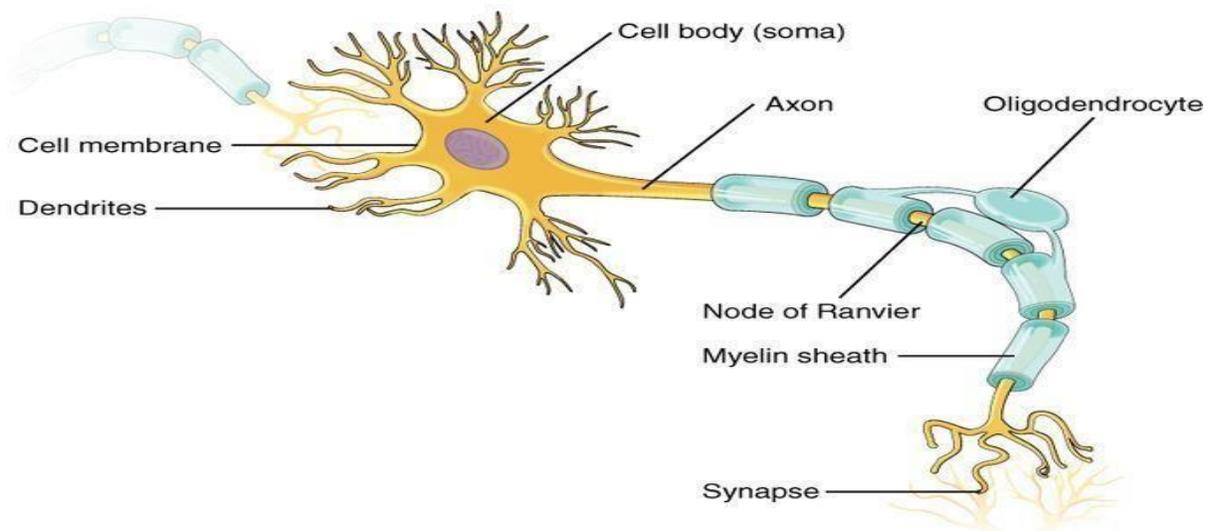

Dendrites, cell bodies, axons, and synapses are the basic parts of a neuron, but other important structures and materials surround neurons to make them more efficient.

Myelin Sheath

Some axons are covered with myelin, a fatty material that wraps around the axon to form the myelin sheath. This external coating functions as insulation to minimize dissipation of the electrical signal as it travels down the axon. Myelin's presence on the axon greatly increases the speed of conduction of the electrical signal, because the fat prevents any electricity from leaking out. This insulation is important, as the axon from a human motor neuron can be as long as a meter—from the base of the spine to the toes. Periodic gaps in the myelin sheath are called nodes of Ranvier. At these nodes, the signal is “recharged” as it travels along the axon.

Glial Cells

The myelin sheath is not actually part of the neuron. Myelin is produced by glial cells (or simply glia, or “glue” in Greek), which are non-neuronal cells that provide support for the nervous system. Glia function to hold neurons in place (hence their Greek name), supply them with nutrients, provide insulation, and remove pathogens and dead neurons. In the central nervous system, the glial cells that form the myelin sheath are called oligodendrocytes; in the peripheral nervous system, they are called Schwann cells.

Neuron in the central nervous system: This neuron diagram also shows the oligodendrocyte, myelin sheath, and nodes of Ranvier.

Types of Neurons

There are three major types of neurons: sensory neurons, motor neurons, and interneurons. All three have different functions, but the brain needs all of them to communicate effectively with the rest of the body (and vice versa).

Sensory Neurons

Sensory neurons are neurons responsible for converting external stimuli from the environment into corresponding internal stimuli. They are activated by sensory input, and send projections to other elements of the nervous system, ultimately conveying sensory information to the brain or

spinal cord. Unlike the motor neurons of the central nervous system (CNS), whose inputs come from other neurons, sensory neurons are activated by physical modalities (such as visible light, sound, heat, physical contact, etc.) or by chemical signals (such as smell and taste).

Most sensory neurons are pseudounipolar, meaning they have an axon that branches into two extensions—one connected to dendrites that receive sensory information and another that transmits this information to the spinal cord.

Multipolar and pseudounipolar neurons: This diagram shows the difference between: 1) a unipolar neuron; 2) a bipolar neuron; 3) a multipolar neuron; 4) a pseudounipolar neuron.

Motor Neurons

Motor neurons are neurons located in the central nervous system, and they project their axons outside of the CNS to directly or indirectly control muscles. The interface between a motor neuron and muscle fiber is a specialized synapse called the neuromuscular junction. The structure of motor neurons is multipolar, meaning each cell contains a single axon and multiple dendrites. This is the most common type of neuron.

Interneurons

Interneurons are neither sensory nor motor; rather, they act as the “middle men” that form connections between the other two types. Located in the CNS, they operate locally, meaning their axons connect only with nearby sensory or motor neurons. Interneurons can save time and therefore prevent injury by sending messages to the spinal cord and back instead of all the way to the brain. Like motor neurons, they are multipolar in structure.

Stages of the Action Potential

Neural impulses occur when a stimulus depolarizes a cell membrane, prompting an action potential which sends an “all or nothing” signal.

Neural Impulses in the Nervous System

The central nervous system (CNS) goes through a three-step process when it functions: sensory input, neural processing, and motor output. The sensory input stage is when the neurons (or excitable nerve cells) of the sensory organs are excited electrically. Neural impulses from sensory receptors are sent to the brain and spinal cord for processing. After the brain has processed the information, neural impulses are then conducted from the brain and spinal cord to muscles and glands, which is the resulting motor output.

A neuron affects other neurons by releasing a neurotransmitter that binds to chemical receptors. The effect upon the postsynaptic (receiving) neuron is determined not by the presynaptic (sending) neuron or by the neurotransmitter itself, but by the type of receptor that is activated. A neurotransmitter can be thought of as a key, and a receptor as a lock: the key unlocks a certain response in the postsynaptic neuron, communicating a particular signal. However, in order for a presynaptic neuron to release a neurotransmitter to the next neuron in the chain, it must go through a series of changes in electric potential.

Stages of Neural Impulses

“Resting potential” is the name for the electrical state when a neuron is not actively being sig-

naled. A neuron at resting potential has a membrane with established amounts of sodium (Na^+) and potassium (K^+) ions on either side, leaving the inside of the neuron negatively charged relative to the outside. The action potential is a rapid change in polarity that moves along the nerve fiber from neuron to neuron. In order for a neuron to move from resting potential to action potential—a short-term electrical change that allows an electrical signal to be passed from one neuron to another—the neuron must be stimulated by pressure, electricity, chemicals, or another form of stimuli. The level of stimulation that a neuron must receive to reach action potential is known as the threshold of excitation, and until it reaches that threshold, nothing will happen. Different neurons are sensitive to different stimuli, although most can register pain. The action potential has several stages.

1. **Depolarization:** A stimulus starts the depolarization of the membrane. Depolarization, also referred to as the “upswing,” is caused when positively charged sodium ions rush into a nerve cell. As these positive ions rush in, the membrane of the stimulated cell reverses its polarity so that the outside of the membrane is negative relative to the inside.
2. **Repolarization.** Once the electric gradient has reached the threshold of excitement, the “downswing” of repolarization begins. The channels that let the positive sodium ion channels through close up, while channels that allow positive potassium ions open, resulting in the release of positively charged potassium ions from the neuron. This expulsion acts to restore the localized negative membrane potential of the cell, bringing it back to its normal voltage.
3. **Refractory Phase.** The refractory phase takes place over a short period of time after the depolarization stage. Shortly after the sodium gates open, they close and go into an inactive conformation. The sodium gates cannot be opened again until the membrane is repolarized to its normal resting potential. The sodium-potassium pump returns sodium ions to the outside and potassium ions to the inside. During the refractory phase this particular area of the nerve cell membrane cannot be depolarized. Therefore, the neuron cannot reach action potential during this “rest period.”

Synapses

The synapse is the junction where neurons trade information. It is not a physical component of a cell but rather a name for the gap between two cells: the presynaptic cell (giving the signal) and the postsynaptic cell (receiving the signal). There are two types of possible reactions at the synapse—chemical or electrical. During a chemical reaction, a chemical called a neurotransmitter is released from one cell into another. In an electrical reaction, the electrical charge of one cell is influenced by the charge an adjacent cell.

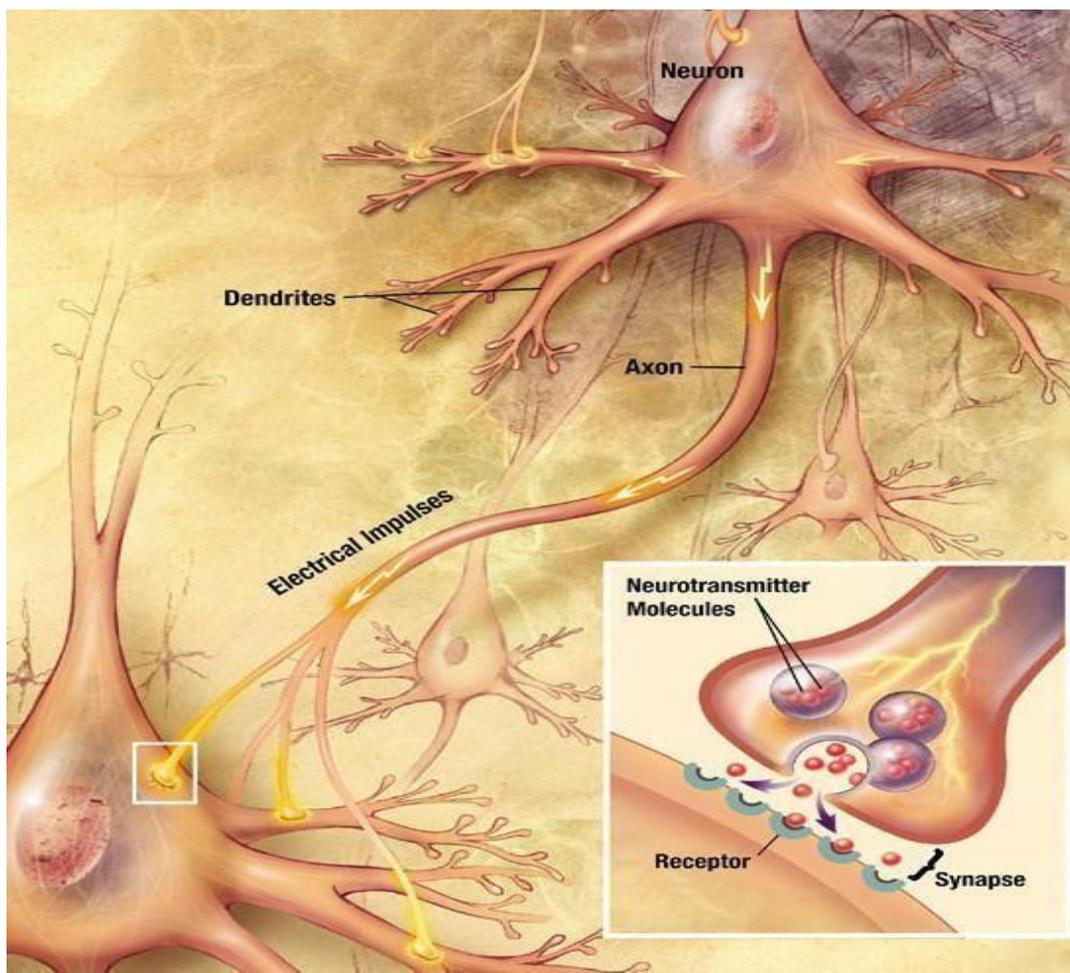

All synapses have a few common characteristics:

- **Presynaptic cell:** a specialized area within the axon of the giving cell that transmits information to the dendrite of the receiving cell.
- **Synaptic cleft:** the small space at the synapse that receives neurotransmitters.
- **G-protein coupled receptors:** receptors that sense molecules outside the cell and thereby activate signals within it.
- **Ligand-gated ion channels:** receptors that are opened or closed in response to the binding of a chemical messenger.
- **Postsynaptic cell:** a specialized area within the dendrite of the receiving cell that contains receptors designed to process neurotransmitters.

The Electrical Synapse

The stages of an electrical reaction at a synapse are as follows:

1. **Resting potential.** The membrane of a neuron is normally at rest with established concentrations of sodium ions (Na^+) and potassium ions (K^+) on either side. The membrane potential (or, voltage across the membrane) at this state is -70 mV , with the inside being negative relative to the outside.
2. **Depolarization.** A stimulus begins the depolarization of the membrane. Depolarization, also referred to as the “upswing,” occurs when positively charged sodium ions (Na^+) suddenly rush through open sodium gates into a nerve cell. If the membrane potential reaches -55 mV , it has reached the threshold of excitation. Additional sodium rushes in, and the membrane of the stimulated cell actually reverses its polarity so that the outside of the membrane is negative relative to the inside. The change in voltage stimulates the opening of additional sodium channels (called a voltage-gated ion channel), providing what is known as a positive feedback loop. Eventually, the cell potential reaches $+40\text{ mV}$, or the action potential.
3. **Repolarization.** The “downswing” of repolarization is caused by the closing of sodium ion channels and the opening of potassium ion channels, resulting in the release of positively charged potassium ions (K^+) from the nerve cell. This expulsion acts to restore the localized negative membranepotential of the cell.
4. **Refractory Phase.** The refractory phase is a short period of time after the repolarization stage. Shortly after the sodium gates open, they close and go into an inactive conformation where the cell’s membrane potential is actually even lower than its baseline -70 mV . The sodium gates cannot be opened again until the membrane has completely repolarized to its normal resting potential, -70 mV . The sodium-potassium pump returns sodium ions to the outside and potassium ions to the inside. During the refractory phase this particular area of the nerve cell membrane cannot be depolarized; the cell cannot be excited.

The Chemical Synapse

The process of a chemical reaction at the synapse has some important differences from an electrical reaction. Chemical synapses are much more complex than electrical synapses, which makes them slower, but also allows them to generate different results. Like electrical reactions, chemical reactions involve electrical modifications at the postsynaptic membrane, but chemical reactions also require chemical messengers, such as neurotransmitters, to operate.

Neuron & chemical synapse: This image shows electric impulses traveling between neurons; the inset shows a chemical reaction occurring at the synapse. A basic chemical reaction at the synapse undergoes a few additional steps:

1. The action potential (which occurs as described above) travels along the membrane of the presynaptic cell until it reaches the synapse. The electrical depolarization of the membrane at the synapse causes channels to open that are selectively permeable, meaning they specifically only allow the entry of positive sodium ions (Na^+).
2. The ions flow through the presynaptic membrane, rapidly increasing their concentration in the interior.
3. The high concentration activates a set of ion-sensitive proteins attached to vesicles, which are small membrane compartments that contain a neurotransmitter chemical.
4. These proteins change shape, causing the membranes of some "docked" vesicles to fuse with the membrane of the presynaptic cell. This opens the vesicles, which releases their neurotransmitter contents into the synaptic cleft, the narrow space between the membranes of the pre- and postsynaptic cells.
5. The neurotransmitter diffuses within the cleft. Some of it escapes, but the rest of it binds to chemical receptor molecules located on the membrane of the postsynaptic cell.
6. The binding of neurotransmitter causes the receptor molecule to be activated in some way. Several types of activation are possible, depending on what kind of neurotransmitter was released. In any case, this is the key step by which the synaptic process affects the behavior of the postsynaptic cell.
7. Due to thermal shaking, neurotransmitter molecules eventually break loose from the receptors and drift away.
8. The neurotransmitter is either reabsorbed by the presynaptic cell and repackaged for future release, or else it is broken down metabolically.

Differences Between Electrical and Chemical Synapses

- Electrical synapses are faster than chemical synapses because the receptors do not need to recognize chemical messengers. The synaptic delay for a chemical synapse is typically about 2 milliseconds, while the synaptic delay for an electrical synapse may be about 0.2 milliseconds.
- Because electrical synapses do not involve neurotransmitters, electrical neurotransmission is less modifiable than chemical neurotransmission.
- The response is always the same sign as the source. For example, depolarization of the presynaptic membrane will always induce a depolarization in the postsynaptic membrane, and vice versa for hyperpolarization.
- The response in the postsynaptic neuron is generally smaller in amplitude than the source.

The amount of attenuation of the signal is due to the membrane resistance of the presynaptic and postsynaptic neurons.

- Long-term changes can be seen in electrical synapses. For example, changes in electrical synapses in the retina are seen during light and dark adaptations of the retina.

Neurotransmitters

Neurotransmitters are chemicals that transmit signals from a neuron across a synapse to a target cell. **KEY TAKEAWAYS**

Key Points

- Neurotransmitters dictate communication between cells by binding to specific receptors and depolarizing or hyperpolarizing the cell.
- Inhibitory neurotransmitters cause hyperpolarization of the postsynaptic cell; excitatory neurotransmitters cause depolarization of the postsynaptic cell.
- Too little of a neurotransmitter may cause the overaccumulation of proteins, leading to disorders like Alzheimer's; too much of a neurotransmitter may block receptors required for proper brain function, leading to disorders like schizophrenia.
- The three neurotransmitter systems in the brain are cholinergic, amino acids, and biogenic amines.

Key Terms

- **reuptake:** The reabsorption of a neurotransmitter by a neuron after the transmission of a neural impulse across a synapse.
- **vesicle:** A membrane-bound compartment found in a cell.
- **action potential:** A short-term change in the electrical potential that travels along a cell (such as a nerve or muscle fiber); the basis of neural communication.

Neurotransmitters are chemicals that transmit signals from a neuron to a target cell across a synapse. When called upon to deliver messages, they are released from their synaptic vesicles on the presynaptic (giving) side of the synapse, diffuse across the synaptic cleft, and bind to receptors in the membrane on the postsynaptic (receiving) side. An action potential is necessary for neurotransmitters to be released, which means that neurons must reach a certain threshold of electric stimulation in order to complete the reaction. A neuron has a negative charge inside the cell membrane relative to the outside of the cell membrane; when stimulation occurs and the neuron reaches the threshold of excitement this polarity is reversed. This allows the signal to pass through the neuron. When the chemical message reaches the axon terminal, channels in the postsynaptic cell membrane open up to receive neurotransmitters from vesicles in the presynaptic cell.

Inhibitory neurotransmitters cause hyperpolarization of the postsynaptic cell (that is, decreasing the voltage gradient of the cell, thus bringing it further away from an action potential), while excitatory neurotransmitters cause depolarization (bringing it closer to an action potential). Neuro-

transmitters match up with receptors like a key in a lock. A neurotransmitter binds to its receptor and will not bind to receptors for other neurotransmitters, making the binding a specific chemical event.

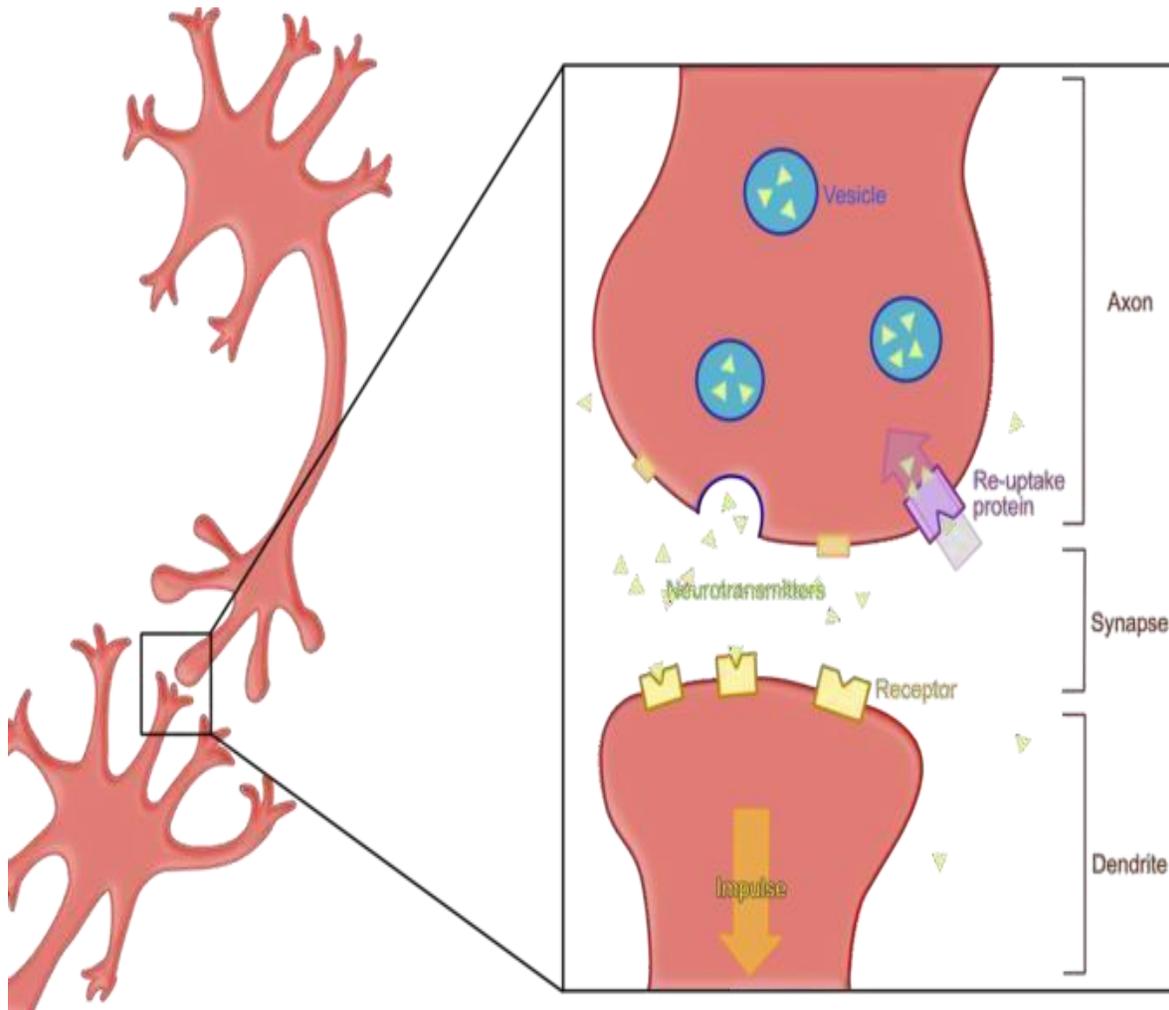

There are several systems of neurotransmitters found at various synapses in the nervous system. The following groups refer to the specific chemicals, and within the groups are specific systems, some of which block other chemicals from entering the cell and some of which permit the entrance of chemicals that were blocked before.

Cholinergic System

The cholinergic system is a neurotransmitter system of its own, and is based on the neurotransmitter acetylcholine (ACh). This system is found in the autonomic nervous system, as well as distributed throughout the brain. The cholinergic system has two types of receptors: the nicotinic receptor and the acetylcholine receptor, which is known as the muscarinic receptor. Both of these receptors are named for chemicals that interact with the receptor in addition to the neurotransmitter acetylcholine. Nicotine, the chemical in tobacco, binds to the nicotinic receptor and activates it similarly to acetylcholine. Muscarine, a chemical product of certain mushrooms, binds to the muscarinic receptor. However, they cannot bind to each others' receptors.

Amino Acids

Another group of neurotransmitters are amino acids, including glutamate (Glu), GABA (gamma-aminobutyric acid, a derivative of glutamate), and glycine (Gly). These amino acids have an amino group and a carboxyl group in their chemical structures. Glutamate is one of the 20 amino acids used to make proteins. Each amino acid neurotransmitter is its own system, namely the glutamatergic, GABAergic, and glycinergic systems. They each have their own receptors and do not interact with each other. Amino acid neurotransmitters are eliminated from the synapse by reuptake. A pump in the cell membrane of the presynaptic element, or sometimes a neighboring glial cell, clears the amino acid from the synaptic cleft so that it can be recycled, repackaged in vesicles, and released again.

The reuptake process: This illustration shows the process of reuptake, in which leftover neurotransmitters are returned to vesicles in the presynaptic cell.

Biogenic Amines

Another class of neurotransmitter is the biogenic amine, a group of neurotransmitters made enzymatically from amino acids. They have amino groups in them, but do not have carboxyl groups and are therefore no longer classified as amino acids.

Neuropeptides

A neuropeptide is a neurotransmitter molecule made up of chains of amino acids connected by peptide bonds, similar to proteins. However, proteins are long molecules while some neuropeptides are quite short. Neuropeptides are often released at synapses in combination with another neurotransmitter.

Dopamine

Dopamine is the best-known neurotransmitter of the catecholamine group. The brain includes several distinct dopamine systems, one of which plays a major role in reward-motivated behavior. Most types of reward increase the level of dopamine in the brain, and a variety of addictive drugs increase dopamine neuronal activity. Other brain dopamine systems are involved in motor control and in controlling the release of several other important hormones.

Effect on the Synapse

The effect of a neurotransmitter on the postsynaptic element is entirely dependent on the receptor protein. If there is no receptor protein in the membrane of the postsynaptic element, then the neurotransmitter has no effect. The depolarizing (more likely to reach an action potential) or hyperpolarizing (less likely to reach an action potential) effect is also dependent on the receptor. When acetylcholine binds to the nicotinic receptor, the postsynaptic cell is depolarized. However, when acetylcholine binds to the muscarinic receptor, it might cause depolarization or hyperpolarization of the target cell.

The amino acid neurotransmitters (glutamate, glycine, and GABA) are almost exclusively associated with just one effect. Glutamate is considered an excitatory amino acid because Glu receptors in the adult cause depolarization of the postsynaptic cell. Glycine and GABA are considered inhibitory amino acids, again because their receptors cause hyperpolarization, making the receiving cell less likely to reach an action potential.

The Right Dose

Sometimes too little or too much of a neurotransmitter may affect an organism's behavior or health. The underlying cause of some neurodegenerative diseases, such as Parkinson's, appears to be related to overaccumulation of proteins, which under normal circumstances would be regulated by the presence of dopamine. On the other hand, when an excess of the neurotransmitter dopamine blocks glutamate receptors, disorders like schizophrenia can occur.

The Structure of Neural Networks

The connections between neurons form a highly complex network. The basic kinds of connections between neurons are chemical synapses and electrical gap junctions, through which either chemical or electrical impulses are communicated between neurons. The method through which neurons interact with neighboring neurons usually consists of several axon terminals connecting through synapses to the dendrites on other neurons. If a stimulus creates a strong enough input signal in a nerve cell, the neuron sends an action potential and transmits this signal along its axon. The axon of a nerve cell is responsible for transmitting information over a relatively long distance, and so most neural pathways are made up of axons. Some axons are encased in a lipid-coated myelin sheath, making them appear a bright white; others that lack myelin sheaths (i.e., are unmyelinated) appear a darker beige color, which is generally called gray.

The process of synaptic transmission in neurons: Neurons interact with other neurons by sending a signal, or impulse, along their axon and across a synapse to the dendrites of a neighboring neuron. Some neurons are responsible for conveying information over long distances. For example, motor neurons, which travel from the spinal cord to the muscle, can have axons up to a meter in length in humans. The longest axon in the human body is almost two meters long in tall individuals and runs from the big toe to the medulla oblongata of the brain stem.

The Capacity of Neural Networks

The basic neuronal function of sending signals to other cells includes the capability for neurons to exchange signals with each other. Networks formed by interconnected groups of neurons are capable of a wide variety of functions, including feature detection, pattern generation, and timing. In fact, it is difficult to assign limits to the types of information processing that can be carried out

by neural networks. Given that individual neurons can generate complex temporal patterns of activity independently, the range of capabilities possible for even small groups of neurons are beyond current understanding. However, we do know that we have neural networks to thank for much of our higher cognitive functioning.

Behaviorist Approach

Historically, the predominant view of the function of the nervous system was as a stimulus-response associator. In this conception, neural processing begins with stimuli that activate sensory neurons, producing signals that propagate through chains of connections in the spinal cord and brain, giving rise eventually to activation of motor neurons and thereby to muscle contraction or other overt responses. Charles Sherrington, in his influential 1906 book *The Integrative Action of the Nervous System*, developed the concept of stimulus-response mechanisms in much more detail, and behaviorism, the school of thought that dominated psychology through the middle of the 20th century, attempted to explain every aspect of human behavior in stimulus-response terms.

Hybrid Approach

However, experimental studies of electrophysiology, beginning in the early 20th century and reaching high productivity by the 1940s, showed that the nervous system contains many mechanisms for generating patterns of activity intrinsically—without requiring an external stimulus. Neurons were found to be capable of producing regular sequences of action potentials (“firing”) even in complete isolation. When intrinsically active neurons are connected to each other in complex circuits, the possibilities for generating intricate temporal patterns become far more extensive. A modern conception views the function of the nervous system partly in terms of stimulus-response chains, and partly in terms of intrinsically generated activity patterns; both types of activity interact with each other to generate the full repertoire of behavior.

Hebbian Theory

In 1949, neuroscientist Donald Hebb proposed that simultaneous activation of cells leads to pronounced increase in synaptic strength between those cells, a theory that is widely accepted today. Cell assembly, or Hebbian theory, asserts that “cells that fire together wire together,” meaning neural networks can be created through associative experience and learning. Since Hebb’s discovery, neuroscientists have continued to find evidence of plasticity and modification within neural networks. What is The Central and Peripheral Nervous Systems – Structure and functions. Neuroplasticity ?

The Central and Peripheral Nervous Systems – Structure and functions. Neuroplasticity

The Central Nervous System

- The central nervous system consists of the brain and spinal cord.
- The brain plays a central role in the control of most bodily functions, including awareness, movements, sensations, thoughts, speech, and memory.
- Some reflex movements can occur via spinal cord pathways without the participation of brain structures.
- The spinal cord is connected to a section of the brain called the brainstem and runs through the spinal canal.

- Cranial nerves exit the brainstem.
- Nerve roots exit the spinal cord to both sides of the body.
- The spinal cord carries signals (messages) back and forth between the brain and the peripheral nerves.
- Cerebrospinal fluid surrounds the brain and the spinal cord and also circulates within the cavities (called ventricles) of the central nervous system.
- The leptomeninges surround the brain and the spinal cord.
- The cerebrospinal fluid circulates between 2 meningeal layers called the
- pia matter and
- the arachnoid
- (or pia-arachnoid membranes).
- The outer, thicker layer serves the role of a protective shield and is called the dura matter.
- The basic unit of the central nervous system is the neuron (nerve cell).
- Billions of neurons allow the different parts of the body to communicate with each other via the brain and the spinal cord.
- A fatty material called myelin coats nerve cells to insulate them and to allow nerves to communicate quickly.

Brain and Cerebrum Location

The cerebrum is the largest part of the brain and controls voluntary actions, speech, senses, thought, and memory. The surface of the cerebral cortex has grooves or infoldings (called sulci), the largest of which are termed fissures. Some fissures separate lobes. The convolutions of the cortex give it a wormy appearance. Each convolution is delimited by two sulci and is also called a gyrus (gyri in plural). The cerebrum is divided into two halves, known as the right and left hemispheres. A mass of fibers called the corpus callosum links the hemispheres. The right hemisphere controls voluntary limb movements on the left side of the body, and the left hemisphere controls voluntary limb movements on the right side of the body. Almost every person has one dominant hemisphere. Each hemisphere is divided into four lobes, or areas, which are interconnected.

- The frontal lobes are located in the front of the brain and are responsible for voluntary movement and, via their connections with other lobes, participate in the execution of sequential tasks; speech output; organizational skills; and certain aspects of behavior, mood, and memory.
- The parietal lobes are located behind the frontal lobes and in front of the occipital lobes. They process sensory information such as temperature, pain, taste, and touch. In addition, the processing includes information about numbers, attentiveness to the position of one's body parts, the space around one's body, and one's relationship to this space.
- The temporal lobes are located on each side of the brain. They process memory and auditory (hearing) information and speech and language functions.
- The occipital lobes are located at the back of the brain. They receive and process visual information.

The cortex, also called gray matter, is the most external layer of the brain and predominantly contains neuronal bodies (the part of the neurons where the DNA-containing cell nucleus is located). The gray matter participates actively in the storage and processing of information. An isolated clump of nerve cell bodies in the gray matter is termed a nucleus (to be differentiated from a

cell nucleus). The cells in the gray matter extend their projections, called axons, to other areas of the brain.

Fibers that leave the cortex to conduct impulses toward other areas are termed efferent fibers, and fibers that approach the cortex from other areas of the nervous system are termed afferent (nerves or pathways). Fibers that go from the motor cortex to the brainstem (for example, the pons) or the spinal cord receive a name that generally reflects the connections (that is, corticopontine tract for the former and corticospinal tract for the latter). Axons are surrounded in their course outside the gray matter by myelin, which has a glistening whitish appearance and thus gives rise to the term white matter.

Cortical areas receive their names according to their general function or lobe name. If in charge of motor function, the area is called the motor cortex. If in charge of sensory function, the area is called a sensory or somesthetic cortex. The calcarine or visual cortex is located in the occipital lobe (also termed occipital cortex) and receives visual input. The auditory cortex, localized in the temporal lobe, processes sounds or verbal input. Knowledge of the anatomical projection of fibers of the different tracts and the relative representation of body regions in the cortex often enables doctors to correctly locate an injury and its relative size, sometimes with great precision.

Central Structures of the Brain

The central structures of the brain include the thalamus, hypothalamus, and pituitary gland. The hippocampus is located in the temporal lobe but participates in the processing of memory and emotions and is interconnected with central structures. Other structures are the basal ganglia, which are made up of gray matter and include the amygdala (localized in the temporal lobe), the caudate nucleus, and the lenticular nucleus (putamen and globus pallidus). Because the caudate and putamen are structurally similar, neuropathologists have coined for them the collective term striatum.

- The thalamus integrates and relays sensory information to the cortex of the parietal, temporal, and occipital lobes. The thalamus is located in the lower central part of the brain (that is, upper part of the brainstem) and is located medially to the basal ganglia. The brain hemispheres lie on the thalamus. Other roles of the thalamus include motor and memory control.
- The hypothalamus, located below the thalamus, regulates automatic functions such as appetite, thirst, and body temperature. It also secretes hormones that stimulate or suppress the release of hormones (for example, growth hormones) in the pituitary gland.
- The pituitary gland is located at the base of the brain. The pituitary gland produces hormones that control many functions of other endocrine glands. It regulates the production of many hormones that have a role in growth, metabolism, sexual response, fluid and mineral balance, and the stress response.
- The ventricles are cerebrospinal fluid-filled cavities in the interior of the cerebral hemispheres.

Base of the Brain

The base of the brain contains the cerebellum and the brainstem. These structures serve complex functions. Below is a simplified version of these roles:

- Traditionally, the cerebellum has been known to control equilibrium and coordination and contributes to the generation of muscle tone. It has more recently become evident, however, that the cerebellum plays more diverse roles such as participating in some types of memory and exerting a complex influence on musical and mathematical skills.
- The brainstem connects the brain with the spinal cord. It includes the midbrain, the pons, and the medulla oblongata. It is a compact structure in which multiple pathways traverse from the brain to the spinal cord and vice versa. For instance, nerves that arise from cranial nerve nuclei are involved with eye movements and exit the brainstem at several levels. Damage to the brainstem can therefore affect a number of bodily functions. For instance, if the corticospinal tract is injured, a loss of motor function (paralysis) occurs, and it may be accompanied by other neurologic deficits, such as eye movement abnormalities, which are reflective of injury to cranial nerves or their pathways in the brainstem.
- The midbrain is located below the hypothalamus. Some cranial nerves that are also responsible for eye muscle control exit the midbrain.
- The pons serves as a bridge between the midbrain and the medulla oblongata. The pons also contains the nuclei and fibers of nerves that serve eye muscle control, facial muscle strength, and other functions.
- The medulla oblongata is the lowest part of the brainstem and is interconnected with the cervical spinal cord. The medulla oblongata also helps control involuntary actions, including vital processes, such as heart rate, blood pressure, and respiration, and it carries the corticospinal (that is, motor function) tract toward the spinal cord.

Peripheral Nervous System Function

Nerve fibers that exit the brainstem and spinal cord become part of the peripheral nervous system. Cranial nerves exit the brainstem and function as peripheral nervous system mediators of many functions, including eye movements, facial strength and sensation, hearing, and taste.

The optic nerve is considered a cranial nerve but it is generally affected in a disease of the central nervous system known as multiple sclerosis, and, for this and other reasons, it is thought to represent an extension of the central nervous system apparatus that controls vision. In fact, doctors can diagnose inflammation of the head of the optic nerve by using an ophthalmoscope, as if the person's eyes were a window into the central nervous system.

Nerve roots leave the spinal cord to the exit point between two vertebrae and are named according to the spinal cord segment from which they arise (a cervical eight nerve root arises from cervical spinal cord segment eight). Nerve roots are located anterior with relation to the cord if efferent (for example, carrying input toward limbs) or posterior if afferent (for example, to spinal cord). Fibers that carry motor input to limbs and fibers that bring sensory information from the limbs to the spinal cord grow together to form a mixed (motor and sensory) peripheral nerve. Some lumbar and all sacral nerve roots take a long route downward in the spinal canal before they exit in a bundle that resembles a horse's tail, hence its name, cauda equina.

The spinal cord is also covered, like the brain, by the pia matter and the arachnoid membranes. The cerebrospinal fluid circulates around the pia and below the outer arachnoid, and this space is also termed the subarachnoid space. The roots of the cauda equina and the rootlets that make up the nerve roots from higher segments are bathed in cerebrospinal fluid. The dura surrounds the pia-arachnoid of the spinal cord, as it does for the brain.

The neuroanatomical basis for multiple brain functions is oversimplified in the above summary. A good example is the neuroanatomical substrate for memory function. Damage to multiple areas of the brain can affect memory. These include structures such as the frontal and temporal lobes, the thalamus, the cerebellum, the putamen, mamillary bodies and fornix, and a convolution above the corpus callosum known as the cingulate gyrus. These structures are variably involved in complex processes such as the storing, processing, or retrieval of memories.

Spinal Cord Nerves

The spinal cord is an extension of the brain and is surrounded by the vertebral bodies that form the spinal column (see Multimedia File 3). The central structures of the spinal cord are made up of gray matter (nerve cell bodies), and the external or surrounding tissues are made up of white matter. Within the spinal cord are 30 segments that belong to 4 sections (cervical, thoracic, lumbar, sacral), based on their location:

- **Eight cervical segments:** These transmit signals from or to areas of the head, neck, shoulders, arms, and hands.
- **Twelve thoracic segments:** These transmit signals from or to part of the arms and the anterior and posterior chest and abdominal areas.
- **Five lumbar segments:** These transmit signals from or to the legs and feet and some pelvic organs.
- **Five sacral segments:** These transmit signals from or to the lower back and buttocks, pelvic organs and genital areas, and some areas in the legs and feet.
- **A coccygeal remnant** is located at the bottom of the spinal cord.

The Peripheral Nervous System

What exactly is the peripheral nervous system and what role does it play in the body? First, it is important to realize that the nervous system is divided into two parts: the central nervous system and the peripheral nervous system. The central nervous system includes the brain and spinal cord, while the peripheral nervous system includes all of the nerves that branch out from the brain and spinal cord and extend to other parts of the body including muscles and organs. Each part of the system plays a vital role in how information is communicated throughout the body.

What Is the Peripheral Nervous System?

The peripheral nervous system (PNS) is the division of the nervous system containing all the nerves that lie outside of the central nervous system (CNS). The primary role of the PNS is to connect the CNS to the organs, limbs, and skin. These nerves extend from the central nervous system to the outermost areas of the body. The peripheral system allows the brain and spinal cord to receive and send information to other areas of the body, which allows us to react to stimuli in our environment.

The nerves that make up the peripheral nervous system are actually the axons or bundles of axons from nerve cells or neurons. In some cases, these nerves are very small but some nerve bundles are so large that they can be easily seen by the human eye. The peripheral nervous system itself is divided into two parts: the somatic nervous system and the autonomic nervous system. Each of these components plays a critical role in how the peripheral nervous system operates.

The Somatic Nervous System

The somatic system is the part of the peripheral nervous system responsible for carrying sensory and motor information to and from the central nervous system. The somatic nervous system derives its name from the Greek word soma, which means "body." The somatic system is responsible for transmitting sensory information as well as for voluntary movement. This system contains two major types of neurons:

- **Motor neurons:** Also called efferent neurons, motor neurons carry information from the brain and spinal cord to muscle fibers throughout the body. These motor neurons allow us to take physical action in response to stimuli in the environment.
- **Sensory neurons:** Also called afferent neurons, sensory neurons carry information from the nerves to the central nervous system. It is these sensory neurons that allow us to take in sensory information and send it to the brain and spinal cord. In other words, it is the autonomic system that controls aspects of the body that are usually not under voluntary control. This system allows these functions to take place without needing to consciously think about them happening. The autonomic system is further divided into two branches:
- **Parasympathetic system:** This helps maintain normal body functions and conserve physical resources. Once a threat has passed, this system will slow the heart rate, slow breathing, reduce blood flow to muscles, and constrict the pupils. This allows us to return our bodies to a normal resting state.
- **Sympathetic system:** By regulating the flight-or-fight response,¹ the sympathetic system prepares the body to expend energy to respond to environmental threats. When action is needed, the sympathetic system triggers a response by accelerating heart rate, increasing breathing rate, boosting blood flow to muscles, activating sweat secretion, and dilating the pupils.

Structure

The peripheral nervous system is itself classified into two systems: the somatic nervous system and the autonomic nervous system. Each system contains afferent and efferent components. The **afferent** arm consists of sensory (or afferent) neurons running from receptors for stimuli to the CNS. Afferent nerves detect the external environment via receptors for external stimuli such as sight, hearing, pressure, temperature etc. Afferent nerves exist in both the somatic and autonomic nervous systems as both can use sensory signals to alter their activity.

The **efferent** arm consists of motor (or efferent) neurons running from the CNS to the effector organ. Effector organs can either be muscles or glands. The efferent nerves of the **somatic nervous system** of the PNS is responsible for voluntary, conscious control of skeletal muscles (effector organ) using motor (efferent) nerves.

The efferent nerves of the **autonomic (visceral) nervous system** control the visceral functions of the body. These visceral functions include the regulation of heart rate, digestion, salivation, urination, digestion and many more. The efferent arm of this system can be further subdivided into parasympathetic motor or sympathetic motor. The **enteric nervous system** is sometimes classified as a separate component of the autonomic nervous system and is sometimes even considered a third independent branch of the PNS.

Neuroplasticity:

The brain's ability to reorganize itself by forming new neural connections throughout life. Neuroplasticity allows the neurons (nerve cells) in the brain to compensate for injury and disease and to adjust their activities in response to new situations or to changes in their environment. Brain

reorganization takes place by mechanisms such as "axonal sprouting" in which undamaged axons grow new nerve endings to reconnect neurons whose links were injured or severed. Undamaged axons can also sprout nerve endings and connect with other undamaged nerve cells, forming new neural pathways to accomplish a needed function.

For example, if one hemisphere of the brain is damaged, the intact hemisphere may take over some of its functions. The brain compensates for damage in effect by reorganizing and forming new connections between intact neurons. In order to reconnect, the neurons need to be stimulated through activity. Neuroplasticity sometimes may also contribute to impairment. For example, people who are deaf may suffer from a continual ringing in their ears (**tinnitus**), the result of the rewiring of brain cells starved for sound. For neurons to form beneficial connections, they must be correctly stimulated. Neuroplasticity is also called brain plasticity or brain malleability.

Types Of Cortical Neuroplasticity

Developmental plasticity occurs most profoundly in the first few years of life as neurons grow very rapidly and send out multiple branches, ultimately forming too many connections. In fact, at birth, each neuron in the cerebral cortex (the highly convoluted outer layer of the cerebrum) has about 2,500 synapses. By the time an infant is two or three years old, the number of synapses is approximately 15,000 per neuron. This amount is about twice that of the average adult brain. The connections that are not reinforced by sensory stimulation eventually weaken, and the connections that are reinforced become stronger. Eventually, efficient pathways of neural connections are carved out.

Throughout the life of a human or other mammal, these neural connections are fine-tuned through the organism's interaction with its surroundings. During early childhood, which is known as a critical period of development, the nervous system must receive certain sensory inputs in order to develop properly. Once such a critical period ends, there is a precipitous drop in the number of connections that are maintained, and the ones that do remain are the ones that have been strengthened by the appropriate sensory experiences. This massive "pruning back" of excess synapses often occurs during adolescence.

Homologous area adaptation

Homologous area adaptation occurs during the early critical period of development. If a particular brain module becomes damaged in early life, its normal operations have the ability to shift to brain areas that do not include the affected module. The function is often shifted to a module in the matching, or homologous, area of the opposite brain hemisphere. The downside to this form of neuroplasticity is that it may come at costs to functions that are normally stored in the module but now have to make room for the new functions. An example of this is when the right parietal lobe (the parietal lobe forms the middle region of the cerebral hemispheres) becomes damaged early in life and the left parietal lobe takes over visuospatial functions at the cost of impaired arithmetical functions, which the left parietal lobe usually carries out exclusively. Timing is also a factor in this process, since a child learns how to navigate physical space before he or she learns arithmetic.

Compensatory masquerade

The second type of neuroplasticity, compensatory masquerade, can simply be described as the brain figuring out an alternative strategy for carrying out a task when the initial strategy cannot be followed due to impairment. One example is when a person attempts to navigate from one

location to another. Most people, to a greater or lesser extent, have an intuitive sense of direction and distance that they employ for navigation. However, a person who suffers some form of brain trauma and impaired spatial sense will resort to another strategy for spatial navigation, such as memorizing landmarks. The only change that occurs in the brain is a reorganization of preexisting neuronal networks.

Cross-modal reassignment

The third form of neuroplasticity, cross-modal reassignment, entails the introduction of new inputs into a brain area deprived of its main inputs. A classic example of this is the ability of an adult who has been blind since birth to have touch, or somatosensory, input redirected to the visual cortex in the occipital lobe (region of the cerebrum located at the back of the head) of the brain—specifically, in an area known as V1. Sighted people, however, do not display any V1 activity when presented with similar touch-oriented experiments. This occurs because neurons communicate with one another in the same abstract “language” of electrochemical impulses regardless of sensory modality. Moreover, all the sensory cortices of the brain—visual, auditory, olfactory (smell, gustatory (taste and somatosensory)—have a similar six-layer processing structure. Because of this, the visual cortices of blind people can still carry out the cognitive functions of creating representations of the physical world but base these representations on input from another sense—namely, touch. This is not, however, simply an instance of one area of the brain compensating for a lack of vision. It is a change in the actual functional assignment of a local brain region.

Map expansion

Map expansion, the fourth type of neuroplasticity, entails the flexibility of local brain regions that are dedicated to performing one type of function or storing a particular form of information. The arrangement of these local regions in the cerebral cortex is referred to as a “map.” When one function is carried out frequently enough through repeated behaviour or stimulus, the region of the cortical map dedicated to this function grows and shrinks as an individual “exercises” this function. This phenomenon usually takes place during the learning and practicing of a skill such as playing a musical instrument. Specifically, the region grows as the individual gains implicit familiarity with the skill and then shrinks to baseline once the learning becomes explicit. (Implicit learning is the passive acquisition of knowledge through exposure to information, whereas explicit learning is the active acquisition of knowledge gained by consciously seeking out information.) But as one continues to develop the skill over repeated practice, the region retains the initial enlargement.

Map expansion neuroplasticity has also been observed in association with pain in the phenomenon of phantom limb syndrome. The relationship between cortical reorganization and phantom limb pain was discovered in the 1990s in arm amputees. Later studies indicated that in amputees who experience phantom limb pain, the mouth brain map shifts to take over the adjacent area of the arm and hand brain maps. In some patients, the cortical changes could be reversed with peripheral anesthesia. What is Methods of Physiological Psychology: Invasive methods – Anatomical methods, degeneration techniques, lesion techniques, chemical methods, microelectrode studies. Non-invasive methods – EEG, Scanning methods?

Methods of Physiological Psychology: Invasive methods – Anatomical methods, degeneration techniques, lesion techniques, chemical methods, microelectrode

studies. Non-invasive methods – EEG, Scanning methods

Methods of Physiological Psychology: Invasive methods

As a generally noninvasive subset of neuroscience methods, psychophysiological methods are used across a variety of disciplines in order to answer diverse questions about psychology, both mental events and behavior. Many different techniques are classified as psychophysiological. Each technique has its strengths and weaknesses, and knowing them allows researchers to decide what each offers for a particular question. Additionally, this knowledge allows research consumers to evaluate the meaning of the results in a particular experiment.

Learning Objectives

- Learn what qualifies as psychophysiology within the broaderfield of neuroscience.
- Review and compare several examples of psychophysiologicalmethods.
- Understand advantages and disadvantages of differentpsychophysiological methods.

History

In the mid-19th century, a railroad worker named Phineas Gage was in charge of setting explosive charges for blasting through rock in order to prepare a path for railroad tracks. He would lay the charge in a hole drilled into the rock, place a fuse and sand on topof the charge, and pack it all down using a tamping iron (a solid iron rod approximately one yard long and a little over an inch in diameter). On a September afternoon when Gage was performing this task, his tamping iron caused a spark that set off the explosive prematurely, sending the tamping iron flying through the air.

Unfortunately for Gage, his head was above the hole and the tamping iron entered the side of his face, passed behind his left eye, and exited out of the top of his head, eventually landing 80 feet away. Gage lost a portion of his left frontal lobe in the accident, but survived and lived for another 12 years. What is most interesting from a psychological perspective is that Gage’s personality changedas a result of this accident. He became more impulsive, he had trouble carrying out plans, and, at times, he engaged in vulgarprofanity, which was out of character. This case study leads one to believe that there are specific areas of the brain that are associated with certain psychological phenomena. When studying psychology, the brain is indeed an interesting source of information. Although it would be impossible to replicate the type of damage done to Gagein the name of research, methods have developed over the years that are able to safely measure different aspects of nervous system activity in order to help researchers better understand psychologyas well as the relationship between psychology and biology.

Introduction

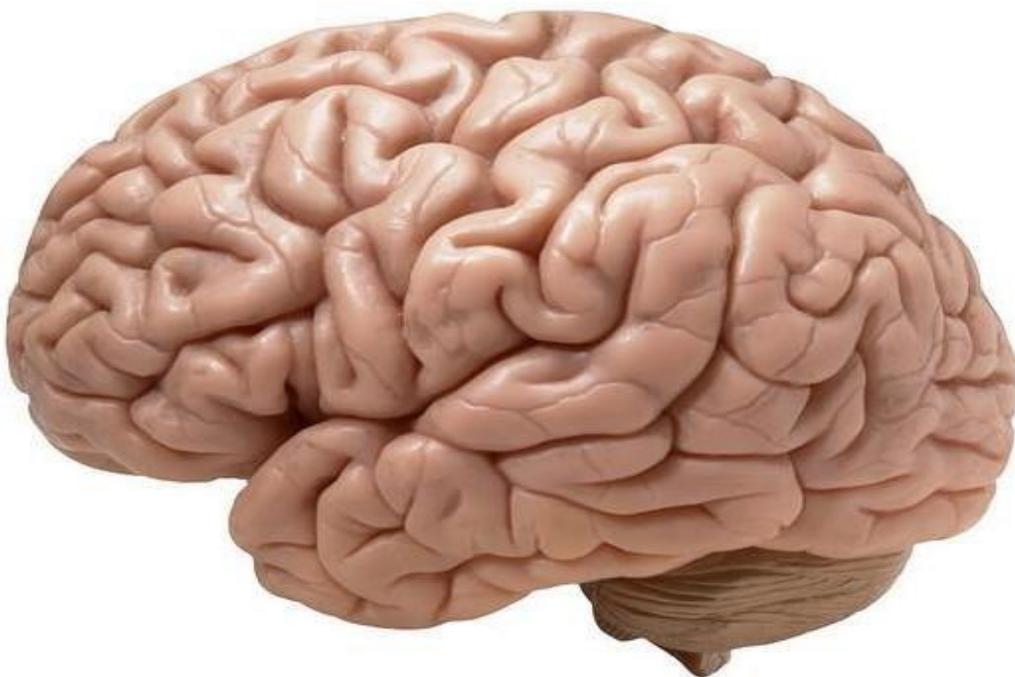

Psychophysiology is defined as any research in which the dependent variable (what the researcher measures) is a physiological measure, and the independent variable (what the researcher manipulates) is behavioral or mental. In most cases the work is done noninvasively with awake human participants. Physiological measures take many forms and range from blood flowor neural activity in the brain to heart rate variability and eye movements. These measures can provide information about processes including emotion, cognition, and the interactions between them. In these ways, physiological measures offer a very flexible set of tools for researchers to answer

questions about behavior, cognition, and health.

Psychophysiological methods are a subset of the very large domain of **neuroscience methods**. Many neuroscience methods are **invasive**, such as involving **lesions** of neural tissue, injection of neutrally active chemicals, or manipulation of neural activity via electrical stimulation. The present survey emphasizes **noninvasive** methods widely used with human subjects.

Crucially, in examining the relationship between physiology and overt behavior or mental events, psychophysiology does not attempt to replace the latter with the former. As an example, happiness is a state of pleasurable contentment and is associated with various physiological measures, but one would not say that those physiological measures are happiness. We can make inferences about someone's cognitive or emotional state based on his or her self-report, physiology, or overt behavior. Sometimes our interest is primarily in inferences about internal events and sometimes primarily in the physiology itself. Psychophysiology addresses both kinds of goals.

Central Nervous System (CNS)

The adult human brain only makes up about 2% (i.e. \approx 3 pounds) of the average adult's weight, but it uses 20% of the body's energy! [Image: _DJ_, <https://goo.gl/eHPH5L>, CC BY-SA 2.0, <https://goo.gl/rxiUsF>] This module provides an overview of several popular psychophysiological methods, though it is far from exhaustive. Each method can draw from a broad range of data-analysis strategies to provide an even more expansive set of tools. The psychophysiological methods discussed below focus on the central nervous system. Structural magnetic resonance imaging (sMRI) is a noninvasive technique that allows researchers and clinicians to view anatomical structures within a human. The participant is placed in a magnetic field that may be 66,000 times greater than the Earth's magnetic field, which causes a small portion of the atoms in his or her body to line up in the same direction. The body is then pulsed with low-energy radio frequencies that are absorbed by the atoms in the body, causing them to tip over.

As these atoms return to their aligned state, they give off energy in the form of harmless electromagnetic radiation, which is measured by the machine. The machine then transforms the measured energy into a three-dimensional picture of the tissue within the body. In psychophysiology research, this image may be used to compare the size of structures in different groups of people (e.g., are areas associated with pleasure smaller in individuals with depression?) or to increase the accuracy of spatial locations as measured with functional magnetic resonance imaging (fMRI).

Peripheral Nervous System

The psychophysiological methods discussed above focus on the central nervous system. Considerable research has also focused on the **peripheral nervous system**. These methods include skin conductance, cardiovascular responses, muscle activity, pupil diameter, eye blinks, and eye movements. Skin conductance, for example, measures the electrical conductance (the inverse of resistance) between two points on the skin, which varies with the level of moisture. Sweat glands are responsible for this moisture and are controlled by the **sympathetic nervous system (SNS)**. Increases in skin conductance can be associated with changes in psychological activity. For example, studying skin conductance allows a researcher to investigate whether psychopaths react to fearful pictures in a normal way. Skin conductance provides relatively poor temporal resolution, with the entire response typically taking several seconds to emerge and resolve. However, it is an easy way to measure SNS response to a variety of stimuli.

Cardiovascular measures include heart rate, heart rate variability, and blood pressure. The heart is innervated by the **parasympathetic nervous system (PNS)** and SNS. Input from the PNS decreases heart rate and contractile strength, whereas input from the SNS increases heart rate and contractile strength. Heart rate can easily be monitored using a minimum of two electrodes and is measured by counting the number of heartbeats in a given time period, such as one minute, or by assessing the time between successive heartbeats. Psychological activity can prompt increases and decreases in heart rate, often in less than a second, making heart rate a sensitive measure of cognition.

In recent years a wide range of experimental methods has become available to advance the understanding of the structure and function of human auditory cortex. Among the noninvasive approaches are electroencephalography (EEG) and magnetoencephalography (MEG), which record cortical activity at a distance using electrodes glued to the scalp or from sensors distributed around the head, and brain-imaging methods based on changes in cerebral blood flow, including positron emission tomography (PET) and functional magnetic resonance imaging (fMRI). Invasive approaches involve electrophysiological recording from and electrically stimulating or locally cooling cortex directly, usually in neurosurgical patients undergoing diagnosis and treatment of medically intractable epilepsy.

Brief Historic Overview

Progress in invasive human brain research has paralleled advances in the field of functional neurosurgery, electronic engineering, computer technology, and signal processing. Although technical aspects of invasive human brain research have changed markedly over the years, the importance of a multidisciplinary research team, pioneered by neurosurgeon Wilder Penfield, has remained. Today, research of this kind draws heavily on the disciplines of anatomy, physiology, psychophys-

ics, neuropsychology, radiology, theoretical modeling, statistics, acoustics, signal processing, electronic engineering, and computer programming.

With the awake patient's brain exposed, Penfield and his team carefully recorded bodily movements and verbal reports of sensations evoked by an electrical stimulus delivered to a cortical site through a hand-held stimulator. The anatomical location of each stimulated cortical locus was documented on a high-resolution intraoperative photograph of the brain surface. The results provided the first direct, systematic evidence of how human cerebral cortex is functionally organized.

Contemporary Research Research Subjects

Invasive studies of auditory cortex in humans are carried out in neurosurgical patients, the vast majority of whom are being treated for medically intractable epilepsy. Epilepsy is a common neurological disorder that affects approximately 50 million people worldwide (World Health Organization, 2005). These individuals are at risk of losing consciousness suddenly and without warning and thus often are unable to operate a motor vehicle or hold a job that requires sustained vigilance and attention. There is also evidence that persistent seizure activity may lead to structural brain damage (Bonilha et al., 2006; Bernhardt et al., 2009). It is estimated that in the United States alone, more than 400,000 individuals with epilepsy continue to have seizures despite receiving appropriate medical treatment (Engel, 2001). A subset of this medically refractory patient population can be treated effectively with surgery that removes brain tissue that is the source of the seizure activity.

These patients also are ideal subjects for invasive brain research. Third, their seizure focus must be localized to a circumscribed portion of the brain that can be safely removed surgically. Making this latter determination is the most challenging aspect of the presurgical evaluation process, which includes EEG recording, anatomical magnetic resonance imaging (MRI), and formal neuropsychological testing. The patient's history and test data are discussed at a multidisciplinary epilepsy surgery conference where a consensus is sought regarding whether the patient is a candidate for surgery, and, if so, the type of operation that should be performed. Surgical patients then wishing to participate in research are given a detailed explanation of the planned research protocols and provide informed consent before becoming a "research subject" and undergoing additional "research only" preoperative testing.

Validity of Invasive Recordings

Although these invasive studies are intended to provide insights into the functional organization of normal human auditory cortex, interpreting the results obtained is done within the context of repeated seizure activity experienced by the study patients, often over periods of years, as well as the present and long-term use of multiple antiepileptic drugs. Surgical patients serving as research subjects are only those diagnosed with a focal seizure disorder. The seizure focus is typically localized to the mesial portion of the temporal lobe, including the hippocampus, where anatomical malformations have been well documented in individuals with drug resistant temporal lobe epilepsy (Gloor, 1991). Thalamic atrophy is reported to be most intense in thalamic nuclei having strong connections with limbic structures (Bonilha et al., 2006).

Epileptic discharges that occasionally invade cortex under study from a distant seizure focus are routinely detected and excluded from analyses. There is also evidence that in addition to mesial

temporal malformations there is progressive atrophy of temporopolar, orbitofrontal, insular, and parietal areas (Bernhardt et al., 2009) as well as widespread thinning of neocortex, including lateral temporal regions (Bonilha et al., 2006 ; Bernhardt et al., 2010) that are considered to be auditory or auditory-related cortex. Thus, one cannot rule out the possibility that pathological processes associated with seizure disorders influence activity recording from distant cortical sites. We also note, however, that data obtained from the auditory core in particular bear a striking resemblance to those recorded from core cortex in the monkey (Fishman et al., 2001 ; Steinschneider et al., 2005 ; Ray et al., 2008 ; Brugge et al., 2009), suggesting that functional organization and certain stimulus–response relationships found in this area have been relatively spared.

Summary

The methodology of invasive research of human auditory cortex has made tremendous progress since the early studies of Penfield and his colleagues. These developments have paralleled the strides made in developing noninvasive imaging and electrophysiological recording methods. By employing invasive and noninvasive approaches in complementary ways to studies of the functional organization of auditory cortex, the knowledge gained promises to be far greater than that obtainable by relying on any one method alone. Despite advances, however, technical shortcomings continue to impose limitations on invasive cortical electrophysiological recording and stimulation as research tools.

Chronically implanted electrode arrays are tethered to head-mounted connectors that are, in turn, connected to external electronic instruments. Current data acquisition systems and surgical techniques allow for extensive (>200 contacts) electrode coverage making the external cables bulky and sometimes uncomfortable for the patient. External electrical (power line) noise easily coupled to wires often introduces unwanted interference during recording sessions.

Wires can, and do, break, especially during seizures, resulting in loss of both clinical and research data. All of these considerations have a direct impact on the conduct and outcome of research, which in turn relate directly to patient safety and successful diagnosis of brain disorders and to successful development of neural prostheses.

Anatomical methods

Anatomy / Physiological Function X-ray picture. CAT scanning was invented in 1972 by the British engineer Godfrey N. Hounsfield and the South African (later American) physicist Alan Cromack. CAT (Computed Axial Tomography) is an x-ray procedure which combines many x-ray images with the aid of a computer to generate cross-sectional views, and when needed 3D images of the internal organs and structures of the human body. A large donut-shaped x-ray machine takes x-ray images at many different angles around the body. Those images are processed by a computer to produce cross-sectional picture of the body. In each of these pictures the body is seen as an x-ray 'slice' of the body, which is recorded on a film. This recorded image is called a tomogram.

CAT scans are performed to analyze, for example, the head, where traumatic injuries (such as blood clots or skull fractures), tumors, and infections can be identified. In the spine the bony structure of the vertebrae can be accurately defined, as can the anatomy of the spinal cord. CAT scans are also extremely helpful in defining body organ anatomy, including visualizing the liver, gallbladder, pancreas, spleen, aorta, kidneys, uterus, and ovaries. The amount of radiation a person receives during a CAT scan is minimal. In men and non-pregnant women it has not been shown to produce any adverse effects. However, doing a CAT test hides some risks. If the subject

or the patient is pregnant it maybe recommended to do another type of exam to reduce the possible risk of exposing her fetus to radiation. Also in cases of asthma or allergies it is recommended to avoid this type of scanning. Since the CAT scan requires a contrast medium, there's a slight risk of an allergic reaction to the contrast medium. Having certain medical conditions; Diabetes, asthma, heart disease, kidney problems or thyroid conditions also increases the risk of a reaction to contrast medium.

MRI

Although CAT scanning was a breakthrough, in many cases it was substituted by magnetic resonance imaging (MRI), a method of looking inside the body without using x-rays, harmful dyes or surgery. Instead, radio waves and a strong magnetic field are used in order to provide remarkably clear and detailed pictures of internal organs and tissues. MRI head side

History and Development of MRI

MRI is based on a physics phenomenon called nuclear magnetic resonance (NMR), which was discovered in the 1930s by Felix Bloch (working at Stanford University) and Edward Purcell (from Harvard University). In this resonance, magnetic field and radio waves cause atoms to give off tiny radio signals. In the year 1970, Raymond Damadian, a medical doctor and research scientist, discovered the basis for using magnetic resonance imaging as a tool for medical diagnosis. Four years later a patent was granted, which was the world's first patent issued in the field of MRI. In 1977, Dr. Damadian completed the construction of the first "whole-body" MRI scanner, which he called the "Indomitable". The medical use of magnetic resonance imaging has developed rapidly. The first MRI equipment in healthcare was available at the beginning of the 1980s. In 2002, approximately 22,000 MRI scanners were in use worldwide, and more than 60 million MRI examinations were performed.

A full size MRI-Scanner

Common Uses of the MRI Procedure Because of its detailed and clear pictures, MRI is widely used to diagnose sports-related injuries, especially those affecting the knee, elbow, shoulder, hip and wrist. Furthermore, MRI of the heart, aorta and blood vessels is a fast, non-invasive tool for diagnosing artery disease and heart problems. The doctors can even examine the size of the heart-chambers and determine the extent of damage caused by a heart disease or a heart attack. Organs like lungs, liver or spleen can also be examined in high detail with MRI. Because no radiation exposure is involved, MRI is often the preferred diagnostic tool for examination of the male and female reproductive systems, pelvis and hips and the bladder.

Risks

An undetected metal implant may be affected by the strong magnetic field. MRI is generally avoided in the first 12 weeks of pregnancy. Scientists usually use other methods of imaging, such as ultrasound, on pregnant women unless there is a strong medical reason to use MRI.

PPT MR III

Reconstruction of nerve fibers

There has been some further development of the MRI: The DT-MRI (diffusion tensor magnetic resonance imaging) enables the measurement of the restricted diffusion of water in tissue and gives a 3-dimensional image of it. History: The principle of using a magnetic field to measure

diffusion was already described in 1965 by the chemist Edward O. Stejskal and John E. Tanner. After the development of the MRI, Michael Moseley introduced the principle into MR Imaging in 1984 and further fundamental work was done by Dennis LeBihan in 1985. In 1994 the engineer Peter J. Basser published optimized mathematical models of an older diffusion-tensor model. This model is commonly used today and supported by all new MRI-devices.

The DT-MRI technique takes advantage of the fact that the mobility of water molecules in brain tissue is restricted by obstacles like cell membranes. In nerve fibers mobility is only possible alongside the axons. So measuring the diffusion gives rise to the course of the main nerve fibers. All the data of one diffusion-tensor are too much to process in a single image, so there are different techniques for visualization of different aspects of this data: - Cross section images - tractography (reconstruction of main nerve fibers) - tensor glyphs (complete illustration of diffusion-tensor information) The diffusion manner changes by patients with specific diseases of the central nervous system in a characteristic way, so they can be discerned by the diffusion-tensor technique. Diagnosis of apoplectic strokes and medical research of diseases involving changes of the white matter, like Alzheimer's disease or Multiple sclerosis are the main applications. Disadvantages of DT-MRI are that it is far more time consuming than ordinary MRI and produces large amounts of data, which first have to be visualized by the different methods to be interpreted.

fMRI

The fMRI (Functional Magnetic Resonance) Imaging is based on the Nuclear magnetic resonance (NMR). The way this method works is the following: All atomic nuclei with an odd number of protons have a nuclear spin. A strong magnetic field is put around the tested object which aligns all spins parallel or antiparallel to it. There is a resonance to an oscillating magnetic field at a specific frequency, which can be computed in dependence on the atom type (the nuclei's usual spin is disturbed, which induces a voltage $s(t)$, afterwards they return to the equilibrium state). At this level different tissues can be identified, but there is no information about their location. Consequently the magnetic field's strength is gradually changed, thereby there is a correspondence between frequency and location and with the help of Fourier analysis we can get one-dimensional location information. Combining several such methods as the Fourier analysis it is possible to get a 3D image.

fMRI picture

The central idea for fMRI is to look at the areas with increased blood flow. Hemoglobin disturbs the magnetic imaging, so areas with an increased blood oxygen level dependant (BOLD) can be identified. Higher BOLD signal intensities arise from decreases in the concentration of deoxygenated haemoglobin. An fMRI experiment usually lasts 1-2 hours. The subject will lie in the magnet and a particular form of stimulation will be set up and MRI images of the subject's brain are taken. In the first step a high resolution single scan is taken. This is used later as a background for highlighting the brain areas which were activated by the stimulus. In the next step a series of low resolution scans are taken over time, for example, 150 scans, one every 5 seconds. For some of these scans, the stimulus will be presented, and for some of the scans, the stimulus will be absent. The low resolution brain images in the two cases can be compared, to see which parts of the brain were activated by the stimulus. The rest of the analysis is done using a series of tools which correct distortions in the images, remove the effect of the subject moving their head during the experiment, and compare the low resolution images taken when the stimulus was off with those taken when it was on. The final statistical image shows up bright in those parts of the brain which were

activated by this experiment. These activated areas are then shown as coloured blobs on top of the original high resolution scan. This image can also be rendered in 3D.

fMRI has moderately good spatial resolution and bad temporal resolution since one fMRI frame is about 2 seconds long. However, the temporal response of the blood supply, which is the basis of fMRI, is poor relative to the electrical signals that define neuronal communication. Therefore, some research groups are working around this issue by combining fMRI with data collection techniques such as electroencephalography (EEG) or magnetoencephalography (MEG), which has much higher temporal resolution but rather poorer spatial resolution.

PET

Positron emission tomography, also called PET imaging or a PET scan, is a diagnostic examination that involves the acquisition of physiologic images based on the detection of radiation from the emission of positrons. It is currently the most effective way to check for cancer recurrences. Positrons are tiny particles emitted from a radioactive substance administered to the patient. This radiopharmaceutical is injected to the patient and its emissions are measured by a PET scanner. A PET scanner consists of an array of detectors that surround the patient. Using the gamma ray signals given off by the injected radionuclide, PET measures the amount of metabolic activity at a site in the body and a computer reassembles the signals into images. PET's ability to measure metabolism is very useful in diagnosing Alzheimer's disease, Parkinson's disease, epilepsy and other neurological conditions, because it can precisely illustrate areas where brain activity differs from the norm. It is also one of the most accurate methods available to localize areas of the brain causing epileptic seizures and to determine if surgery is a treatment option. PET is often used in conjunction with an MRI or CT scan through "fusion" to give a full three-dimensional view of an organ.

Degeneration techniques

The hippocampus was stimulated with sufficient voltage to produce four negative peaks in a response wave recorded from the dorsal septum. The peaks had latencies of 5, 12, 25 and 50 msec, respectively. Transection of the fornix body with a scalpel eliminated the entire wave complex. Removal by suction of the postsplenial gyrus, gyrus cinguli and olfactory tubercle had little or no effect on the wave complex. Bilateral electrolytic coagulation of the anterior thalamic nuclei did not affect the wave complex.

Suction removal of the suprasylvian and ectosylvian gyri eliminated the long latency responses. Following lesions in the septum and body of the fornix, degeneration was observed in the fornix longus, the ventral surface of the corpus callosum and the corona radiata. Terminals were observed in the suprasylvian and ectosylvian gyri. Small cautery lesions in these gyri resulted in degeneration in the contralateral ectosylvian gyrus, fornix longus, body and columns of the fornix, hippocampus, mamillary body and thalamus. Degeneration including terminals was also seen in other limbic structures. We conclude that the hippocampus, in addition to its direct connections to the septum, has indirect projection to the septum via the suprasylvian and ectosylvian gyri.

The corticopetal connections are perhaps collaterals of other direct projection targets of the hippocampus to the septum, mamillary body, and anterior nuclei. Direct corticofugal connections to the septum, hippocampus and other structures are collaterals from direct contralateral cortico-cortical projections of the suprasylvian and ectosylvian gyri. Such connections perhaps influence

overt behavior by mediating secondary cues; or exert an influence on drive mechanisms through the posterior hypothalamus.

Lesion method

In the lesion method, patients with brain damage are examined to determine which brain structures are damaged and how this influences the patient's behavior. Researchers attempt to correlate a specific brain area to an observed behavior by using reported experiences and research observations. Researchers may conclude that the loss of functionality in a brain region causes behavioral changes or deficits in task performance. For example, a patient with a lesion in the parietal-temporal-occipital association area will exhibit agraphia, a condition in which he/she is not able to write, despite having no deficits in motor ability. If damage to a particular brain region (structure X) is shown to correlate with a specific change in behavior (behavior Y), researchers may deduce that structure X has a relation to behavior Y.

In humans, lesions are most often caused by tumors or strokes. Through current brain imaging technologies, it is possible to determine which area was damaged during a stroke. Loss of function in the stroke victim may then be correlated with that damaged brain area. While lesion studies in humans have provided key insights into brain organization and function, lesions studies in animals offer many advantages.

First, animals used in research are reared in controlled environmental conditions that limit variability between subjects. Secondly, researchers are able to measure task performance in the same animal, before and after a lesion. This allows for within-subject comparison. And third the control groups can be watched who either did not undergo surgery or who did have surgery in another brain area. These benefits also increase the accuracy of the hypothesis being tested which is more difficult in human research because the before-after comparison and control experiments drop out.

Visualization of iron rod passing through brain of Phineas Gage

To strengthen conclusions regarding a brain area and task performance, researchers may perform double dissociation. The goal of this method is to prove that two dissociations are independent. Through comparison of two patients with differing brain damage and contradictory disease patterns, researchers may localize different behaviors to each brain area. Broca's area is a region of the brain responsible for language processing, comprehension and speech production. Patients with a lesion in Broca's area will exhibit Broca's aphasia or non-fluent aphasia. These patients are unable to speak fluently; a sentence produced by a patient with damage to the Broca's area may sound like: "I ... er ... wanted ... ah ... well ... I ... wanted to ... er ... go surfing ... and ..er ... well...". On the other hand, Wernicke's area is responsible for speech comprehension. A patient with a lesion in this area has Wernicke's aphasia. They may be able to produce language, but lack the ability to produce meaningful sentences. Patients may produce 'word salad': " I then did this chingo for some hours after my dazi went through meek and been sharko". Patients with Wernicke's aphasia are often unaware of speech deficits and may believe that they are speaking properly.

Certainly one of the famous "lesion" cases was that of Phineas Gage. On 13 September 1848 Gage, a railroad construction foreman, was using an iron rod to tamp an explosive charge into a body of rock when premature explosion of the charge blew the rod through his left jaw and out the

top of his head. Miraculously, Gage survived, but reportedly underwent a dramatic personality change as a result of destruction of one or both of his frontal lobes. The uniqueness of Gage case (and the ethical impossibility of repeating the treatment in other patients) makes it difficult to draw generalizations from it, but it does illustrate the core idea behind the lesion method. Further problems stem from the persistent distortions in published accounts of Gage—see the Wikipedia article Phineas Gage.

Chemical methods

Lesion method

In the lesion method, patients with brain damage are examined to determine which brain structures are damaged and how this influences the patient's behavior. Further problems stem from the persistent distortions in published accounts of Gage—see the Wikipedia article Phineas Gage.

- Most commonly used technique today.
- Instead of an electrode, use a cannula or tube.
- Allows you to place chemicals in place where they can kill or influence neurons.

Neurotoxins

- 6-Hydroxydopamine (6-HDA)
- Destroys dopamine neurons but leaves other neurons alone.
- Advantage: Allows you to only kill one type of neuron.
- Kanic Acid • Destroys somas (cell bodies) of neurons, but leaves axon tracts from other neurons alone.

Advantage:

Can kill neurons in one area, but does not disturb neuron tracts from other areas

Chemical Stimulation Techniques.

- Are the opposite of chemical lesioning
- Researcher may stimulate neurons by putting in a neurotransmitter.
- May also put in agonists (analogs of neurotransmitters that behave like them).
- May put in compounds with unknown effects.
- General Cannulation Procedures
- Make a trephine hole.
- Insert cannula with stereotaxic device.
- Cement in place with dental cement.
- Allow animal to recover and behave normally.
- Later, deliver compound by injection (usually when the animal is behaving).
- Observe the animal.

Disadvantage

- Over time the area fills up with the chemical.
- Solution: Use a push-pull technique.

Microelectrode studies

Microelectrodes are electrodes with tip areas of the order of micrometers, i.e., so small that they do not induce significant damage in the sample to be tested. Such requirements are especially important in living tissue, where microelectrodes have found their widest application; for intracellular recordings tip diameters less than 1 μm are required. Microelectrodes can also be used in combination with recent techniques of molecular biology.

Microelectrodes are basically of four types: glass micropipettes, ion-selective microelectrodes, solid-state microelectrodes, and enzyme microelectrodes (Figure 1). Glass micropipettes are used to record steady-state (DC) and alternating (AC) electrical potentials. If the glass micropipette is plugged with an ion-selective membrane, the microelectrode will record a potential that is proportional to the external activity of the ion to which the membrane is sensitive. Metal microelectrodes are well suited to recording AC potentials in situations where mechanical strength is required. Metal microelectrodes can also be used for cyclic voltammetry or amperometry purposes. If a metal microelectrode made from an inert metal or carbon is maintained at a given potential, the current can only pass the solution–electrode interphase if electrons can be provided or taken up by the chemical processes at the electrode surface. In cyclic voltammetry the voltage between the metal microelectrode and the reference electrode is varied in a cyclical manner. The voltage at which current can flow and the magnitude of the currents will characterize the chemical composition of the external media. Ambient oxygen concentrations can be measured in this way as the current flow obtained at a voltage of 600 mV relative to an Ag/AgCl reference electrode. If the electrode is prepared with specific enzymes attached to the tip area, it can be used to record substrates that in themselves do not participate in redox processes, e.g., glucose.

Calcium in Living Cells

Microelectrode Pulling and Silanization MEs can be prepared “on-demand” and in “batch” methods. The first method consists in preparing (i.e., pulling and silanizing) MEs on the experimental day, which has the obvious advantage of having “freshly” prepared electrodes and of being able to manufacture as many as desired a day. Protocols have been described (reviewed in Ammann, 1986). The batch method that we use consists of preparing a batch of MEs that can be kept for several days in a dry, dust-proof container. MEs are pulled on a programmable horizontal stage puller (Model P80 PC or comparable, Sutter Instruments, USA). By trial-and-error, and according to the type of biological preparations studied, a satisfactory shape of ME can be found. However, several aspects of ME pulling have to be taken into account when designing its shape.

As ion-selective MEs have an intrinsically high resistance (i.e., > 50–100 G Ω), the signal-to-noise ratio has to be minimized. This can be achieved in two ways: the first, and most obvious, is to increase the tip diameter, within certain limits, which are dictated by the size of the cell type. In our case, we impale cardiac cells in whole muscle. Cell length is typically between 50 and 150 μm and tip diameters less than 0.5 μm are needed. However, there is a trade-off between tip diameter and detection limit of the electrode (see below).

That is, increasing tip diameter improves electrode response (in terms of detection limit and speed of response), but is more likely to damage the cell during impalement. Another simple way to decrease the resistance is to decrease the length of the ME shank. This further helps to reduce

capacitative artifacts, that are encountered when the level of physiological solution fluctuates in the experimental bath (Vaughan-Jones and Kaila, 1986), and also helps electrolyte filling (see below). In contracting muscular preparations, the shank should also possess some flexibility to avoid dislodging of the ME during a contraction.

Electrochemical arrays

Microelectrodes are employed to induce electrochemical reactions resulting in the production of an acid, which is required to iteratively deblock the 5'-DMTr groups of growing DNA chains (Egeland and Southern, 2005). The acid is produced only at specified sites by electrochemical oxidation of hydroquinone using individually addressable microelectrodes. As shown in Figure 12, the diffusion of the acid to its intended location on the DNA array is controlled by an adjacent cathode, which prevents the 5'-DMTr deblocking of neighboring sites by consuming any diffused acid.

Summary

MER has a long history in the experimental study and clinical treatment of movement disorders, particularly to delineate the anatomic relationships for targeting. MER offers a degree of precision unparalleled by any other implantation technology and can allow for correction of stereotactic targeting error and provide confirmation that the physiologic target has been identified. Improvements in imaging and stereotactic technology have mitigated some of these benefits, and MER may be associated with increased complexity and risk of complications without necessarily improving outcome. Although excellent outcomes have been reported with and without MER, a direct comparison has never been performed. With the advent of new technologies for intraoperative targeting, the role of MER in the stereotactic implantation of DBS electrodes is likely to continue to evolve.

Non-invasive methods – EEG

Researchers working on the field of **Neuroscience** have surely sometimes thought about this question. It might sound like Sci-Fi for the common laymen, but **neuro-implants** are a reality nowadays. In this post I would like to give an introduction to the different brain recording techniques and comment the pros and cons of **invasive vs. non-invasive recording techniques**. An **electroencephalogram (EEG)** is the recording of the brain electrical activity. A set of electrodes are placed on the scalp of the subject. This technique is **non-invasive** since no surgery is required. **EEG** is a fast and cheap technique. The main drawback is that by recording the electrical activity far away from the source (i.e. the neurones inside the skull), the signal we pick up is distorted and its amplitude reduced. Moreover **EEG** is often contaminated with artefacts.

The next technique in the increasing invasiveness scale is called **Electrocorticogram (ECoG)**. This technique requires opening the skull of the subject and placing an electrode array on the exposed brain. The quality of the signal (in terms of distortion and amplitude) is much better than **EEG**, but obviously surgery is required. In principle, this technique does not damage the brain, or at least not too much. It is often used in severe epileptic patients before undergoing surgery to localise the brain focus of the seizures.

The most invasive technique is called **deep brain recording**. In this case a **microelectrode** is placed deep inside the brain. This procedure destroys the neurones it finds in its way irreversibly. The advantage of this technique is that we can record signals from very well defined spatial loca-

tions. An important use of this technique, together with **deep brain stimulation** (i.e. rather than recording, you can also use the same electrodes to inject electrical currents), is in the treatment of Parkinson's disease patients. After stimulating deep brain areas, the patients greatly improve their motor skills.

A very interesting and popular application, the so-called **brain computer interface (BCI)**, uses brain activity to control external actuators. In order for a **BCI** to be reliable, we need a reliable brain recording.

Key Points

- Neuroimaging, or brain scanning, includes the use of various techniques to either directly or indirectly image the structure, function, or pharmacology of the brain.
- Neuroimaging falls into two broad categories: structural imaging and functional imaging.
- Electroencephalography (EEG) is used to show brain activity under certain psychological states, such as alertness or drowsiness.
- Positron emission tomography (PET) scans show brain processes by using the sugar glucose in the brain to illustrate where neurons are firing.
- Magnetic resonance imaging (MRI) scans use echo waves to discriminate among grey matter, white matter, and cerebrospinal fluid.
- Functional magnetic resonance imaging (fMRI) scans are a series of MRIs measuring brain function via a computer's combination of multiple images taken less than a second apart.

Key Terms

- **conductivity**: The ability of a material to conduct electricity, heat, fluid, or sound.
- **magnetic field**: A condition in the space around a magnet or electric current in which there is a detectable magnetic force and two magnetic poles are present.

Neuroimaging falls into two broad categories:

1. Structural imaging, which deals with the structure of the brain and the diagnosis of large-scale intracranial disease (such as a tumor), as well as injury.
2. Functional imaging, which is used to diagnose metabolic diseases and lesions on a finer scale (such as Alzheimer's disease), and also for neurological and cognitive-psychology research. Functional imaging allows the brain's information processing to be visualized directly, because activity in the involved area of the brain increases metabolism and "lights up" on the scan. Four of the most common types of brain scans are EEG, PET, MRI, and fMRI.'

Electroencephalography (EEG)

Electroencephalography (EEG) is used to show brain activity in certain psychological states, such as alertness or drowsiness. It is useful in the diagnosis of seizures and other medical problems that involve an overabundance or lack of activity in certain parts of the brain. To prepare for an EEG, electrodes are placed on the face and scalp. After placing each electrode in the right position, the electrical potential of each electrode can be measured. According to a person's state (waking, sleeping, etc.), both the frequency and the form of the EEG signal differ. Patients who suffer from epilepsy show an increase of the amplitude of firing visible on the EEG record. The disadvantage of EEG is that the electric conductivity – and therefore the measured electrical po-

tentials—may vary widely from person to person and also over time, due to the natural conductivities of other tissues such as brain matter, blood, and bones. Because of this, it is sometimes unclear exactly which region of the brain is emitting a signal.

Scanning methods Introduction

The analytical operation of miniaturized voltammetric sensors above, at, and inside cultured or isolated living cells, living cell clusters and macro- or microstructures of immobilized bio-(macro-)molecules for sensitive local determination of biological activity is a unique strategy across disciplines. The aim is to inspect, on a fundamental level, physiological, pathological and molecular life science phenomena with high spatial and temporal resolution. The output of the bioanalysis using micro- and nanoelectrode voltammetry is data and knowledge generation in support of advancements in modern personal healthcare, drug development and nutrition, all issues that are more than ever before acute for an increasingly ageing global society. Examples of foundational explorations of the tailored bioelectroanalytical methodology are the 1969 analyses of oxygen profiles in and above microbial slime and the 1973 initiation of voltammetry in brain tissue with the sensitive tips made of metal and carbon, respectively. The two decades later, the move to, for instance, electrochemical detection of distinct biological processes of chemical neurotransmission at the level of single living cells and single-vesicle exocytosis was the logical result of the accomplishment of continuous sensor and apparatus improvements. This was driven by the scientific desire and methodical necessity to extend investigations into the function of biological entities to actions within or at the smallest complete building blocks of living organisms. Selection of target cells and sensor tip positioning at or in close proximity to their membranes were initially performed in conventional electrophysiology set-ups with inverted microscopes employed for cell visualization and manually operated three-dimensional micropositioning devices used for voltammetric sensor and/or culture plate movement. However, at approximately the same time as the progression of single cell voltammetry, the invention of scanning electrochemical microscopy (SECM) occurred and the novel scanning probe system became rather quickly a favoured complementary analytical platform for the inspection and visualization of cellular activities.

In a scanning electrochemical microscope, a scanning electrochemical probe (SECM tip) is a sensitive collector of redox species as the basis of a faradaic current signal that depends on both the distance to the sample and the absence or presence of sample surface redox activity. Careful computer-controlled movement across a sample of interest and acquisition of localized SECM tip currents is performed as a function of lateral (x, y) tip positions. In the optimal case, the collected data can be used to generate an interpretable real-time replication of sample topography and/or a genuine image of spatially resolved concentration profiles of redox active species in close vicinity to the evaluated sample and with a lateral resolution that is governed roughly by the tip dimension.

A few tens of review articles are at present available on the broad topic 'SECM' and they are together a good primary source of information about the theory and practice of SECM experimentation, the technical accomplishments that helped advance SECM instrumentation and, last but not least, the many special applications in the fields of materials, energy, natural and life sciences. With special focus on biological applications of SECM several reviews are recommended.

Not considering mergers with other scanning microscopy techniques such as, among others,

atomic force microscopy (AFM), scanning ion conductance microscopy (SICM) and near-field optical scanning microscopy (NSOM), the most frequently applied operation modes of SECM are the amperometric feedback and the generator/collector (G/C) modes, with the SECM tip moved at either constant z height or at constant tip-to-sample distance across the sample surface. Here, a summary of adaptations of the various technical SECM solutions for biological, single-cell and single-molecule studies is followed by the classifications of possible applications.

A careful selection of cutting-edge articles from about the last 5 years will then be summarized with the aim of highlighting the enormous level of sophistication at which SECM works on living cells and immobilized bio-macromolecules. A discussion of the promising potentials of state-of-the-art 'biological' SECM-based detection and imaging and recommendations for near- and far-term future goals of applications of scanning miniaturized electrochemical sensors on biological cells and molecular biological entities are provided as part of the concluding section.

2. Scanning electrochemical microscopy-based live cell imaging: technical aspects, targets and potentials

Living cells are lipid double-layer membrane-confined three-dimensional small objects with heights and diameters in the low micrometre scale. They exist in primary cell cultures freshly isolated from the body tissue of interest or in secondary cell cultures as passaged constituents of cell lines. Usually, cultured living cells are used for electrophysiology experiments as seeds on thin glass coverslips or the bottom of plastic Petri dishes, with or without cell adhesion-enhancing surface layers of, for instance, poly-L-lysine. For SECM work on individual cells, careful maintenance of a suitable density of the cell population is important just to have enough healthy but distant choices. is a graphical illustration of the principles of SECM studies on single living cells.

Selections of SECM tips for the voltammetric detection of biological cell activity include bare or chemically modified micro- or nanometre diameter disc-shaped noble metal or carbon electrodes. Independent of their size, scanning SECM tips should traverse gently over the cell to be screened and with appropriate precautions. The required contactless movement in the x/y plane is possible in computer-controlled constant-height or constant-distance modes.

A typical 'bio-SECM' is mounted on the base plate of an inverted microscope with reasonable magnification to aid the visual assessment of cell quality before approach and to facilitate coarse alignment between a healthy cell of choice and the SECM tip prior to operation. Constant-distance mode cellular scanning electrochemical microscopy SECM with nanometre-sized electrochemical sensors moving at constant distance over the membranes of selected cells creates images of cell topography and offers the chance for improved resolution of cell activity at neighbouring membrane locations. Moreover, it is able to explore, for instance, the spatial heterogeneity of a cell response to external stimuli. Suitable nanodisc electrodes are obviously more difficult to fabricate and handle. A collection of recent comprehensive reviews as the source of details on nanoelectrode fabrication, their electrochemical behaviour and potential applications can be found in. The operation of nanodisc electrodes on single cells requires the preservation of a nanometre tip-to-sample working distance for the entire duration of lateral tip displacement relative to the fixed biological sample. Special feedback loop-regulated tip-to-sample distance control units were developed that use the magnitude of shear force-based dampening of intentionally induced vibrations of the nano-SECM tip as the input signal. Corresponding practical bio-SECM setups were realized with optical, piezoelectric or tuning fork-based readouts of tip vibration dampening. Exemplary accomplishments of shear force-supported constant-distance cellular bio-SECM prior to the actual period of this review are, for instance, the spatially resolved detection of neuro-

transmitter secretion from single pheochromocytoma (PC12) cells, localized measurement of stimulated NO release from adherently growing endothelial cells and simultaneous detection of the cellular expression activity of secreted alkaline phosphatase outside and green fluorescent protein inside of gene-transfected single HeLa cells. Though, currently, shear force-based feedback is the leading methodology for constant-distance SECM work on cells, the specific positioning task has also been accomplished with alternative distance-dependent signal inputs for the regulating control units.

Muscular and Glandular system: Types and functions Biological basis of Motivation: Hunger, Thirst, Sleep and Sex Biological basis of emotion: The Limbic system, Hormonal regulation of behavior Genetics and behavior: Chromosomal anomalies; Nature-Nurture controversy [Twin studies and adoption studies]

Muscular system: Types and functions

A muscle is a group of muscle tissues which contract together to produce a force. A muscle consists of fibers of muscle cells surrounded by protective tissue, bundled together many more fibers, all surrounded in a thick protective tissue. A muscle uses ATP to contract and shorten, producing a force on the objects it is connected to. There are several types of muscle, which act on various parts of the body.

Structure of Muscle

A muscle consists of many muscle tissues bundled together and surrounded by epimysium, a tough connective tissue similar to cartilage. The epimysium surrounds bundles of nerve cells that run in long fibers, called fascicles. These fascicles are surrounded by their own protective layer, the perimysium. This layer allows nerves and blood to flow to the individual fibers. Each fiber is then wrapped in an endomysium, another protective layer. As seen in the image below, a muscle is arranged in a basic pattern of bundled fibers separated by protective layers.

These layers and bundles allow different parts of a muscle to contract differently. The protective layer surrounding each bundle allows the different bundles to slide past one another as they contract. The epimysium connects to tendons, which attach to the periosteum connective tissue that surrounds bones. Being anchored to two bones allows movement of the skeleton when the muscle contracts. A different type of muscle surrounds many organs, and the epimysium connects to other connective tissues to produce forces on the organs, controlling everything from circulation to food processing.

Function of Muscle

Whether it is the largest muscle in your body or the tiny muscle controlling the movement of your eye, every muscle functions in a similar manner. A signal is sent from the brain along a bundle of nerves. The electronic and chemical message is passed quickly from nerve cell to nerve cell and finally arrives at the motor end plate. This interface between the muscle and nerve cells releases a chemical signal, acetylcholine, which tells the muscle fiber to contract. This message is distributed to all the cells in the fiber connected to the nerve.

This signal causes the myosin proteins to grab onto the actin filaments around them. These are the purple proteins in the image below. Myosin uses ATP as an energy source to crawl along the green filament, actin. As you can see, the many small heads of the myosin fibers crawling along the actin filaments effectively shortens the length of each muscle cell. The cells, which are connected end-to-end in a long fibers, contract at the same time and shorten the whole fiber. When a signal is sent to an entire muscle or group of muscles, the resulting contraction results in movement or force being applied.

A muscle can be used in many different ways throughout the body. A certain muscle might contract rarely with a lot of force, whereas a different muscle will contract continually with minimal force. Animals have developed a plethora of uses for the forces a muscle can create. Muscles have evolved for flying, swimming, and running. They have also evolved to be pumps used in the circulatory and digestive systems. The heart is a specialized muscle, which is used exclusively for pumping blood throughout the body. These different types of muscle will be discussed below.

Types of Muscle

Skeletal Muscle

When you think of a muscle, most people generally think of a skeletal muscle. The biceps, triceps, and quadriceps are all common names for muscles that body builders tend to focus on. In fact, these general muscles are often composed of many small muscles that attach to different places to give a joint its full range of motion. Skeletal muscle is a striated muscle. This means that each muscle fiber has striations, or linear marks, which can be seen when this muscle is put under a microscope. The striations correspond to the sarcomeres present in striated muscles, which are highly organized bundles of muscle cells which can contract quickly in concert.

Skeletal muscle is controlled via the somatic nervous system, also known as the voluntary nervous system. Point your finger to the ceiling. This is your somatic nervous system in action, controlling your skeletal muscles.

Cardiac Muscle

Cardiac muscle, while similar to skeletal muscle in some ways, is connected to the autonomous nervous system. This system controls vital organs such as the heart and lungs and allows us to not have to focus on pumping our heart each time it needs to beat. While there is a certain amount of conscious control we have over the autonomous nervous system, it will always kick in when we are unconscious. For instance, you can hold your breath if you like but you do not have to remember to breathe all the time. Cardiac muscle surrounds the chambers of the heart and is used to pump blood through the body.

Cardiac muscle is similar to skeletal muscle in that it is striated. Unlike skeletal muscle, cardiac muscle fibers are arranged in a branching pattern instead of a linear pattern. Both skeletal muscle and cardiac muscle need to contract quickly and often, which is why the striations can be seen.

Smooth Muscle

Unlike skeletal and cardiac muscle, smooth muscle is not striated. This is because the individual muscle cells are not perfectly aligned into sarcomeres. Instead, they are displaced throughout the fibers. This gives smooth muscle the ability to contract for longer, although the contraction happens more slowly. Consider the muscle that contracts the sphincter on your bladder. This muscle

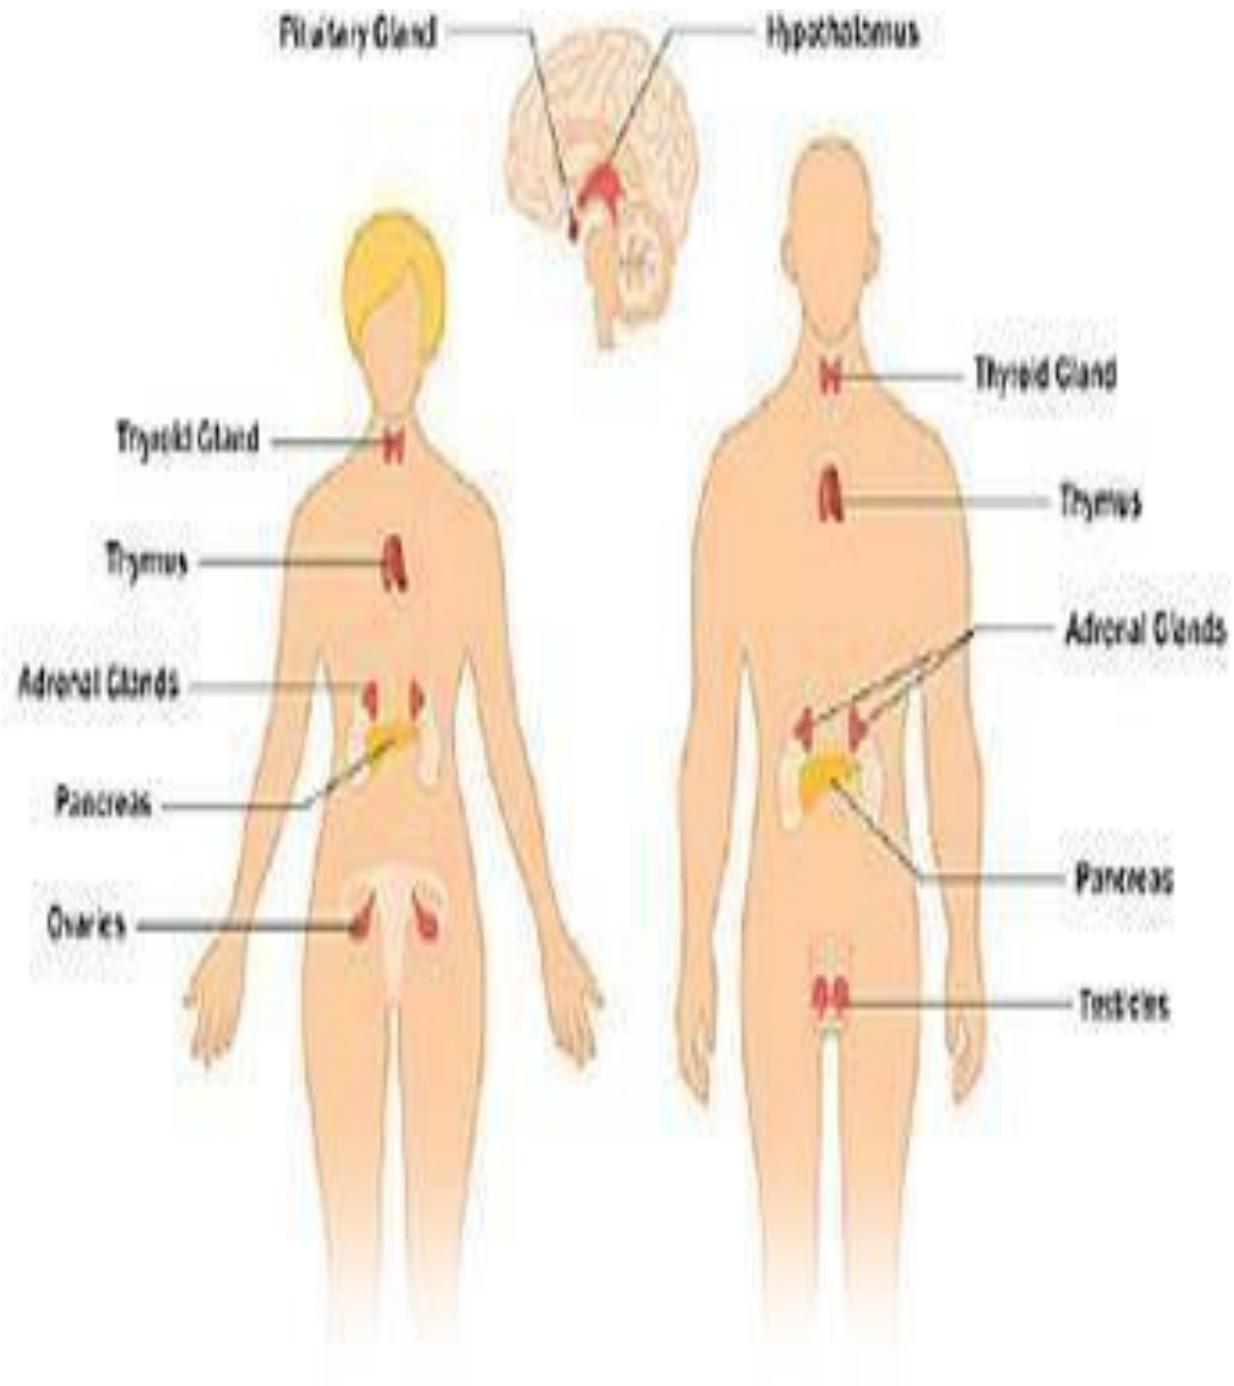

may need to stay clamped shut for hours at a time and only gets a minute of relief when you go to the bathroom. Many other smooth muscles operate in the same manner.

Like cardiac muscle, smooth muscle is mostly controlled by the autonomous nervous system. The many muscles that line your digestive tract work together to move food through the digestive system. Muscles attach to your hair follicles that allow your hairs to stand up when it's cold. Smooth muscle is almost everywhere in your body and aids in everything from circulation to digestion.

Glandular System Types and functions Endocrine System?

The endocrine system is a network of glands in your body that make the hormones that help cells talk to each other. They're responsible for almost every cell, organ, and function in your body. If your endocrine system isn't healthy, you might have problems developing during puberty, getting pregnant, or managing stress. You also might gain weight easily, have weak bones, or lack energy because too much sugar stays in your blood instead of moving into your cells where it's needed for energy.

What Is a Gland?

A gland is an organ that makes and puts out hormones that do a specific job in your body. Endocrine glands release the substances they make into your bloodstream.

Endocrine System Functions

Your endocrine system:

- Makes hormones that control your moods, growth and development, metabolism, organs, and reproduction
- Controls how your hormones are released

- Sends those hormones into your bloodstream so they can travel to other body parts

Parts of the Endocrine System

Many glands make up the endocrine system. The hypothalamus, pituitary gland, and pineal gland are in your brain. The thyroid and parathyroid glands are in your neck. The thymus is between your lungs, the adrenals are on top of your kidneys, and the pancreas is behind your stomach. Your ovaries (if you're a woman) or testes (if you're a man) are in your pelvic region.

- **Hypothalamus.** This organ connects your endocrine system with your nervous system. Its main job is to tell your pituitary gland to start or stop making hormones.
- **Pituitary gland.** This is your endocrine system's master gland. It uses information it gets from your brain to tell other glands in your body what to do. It makes many important hormones, including growth hormone; prolactin, which helps breastfeeding moms make milk; and luteinizing hormone, which manages estrogen in women and testosterone in men.
- **Pineal gland.** It makes a chemical called melatonin that helps your body get ready to go to sleep.
- **Thyroid gland.** This gland makes thyroid hormone, which controls your metabolism. If this gland doesn't make enough (a condition called hypothyroidism), everything happens more slowly. Your heart rate might slow down. You could get constipated. And you might gain weight. If it makes too much (hyperthyroidism), everything speeds up. Your heart might race. You could have diarrhea. And you might lose weight without trying.
- **Parathyroid.** This is a set of four small glands behind your thyroid. They play a role in bone health. The glands control your levels of calcium and phosphorus.
- **Thymus.** This gland makes white blood cells called T-lymphocytes that fight infection and are crucial as a child's immune system develops. The thymus starts to shrink after puberty.
- **Adrenals.** Best known for making the "fight or flight" hormone adrenaline (also called epinephrine), these two glands also make hormones called corticosteroids. They affect your metabolism and sexual function, among other things.
- **Pancreas.** This organ is part of both your digestive and endocrine systems. It makes digestive enzymes that breakdown food. It also makes the hormones insulin and glucagon. These ensure you have the right amount of sugar in your bloodstream and your cells.
- If you don't make insulin, which is the case for people with type 1 diabetes, your blood sugar levels can get dangerously high. In type 2 diabetes, the pancreas usually makes some insulin but not enough.
- **Ovaries.** In women, these organs make estrogen and progesterone. These hormones help develop breasts at puberty, regulate the menstrual cycle, and support a pregnancy.
- **Testes.** In men, the testes make testosterone. It helps them grow facial and body hair at puberty. It also tells the penis to grow larger and plays a role in making sperm.

Biological basis of Motivation

Psychologists have to gather specialized knowledge in considering the ways in which the biological structure and functions of the body affect behaviour. The biological processes are the essential part of human psychology. Our understanding of human behaviour cannot be complete without knowledge of the brain and others part of the nervous system. Biological factors are central to every sensory experience, states of consciousness, motivation and emotion, development

through out the life span and physical and psychological health and wellbeing.

Executive summary

Biological bases influence the learning, memory, and motivation. The biological factors is very important because it is controlling our behaviour .We might not be able to understand behaviour withoutan understanding of our biological makeup.

Objectives of the study:

Basically this study aims to

1. Collect information on the situation of biological factors of ourbehaviour.
2. Explore ways how to improve the behavior.
3. The function of the neuron is fundamental biological aspects ofthe body.

Findings

Biological basis of learning

Learning can be defined as a relatively permanent change in behaviour based on experience. Learning is the aspect of newthings by using past experience. Many psychologists believe learning is based on the strengthening of the neural connections between stimuli and specific patterns of muscle movements, while others said that learning involvoves changes in cognition. The existence of biological constraints is consistent with assess mental discussion of behavior. Freshly there are making suitable by alternative benefits that promote survival for organism that rapidly learn or neglecte that certain behaviors. Such as, our ability to learning avoid touching hot surfaces increase our change in survival(barkow, and tooby 1992; terry, 2003).

Neuclei areas are group of neurons forming structures with specific function. For example each of the different colour on our brainmodel represent and individual areas each with it own internal structure and function (Jeanette, J Norden Venderbilt university school and medicine). Telen-cephalon; – consists of two cerebral hemispheres the outer covering of the hemespheres is called the cortex. The cortex is responsible for voluntary action or thought and for subjective experience. Mesencephalon; – contain many small nuclei that are important to relexs, such as reflexs turning of the eyes toward the source of an objects or sound.

Metencephalon: – A structure that connect the cerebellum with the rest of the body and cerebel-lum that involved in learned skilled motor movement. The role of biological factors of learning has an example that discussed john and his associates. On one fateful evening, they ate eight hot dog. Two hour leter, they become more than just a little nauseated. As a result, it was many year until they ate another hot dog. This experience of learning to dislike hot dogs is an example of a learned taste aversion. (Garcia, Hankins and Rusiniak, 1974)

Biological basis of memory

Memory consists in remembering what has previously been learned .It would be better, however, to say that memory consists in learning, retaining and remembering what has previously been learned (psychology; Methuen and co. Ltd; London; 1964. Memory processes are distributed across the brain, relating to different information processing systems involve during the intitle exposure to a stimulus. (Friedman and Donoghue 2000). A theory stated by Canadian researchar Donald Hebb (1949) is still considerd to provide a general model of the biological processresponsible for memory (Jeffrey and Reid, 1997; Tsien, 2007). According to Hebb, each experience acti-

vates a unique pattern of neurons in the brain. These activities cause structural changes to occur in those neurons near the synaptic gaps that link them. To Hebb, these changes in the functioning of synapses in the brain, which he termed "synaptic facilitation", is the biological basis of memory.

Many different brain areas play a role in memory. The cerebellum plays a critical role in the timing of learned, skilled motor movements. Nuclei deep in the hemisphere called the basal ganglia are involved in motor programs. Many different areas of the brain contribute to attention, these include cortical areas of the reticular formation, all areas which contribute to alertness and attention awareness. The hippocampus is a part of the brain's limbic systems that plays a central role in the consolidation of memories. The hippocampus is an older cortical area involved in multiple aspects of memory. The left hippocampus is more involved in the memory of facts, episodes and words. It is also responsible for constructing. The right hippocampus is more involved in spatial memory. The hippocampus aims in the initial encoding of information that is like a kind of neurological e-mail system. (Smith, 2000; Wheeler, Petersen, and Buckner 2000; Wilson; 2000).

The results of research on the brain's role in memory reveal two ways in which STM (short term memory) and LTM (long term memory). Firstly there is extensive evidence that physical changes in neural synapses are involved in LTM and but not in STM. And secondly there is evidence that different brain structures are involved in different ways in the three stages of memory.

Biological basis of motivation

Motivation: motivation refers to the reasons why any behaviour occurs or specifically, to the forces or processes that initiate the behaviour, direct it, and contribute to its strength. (Psychology, Wadsworth Publishing Company; 1984; Eating behaviour is subject to homeostasis, as most people's weight stays within a relatively stable range. The hypothalamus in the brain is central to the regulation of food intake. Acting as a kind of internal weight thermostat, the hypothalamus calls for either greater or less food intake (Capaldi, 1996; Woods et al, 2000; Berthoud, 2000).

Thirst is the biological process as like as drinking circuits. Drinking circuits is the association of tissue, body, and neuron with in nerve and cell. It is associated with the hypothalamus deeply as like the other drinking circuits. (Thompson et. Al; 1980). Sex is the powerful biological motivation. The sex motivations easily understand the influence of sex hormone. It is related with the increase of age. Sex hormone influence the body to create a kind of pressure for sex activities. This pressure to be continued that time the sex activities is not complete. (Morgan, King. Weisz and Schopler, 1993).

Most of the motivations are based on the body's need to maintain a certain level of essential elements; adequate sugar in the blood to nourish cells, enough water in the body. These levels are regulated to homeostatic mechanisms. These mechanisms imbalance in the body and stimulate actions that restore the proper balance.

Hunger

The biological drive of **hunger**, or desiring to eat, relates to the end of this motivated behavior once we are full, called **satiety**. Basically, we eat because there is a deprivation in the amount of glucose in our blood to sustain activity and once we have restored that glucose level to its set point, hunger ends. In other words, we have achieved homeostasis again. The feeling of hunger is not pleasant and results in feeling shaky, lethargic, and possibly being sick to our stomach. We want to do something about this. So how do we know when to eat?

Signals arise from both the stomach (surprising, right?) and the blood, but the stomach plays less of a role than we might realize. We all have experienced hunger pangs or our stomach growling, or the feeling of being full especially after one of our main food holidays (Christmas, Easter, or Thanksgiving). These stomach indicators relate to being very hungry (i.e. being famished) or very full (i.e. stuffed) but that is about it.

What about other possible signals? I mentioned the blood and the brain receives information from the blood about levels of glucose, or sugar used by body cells for energy. When our glucose levels are low we are motivated to eat and restore these levels. The brain also regulates hunger through the action of the hormone ghrelin which increases appetite and leptin which reduces appetite. Other important hormones include GLP-1 which reduces appetite and tells the pancreas to release insulin, CCK which improves digestion by reducing the rate at which food is emptied from the stomach and into the small intestine, PYY which causes satiety by being secreted into the bloodstream by the small intestine and then binding to receptor sites in the brain, and neuropeptide Y which leads to increased consumption of carbohydrates.

Though many areas of the brain are involved in the regulation of hunger, the **hypothalamus** plays a pivotal role. In terms of knowing when to start eating, the lateral hypothalamus is involved and if stimulated with an electrode, an animal that is in a state of satiation will begin eating. In terms of satiety, the ventromedial hypothalamus tells an animal to stop eating but if destroyed, overeating results. Finally, the paraventricular nucleus is involved in satiety as shown by stimulating it and in overeating if destroyed or damaged. It helps to regulate blood sugar levels.

In addition to these internal signals to eat, several external cues are important too. First, we sometimes eat not because we are hungry, but because it is time to eat. Time of day factors in such that most people eat at noon because our society has been told that we should eat then. Or we might eat on our lunch break at work whether we are hungry or not. Second, social factors play in. We may eat because our friends are doing so and don't want to be left out. Third, the sight of food, or its smell, may motivated us to eat. Fourth, to deal with life we sometimes engage in comfort eating as a tension reduction strategy, or to deal with stress (See Module 4).

Fifth, but more so a cue as to what to eat, culture plays in. Some cultures find our eating of ground beef from cows to be appalling, as much as we find their eating of cats or dogs to be so. Sixth, and as mentioned already, we tend to overeat during certain times of the year such as holidays – Thanksgiving, Christmas, and Easter. Going back to our discussion of behavioral change from Module 6, if we are trying to get in shape by reducing our caloric intake, we need to take into consideration temptations that could lead us to engage in undesirable or problem behavior. Social eating is one such example of eating when we are not actually hungry.

Thirst

There are two kinds of thirst that we can experience. Yes, two. If you eat a salty meal you experience the first type called **intracellular thirst**. Excessive salt, such as found in potato chips, causes fluid to be drawn out of our cells and as they “shrink” we become thirsty. No worries. If we drink water (nothing added to it such as the flavor aides) we can restore this deficiency. The second type of thirst occurs when we are sweating, have diarrhea, vomit, or are bleeding, and

is called **extracellular thirst**. Essentially, water is lost from the fluid surrounding our cells and drinking a saline solution helps such as Gatorade or Powerade.

Sleep

Though we know that sleep is a necessary requirement for all human beings, and is essential for survival, the exact reason(s) is/are not as clear. We spend about one-third of our time sleeping. Several brain structures are involved in the regulation of sleep. First, the hypothalamus contains the **suprachiasmatic nucleus** (SCN) which is a cluster of cells that receives information about light exposure from the eyes and controls our behavioral rhythms. People with damage to this area sleep erratically during the day because their light-dark cycle and circadian rhythms are not in synch. During all stages of sleep but REM sleep, the **thalamus**, or sensory relay station, becomes quiet and allows you to tune out the external world. The **pineal gland** receives signals from the SCN and increases production of the hormone melatonin, which aids in sleeping once the lights are off.

Sleep is regulated by two internal biological mechanisms. First, **circadian rhythms** affect fluctuations in wakefulness, metabolism, body temperature, and the release of hormones. Specifically, they control the timing of sleep and lead you to feel sleepy at night. Second, sleep-wake homeostasis tracks how much sleep you need and gives the body a reminder to sleep after a certain amount of time. It also regulates sleep intensity. How much sleep do you need? There is no magic number and in general, it is recommended that adults sleep 7-9 hours a night while babies sleep 16-18 hours a day and school-aged children and teens sleep about 9.5 hours.

Sex

Sexual behavior is an interesting type of motivated behavior as it is not needed for survival in the same sense as hunger or thirst, but is needed for reproduction and continuation of the species. Understanding sexual behavior is important, as a 2017 survey conducted by the Centers for Disease Control and Prevention (CDC) of high school students shows:

- 40% of students said they had sexual intercourse
- 10% have had more than one sexual partner
- 30% had sexual intercourse during the previous 3 months and of this, 46% did not use a condom the last time they had sex and 14% did not use any method to prevent pregnancy.
- In terms of health outcomes, 21% of all new HIV diagnoses in the US in 2016 were people aged 13-24, half of the 20 million new STD cases in the US were people aged 15-24, and about 210,000 babies were born to girls aged 15-19 in 2016

Human sexual behavior is activated by the sex hormones estrogens, progestins, and androgens. All three circulate in the blood of males and females but females have greater levels of the first two and males have higher levels of the last. Recall from Module 10 that during adolescence hormone levels rise and lead to increases in sexual desire and behavior. According to Masters and Johnson (1966) there is a distinct pattern of physiological arousal for men and women, before, during, and after sexual activity, and called the **sexual response pattern**.

How so? Phase 1 is excitement and is characterized by increased muscle tension, faster heart rate, the breasts becoming fuller and the nipples hardening, vaginal lubrication beginning, and the man secreting a lubricating liquid. Phase 2 is plateau and extends to the brink of orgasm and is an intensification of the changes began in phase 1. Phase 3 is orgasm and is the climax of the

cycle but lasts only a few seconds. The uterus in women and the penis in men undergo rhythmic contractions, and in men results in the ejaculation of semen.

For men and women, the phase is intensely pleasurable and leads to a release of both physical and psychological tension. Phase 4 is resolution and now the body returns to its normal level of functioning. Swelled or erect body parts return to normal and sexual partners experience intimacy, fatigue, and a general sense of well-being. Men enter a refractory period during which they cannot achieve an orgasm again. How long this last depends on the man and the time lengthens with age.

Biological basis of emotion: The Limbic system, Hormonal regulation of behavior

The experience of emotion is accompanied by activation of two major areas of the nervous system: the brain and the autonomic nervous system.

Activation of Brain Regions

The area of the brain known as the **Limbic System** is highly involved in emotion. One structure in the limbic system, called the **Amygdala**, plays a particularly important role in regulating emotion. Researchers believe that sensory information about emotion-evoking events moves along two pathways in the brain. The information goes first to the thalamus and from there moves simultaneously to the amygdala and the cortex of the brain. The amygdala processes the information quickly and sends signals to the hypothalamus, which in turn activates the autonomic nervous system. The cortex, on the other hand, processes the information more slowly, allowing people to appraise or evaluate the event.

Example: When information travels from the sense organs to the thalamus to the amygdala, people respond instantaneously, without thinking, to events in their environment. A parent may snatch her child away from a curb without thinking if she hears the sound of squealing tires coming toward them.

KEY TAKEAWAYS

Key Points

- The limbic system, autonomic nervous system, and reticular activating system all interact in the physiological processing of emotion.
- The limbic system categorizes human emotional experiences as either pleasant or unpleasant mental states. Neurochemicals such as dopamine, noradrenaline, and serotonin are important components of the limbic system.
- The autonomic nervous system, together with the hypothalamus, regulates pulse, blood pressure, breathing, and arousal in response to emotional cues.
- When activated, the sympathetic nervous system prepares the body for emergency actions by controlling the glands of the endocrine system. Conversely, the parasympathetic nervous system functions when the body is relaxed or at rest and helps the body store energy for future use.
- The reticular activating system is believed to first arouse the cortex and then maintain its wakefulness so that sensory information and emotion can be interpreted more effectively.

Key Terms

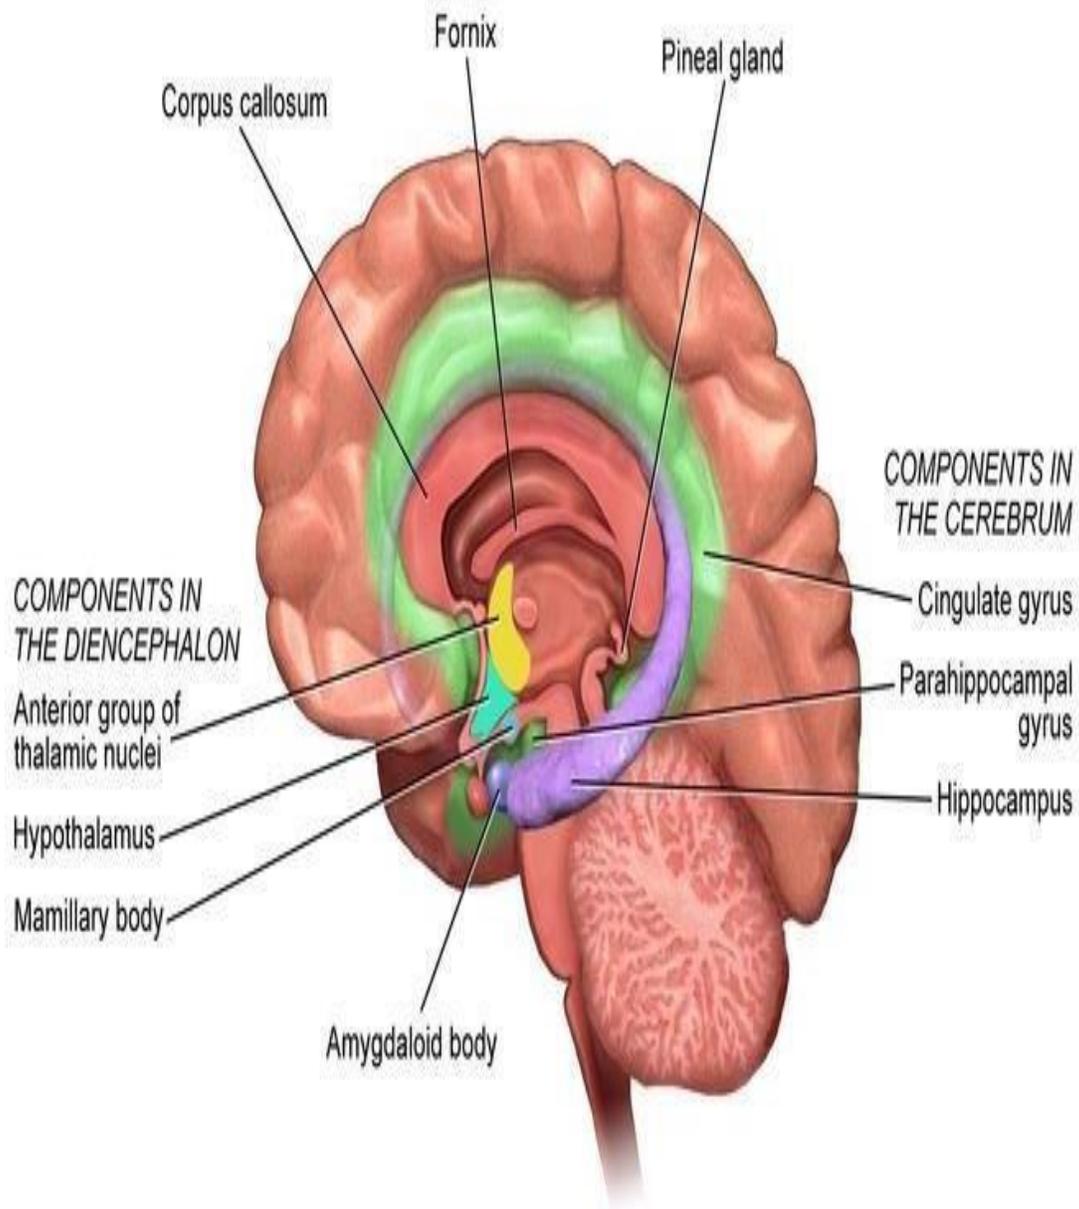

- **homeostasis:** Equilibrium of the body, in which biological conditions (such as body temperature) are maintained at optimal levels.
- **cerebral cortex:** The grey, folded, outermost layer of the cerebrum that is responsible for higher brain processes such as sensation, voluntary muscle movement, thought, reasoning, and memory.
- **amygdala:** A part of the brain located in the medial temporal lobe. It is believed to play a key role in emotion in both animals and humans, particularly in the formation of fear-based memories.
- **hippocampus:** A part of the limbic system, located in the temporal lobe of the brain and consisting mainly of grey matter. It plays a role in memory and emotion.
- **emotion:** The complex psychophysiological experience of an individual's state of mind as it is interacting with biochemical (internal) and environmental (external) influences. Emotions can be explained in biological and neurological terms. The limbic system, autonomic nervous system, and reticular activating system all interact to assist the body in experiencing and processing emotions.

The Limbic System

The limbic system is the area of the brain most heavily implicated in emotion and memory. Its structures include the hypothalamus, thalamus, amygdala, and hippocampus. The hypothalamus plays a role in the activation of the sympathetic nervous system, which is a part of any emotional reaction. The thalamus serves as a sensory relay center; its neurons project signals to both the amygdala and the higher cortical regions for further processing. The amygdala plays a role in processing emotional information and sending that information on to cortical structures. The hippocampus integrates emotional experience with cognition.

Other parts of the limbic system include the olfactory bulbs, anterior nuclei, fornix, column of fornix, mammillary body, septum pellucidum, habenular commissure, cingulate gyrus, parahippocampal gyrus, limbic cortex, and limbic midbrain areas.

The Limbic System

The limbic system: The limbic system is the area of the brain involved with emotion and memory. Its structures include the hypothalamus, thalamus, amygdala, and hippocampus. The processes of the limbic system control our physical and emotional responses to environmental stimuli. This system categorizes the experience of an emotion as a pleasant or unpleasant mental state. Based on this categorization, neurochemicals such as dopamine, noradrenaline, and serotonin increase or decrease, causing the brain's activity level to fluctuate and resulting in changes in body movement, gestures, and poses.

Hormones and Behavior: Basic Concepts

Behavioral endocrinology is the scientific study of the interaction between hormones and behavior. This interaction is bidirectional: hormones can affect behavior, and behavior can feedback to influence hormone concentrations. Hormones are chemical messengers released from endocrine glands that influence the nervous system to regulate the physiology and behavior of individuals. Over evolutionary time, hormones regulating physiological processes have been co-opted to influence behaviors linked to these processes. For example, hormones associated with gamete maturation such as estrogens are now broadly associated with the regulation of female sexual behaviors.

Such dual hormonal actions ensure that mating behavior occurs when animals have mature gametes available for fertilization. Generally speaking, hormones change gene expression or cellular function, and affect behavior by increasing the likelihood that specific behaviors occur in the presence of precise stimuli. Hormones achieve this by affecting individuals' sensory systems, central integrators, and/or peripheral effectors. To gain a full understanding of hormone-behavior interactions, it is important to monitor hormone values, as well as receptor interactions in the brain. Because certain chemicals in the environment can mimic natural hormones, these chemicals can have profound effects on the behavior of humans and other animals.

Behavioral Endocrinology Techniques A number of methods are used to gather the evidence needed to establish hormone-behavior relationships. Much of the recent progress in behavioral endocrinology has resulted from technical advances in the tools that allow us to detect, measure, and probe the functions of hormones and their receptors. These techniques, with a brief description, are listed in Table

1. Several of these techniques are the result of advanced research in behavioral endocrinology, including the time-honored ablation-replacement techniques, bioassays, as well as modern assays that utilize the concept of competitive binding of antibodies that include radioimmunoassay (RIA), enzyme-linked immunosorbent assay (ELISA; enzyme-linked immunoassay (EIA)), autoradiography, and immunocytochemistry. Other techniques commonly used in behavioral endocrinology include neural stimulation and single-unit recording, techniques that activate or block hormone receptors with drugs, and gene arrays and genetic manipulations including interfering with RNA and use of viral gene vectors to deliver novel genes directly into the brain. Because hormones must interact with specific receptors to evoke a response, many of these techniques are used to influence or measure hormone secretion, hormone binding, or the physiological and behavioral effects that ensue after hormones bind to their respective receptors.

Hormones

Hormones are organic chemical messengers produced and released by specialized glands called 'endocrine glands.' Endocrine is derived from the Greek root words endon, meaning 'within,' and krinein, meaning 'to release,' whereas the term hormone is based on the Greek word hormon, meaning 'to excite.' Hormones are released from these glands into the bloodstream (or the tissue fluid system in invertebrates), where they act on target organs (or tissues) generally at some distance from their origin. Hormones coordinate the physiology and behavior of an animal by regulating, integrating, and controlling its bodily function. Hormones are similar in function to other chemical mediators including neurotransmitters and cytokines. Indeed, the division of chemical mediators into categories mainly reflects the need by researchers to organize biological systems

into endocrine, nervous, and immune systems, rather than real functional differences among these chemical signals. Hormones often function locally as neurotransmitters and also interact with neurotransmitters and cytokines to influence behavior.

Hormones can be grouped into four classes:

- (1) peptides or proteins,
- (2) steroids,
- (3) monoamines, and
- (4) lipidbased hormones. Generally, only one class of hormone is produced by a single endocrine gland, but there are some notable exceptions.

It is important and useful to discriminate among the four types of hormones because they differ in several important characteristics, including their mode of release, how they move through the blood, the location of their target tissue receptors, and the manner by which the interaction of the hormone with its receptor results in a biological response.

Protein Hormones

Most vertebrate hormones are proteins. Protein hormones that comprise only a few amino acids in length are called 'peptide hormones,' whereas larger ones are called 'protein' or 'polypeptide hormones.' Protein and peptide hormones include insulin, the glucagons, the neurohormones of the hypothalamus, the tropic hormones of the anterior pituitary, inhibin, calcitonin, parathyroid hormone, the gastrointestinal (gut) hormones, ghrelin, leptin, adiponectin, and the posterior pituitary hormones. Protein and peptide hormones can be stored in endocrine cells and are released into the circulatory system by means of exocytosis. Protein and peptide hormones are soluble in blood, and therefore, do not require a carrier protein to travel to their target cells, as do steroid hormones.

Steroid Hormones

The adrenal glands, the gonads, and the brain are the most common sources of steroid hormones in vertebrates. Vertebrate steroid hormones have a characteristic chemical structure that includes three six-carbon rings plus one conjugated five-carbon ring. In the nomenclature of steroid biochemistry, substances are identified by the number of carbon atoms in their chemical structure. The precursor to all vertebrate steroid hormones is cholesterol.

The cholesterol molecule contains 27 carbon atoms (a C₂₇ substance), although cholesterol itself is not a true steroid and can be stored within lipid droplets inside cells. Because steroid hormones are fat soluble and move easily through cell membranes, they are never stored, but leave the cells in which they were produced almost immediately. A signal to produce steroid hormones is also a signal to release them.

How Might Hormones Affect Behavior?

All behavioral systems, including animals, comprise three interacting components:

- (1) input systems (sensory systems),
- (2) integrators (the central nervous system), and
- (3) output systems, or effectors (e.g., muscles).

Again, hormones do not cause behavioral changes. Rather, hormones influence these three sys-

tems so that specific stimuli are more likely to elicit certain responses in the appropriate behavioral or social context. In other words, hormones change the probability that a particular behavior will be emitted in the appropriate situation. This is a critical distinction that affects conceptualization of hormone–behavior relationships. For example, female rodents must adopt a rigid mating posture (called ‘lordosis’) for successful copulation to occur. Females only show this posture when blood estrogen concentrations are high coincident with the maturing ova. Females adopt the lordosis posture in response to tactile stimuli provided by a mounting male. Estrogens affect sensory input by increasing the receptive field size in sensory cells in the flanks.

Estrogen affects protein synthesis, the electrophysiological responses of neurons, and the appearance of growth-like processes on neurons in the central nervous system, thus altering the speed of processing and connectivity of neurons. Finally, estrogen affects the muscular output that results in lordosis, as well as chemosensory stimuli important in attracting a mating partner.

How Might Behavior Affect Hormones?

The female rodent mating posture example demonstrates how hormones can affect behavior, but, as noted previously, the reciprocal relation also occurs, that is, behavior can affect hormone concentrations. For example, chemosensory cues from males may elevate blood estradiol concentrations in females, and thereby stimulate proceptive or male-seeking behaviors. Similarly, male mammals that lose an aggressive encounter decrease circulating testosterone concentrations for several days or even weeks afterward. Similar results have also been reported in humans.

Human testosterone concentrations are affected not only in those involved in physical combat, but also in those involved in simulated battles. For example, testosterone concentrations are elevated in winners and reduced in losers of regional chess tournaments.

Types of Evidence for Establishing Hormone–Behavior Interactions

What sort of evidence would be sufficient to establish that a particular hormone affected a specific behavior or that a specific behavior changed hormone concentrations? Experiments to test hypotheses about the effects of hormones on behavior must be carefully designed, and, generally, three conditions must be satisfied by the experimental results to establish a causal link between hormones and behavior:

- (1) a hormonally dependent behavior should disappear when the source of the hormone is removed or the actions of the hormone are blocked,
- (2) after the behavior stops, restoration of the missing hormonal source or its hormone should reinstate the absent behavior, and
- (3) finally, hormone concentrations and the behavior in question should be covariant, that is, the behavior should be observed only when hormone concentrations are relatively high and never or rarely observed when hormone concentrations are low.

Genetics and behavior: Chromosomal anomalies; Nature- Nurture controversy [Twin studies and adoption studies]

Behaviour genetics, also called psychogenetics, the study of the influence of an organism’s genetic composition on its behaviour and the interaction of heredity and environment insofar as they affect behaviour. The question of the determinants of behavioral abilities and disabilities has commonly been referred to as the “nature-nurture” controversy.

Early History

The relationship between behaviour and genetics, or heredity, dates to the work of English scientist Sir Francis Galton (1822–1911), who coined the phrase “nature and nurture.” Galton studied the families of outstanding men of his day and concluded, like his cousin Charles Darwin, that mental powers run in families. Galton became the first to use twins in genetic research and pioneered many of the statistical methods of analysis that are in use today. In 1918 British statistician and geneticist Ronald Aylmer Fisher published a paper that showed how Gregor Mendel’s laws of inheritance applied to complex traits influenced by multiple genes and environmental factors.

The first human behavioral genetic research on intelligence and mental illness began in the 1920s, when environmentalism (the theory that behaviour is a result of nongenetic factors such as various childhood experiences) became popular and before Nazi Germany’s abuse of genetics made the notion of hereditary influence abhorrent. Although genetic research on human behaviour continued throughout the following decades, it was not until the 1970s that a balanced view came to prevail in psychiatry that recognized the importance of nature as well as nurture. In psychology, this reconciliation did not take hold until the 1980s. Much behavioral genetic research today focuses on identifying specific genes that affect behavioral dimensions, such as personality and intelligence, and disorders, such as autism, hyperactivity, depression, and schizophrenia.

Methods Of Study

Quantitative genetic methods are used to estimate the net effect of genetic and environmental factors on individual differences in any complex trait, including behavioral traits. In addition, molecular genetic methods are used to identify specific genes responsible for genetic influence. Research is carried out in both animals and humans; however, studies using animal models tend to provide more-accurate data than studies in humans because both genes and environment can be manipulated and controlled in the laboratory.

By mating related animals such as siblings for many generations, nearly pure strains are obtained in which all offspring are genetically highly similar. It is possible to screen for genetic influence on behaviour by comparing the behaviour of different inbred strains raised in the same laboratory environment. Another method, known as selective breeding, evaluates genetic involvement by attempting to breed for high and low extremes of a trait for several generations. Both methods have been applied to a wide variety of animal behaviours, especially learning and behavioral responses to drugs, and this research provides evidence for widespread influence of genes on behaviour. Because genes and environments cannot be manipulated in the human species, two quasi-experimental methods are used to screen for genetic influence on individual differences in complex traits such as behaviour.

The twin method relies on the accident of nature that results in identical (monozygotic, MZ) twins or fraternal (dizygotic, DZ) twins. MZ twins are like clones, genetically identical to each other because they came from the same fertilized egg. DZ twins, on the other hand, developed from two eggs that happened to be fertilized at the same time. Like other siblings, DZ twins are only half as similar genetically as MZ twins. To the extent that behavioral variability is caused by environmental factors, DZ twins should be as similar for the behavioral trait as are MZ twins be-

cause both types of twins are reared by the same parents in the same place at the same time. If the trait is influenced by genes, then DZ twins ought to be less similar than MZ twins.

For schizophrenia, for example, the concordance (risk of one twin's being schizophrenic if the other is) is about 45 percent for MZ twins and about 15 percent for DZ twins. For intelligence as assessed by IQ tests, the correlation, an index of resemblance (0.00 indicates no resemblance and 1.00 indicates perfect resemblance), is 0.85 for MZ twins and 0.60 for DZ twins for studies throughout the world of more than 10,000 pairs of twins. The twin method has been robustly defended as a rough screen for genetic influence on behaviour.

Chromosomal Abnormalities

Almost every cell in our body contains 23 pairs of chromosomes, for a total of 46 chromosomes. Half of the chromosomes come from our mother, and the other half come from our father. The first 22 pairs are called autosomes. The 23rd pair consists of the sex chromosomes, X and Y. Females usually have two X chromosomes, and males usually have one X and one Y chromosome in each cell. All of the information that the body needs to grow and develop comes from the chromosomes. Each chromosome contains thousands of genes, which make proteins that direct the body's development, growth, and chemical reactions.

Many types of chromosomal abnormalities exist, but they can be categorized as either numerical or structural. Numerical abnormalities are whole chromosomes either missing from or extra to the normal pair. Structural abnormalities are when part of an individual chromosome is missing, extra, switched to another chromosome, or turned upside down. Chromosomal abnormalities can occur as an accident when the egg or the sperm is formed or during the early developmental stages of the fetus. The age of the mother and certain environmental factors may play a role in the occurrence of genetic errors. Prenatal screening and testing can be performed to examine the chromosomes of the fetus and detect some, but not all, types of chromosomal abnormalities.

Chromosomal abnormalities can have many different effects, depending on the specific abnormality. For example, an extra copy of chromosome 21 causes Down syndrome (trisomy 21). Chromosomal abnormalities can also cause miscarriage, disease, or problems in growth or development. The most common type of chromosomal abnormality is known as aneuploidy, an abnormal chromosome number due to an extra or missing chromosome. Most people with aneuploidy have trisomy (three copies of a chromosome) instead of monosomy (single copy of a chromosome). Down syndrome is probably the most well-known example of a chromosomal aneuploidy. Besides trisomy 21, the major chromosomal aneuploidies seen in live-born babies are: trisomy 18; trisomy 13; 45, X (Turner syndrome); 47, XXY (Klinefelter syndrome); 47, XYY; and 47, XXX.

Structural chromosomal abnormalities result from breakage and incorrect rejoining of chromosomal segments. A range of structural chromosomal abnormalities result in disease. Structural rearrangements are defined as balanced if the complete chromosomal set is still present, though rearranged, and unbalanced if information is additional or missing. Unbalanced rearrangements include deletions, duplications, or insertions of a chromosomal segment. Ring chromosomes can result when a chromosome undergoes two breaks and the broken ends fuse into a circular chromosome. An isochromosome can form when an arm of the chromosome is missing and the remaining arm duplicates.

Balanced rearrangements include inverted or translocated chromosomal regions. Since the full complement of DNA material is still present, balanced chromosomal rearrangements may go undetected because they may not result in disease. A disease can arise as a result of a balanced rearrangement if the breaks in the chromosomes occur in a gene, resulting in an absent or nonfunctional protein, or if the fusion of chromosomal segments results in a hybrid of two genes, producing a new protein product whose function is damaging to the cell.

Nature-Nurture controversy [Twin studies and adoption studies]

Genetics researchers now know that while an individual's DNA is essentially immutable, a wide range of environmental factors can confer what are called epigenetic differences. Epigenetics influences which genes in an individual's genome may be turned on or turned off. Such factors as exercise, sleep, trauma, aging, stress, illness and diet have been shown to have epigenetic effects, some of which can be passed on to future generations.

Researchers are seeking ways to deliberately alter gene expression in hopes of finding preventives or treatments for diseases like diabetes with a strong genetic component. There can also be changes in the genome of an identical twin when the egg divides, resulting in a defect in a particular gene, Dr. Segal said. In a pair of identical twin girls, one can experience a phenomenon called X-linked inactivation. Two of the identical Dionne quintuplets were colorblind as a result of such a genetic effect.

Dr. Segal, who has also written "Twin Misconceptions: False Beliefs, Fables, and Facts About Twins," said the studies highlight the importance of keeping twins, especially identical twins, together when they are adopted. As was depicted in the documentary, Dr. Segal said, "The triplets deeply resented having been separated. They lost out on wonderful years they could have had together. There was an immediate bond, an understanding of one another, that was obvious as soon as they found each other."

New research into epigenetics—the science of how the environment influences genetic expression—is changing the conversation. As psychologist David S. Moore explains in his newest book, *The Developing Genome*, this burgeoning field reveals that what counts is not what genes you have so much as what your genes are doing. And what your genes are doing is influenced by the ever-changing environment they're in. Factors like stress, nutrition, and exposure to toxins all play a role in how genes are expressed—essentially which genes are turned on or off. Unlike the static conception of nature or nurture, epigenetic research demonstrates how genes and environments continuously interact to produce characteristics throughout a lifetime.

The Nature vs. Nurture Debate

Are you the way you are because you were born that way, or because of the way you were raised? Do your genetics and biology dictate your personality and behavior, or is it your environment and how you were raised? These questions are central to the age-old **nature-nurture** debate. In the history of psychology, no other question has caused so much controversy and offense: We are so concerned with nature–nurture because our very sense of moral character seems to depend on it. While we may admire the athletic skills of a great basketball player, we think of his height as simply a gift, a payoff in the "genetic lottery." For the same reason, no one blames a short person for his height or someone's congenital disability on poor decisions: To state the obvious, it's "not their fault." But we do praise the concert violinist (and perhaps her parents and teachers as well)

for her dedication, just as we condemn cheaters, slackers, and bullies for their bad behavior. The problem is, most human characteristics aren't usually as clear-cut as height or instrument-mastery, affirming our nature–nurture expectations strongly one way or the other. In fact, even the great violinist might have some inborn qualities—perfect pitch, or long, nimble fingers— that support and reward her hard work. And the basketball player might have eaten a diet while growing up that promoted his genetic tendency for being tall. When we think about our own qualities, they seem under our control in some respects, yet beyond our control in others. And often the traits that don't seem to have an obvious cause are the ones that concern us the most and are far more personally significant. What about how much we drink or worry? What about our honesty, or religiosity, or sexual orientation? They all come from that uncertain zone, neither fixed by nature nor totally under our own control.

Figure 1. Researchers have learned a great deal about the nature- nurture dynamic by working with animals. But of course many of the techniques used to study animals cannot be applied to people. Separating these two influences in human subjects is a greater research challenge. [Photo: mharrsch] With people, however, we can't assign babies to parents at random, or select parents with certain behavioral characteristics to mate, merely in the interest of science (though history does include horrific examples of such practices, in misguided attempts at "eugenics," the shaping of human characteristics through intentional breeding). In typical human families, children's biological parents raise them, so it is very difficult to know whether children act like their parents due to genetic (nature) or environmental (nurture) reasons. Nevertheless, despite our restrictions on setting up human-based experiments, we do see real-world examples of nature-nurture at work in the human sphere—though they only provide partial answers to our many questions. The science of how genes and environments work together to influence behavior is called **behavioral genetics**. The easiest opportunity we have to observe this is the **adoption study**. When children are put up for adoption, the parents who give birth to them are no longer the parents who raise them. This setup isn't quite the same as the experiments with dogs (children aren't assigned to random adoptive parents in order to suit the particular interests of a scientist) but adoption still tells us some interesting things, or at least confirms some basic expectations. For instance, if the biological child of tall parents were adopted into a family of short people, do you suppose the child's growth would be affected? What about the biological child of a Spanish-speaking family adopted at birth into an English-speaking family? What language would you expect the child to speak? And what might these outcomes tell you about the difference between height and language in terms of nature-nurture?

Figure 2. Studies focused on twins have led to important insights about the biological origins of many personality characteristics. Another option for observing nature-nurture in humans involves **twin studies**. There are two types of twins: monozygotic (MZ) and dizygotic (DZ). Monozygotic twins, also called “identical” twins, result from a single zygote (fertilized egg) and have the same DNA. They are essentially clones. Dizygotic twins, also known as “fraternal” twins, develop from two zygotes and share 50% of their DNA. Fraternal twins are ordinary siblings who happen to have been born at the same time. To analyze nature–nurture using twins, we compare the similarity of MZ and DZ pairs. Sticking with the features of height and spoken language, let’s take a look at how nature and nurture apply: Identical twins, unsurprisingly, are almost perfectly similar for height. The heights of fraternal twins, however, are like any other sibling pairs: more similar to each other than to people from other families, but hardly identical. This contrast between twin types gives us a clue about the role genetics plays in determining height.

Now consider spoken language. If one identical twin speaks Spanish at home, the co-twin with whom she is raised almost certainly does too. But the same would be true for a pair of fraternal twins raised together. In terms of spoken language, fraternal twins are just as similar as identical twins, so it appears that the genetic match of identical twins doesn’t make much difference. Twin and adoption studies are two instances of a much broader class of methods for observing nature-nurture called **quantitative genetics**, the scientific discipline in which similarities among individuals are analyzed based on how biologically related they are. We can do these studies with siblings and half-siblings, cousins, twins who have been separated at birth and raised separately (Bouchard, Lykken, McGue, & Segal, 1990; such twins are very rare and play a smaller role than is commonly believed in the science of nature–nurture), or with entire extended families (see Plomin, DeFries, Knopik, & Neiderhiser, 2012, for a complete introduction to research methods relevant to nature–nurture).

For better or for worse, contentions about nature–nurture have intensified because quantitative genetics produces a number called a **heritability coefficient**, varying from 0 to 1, that is meant to provide a single measure of genetics’ influence of a trait. In a general way, a heritability coefficient measures how strongly differences among individuals are related to differences among their genes. But beware: Heritability coefficients, although simple to compute, are deceptively difficult to interpret. Nevertheless, numbers that provide simple answers to complicated questions tend to have a strong influence on the human imagination, and a great deal of time has been spent discussing whether the heritability of intelligence or personality or depression is equal to one number or another.

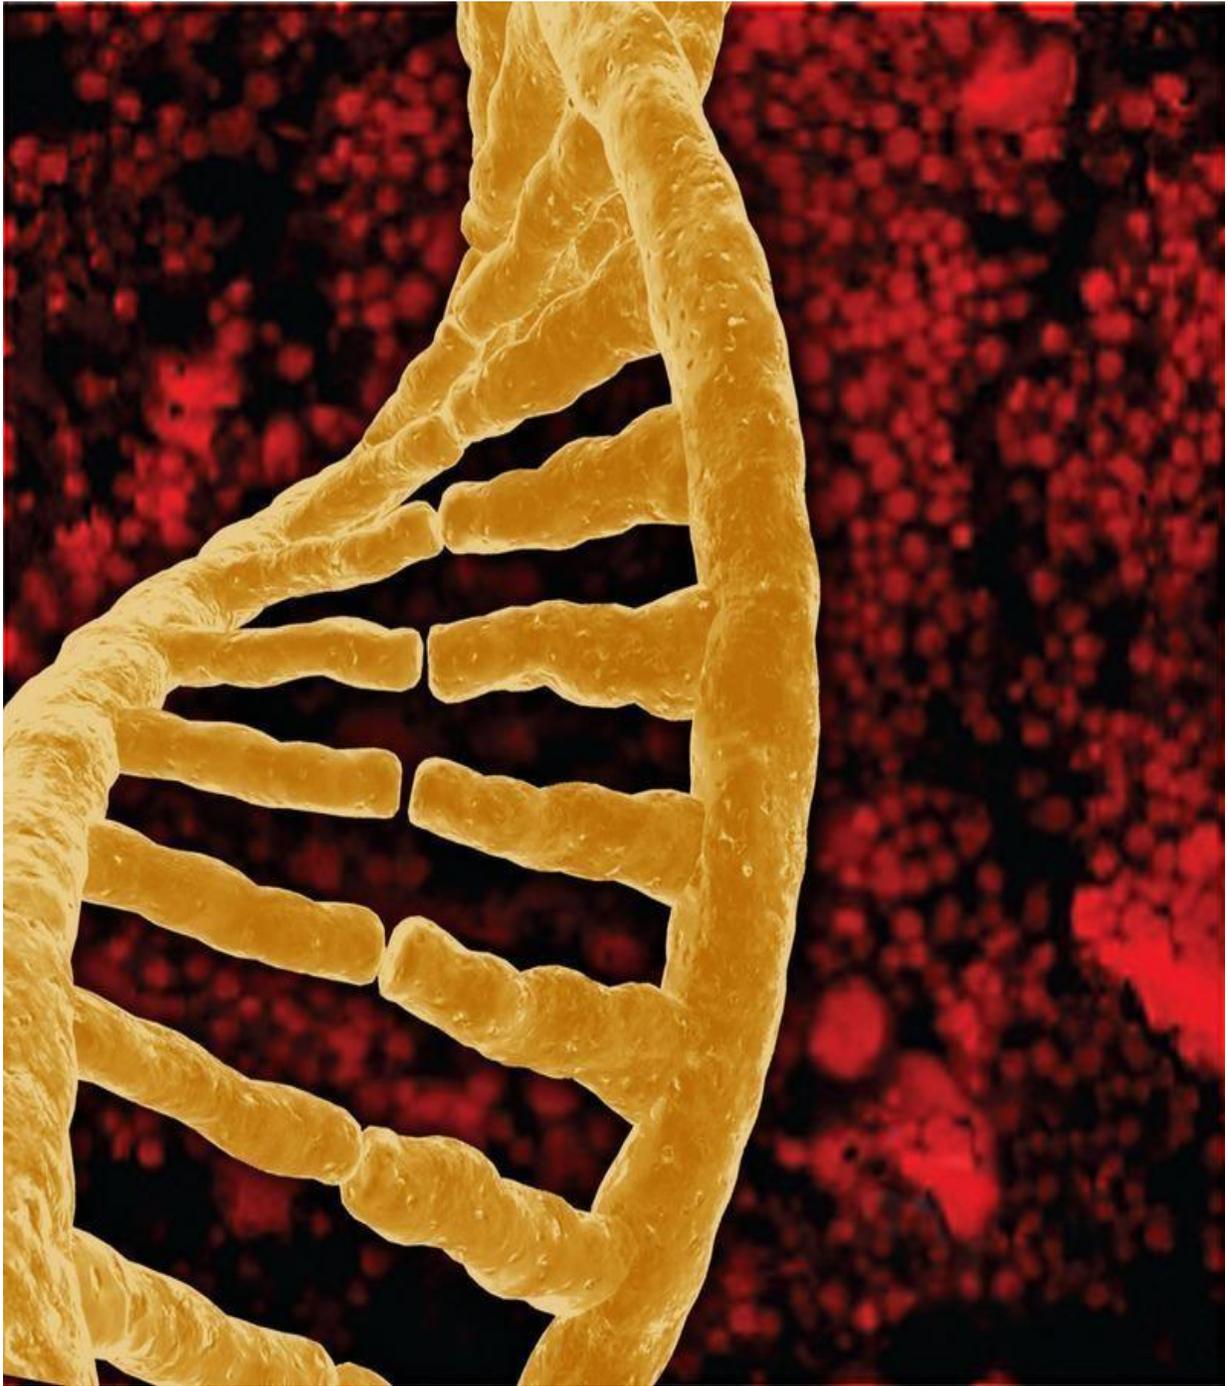

Figure 3. Quantitative genetics uses statistical methods to study the effects that both heredity and environment have on test subjects. These methods have provided us with the heritability coefficient which measures how strongly differences among individuals for a trait are related to differences among their genes. One reason nature–nurture continues to fascinate us so much is that we live in an era of great scientific discovery in genetics, comparable to the times of Copernicus, Galileo, and Newton, with regard to astronomy and physics. Every day, it seems, new discoveries are made, new possibilities proposed. When Francis Galton first started thinking about nature–nurture in the late-19th century he was very influenced by his cousin, Charles Darwin, but genetics per se was unknown.

Mendel's famous work with peas, conducted at about the same time, went undiscovered for 20 years; quantitative genetics was developed in the 1920s; DNA was discovered by Watson and Crick in the 1950s; the human genome was completely sequenced at the turn of the 21st century; and we are now on the verge of being able to obtain the specific DNA sequence of anyone at a relatively low cost. No one knows what this new genetic knowledge will mean for the study of nature–nurture, but as we will see in the next section, answers to nature–nurture questions have turned out to be far more difficult and mysterious than anyone imagined.

About Nature–Nurture

It would be satisfying to be able to say that nature–nurture studies have given us conclusive and complete evidence about where traits come from, with some traits clearly resulting from genetics and others almost entirely from environmental factors, such as childrearing practices and personal will; but that is not the case. Instead, everything has turned out to have some footing in genetics. The more genetically-related people are, the more similar they are—for everything: height, weight, intelligence, personality, mental illness, etc. Sure, it seems like common sense that some traits have a genetic bias. For example, adopted children resemble their biological parents even if they have never met them, and identical twins are more similar to each other than are fraternal twins.

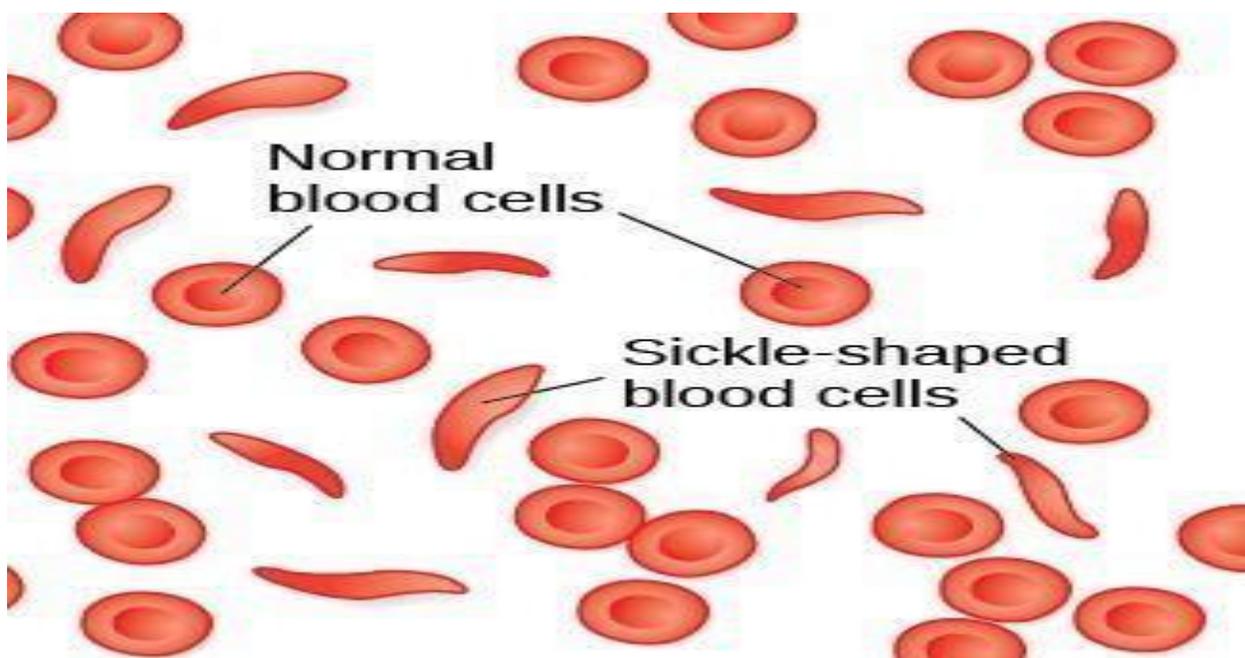

And while certain psychological traits, such as personality or mental illness (e.g., schizophrenia), seem reasonably influenced by genetics, it turns out that the same is true for political attitudes, how much television people watch (Plomin, Corley, DeFries, & Fulker, 1990), and whether or not they get divorced (McGue & Lykken, 1992). It may seem surprising, but genetic influence on behavior is a relatively recent discovery. In the middle of the 20th century, psychology was dominated by the doctrine of behaviorism, which held that behavior could only be explained in terms of environmental factors. Psychiatry concentrated on psychoanalysis, which probed for roots of behavior in individuals' early life-histories. The truth is, neither behaviorism nor psychoanalysis is incompatible with genetic influences on behavior, and neither Freud nor Skinner was naive about the importance of organic processes in behavior. Nevertheless, in their day it was widely thought that children's personalities were shaped entirely by imitating their parents' behavior, and that schizophrenia was caused by certain kinds of "pathological mothering."

Whatever the outcome of our broader discussion of nature–nurture, the basic fact that the best predictors of an adopted child's personality or mental health are found in the biological parents he or she has never met, rather than in the adoptive parents who raised him or her, presents a significant challenge to purely environmental explanations of personality or psychopathology. The message is clear: You can't leave genes out of the equation. But keep in mind, no behavioral traits are completely inherited, so you can't leave the environment out altogether, either. Trying to untangle the various ways nature-nurture influences human behavior can be messy, and often common-sense notions can get in the way of good science. One very significant contribution of behavioral genetics that has changed psychology for good can be very helpful to keep in mind: When your subjects are biologically-related, no matter how clearly a situation may seem to point to environmental influence, it is never safe to interpret a behavior as wholly the result of nurture without further evidence.

For example, when presented with data showing that children whose mothers read to them often

are likely to have better reading scores in third grade, it is tempting to conclude that reading to your kids out loud is important to success in school; this may well be true, but the study as described is inconclusive, because there are genetic as well as environmental pathways between the parenting practices of mothers and the abilities of their children. This is a case where “correlation does not imply causation,” as they say. To establish that reading aloud causes success, a scientist can either study the problem in adoptive families (in which the genetic pathway is absent) or by finding a way to randomly assign children to oral reading conditions. Psychological researchers study genetics in order to better understand the biological basis that contributes to certain behaviors. While all humans share certain biological mechanisms, we are each unique. And while our bodies have many of the same parts—brains and hormones and cells with genetic codes—these are expressed in a wide variety of behaviors, thoughts, and reactions.

Why do two people infected by the same disease have different outcomes: one surviving and one succumbing to the ailment? How are genetic diseases passed through family lines? Are there genetic components to psychological disorders, such as depression or schizophrenia? To what extent might there be a psychological basis to health conditions such as childhood obesity?

To explore these questions, let's start by focusing on a specific disease, sickle-cell anemia, and how it might affect two infected sisters. **Sickle-cell anemia** is a genetic condition in which red blood cells, which are normally round, take on a crescent-like shape (Figure 5). The changed shape of these cells affects how they function: sickle-shaped cells can clog blood vessels and block bloodflow, leading to high fever, severe pain, swelling, and tissue damage.

Figure 5. Normal blood cells travel freely through the blood vessels, while sickle-shaped cells form blockages preventing blood flow. Many people with sickle-cell anemia—and the particular genetic mutation that causes it—die at an early age. While the notion of “survival of the fittest” may suggest that people suffering from this disease have a low survival rate and therefore the disease will become less common, this is not the case. Despite the negative evolutionary effects associated with this genetic mutation, the sickle-cell gene remains relatively common among people of Afri-

candescent. Why is this? The explanation is illustrated with the following scenario. Imagine two young women—Luwi and Sena—sisters in rural Zambia, Africa. Luwi carries the gene for sickle-cell anemia; Sena does not carry the gene. Sickle-cell carriers have one copy of the sickle-cell gene but do not have full-blown sickle-cell anemia. They experience symptoms only if they are severely dehydrated or are deprived of oxygen (as in mountain climbing). Carriers are thought to be immune from malaria (an often deadly disease that is widespread in tropical climates) because changes in their blood chemistry and immune functioning prevent the malaria parasite from having its effects (Gong, Parikh, Rosenthal, & Greenhouse, 2013). However, full-blown sickle-cell anemia, with two copies of the sickle-cell gene, does not provide immunity to malaria.

MCQs

- 1) Higher motor commands originate in all the following centers, except :-
 - a. cerebral cortex
 - b. thalamus
 - c. caudate nucleus
 - d. cerebellumAns:- B

- 2) A reflex action :-
 - a. is a fast brief response to a sensory stimulus
 - b. is involved in regulation of voluntary movements
 - c. includes at least three sequential sets of neurons in its pathway
 - d. is always initiated whenever its specific receptors are effectively stimulated by a specific stimulusAns:- D

- 3) Reflex actions could be classified according to :-
 - a. the type of sensory receptors initiating them
 - b. the type of afferent nerves mediating them
 - c. the type of efferent nerves mediating them
 - d. the type of neurotransmitters mediating themAns:- C

- 4) Events of reflex actions include all the following, except :-
 - a. stimulation of sensory receptors
 - b. stimulation of central synapses
 - c. inhibition of sensory receptors
 - d. inhibition of central synapsesAns:- C

- 5) A reflex arc includes :-
 - a. at least two sets of sequential neurons
 - b. at least two sequential sets of central synapses
 - c. at least two types of sensory receptors
 - d. at least two types of efferent neuronsAns:- A

- 6) The central terminals of afferent neurons mediating spinal reflexes are distributed within the spinal cord, so that :-

- a- all of them terminate in the same spinal segment of their entry to the cord
 - b- all of them terminate on interneurons
 - c- all of them subserve spinal reflexes
 - d- they provide pathways for divergence of the incoming sensory impulses Ans:- D
- 7) Interneurons :-**
- a- provide communication between the central ends of afferent neurons
 - b- provide communication between dendrites of the efferent neurons
 - c- influence the rate of discharge from the alpha motor neurons
 - d- participate in ascending sensory pathways Ans:- C
- 8) The divergence function of interneurons is involved in :-**
- a. temporal summation
 - b- spatial summation
 - c- reverberation
 - d- irradiation Ans:- D
- 9) Interneuron after-discharge circuits prolong the duration of :-**
- a- sensory input to the spinal motor centers
 - b- synaptic delay in central synapses
 - c- discharge of efferent neurons
 - d- conscious perception of the evoked sensation Ans:- C
- 10) A flexor withdrawal reflex shows all the following properties, except :-**
- a. recruitment
 - b- prepotent
 - c- non-fatigable
 - d- irradiation Ans:- C
- 11) Flexor reflexes do not involve :-**
- a. flexor muscles
 - b- extensor muscles
 - c- reciprocal inhibition
 - d- reflex spasm of the involved muscles Ans:- D
- 12) The ability of stronger stimuli to produce wider range of reflex responses depends upon :-**
- a- presence of reverberating circuits in reflex pathway
 - b- presence of parallel-chain circuits in reflex pathway
 - c- convergence of interneurons
 - d- divergence of interneurons Ans:- D
- 13) Recruitment of a reflex response is due to :-**
- a- difference in the amount of presynaptic inputs to the various efferent neurons initiating the

reflex

- b-** difference in the conduction velocity of the various afferent neurons mediating the reflex
- c-** delay at the neuromuscular junction
- d-** presence of inhibitory interneurons in the reflex pathway Ans:- A

14) After-discharge of reflex responses :-

- a-** increase the magnitude of the reflex responses
- b-** delays the onset of fatigue of reflex responses
- c-** involves interneuron circuits
- d-** depends upon spatial summation Ans:- C

15) Central delay of reflex actions :-

- a.** is due to presence of inhibitory interneurons in the reflex pathway
- b-** is the time between stimulation of receptors and response of the effector muscle
- c-** is longer in the flexor reflex than in the stretch reflex
- d-** is determined by the velocity of conduction of impulses along the afferent and efferent neurons in the reflex pathway Ans:- C

16) Fatigue of reflexes :-

- a-** develops gradually and recovers rapidly
- b-** develops rapidly and recovers slowly
- c-** develops gradually and recovers slowly
- d-** develops rapidly and recovers rapidly Ans:- C

17) In flexor withdrawal reflexes contraction of flexor muscles is associated with reciprocal inhibition of :-

- a-** synergistic flexor muscles
- b-** contralateral extensor muscles
- c-** ipsilateral extensor muscles
- d-** both 'a' and 'b' are correct Ans:- C

18) Reciprocal inhibition between reflexes depends upon all the following, except :-

- a-** presence of inhibitory interneurons in the reflex pathways
- b-** presence of excitatory interneurons in the reflex pathways
- c-** presence of anion channels in membranes of the involved neurons
- d-** release of inhibitory transmitters which block cation channels in the reflex pathways Ans:- D

19) stretch reflex is characterized by the following except :-

- a-** disynaptic reflex
- b-** high localization
- c-** shows reciprocal innervations.
- d-** it is of graded response Ans:- A

20) Stretch of an innervated muscle evokes :-

- a- contraction of its spindles
 - b- contraction of its extrafusal fibers
 - c- contraction of antagonistic muscles
 - d- relaxation of synergistic muscles
- Ans:- B

21) Muscle spindles :-

- a- are found in all skeletal muscles
 - b- are found only in large skeletal muscles
 - c- consist of small numbers of extrafusal muscle fibers
 - d- consist of a large number of extrafusal muscle fibers
- Ans:- A

22) The nuclear-bag fibers of muscle spindles are innervated by :-

- a- A γ nerve fibers
 - b- A β nerve fibers
 - c- A δ nerve fibers
 - d- Ia nerve fibers
- Ans:- D

23) The nuclear-chain fibers of spindles are innervated by :-

- a- A α and A δ nerve fibers
 - b- A δ and C nerve fibers
 - c- Ia and II nerve fibers
 - d- only type II nerve fibers
- Ans:- C

24) The central ends of afferents from muscle spindles synapse with all the following types of neurons, except :-

- a- α -motor neurons of the same muscle
 - b- γ -motor neurons of the same muscle
 - c- local interneurons
 - d- 2nd order neurons of ascending sensory pathways
- Ans:- B

25) γ -motor innervation of muscle spindles produces :-

- a- contraction of the central region of the spindle fibers
 - b- increased sensory discharge from the central region of the spindle fibers
 - c- decreased sensory discharge from the central region of the spindle fibers
 - d- relaxation of the peripheral regions of the spindle fibers
- Ans:- B

26) Discharge from muscle spindles could be increased by all the following, except :-

- a- increased α -motor neuron discharge
 - b- increased γ -motor neuron discharge
 - c- stretch of the intrafusal muscle fibers
 - d- stretch of the extrafusal muscle fibers
- Ans:- A

- 27)** Increased γ -motor neuron discharge stimulates muscle spindles, because :-
- a- it produces stretch of the extrafusal muscle fibers
 - b- it causes stretch of the peripheral regions of the intrafusal fibers
 - c- it causes stretch of the central region of the intrafusal fibers
 - d- it stimulates directly the sensory fibers innervating muscle spindles Ans:- C
- 28)** γ -motor neuron discharge to a muscle is inhibited by impulses reaching the γ -motor neurons from all the following source, except :-
- a- Golgi tendon organs of the same muscle
 - b- spindles of antagonistic muscles
 - c- medullary reticular formation
 - d- pontine reticular formation Ans:- D
- 29)** When the γ -motor neuron discharge to a muscle decreases, it causes :-
- a- increased muscle spindle discharge
 - b- shortening of the spindle fibers
 - c- stronger contraction of the extrafusal muscle fibers
 - d- decreased spindle sensitivity to stretch Ans:- D
- 30)** The role of muscle spindles in the maintenance of the upright posture depends upon all the following, except :-
- a- contraction of the peripheral contractile part of spindle fibers
 - b- increased sensory discharge from spindles of postural muscles
 - c- increased supraspinal facilitation to the γ -motor neurons of postural muscles
 - d- presence of greater numbers of spindles in postural muscles Ans:- D
- 31)** The role of γ -motor neurons in regulation of equilibrium is achieved by :-
- a- initiating contraction of spindle fibers which directly antagonize postural deviation
 - b- increasing spindle sensitivity to stretch
 - c- directly stimulating extrafusal muscle fibers to antagonize postural deviation
 - d- directly adjusting the discharge of α -motor neurons innervating the extrafusal muscle fibers to antagonize postural deviation Ans:- B
- 32)** Interruption of γ -motor neuron discharge to a skeletal muscle produces :-
- a- contraction of the muscle
 - b- contraction of the spindle fibers
 - c- relaxation of the spindle fibers
 - d- increased sensory discharge from the spindle fibers Ans:- C
- 33)** Co-activation of α and γ -motor neurons :-
- a. increases γ -motor neuron discharge whenever the activity of α -motor neurons rises to a high level
 - b. is mediated by interneurons that link the α and γ -motor neurons

- c. maintains the proprioceptive information to higher centers during muscle contraction
- d. increases the α -motor neuron discharge whenever the activity of γ -motor neurons rises to a high level Ans:- C

34) Increased sensory discharge from muscle spindles :-

- a- decreases muscle tone
- b- increases muscle tone
- c- could either increase or decrease muscle tone according to the muscle affected
- d- has no effect on muscle tone Ans:- C

35) Interruption of spindle discharge from a muscle causes contraction of the muscle to become jerky and irregular due to :-

- a- increased activity of reverberating circuits causing fluctuation of the motor discharge to the muscle
- b- increased activity of inhibitory interneurons causing oscillating inhibition of the α -motor neurons of the muscle
- c- irregular discharge of excitatory inputs to the α -motor neurons of the muscle
- d- post-tetanic potentiation of the α -motor neurons of the muscle Ans:- C

36) Whenever the position of a joint is stabilized at a certain attitude, the nervous system produces this by :-

- a- increasing the α -motor neuron discharge to all muscles attached to the joint
- b- increasing the γ -motor neuron discharge to all muscles attached to the joint
- c- increasing γ -motor neuron discharge to postural muscles
- d- co-activation of α and γ -motor neurons innervating the involved muscles Ans:- D

37) The highly localized nature of stretch reflex is due to :-

- a- the limited number of interneurons in the reflex pathway
- b- all the central ends of afferents from spindles of the stretched muscle terminate on the α -motor neurons of the muscle
- c- the α -motor neurons of the stretched muscle receive most of the central terminals of afferents coming from spindles of the muscle
- d- activation of inhibitory interneurons which inhibit the motor neurons of the surrounding muscles Ans:- C

38) The shortest reflex time is recorded with :-

- a- a flexor withdrawal reflex
- b- an inverse stretch reflex
- c- a stretch reflex
- d- a scratch reflex Ans:- C

39) When a skeletal muscle is suddenly stretched :-

- a- it relaxes suddenly

- b-** it develops a static stretch reflex
- c-** it develops a dynamic stretch reflex
- d-** it develops clonic contractions Ans:- C

40) Sensory impulses from spindles of a stretched muscle could inhibit antagonistic muscles by :-

- a-** directly inhibiting γ -motor neurons of the antagonistic muscles
- b-** directly inhibiting the α -motor neurons of the antagonistic muscles
- c-** inhibiting the transmitter release from the central terminals of afferents from the spindles of the antagonistic muscles
- d-** activation of inhibitory interneurons Ans:- D

41) Antigravity muscles maintain stretch reflex for prolonged periods without fatigue, because :-

- a-** they are heavily innervated by α -motor neurons
- b-** they obtain their energy needs mainly from anaerobic metabolic processes
- c-** they contain exceptionally high levels of creatine phosphate
- d-** they are rich in mitochondria Ans:- D

42) The discharge from Golgi tendon organs initiated by excessive stretch of a skeletal muscle produces :-

- a-** inhibition of α -motor neurons of antagonistic muscles
- b-** inhibition of γ -motor neurons of antagonistic muscles
- c-** inhibition of α -motor neurons of the same muscle
- d-** stimulation of γ -motor neurons of the same muscle Ans:- C

43) Inverse stretch reflex :-

- a-** increases the possibility of avulsion of the excessively stretched muscle from its bony attachments
- b-** has no reciprocal innervation circuits
- c-** is clinically manifested by lengthening reaction
- d-** is clinically tested by examining the tendon jerks Ans:- C

44) Skeletal muscle tone :-

- a-** is a dynamic stretch reflex
- b-** has a dynamic state
- c-** is increased during rest
- d-** is decreased during standing upright Ans:- B

45) γ -motor neurons control muscle tone by :-

- a-** adjusting the supraspinal facilitatory discharge
- b-** adjusting the α -motor neuron discharge
- c-** adjusting the muscle spindle discharge
- d-** adjusting the activity of interneurons in the reflex arc of muscle tone Ans:- C

46) Adequate level of muscle tone is essential for the accurate performance of voluntary movements, because :-

- a- it adjusts the α -motor neuron discharge initiating voluntary movements
- b- it adjusts posture of proximal joints of the acting limbs
- c- it adjusts the upright posture of the whole body during voluntary movements
- d- it adjusts sensitivity of the spindles of the involved muscles

Ans:- B

47) A tendon jerk :-

- a- is a dynamic stretch reflex
- b- is a static stretch reflex
- c- is evoked by gradually stretching the muscle
- d- is evoked by stimulation of tendon receptors

Ans:- A

48) The tendon jerk which has its center in the 5th and 6th cervical segments of the spinal cord is

- a. the jaw jerk
- b- the deltoid jerk
- c- the biceps jerk
- d- the triceps jerk

Ans:- C

49) Tendon jerks are clinically examined to assess :-

- a- integrity of muscle spindles
- b- integrity of reflex pathway
- c- the total reflex time of the jerk
- d- central delay time of the jerk

Ans:- B

50) Absence of a tendon jerk could result from any of the following conditions, except :-

- a- lesions of supraspinal facilitatory centers
- b- lesions of the efferent neurons
- c- lesions of the afferent neurons
- d- lesions of the spinal nerve centers

Ans:- A

51) Exaggeration of tendon jerks could result from any of the following conditions, except :-

- a- lesions of supraspinal facilitatory centers
- b- lesions of supraspinal inhibitory centers
- c- increased γ -motor neuron discharge
- d- anxiety

Ans:- A

52) Clonus :-

- a- is a sign of decreased supraspinal facilitation
- b- initiated by briefly stretching the tendon of the muscle
- c- is manifested as oscillating mechanical vibrations following tendon jerks
- d- associates exaggeration of tendon jerks

Ans:- D

- 53**) The central nervous system includes all the following components, except :-
- a- spinal cord
 - b- medulla oblongata
 - c- autonomic ganglia
 - d- diencephalon Ans:- C
- 54**) The central nervous system is connected with the peripheral nervous system by all the following types of nerve fibers, except :-
- a- postganglionic autonomic fibers
 - b- preganglionic autonomic fibers
 - c- somatic motor fibers
 - d- autonomic sensory fibers Ans:- A
- 55**) The sensory system is involved in all the following, except :-
- a- initiation of reflex movements
 - b- initiation of voluntary movements
 - c- learning processes
 - d- initiation of emotional responses Ans:- B
- 56)** The two-element sensory receptors differ from other types of receptors in being:-
- a- more numerous
 - b- more widely spread in the body
 - c- more sensitive
 - d- composed of specialized cells at the sensory nerve terminals Ans:- D
- 57)** Sensory receptors are classified functionally according to the following criteria, except :-
- a- their location in the body
 - b- the nature of tissues in which they are found
 - c- the nature of stimuli acting on them
 - d- their connection with cerebral cortex Ans:- A
- 58)** Most sensory receptors :-
- a- are stimulated by different types of stimuli
 - b- are stimulated only by specific stimuli
 - c- possess a high threshold for their specific stimuli
 - d- only 'b' and 'c' are correct Ans:- B
- 59.** A specific stimulus produces a receptor potential by :-
- a- inhibiting Na⁺ influx into receptor
 - b- inhibiting K⁺ efflux from receptor
 - c- enhancing Na⁺ influx into receptor
 - d- enhancing K⁺ efflux from receptor Ans:- C

60) Receptor potential initiated by an adequate stimulus :-

- a- develops always at its full magnitude
- b- undergoes temporal summation only
- c- undergoes spatial summation only
- d- could initiate an action potential Ans:- D

61) Once initiated, the receptor potential :-

- a- spreads to a long distance along the sensory nerve fiber
- b- amplitude is not related to the strength of the stimulus
- c- always generates an action potential from the receptor
- d- stays for a variable period depending on the type of the receptor Ans:- D

62) Receptor potential generates :-

- a- an electrotonic current which is transmitted along sensory fibers to the CNS
- b- a nerve impulse at the receptive region of the receptor
- c- a state of hyperpolarization of the receptor membrane
- d- a nerve impulse at the spike-initiating region of the receptor Ans:- D

63) When stimulated by effective steady stimuli, sensory receptors :-

- a. continuously discharge impulses
- b- stop discharging after a short time
- c- produce an initial high rate of impulse discharge followed by decline of this rate
- d- differ in their response ; some types discharge continuously, while other types do not respond at all Ans:- C

64) Slowly adapting receptors include all the following types, except :-

- a- Golgi tendon organs
- b- warmth receptors
- c- free nerve endings
- d- Meissner corpuscles Ans:- D

65) Slowly adapting receptors differ from rapidly adapting receptors in :-

- a. stopping to discharge after a relatively longer period of constant stimulation
- b- detecting the dynamic properties of stimuli
- c- detecting velocity of stimuli
- d- generating receptor potentials as long as stimulus is applied. Ans:- D

66) Rapidly adapting receptors are involved in :-

- a- static reflex responses
- b- detection of joint movements
- c- regulation of heart rate
- d- only 'a' and 'b' are correct Ans:- B

67) Receptors detect stimulus intensity by :-

- a- lowering the threshold for receptor stimulation
- b- by generating receptor potentials having higher magnitudes
- c- by generating nerve impulses that are transmitted along sensory fibers at higher velocities
- d- by enhancing the central effects of sensory impulses Ans:- B

68) General sensations :-

- a- originate from all sensory receptors of the body
- b- are mediated by somatic sensory fibers only
- c- include the sense of movement
- d- include the sense of equilibrium Ans:- C

69) Detection of the stimulus modality depends upon :-

- a- the location of the receptors in the body
- b- the magnitude of the stimulus
- c- the anatomical connections between the receptors and specific sensory areas in the cerebral cortex
- d- the magnitude of the receptor potential Ans:- C

70) Receptors detect stimulus intensity by :-

- a. lowering the threshold for stimulating receptors
- b. raising the threshold for stimulating receptors
- c. decreasing the magnitude of receptor potential
- d. raising the magnitude of receptor potential Ans:- D

71) The ability to localize the site of stimuli depends upon :-

- a- the type of the stimulated receptor
- b- connections between the receptor and the sensory cortex
- c- the rate of adaptation of the stimulated receptors
- d- the nature of the stimulus Ans:- B

72) Touch receptors :-

- a- are found only in the skin
- b- are all encapsulated receptors
- c- include two-element receptors
- d- are stimulated by vibration Ans:- D

73) Rapidly adapting tactile receptors include all the following types, except :-

- a- Merkel discs
- b- Meissner corpuscles
- c- Pacinian corpuscles
- d- hair end organs Ans:- A

74) Fine touch :-

- a- is detected by slowly adapting touch receptors
- b- is transmitted by the spinothalamic tract
- c- is characterized by its emotional affect
- d- is not involved in feeling the texture of touched objects Ans:- A

75) Crude touch is more effective than fine touch in evoking an emotional response because :-

- a- its provoking stimuli are stronger
- b- its central pathway connects with the limbic system
- c- it is stimulated during emotional excitement
- d- the provoking stimuli have an emotional nature Ans:- B

76) A more developed two-point tactile discrimination :-

- a- indicates a greater threshold distance for feeling of two points of touch applied simultaneously
- b- is seen in the proximal regions of the body compared with the distal regions
- c- is inversely related to the size of the receptive fields of the stimulated sensory units
- d- depends upon the type of the involved touch receptor Ans:- C

77) Proprioceptive sensations include all the following, except :-

- a. position sense
- b- equilibrium sense
- c- movement sense
- d- kinesthetic sense Ans:- B

78) Proprioceptors include all the following types of receptors, except :-

- a- muscle spindles
- b- pressure receptors
- c- vestibular receptors
- d- joint receptors Ans:- C

79) Proprioceptive sensations are transmitted by all the following pathways, except :-

- a- spinothalamic tracts
- b- spinocerebellar tract
- c- gracile tract
- d- cuneocerebellar tract Ans:- A

80) Astereognosis :-

- a- indicates inability to localize the site of touch on the body surface
- b- results from lesions of the secondary somatic sensory area
- c- associates parietal lobe neglect
- d- results from loss of crude touch sensation Ans:- C

81) Parietal lobe neglect :-

- a- is characterized by inability to use skeletal muscles on the opposite side of the body
- b- is characterized by inability to use skeletal muscles on the same side of the body
- c- results from damage of primary sensory cortex.
- d- causes loss of sensations on the same side of the body Ans:- A

82) Tactile receptors include all the following receptors, except :-

- a- free nerve endings
- b- hair follicle receptors
- c- hair cell receptors
- d- Ruffini nerve endings Ans:- C

83) Pain receptors :-

- a- become more sensitive with prolonged stimulation
- b- are stimulated by prostaglandins
- c- are more numerous in viscera than other tissues
- d- include different morphological types Ans:- A

84) Pain threshold :-

- a- is the highest intensity of stimulus that causes pain
- b- is the lowest intensity of stimulus that causes pain
- c- differs markedly among different individuals
- d- is elevated by substance P Ans:- B

85) Fast pain differs from slow pain in :-

- a- being transmitted in the dorsal column pathway
- b- evoking a depressor autonomic reaction
- c- having a sharp quality
- d- arising from encapsulated pain receptors Ans:- C

86) Double pain sensation that is occasionally felt following painful stimulation of the skin is due to :-

- a- repetition of the painful stimulus
- b- presence of dual pain pathways
- c- perception of pain at two different higher centers
- d- application of two painful stimuli simultaneously at two different sites Ans:- B

87) Cutaneous pain :-

- a- is always sharp in character
- b- is transmitted by A δ sensory fibers
- c- is always followed by hyperalgesia
- d- evokes spasm of nearby muscles Ans:- B

- 88)** Primary cutaneous hyperalgesia
- a- develops in the normal skin region around the area of flare
 - b- is an abnormal condition in the skin in which painful stimuli become more severe
 - c- is due to changes in threshold of pain receptors
 - d- is associated with throbbing type of pain Ans:- C
- 89)** Deep pain shows the following characteristics, except :-
- a- dull aching
 - b- throbbing
 - c- evokes flexor reflexes
 - d- diffuse Ans:- C
- 90)** Intermittent Claudications evoke
- a. visceral pain
 - b. deep pain
 - c- cutaneous hyperalgesia
 - d- colicky pain Ans:- B
- 91)** Pain sensation :-
- a- is evoked by strong stimulation of specific receptors
 - b- produces reactions that block transmission of pain impulses
 - c- arises from small encapsulated receptors
 - d- occurs when the stimulus causes damage of the sensory receptors Ans:- A
- 92)** Reaction to pain includes all the following, except :-
- a- increased heart rate
 - b- depression
 - c- withdrawal reflexes
 - d- stoppage of impulse discharge from nociceptors in chronic painful conditions Ans:- D
- 93)** Pain produced by muscle spasm results from :-
- a- mechanical stimulation of pain receptor by muscle spasm
 - b- decreased release of lactic acid from the spastic muscle fibers
 - c- release of compounds from the spastic muscle which increase the threshold for stimulation of pain receptors
 - d- decreased oxygen supply to the muscle Ans:- D
- 94)** Visceral pain :-
- a- is more common than the other types of pain
 - b- arises only from wall of the visceral organs
 - c- is often well localized
 - d- evokes depressor autonomic reactions Ans:- D

95) Stimuli which evoke true visceral pain include all the following, except :-

- a- sharp cutting
 - b- stretching
 - c- spasm
 - d- chemical irritation
- Ans:- A

96) Visceral pain is usually felt :-

- a. deeply in the diseased viscera
 - b- in deep tissues close to the diseased viscera
 - c- in skin areas that just overlie the diseased viscera
 - d- in skin areas remote from the diseased viscera
- Ans:- D

97) Intracranial headache could result from painful stimuli applied on :-

- a- the dura lining the inner surface of the bones of cranial vault
 - b- the brain tissue
 - c- wall of big intracranial veins
 - d- arachnoid mater
- Ans:- C

98) Intracranial headache may result from all the following clinical causes, except :-

- a- decreased CSF pressure
 - b- spasm of scalp muscles
 - c- distension of big venous sinuses
 - d- pressure upon tentorium cerebelli
- Ans:- B

99) Transmitters in pain control system include all the following, except :-

- a- serotonin
 - b- acetylcholine
 - c- enkephalin
 - d- norepinephrine
- Ans:- B

100) Enkephalin binds best with :- a- delta 'δ' opiate receptors

- b- mu 'μ' opiate receptors
 - c- kappa 'κ' opiate receptors
 - d- all opiate receptors with equal affinity
- Ans:- A

101) Pain control system :-

- a- is activated whenever a painful stimulus is applied to body tissues
 - b- is never activated naturally
 - c- is activated only by administration of opiate drugs
 - d- is activated naturally under conditions associated with strong emotional excitement
- Ans:- D

102) Enkephalin blocks pain transmission by :-

- a- blocking the response of pain receptors to painful stimuli
 - b- slowing down transmission of pain impulses through synapses in the pain pathway
 - c- inhibiting the response of the cerebral cortical somatic sensory area to pain signals
 - d- blocking Ca⁺⁺ channels in the central terminals of pain sensory fibers
- Ans:- D

103) The spinal pain gate is :-

- a. Ligand controlled
 - b- voltage controlled
 - c- opened by enkephalin
 - d- closed by substance P
- Ans:- A

104) Thermal sensations :-

- a- are evoked by all changes in environmental temperatures
 - b- are evoked by stimulation of thermo-sensitive pain receptors
 - c- are involved in regulation of metabolic activity
 - d- are transmitted by A β sensory fibers
- Ans:- C

105) Thermal receptors are :-

- a. slowly adapting receptors
 - b- rapidly adapting receptors
 - c- biphasic receptors
 - d- all encapsulated receptors
- Ans:- A

106) Connexons of gap junctions in electric synapses :-

- a- are Ligand-gated
 - b- are voltage-gated
 - c- allow transmission of potential changes in both directions between the pre- and post-synaptic neurons
 - d- close whenever the presynaptic neuron becomes hyperpolarized
- Ans:- C

107) Chemical synapses in the nervous system :-

- a- allow diffusion of chemical substances from the presynaptic neuron into the postsynaptic neuron
 - b- allow transmission of potential changes in one direction only; from the presynaptic to the postsynaptic neurons
 - c- have potential-gated ionic channels
 - d- are more numerous in the peripheral nervous system than the central nervous system
- Ans:- B

108) Synaptic cleft :-

- a. is the space between two synapses on the surface of neurons
- b- allow diffusion of transmitters between neurons

- c- is filled with intracellular fluid
- d- ranges between 20 – 30 μm in width Ans:- B

109) Synaptic knobs :-

- a- synthesize different types of neurotransmitters
- b- release neurotransmitters by diffusion across their membranes
- c- have ligand-gated Ca^{++}
- d- are located at the terminal end of dendrites Ans:- A

110) Synaptic transmission depends upon :-

- a. direct transmission of impulses from the presynaptic neuron to the postsynaptic neuron
- b- diffusion of neurotransmitters from synaptic knobs into the soma and dendrites of postsynaptic neurons
- c- presence of voltage-gated Ca^{++} channels in membrane of synaptic knobs
- d- presence of voltage-gated Ca^{++} channels in the subsynaptic membrane Ans:- C

111) Postsynaptic receptors include all the following types, except :-

- a- G-protein coupled receptors
- b- ligand-gated cation channels
- c- G-protein regulated K^{+} channels
- d- voltage-gated Cl^{-} channels Ans:- D

112) When opened, the ligand-gated cation channels do not allow diffusion of Cl^{-} because :-

- a- the size of Cl^{-} is bigger than the bore of the channels
- b- intracellular negativity causes complete inhibition of Cl^{-} influx
- c- the channels are specific for diffusion of Na^{+} only
- d- the inner surface of the channels is negatively charged Ans:- D

113) Opening of ligand-gated Cl^{-} channels causes :-

- a- inhibition of the postsynaptic neuron
- b- depolarization of the postsynaptic neuron
- c- initiation of an action potential
- d- block of ligand-gated cation channels Ans:- A

114) IPSP differs from EPSP in :-

- a. being of shorter duration
- b- being unable to summate spatially
- c- moving the membrane potential away from threshold
- d- depending upon opening of voltage K^{+} channels Ans:- C

115) When EPSP and IPSP occur simultaneously the postsynaptic membrane :-

- a- becomes depolarized
- b- becomes hyperpolarized

- c- initiates an action potential
- d- shows potential changes that depend upon the summation of their effects Ans:- D

116) When a postsynaptic neuron is adequately stimulated, action potentials develop at the initial segment of the axon because :-

- a- it contains many voltage-gated Na⁺ channels
- b- it contains the highest concentration of ligand-gated cation channels
- c- it contains many voltage-gated Ca⁺⁺ channels
- d- it is more sensitive to the direct stimulant effect of neurotransmitters Ans:- A

117) IPSP could result from :-

- a. opening of K⁺ channels
- b- opening of ligand-gated cation channels
- c- closure of Cl⁻ channels
- d- closure of potential-gated Ca⁺⁺ channels Ans:- A

118) Synaptic transmission terminated by :-

- a- block of presynaptic receptors
- b- elevation of Ca⁺⁺ concentration in synaptic cleft
- c- reuptake of neurotransmitters by postsynaptic neurons
- d- degradation of neurotransmitters by specific enzymes Ans:- D

119) Presynaptic inhibition is characterized by all the following, except :-

- a. increased Cl⁻ influx into presynaptic terminals
- b- increased Ca⁺⁺ influx into presynaptic terminals
- c- decreased response of postsynaptic receptors
- d- hyperpolarization of presynaptic terminals Ans:- B

120) Presynaptic inhibition depends upon :-

- a- augmented release of chemical transmitter from presynaptic terminals
- b- continued depolarization of presynaptic terminals
- c- GABA receptors in presynaptic terminals
- d- opening of voltage-gated Ca⁺⁺ channels in presynaptic terminals Ans:- C

121) In chemical synapses, transmission occurs in a forward direction because :-

- a- neurotransmitter receptors are found only in the postsynaptic membrane
- b- the subsynaptic membrane does not contain neurotransmitter vesicles
- c- the subsynaptic membrane is more sensitive than the membrane of synaptic knob to the effect of neurotransmitters
- d- the subsynaptic membrane contains both ligand-gated and voltage-gated ionic channels
Ans:- B

122) Synaptic delay :-

- a- is the time needed for release of neurotransmitter from synaptic vesicles
- b- the minimal delay time in the central nervous system is about 0.5 millisecond
- c- is determined by the type of the neurotransmitter
- d- is determined by the number of postsynaptic receptors Ans:- B

123) Synaptic fatigue is due to :-

- a. decreased synthesis of neurotransmitters
- b- inability to release neurotransmitters by exocytosis
- c- failure of action potentials to open voltage-gated Ca^{++} channels in presynaptic terminal
- d- imbalance in between rates of synthesis and release of neurotransmitters Ans:- D

124) Synaptic transmission is inhibited by all the following, except

:-

- a- oxygen lack
- b- alkalosis
- c- acidosis
- d- prolonged activity of synapse Ans:- B

125) Post-tetanic Potentiation in synapses :-

- a- is due to increased Ca^{++} concentration in postsynaptic neurons
- b- is due to increased Ca^{++} influx into presynaptic neurons
- c- results from slow prolonged stimulation of synapse
- d- causes fatigue of the synapse Ans:- B

126) Long-term potentiation of synaptic transmission :-

- a- is involved in pain control system
- b- is caused by increased Ca^{++} concentration in presynaptic neurons
- c- results from fast repetitive stimulation of synapse
- d- is associated with decreased Ca^{++} concentration in postsynaptic neurons Ans:- C

127) Drugs which open Cl^- channels in synapses :-

- a- cause depolarization of postsynaptic membrane
- b- cause hyperpolarization of postsynaptic membrane
- c- enhance release of neurotransmitters from synaptic knobs
- d- enhance response of postsynaptic neurons Ans:- B

128) Small-molecule neurotransmitters include all the following types, except :-

- a- Substance P
- b- gamma amino butyric acid
- c- acetylcholine
- d- norepinephrine Ans:- A

129) Neuropeptides :-

- a- are synthesized in the synapticknobs
- b- consist of small molecules
- c- interact with ligand-receptors
- d- could produce prolonged changes in the structure of postsynaptic neurons Ans:- D

130) All the following transmitters are neuropeptides, except :-

- a- neuropeptide Y
- b- somatostatin
- c- dopamine
- d- enkephalin Ans:- C

131) Actions of neuropeptides include all the following, except :-

- a. inhibition of gene transcription
- b- decreased cyclic AMP synthesis
- c- changing intracellular Ca ++ level
- d- activation of ligand-gated receptors Ans:- D

132. What part of a neuron is responsible for receiving information?

- a. axon
- b. terminal fibre
- c. dendrite
- d. myelin sheath Ans:- C

133. Electrical stimulation of the reticular formation would most likely cause an animal to:

- a. sneeze
- b. become blind
- c. wake up if it had been sleeping
- d. stop breathing Ans:- C

134. In evolutionary terms, which is the oldest part of the brain?

- a. the limbic system
- b. the cortex
- c. the right hemisphere
- d. the brain stem Ans:- D

135. The change in electrical charge that occurs in a neuron when a nerve impulse is transmitted is known as the:

- a. action potential
- b. synaptic change
- c. refractory period
- d. ionic charge Ans:- A

136. Schizophrenia and Parkinson's disease are both linked to changes in which

neurotransmitter?

- a. serotonin
 - b. glutamate
 - c. dopamine
 - d. acetylcholine
- Ans:- C

137. The limbic system includes the:

- a. amygdala, hypothalamus, hippocampus
 - b. hypothalamus, medulla, hippocampus
 - c. hippocampus, pons, thalamus
 - d. cerebellum, pons, hypothalamus
- Ans:- A

138. The ___ is to feeling fear as the _____ is to feeling pleasure.

- a. pons/medulla
 - b. amygdala/hypothalamus
 - c. thalamus/hypothalamus
 - d. cerebellum/amygdala
- Ans:- B

139. The effect of neurotransmitters may be:

- a. chemical or electrical
 - b. excitatory or inhibitory
 - c. positive or negative
 - d. active or passive
- Ans:- B

140. The terminal buttons of a neuron are located at the end of its:

- a. axon
 - b. dendrite
 - c. myelin sheath
 - d. nodes of ranvier
- Ans:- A

141. Which lobe is most closely associated with visual processing?

- a. frontal
 - b. temporal
 - c. parietal
 - d. occipital
- Ans:- D

142. Communication within neurons is __, communication between neurons is ____.

- a. excitatory, inhibitory
 - a. frontal
 - b. dorsal
 - c. parietal
 - d. temporal
- Ans:- B

A person who is drunk may have difficulty walking in a straight line because the alcohol has impacted their:

- a. thalamus
 - b. reticular formation
 - c. amygdala
 - d. cerebellum
- Ans:- D

145. Neurotransmitters carry signals across the_____.

- a. refractory gap
 - b. axonal gap
 - c. synaptic gap
 - d. hippocampal gap
- Ans:- C

146. The poison curare is

- a. (n) for the
 - b. inhibitory, excitatory
 - c. chemical, electrical
 - d. electrical, chemical
- Ans:- D

147. Which of the following is NOT a lobe of the brain?
neurotransmitter acetylcholine.

- a. antagonist
 - b. protagonist
 - c. agonist
 - d. cure
- Ans:- A

148. Damage to the hippocampus is most likely to impair:

- a. memory
 - b. balance
 - c. sleep
 - d. breathing
- Ans:- A

149. Which part of the limbic system is involved in an animal's feeling of hunger?

- a. thalamus
 - b. pons
 - c. hippocampus
 - d. hypothalamus
- Ans:- D

150. The___consist of glands that secrete hormones:

- a. nervous system
 - b. immune system
 - c. endocrine system
 - d. cerebral cortex
- Ans:- C

- 151.** Testosterone is to _____ as estrogen is to _.
- a. thyroid, parathyroid
 - b. testes, ovaries
 - c. sympathetic, parasympathetic
 - d. pancreas, pituitary
- Ans:- A
- 152.** What do we call the layer of fatty tissue surrounding the axon of some neurons?
- a. cutaneous coating
 - b. myelin sheath
 - c. dendritic barrier
 - d. synaptic sleeve
- Ans:- B
- 153.** In the context of brain imaging, what does FMRI stand for?
- a. fast moving recovery imaging
 - b. first moveable recording indicator
 - c. flexible motion resistance indicator
 - d. functional magnetic resonance imaging
- Ans:- D
- 154.** Which lobe is primarily responsible for hearing and language?
- a. temporal
 - b. parietal
 - c. frontal
 - d. occipital
- Ans:- A
- 155.** After a car accident, Rhodri had a lot of difficulty planning his day. This is most likely the result of damage to which lobe?
- a. temporal
 - b. parietal
 - c. frontal
 - d. occipital
- Ans:- C
- 156.** Which area of the brain stem controls heart rate and breathing?
- a. reticular formation
 - b. medulla
 - c. pons
 - d. thalamus
- Ans:- B
- 157.** Which structure allows communication between the hemispheres?
- a. reticular formation
 - b. temporal lobe
 - c. contralateral bridge
 - d. corpus callosum
- Ans:- D
- 158.** Which part of the endocrine system is sometimes called the “master gland”?
- a. adrenal gland
 - b. pancreas

- c. pituitary gland
 - d. pineal gland
- Ans:- C

159. Which of the following is NOT part of the endocrine system?

- a. pons
 - b. pancreas
 - c. parathyroid
 - d. pineal gland
- Ans:- A

160. Where would you see the nodes of Ranvier?

- a. on an axon
 - b. in the cell body
 - c. on a dendrite
 - d. a and c
- Ans:- A

161. The brain's ability to change in response to experience or damage is called:

- a. lateralization
 - b. lesioning
 - c. neuroplasticity
 - d. functionality
- Ans:- C

162. Which is the most common neurotransmitter in the brain?

- a. serotonin
 - b. glutamate
 - c. dopamine
 - d. GABA
- Ans:- B

163. Reductionist and materialist approaches to the study of psychological phenomena led psychology to look for explanations in terms of

- a. physiological properties
 - b. psychological properties
 - c. evolution
 - d. social factors
- Answer: A

164. Donders (1818–89) introduced psychology to the concept of being able to ascertain the exact duration of a mental judgement following the presentation of a stimulus. This is referred to as

- a. mental chronometry
 - b. zietgerber
 - c. reaction time
 - d. mental synchronicity
- Answer: A

165. Fechner also proposed the idea that the physical intensity of a physical stimulus is NOT accurately reflected in our perceived intensity of the stimulus. To measure perceived intensity, he proposed the idea of perceptual discrimination – being able to detect changes in the physical intensity itself. The unit of measure was referred to as the

- a. Just Negligible Discrepancy
 - b. Just Noticeable Discrepancy
 - c. Just Noticeable Difference
 - d. Just Negligible Difference
- Answer: C

166. Francis Galton and Alfred Binet also developed methods for measuring and quantifying

- a. personality
 - b. intelligence
 - c. locus of control
 - d. gender
- Answer: B

167. An example of a psychological phenomenon that Wundt proposed was beyond experimental or objective scientific methodology is

- a. complex feelings
 - b. drug--neuron interaction
 - c. altruistic behaviour
 - d. adrenal output
- Answer: A

168. Wundt also emphasised the importance of researching individuals in their ___ and _____ contexts in order to fully appreciate psychological phenomena.

- a. private, social
 - b. private, environmental
 - c. social, cultural
 - d. social, family
- Answer: C

169. Freud's hysteria is now referred to as

- a. dissociative disorder
 - b. personality disorder
 - c. neuroticism
 - d. psychoticism
- Answer: A

170. What did Freud believe to be the cause of hysteria?

- a. neurochemical imbalance
 - b. faulty cognition
 - c. unconscious content
 - d. negative reinforcement
- Answer: C

171. Freud was the founder of a form of talking therapy that aims to help the patient to coax unconscious desires into the conscious awareness. This form of therapy is known as

- a. behaviourism
 - b. humanistic therapy
 - c. transpersonalism
 - d. psychoanalysis
- Answer: D

172. What is the key tenet of Freud's psychoanalytic therapy?

- a. all human behaviour is caused by the Oedipus complex

- b. all human behaviour is caused by unconscious content
- c. all human behaviour is caused by stimulus–response associations
- d. all human behaviour is caused by interactions with the environment Answer: B

173. One of the many means by which Freud analyzed the unconscious content of his patients included

- a. interpreting dreams
- b. gradual exposure
- c. cognitive restructuring
- d. interpreting non-verbal behaviour Answer: A

174. Freud's early ideas regarding the motivation behind human behaviour had important implications for the development of which branch of psychology?

- a. therapeutic psychology
- b. cognitive psychology
- c. atypical psychology
- d. abnormal psychology Answer: D

175. William James's ideas regarding psychological phenomena centred around the idea of

- a. a stream of consciousness
- b. the sea of the subconscious
- c. a stream of subconsciousness
- d. a sea of consciousness Answer: A

176. Two key ideas defined James's concept of a stream of consciousness:

Consciousness has evolved to be

____, in that people choose between alternative courses of action. Consciousness is also____, in that these choices are important in helping the individual to adapt to his/her environment.

- a. selective, functional
- b. functional, selective
- c. transcendent, predetermined
- d. predetermined, transcendent Answer: A

177. The debate over whether our behaviour and thinking are controlled by physiological, unconscious and environmental forces versus being able to behave and think as we wish, is referred to as

- a. the reductionist-determinism debate
- b. the freewill-determinism debate
- c. the biological-freewill debate
- d. the freewill-reductionism debate Answer: B

178. What was the goal of the behaviourist approach to psychology?

- a. to use self-reports of experiences
- b. to objectively predict behaviour
- c. to condition humans to salivate upon the mere presentation of food
- d. to demonstrate the role of freewill in human behaviour via controlled experiments Answer: B

- 179.** Pavlov's work in demonstrating behaviourist principles regarding the relationship between stimuli and behavioural responses became known as
- a. operant conditioning
 - b. associative learning
 - c. classical conditioning
 - d. shaping
- Answer: C
- 180.** Thorndike's work demonstrated another form of behaviourist learning, whereby organisms can be trained to display a specific behavioural response more frequently if the outcome of that behaviour led to the acquisition of a desirable reward. This form of conditioned learning is now referred to as
- a. operant conditioning
 - b. classical conditioning
 - c. positive reinforcement
 - d. social learning
- Answer: A
- 181.** Bartlett, Piaget and Gestalt psychologists like Lewin and Zeigarnik are examples of key figures in psychology who challenged the behaviourist notion that certain processes play no role in determining human behaviour. Which processes are these?
- a. biological processes
 - b. mental processes
 - c. environmental processes
 - d. sociocultural processes
- Answer: B
- 182.** A key weakness of behaviourist theories is
- a. explaining human behaviour based on observations of animal behaviour
 - b. an overwhelming focus on cognitive processes
 - c. the use of self-reported data
 - d. its positive view of all human behaviour
- Answer: A
- 183.** Following criticisms of behaviourism, what was the new approach to exploring psychological phenomena to gain momentum?
- a. cognitive science
 - b. psychoanalysis
 - c. transpersonalism
 - d. phenomenology
- Answer: A
- 184.** Which of the following is an example of an abstract structure that the cognitive approach considers underpins psychological phenomena?
- a. attitudes
 - b. neuronal receptors
 - c. nervous system
 - d. hormones
- Answer: A
- 185.** One of the key methods that cognitive approaches to psychology utilize in order to link sub-

- jective mental phenomena to brain function is
- a. implicit association tests
 - b. neurosurgery
 - c. extrasensory perception
 - d. cognitive neuroscience
- Answer: D
- 186.** Humanistic psychologists argue that in order to properly understand human nature, we need to take account of
- a. subjective human experience
 - b. underlying mental disturbances
 - c. inherent gender differences
 - d. repressed animal instincts
- Answer: A
- 187.** Key figures in psychology who propelled humanism include
- a. Laurel and Hardy
 - b. Maslow and Rogers
 - c. Pegg and Frost
 - d. Watson and Skinner
- Answer: B
- 188.** Which of the following does Rogers NOT list as a feature of a psychologically healthy person?
- a. spontaneity and flexibility
 - b. creativity
 - c. a firm belief in his/her own importance
 - d. the will to follow his/her own instincts
- Answer: C
- 189.** The concept that modern psychologists will usually use techniques that best fit the problem they're investigating is referred to as
- a. expedient psychology
 - b. the path of least resistance
 - c. pragmatic psychology
 - d. the limited horizon hypothesis
- Answer: C
- 190.** Frederic Bartlett carried out an investigation that demonstrated how the accuracy of a person's recall of details from a story could be significantly distorted by
- a. whether or not someone has eaten in the last hour
 - b. the temperature of the room where the experiment was conducted
 - c. the cultural background of the person hearing the story
 - d. the current phase of the moon
- Answer: C
- 191.** What research method has been associated with psychology's return to a focus on the importance of subjective psychological phenomena?
- a. qualitative
 - b. self-reports
 - c. face-to-face interviews
 - d. psychometrics
- Answer: A

192. The most important historical figure to develop the idea of evolution is

- a. Darwin
 - b. Mendel
 - c. Crick
 - d. Buss
- Answer: A

193. System of the body which coordinates and controls its activity is known as _

- a) Organ system
 - b) Muscular system
 - c) Nervous tissue
 - d) Nervous system
- Answer: d

Explanation: Nervous system is the one which is responsible for all the activities of the body. It coordinates and controls the activities of the animal.

194. Peripheral nervous system consists of the brain and spinal cord.

- a) True
 - b) False
- Answer: b

Explanation: Nervous system has two subdivisions, i.e., CNS and PNS. CNS or central nervous system consists of the brain and spinal cord while PNS or peripheral nervous system includes all nervous tissues outside the CNS.

195. Which of the following is NOT the component of the PNS?

- a) Elastic connective tissue
 - b) Cranial nerves
 - c) Spinal nerves
 - d) Ganglia
- Answer: a

Explanation: Peripheral nervous tissue consists of all nervous tissue outside the central nervous system. The main components of PNS are spinal nerves and their branches, cranial nerves and their branches, sensory receptors, and ganglia.

196. Name the basic structural and functional unit of the nervous system.

- a) Neuroglia
 - b) Glial cells
 - c) Neurons
 - d) Perikaryon
- Answer: c

Explanation: Nervous system has been composed of two types of cells, i.e., neurons and neuroglia. Neurons are the basic functional and structural unit of the nervous system.

197. Which of the following cells supports, nourishes, and protect the neurons?

- a) Nissl bodies
- b) Perikaryon
- c) Ganglia

d) Glial cells Answer: d

Explanation: Glial cells (glia = glue) are also called neuroglia, these cells support, nourish, and protect the neurons while ganglia are the cluster of cell bodies which are found in the PNS.

198. What is the speed of nerve impulse?

- a) 60 m/s
 - b) 0.5 – 130 m/s
 - c) 10-30 m/s
 - d) 50 -150 m/s
- Answer: b

Explanation: Nerve impulse or action potential is the electrical signal which travels through the membrane of the neurons. The speed of these signals ranges from 0.5 to 130 m/s.

199. What are Nissl bodies?

- a) Golgi bodies
 - b) Lysosomes
 - c) Cluster of rough endoplasmic reticulum
 - d) Mitochondria
- Answer: c

Explanation: Neurons are made up of three parts, i.e., cell body, dendrites, and axon. The cell body consists of ribosomes and a cluster of endoplasmic reticulum, which is known as Nissl bodies.

200. Which of the following is NOT found in axon?

- a) Endoplasmic reticulum
 - b) Neurofibrils
 - c) Mitochondria
 - d) Microtubules
- Answer: a

Explanation: Endoplasmic reticulum is not present in axons as it does not synthesize protein. An axon contains mitochondria, neurofibrils, and microtubules and the cytoplasm of an axon is called axoplasm.

201. Name the multipolar neuron which is located entirely within the central nervous system.

- a) Motor neuron
 - b) Efferent neuron
 - c) Afferent neuron
 - d) Interneuron
- Answer: d

Explanation: Interneurons are the multipolar neurons, which are found within the CNS. Motor neurons are also known as efferent neurons, they transfer signals from the CNS to effector organs.

202. Out of the following, which one does not affect the speed of conduction of nerve impulse.

- a) No. of ganglia
 - b) Myelin sheath
 - c) Axon diameter
 - d) Temperature
- Answer: a

Explanation: The speed of conduction of nerve impulse depends upon three factors, i.e., myelin sheath, temperature, and axon diameter. Higher the temperature higher would be the speed and

also larger the diameter higher the speed.

203. The eyes are the most complex sense organ of the body.

- a) True
- b) False

Answer: a

Explanation: There are number of receptors in the eye, the lens concentrates light on these receptors which thusly made a motivation. This drive goes to the cerebrum and produces pictures.

204. Which of the following is known as the “window of the brain”?

- a) Sensory organs
- b) Cranial nerves
- c) Eyes
- d) Ganglia

Answer: a

Explanation: Sensory organs are considered as the “window of the brain”. When external stimuli contacted with sensory receptors, it sends signals to the brain in the form of nerve impulse which results in the sensation.

205. Which of the following helps in maintaining the shape of the eye?

- a) Neuroglia
- b) Aqueous humor
- c) Vitreous humor
- d) Perikaryon

Answer: c

Explanation: Vitreous humor is a viscous mass that helps in maintaining the shape of the eye. The lens is surrounded by the aqueous humor from one side and vitreous humor from the other side.

206. Mark the INCORRECT statement about the lens?

- a) Protein found in the lens are α , β , and γ crystalline
- b) Composed of water and proteins
- c) Mainly made up of water
- d) It has a blood supply

Answer: d

Explanation: Though lens does not have a blood supply, it is active. Lens is basically made up of water and protein and many vertebrates have lens protein α , β , and γ crystalline.

207. What is Sclera?

- a) Cornea
- b) White part of the eye
- c) Red part of the eye
- d) Lens

Answer: b

Explanation: Sclera is the white part of the eye which covers the entire eye except for cornea and is made up of collagen fibers and fibroblast.

208. Name the part of the eye, which is involved in focusing light on the retina?

- a) Sclera
- b) Iris
- c) Cornea
- d) Ciliary muscles

Answer: c

Explanation: Fibrous tunic is composed of anterior cornea and posterior sclera. It is a surface coating of an eyeball. Transparent cornea covered colored iris and it helps in focussing light on the retina.

209. Iris is found in which layer of the eyeball?

- a) Vascular tunic
- b) Retina
- c) Fibrous tunic
- d) Microtubules

Answer: a

Explanation: Eyeball is made up of three layers, i.e., fibrous tunic, vascular tunic, and retina. The middle layer of the eyeball is a vascular tunic. It consists of three parts: ciliary body, iris, and choroid.

210. Among the following, which is one is more vascularized and pigmented.

- a) Cornea
- b) Iris
- c) Ciliary body
- d) Choroid

Answer: d

Explanation: Choroid is highly pigmented with melanin and vascularized structure which forms the posterior region of vascular tunic. It absorbs scattered light and also supplies blood.

211. Name the part of the eye which produces aqueous fluid that fills the front part of the eye.

- a) Ciliary body
- b) Cornea
- c) Vitreous humor
- d) Uvea

Answer: a

Explanation: In the back locale of vascular tunic choroid end up a ciliary body. Ciliary body produces the watery liquid that fills the front piece of the eye and it is likewise situated behind the iris.

212. In human ear, secretion of wax is done by_

- a) Cochlea
- b) Vestibule
- c) Basilar membrane
- d) Ceruminous glands

Answer: d

Explanation: Human ear has the number of sweat glands called ceruminous glands. These glands are present on the skin from exterior to interior part. The secretion of these glands called cerumen or wax.

213. Human ear converts sound energy to mechanical energy which is transmitted to the brain through nerve impulse.

a) True

b) False Answer: a

Explanation: The human ear works as a transducer which converts sound energy into mechanical energy to a nerve impulse which is further detected by the brain.

214. Conversion of vibrations into compressed wave takes place in which part of human ear?

a) Inner ear

b) Middle ear

c) Outer ear

d) Exterior ear Answer: a

Explanation: Ear is broadly divided into three parts that are outer, middle, and inner. Sound wave goes through the outer ear gets converted to vibration by middle ear. Passing of vibration to inner ear further converts it in the form of compressed wave.

215. Name the light absorbing pigment present in the Rods?

a) Neuroglia

b) Aqueous humor

c) Rhodopsin

d) Perikaryon View Answer Answer: c

Explanation: The light absorbing pigment present in the rods is rhodopsin and it is also a G-protein coupled receptor which upon activation activates transducin.

216. Name the G- protein, which takes part in vision?

a) Ethylene

b) Adenosine

c) Acetylcholine

d) Transducin Answer: d

Explanation: Rhodopsin activates molecules of transducin which further activates an enzyme to breakdown cyclic GMP. The drop in cyclic GMP will open sodium channel which is responsible for vision.

217. What is the absorption peak of green absorbing cones?

a) 565 nm

b) 535 nm

c) 768 nm

d) 440 nm Answer: b

Explanation: The color vision of our eye is dependent on the three types of cones, i.e., green absorbing, red absorbing cones, and blue absorbing cones.

218. Which of the following is NOT true for Rods?

a) Used for scotopic vision

b) Loss causes night blindness

c) Not very light sensitive

d) Confer achromatic vision Answer: c

Explanation: Rods are very light sensitive while cones are not that much light sensitive. Cones enable us to see colors by producing sharpest images.

219. Name the tiny bone of the middle ear, which convert sound into vibration?

a) Stapes

b) Malleus

c) Incus

d) Anvil Answer: a

Explanation: The space of the middle ear is filled with air where the tympanic membrane separates the inner and external ear. Eardrum transfer sound energy to middle ear, which in turn convert it to vibrate.

220. Organs involve in the sensation of the body is known as

a) Organ system

b) Muscular system

c) Nervous tissue

d) Sensory organs Answer: d

Explanation: Those organs which include hearing, seeing, taste and smell are known as sensory organs. For ex: eye, ear, nose, skin, and tongue.

221. Name the hormone which takes part in the release of FSH and LH from the anterior pituitary.

a) Growth hormone

b) GnRH

c) Somatostatin

d) TRH Answer: b

Explanation: GnRH is Gonadotropin Releasing Hormone, which is responsible for the release of follicle stimulating hormone (FSH), and luteinizing hormone (LH).

222. Chemical messengers secreted by ductless glands are called _____

a) Lymph

b) Platelets

c) Plasma

d) Hormones Answer: d

Explanation: Hormones are the chemical messengers which are secreted by the ductless glands called endocrine glands. These glands are controlled by the endocrine system.

223. Endocrine glands secrete products into the ducts and transfer it into body cavities.

a) True

b) False Answer: b

Explanation: Endocrine glands are called ductless glands. They secrete their products directly into the bloodstreams and circulate in the body.

224. Which of the following is NOT an endocrine gland?

- a) Hypothalamus
 - b) Pituitary
 - c) Parathyroid
 - d) Pancreas
- Answer: a

Explanation: All of them are endocrine glands except hypothalamus. Hypothalamus and thymus are not classified as an endocrine gland, but included in the endocrine system as they involve in the secretion of hormones.

225. Which of this statement is INCORRECT regarding the function of hormones?

- a) Reproduction and sexual differentiation
 - b) Maintenance of internal environment
 - c) Maintain body temperature
 - d) Development and growth
- Answer: c

Explanation: Hormones are released by specialized cells of the endocrine glands and act on distantly located target cells. A single hormone can contribute many functions and sometimes many hormones can perform a single function.

226. Mark the one, which is NOT the precursor of the hormone?

- a) Amino acids
 - b) Cholesterol
 - c) Phospholipids
 - d) Proteins
- Answer: d

Explanation: Chemically, hormone can be divided into two categories, i.e., lipid soluble and water soluble hormones.

227. What is the precursor of steroid hormone?

- a) Protein
 - b) Cholesterol
 - c) Carbohydrate
 - d) Lipid
- Answer: b

Explanation: Cholesterol acts as a precursor of steroid hormone. DHEA is a natural steroid hormone which is synthesized from cholesterol.

228. Which of the is a fat soluble hormone?

- a) Amine hormone
 - b) Peptide hormone
 - c) Thyroid hormone
 - d) Protein hormone
- Answer: c

Explanation: Thyroid is a lipid soluble hormone while amine, peptide, and protein hormones are water soluble, ranging from size 3 to over 200 amino acids.

229. Name the hormone which is synthesized from histidine amino acid?

- a) Histamine
- b) Epinephrine
- c) Norepinephrine
- d) Dopamine

Answer: a

Explanation: Epinephrine, norepinephrine, and dopamine are amine hormones, which are synthesized by modifying amino acid tyrosine.

230. Which of the following is protein hormone?

- a) Oxytocin
- b) Insulin
- c) TSH
- d) Antidiuretic hormone

Answer: b

Explanation: Insulin and human growth hormones are protein hormone while oxytocin and antidiuretic hormones are peptide hormones. TSH or thyroid stimulating hormone has carbohydrate attached to the protein so it comes under glycoprotein hormone.

231. Name the gland, which releases neurohormone.

- a) Hypothalamus
- b) Pituitary
- c) Thyroid
- d) Pancreas

Answer: a

Explanation: Neurohormone are those which changes their function according to their requirements like they can be releasing hormones or inhibiting hormone.

232. Name the process of gaseous exchange in the body.

- a) Lymphatic system
- b) Respiration
- c) Cardiovascular system
- d) Respiratory system

Answer: b

Explanation: Respiration is the process of gaseous exchange in the body while cardiovascular regulates the blood flow throughout the body.

233. Nose, larynx, pharynx, lungs, trachea, and bronchi are the parts of the respiratory system.

- a) True
- b) False

Answer: a

Explanation: Respiratory system consists of all the organs which take part in the respiration. It includes bronchi, trachea, lungs, nose, larynx, and pharynx.

234. Which of the following is NOT the function of the respiratory system?

- a) Regulate blood pH
- b) Helps in gaseous exchange
- c) Protection against blood loss
- d) Contains receptors for the sense of smell

Answer: c

Explanation: Respiratory system helps in regulation of blood, pH, and also contain receptors of smell, produces vocal sound and filter inspired air while cardiovascular system protects against blood loss by the formation of blood clots.

235. Which of this statement is TRUE for pulmonary respiration?

- a) Exchange of gases between alveoli of lungs and the blood
- b) Exchange of gases between blood and tissue cells
- c) Breathing between the atmosphere and the alveoli of the lungs
- d) Production of ATP

Answer: a

Explanation: Pulmonary respiration is the exchange of gases between the alveoli of the lungs and the blood in the capillaries. Exchange of gases between blood and tissue cells occurs in internal respiration.

236. Which of the following controls the normal breathing process?

- a) Amino acids
- b) Cholesterol
- c) Ventral respiratory group
- d) Dorsal respiratory group

Answer: d

Explanation: Ventral respiratory group contains both inspiratory and expiratory neurons and controls forced breathing while dorsal respiratory group contains only inspiratory neurons control normal breathing.

237. Oxygen and hemoglobin bind in a reversible manner to form ___

- a) Carboxyhemoglobin
- b) Oxyhemoglobin
- c) Methoglobin
- d) BPG

Answer: b

Explanation: Oxyhemoglobin is formed by the combination of oxygen and hemoglobin. Oxygen binds to the hemoglobin in a reversible manner. 98% of oxygen is trapped inside RBC.

238. How many oxygen molecules bound to hemoglobin to give 50% saturation?

- a) 6
- b) 4
- c) 2
- d) 7

Answer: c

Explanation: Hemoglobin can bind with maximum 4 oxygen molecules, so for obtaining 50% saturation only 2 molecules of oxygen should be bound to hemoglobin.

239. What is the name of the gland which secretes melatonin?

- a) Pituitary gland
- b) Pineal gland
- c) Thyroid gland
- d) Hypothalamus

Answer: b

Explanation: Pineal gland is the smallest endocrine gland attached to the roof of the brain and secretes melatonin. Melatonin is responsible for settling of the biological clock.

240. Which of the following is Growth hormone inhibiting hormone?

- a) FSH
 - b) TRH
 - c) GHRH
 - d) Somatostatin
- Answer: d

Explanation: Somatostatin works against the growth hormone (GHRH), so it is known as growth inhibiting hormone. It consists of two peptides of 14 and 28 amino acids and is released from neurosecretory nerves.

241. Mark the one, which is not inhibited by the effect of somatostatin.

- a) GH
 - b) TSH
 - c) Glucagon
 - d) Dopamine
- Answer: d

Explanation: Dopamine is prolactin inhibiting hormone (PIH), which inhibits the release of prolactin from the anterior pituitary. It also functions as a neurotransmitter.

242. Gibson's direct theory of perception is important because it shows perception to be

- a. top-down
 - b. constructive
 - c. impoverished
 - d. dynamic
- Answer: D

243. Before light is absorbed by cells in the retina, it travels through a number of structures at the front of the eye. What is the correct order of these structures?

- a. cornea; pupil; lens
 - b. pupil; cornea; lens
 - c. cornea; lens; pupil
 - d. pupil; lens; cornea
- Answer: A

244. What transmits electrical information from the ear to the brain?

- a. outer hair cells
 - b. auditory nerve fibres
 - c. ganglion cells
 - d. rods and cones
- Answer: B

245. How many chambers are there in the human cochlea?

- a. 1
 - b. 2
 - c. 3
 - d. 4
- Answer: C

246. Perception is ...

- a. ... an accurate representation of the world
- b. ... an appropriate representation of the world
- c. ... an adequate representation of the world
- d. ... a native representation of the world Answer: C

247. A driver fails to notice a pedestrian who has just stepped out into the road. This is an example of

- a. change blindness
- b. attentional blindness
- c. space-based attention
- d. inattentional blindness Answer: D

248. In the cochlea, the basal membrane is tonotopic, i.e. sounds are

- a. organized spatially according to frequency
- b. organized in terms of how frequently they fire
- c. organized spatially according to the size of connecting nerve fibres
- d. organized according to left or right ear input Answer: A

249. Which one of the following is NOT a pair of Gestalt psychology principles?

- a. continuity and closure principles
- b. similarity and emergence principles
- c. symmetry and order principles
- d. proximity and eminence principles Answer: D

250. The organ of Corti is responsible for

- a. limiting sound amplitude so as not to damage the inner ear organs
- b. reducing the amount of environmental noise
- c. amplifying attended sounds
- d. converting basilar membrane movement to brain activity Answer: D

251. Name the hormone, which is released by the posterior pituitary.

- a) Oxytocin
- b) TSH
- c) ICSH
- d) Prolactin Answer: a

Explanation: Oxytocin and vasopressin are released by the posterior pituitary. Posterior pituitary does not synthesize hormones, but it can store and release these two hormones.

252. Which area of the temporal lobes is thought to be specialized for processing face-like stimuli?

- a. the fusiform gyrus area (FGA)
- b. the focal face area (FFA)

- c. the fusiform facial area (FFA)
- d. the face formation arena (FFA) Answer: C

253. Which one of the following statements is NOT an account of constructivist perception?

- a. perception is not just sensation, it is an active process
- b. perception is a direct by-product of sensations and hypotheses about the world and how it works
- c. perception is derived from visual information in the optic array
- d. perception is influenced by individual differences Answer: C

254. The auditory ventral stream terminates in

- a. Shatner's bassoon
- b. orbitofrontal cortex
- c. dorsolateral prefrontal cortex
- d. cingulate gyrus Answer: B

255. Rod photoreceptors are principally involved in processing

- a. colour
- b. movement
- c. visual acuity
- d. location Answer: B

256. Cells leaving the eye travel along two major visual routes (and some minor ones). One of these is the lateral geniculate pathway. What is the other major pathway?

- a. The ocular geniculate pathway
- b. The tuberoinfundibular pathway
- c. The mesocortical pathway
- d. The retinotectal pathway Answer: D

257. In the direct theory of perception, information in the visual field that remains constant is the

- a. optic array
- b. optic flow
- c. invariant
- d. affordance Answer: C

258. Two processes that when independently disrupted leave the other one intact are known as

- a. double jeopardy
- b. double entendre
- c. double dissociation
- d. double association Answer: C

259. What is the name for the phenomenon of experiencing one kind of impression when stimulated by a different sensory organ stimulus (e.g. tasting shapes, smelling colour, seeing sounds)?

- a. divided attention
- b. synaesthesia

- c. prosopagnosia
 - d. perceptual load
- Answer: B

260. The fovea contains a concentration of

- a. cones
 - b. rods
 - c. rods and cones
 - d. vitreous humour
- Answer: A

261. Which of the following is NOT an element of Broadbent's theory of attention?

- a. limited capacity processor
 - b. selective filter
 - c. sensory buffer
 - d. spotlight
- Answer: D

262. The direct perception of an object's purpose is the

- a. ecological optic
 - b. affordance
 - c. invariant
 - d. optic array
- Answer: B

263. Glass micro-capillaries are a type of micro electrode.

- a) True
 - b) False
- Answer: a

Explanation: Two types of micro electrodes are generally used: metallic and glass microcapillaries. Metallic electrodes are formed from a fine needle of suitable metal drawn for a fine tip. Glass electrodes are drawn from Pyrex glass of special grade.

264. Glass microcapillaries are preferred over metallic electrodes because of the former _____

- a) polarizes with input current
- b) does not have sustainable current carrying capacity
- c) has less contact surface area
- d) has sustainable current carrying capacity

Answer: d

Explanation: Metallic electrodes polarize with smaller amplifier input currents. Hence, they tend to develop unstable electrode offset potential and are therefore not preferred for steady state potential measurement. On the other hand, in case of glass micro electrodes have a sustainable current carrying capacity because of the large surface area between the metal and the electrolyte.

265. Do metallic micro electrodes exist.

- a) True
 - b) False
- Answer: a

Explanation: Two types of micro electrodes are generally used: metallic and glass microcapillaries. Metallic electrodes are formed from a fine needle of suitable metal drawn for a fine tip. Glass

electrodes are drawn from Pyrex glass of special grade.

266. Metallic micro electrodes have impedance _____ compared to conventional electrodes?

- a) equal
 - b) smaller
 - c) high
 - d) very high
- Answer: d

Explanation: The very high impedance of the metal micro-electrodes is due to the characteristics of the small area metal-electrolyte interface. Because of very high impedance of micro electrodes, amplifiers with extremely high input impedance are required to avoid loading the circuit and to minimize the effects of small change in interface impedance.

267. Which of the following electrode is manufactured by circumferential application of heat to a small area of glass tubing and pulling the glass when it gets soft?

- a) macro metallic electrodes
 - b) micro metallic electrodes
 - c) micro pipette
 - d) surface electrodes
- Answer: c

Explanation: The most commonly used method for making small tip micropipette consists of the circumferential application of heat to a small area of glass tubing which is placed under some initial tension. When the glass softens, the tension is increased very rapidly and the heat is turned off. Proper timing, controlled adjustment of the amount of heat as well as the initial and final tensions and cooling results in the production of microcapillaries with control dimensions.

268. Which of the following metal is preferred for manufacturing micro electrodes?

- a) Stainless steel
 - b) Tungsten
 - c) Iron
 - d) Copper
- Answer: b

Explanation: Tungsten is preferred for constructing micro-electrodes due to its mechanical strength and its apparent inertness. Although tungsten itself is reactive, a surface layer of tungsten oxide will, in most situations, protect the metal against corrosion.

269. _____ are devices which convert one form of energy into another.

- a) transducers
 - b) electrodes
 - c) impulses
 - d) opamp
- Answer: a

Explanation: Transducers are devices which convert one form of energy into another. A number of factors decide the choice of a particular transducer to be used for the study of a specific phenomenon. Many physical, chemical and optical properties and principles can be applied to construct transducers for applications in the medical field.

270. Which type of electrodes are employed to study the electrical activities of individual cells?

- a) milli-electrodes
- b) micro-electrodes
- c) surface-electrodes
- d) pre-jelled electrodes

Answer: b

Explanation: To study the electrical activities of individual cells, micro electrodes are employed. This type of electrode is small enough with respect to the size of the cells. Typical micro electrodes have tip dimensions ranging from 0.5-5 microns.

271. Pulse oximetry is used to measure the oxygen level in blood & heart rate.

- a) True
- b) False

Answer: a

Explanation: Pulse oximetry is a technology used to measure the oxygen level in your blood and your heart rate. A finger pulse oximeter is equipped with technology to rapidly detect changes in your blood oxygen level.

272. Sudden involuntary drop in body core temperature below 35°C (95°F) is called ____

- a) Accidental hyperthermia
- b) Accidental misothermia
- c) Accidental exothermia
- d) Accidental hypothermia

Answer: d

Explanation: Sudden involuntary drop in body core temperature below 35°C (95°F) is called Accidental hypothermia. In this, the body temperature drops very quickly. If not treated on time can lead to patient's death.

273. Which of the following has the widest range of temperature measurement?

- a) RTD
- b) Thermocouple
- c) Thermistor
- d) Mercury thermometer

Answer: b

Explanation: Thermocouple has the widest range of temperature measurement from -184°C to +2300°C. RTD has a range of -200°C to +850°C. Thermistor has a range of 0°C to 100°C where as conventional mercury thermometers range is -37°C to +356°C.

274. The junction at a higher temperature in thermocouple is termed as measuring junction.

- a) True
- b) False

Answer: a

Explanation: The junction at a higher temperature in thermocouple is termed as measuring junction. The junction at lower temperature in the thermocouple is called the reference temperature. The cold junction is usually kept at 0°C.

275. When two wires of different material are joined together at either end, forming two junctions which are maintained at a different temperature, a thermo-motive force is generated causing a current to flow around the circuit. This arrangement is called ____

- a) thermal pair

- b) thermistor
- c) thermocouple
- d) thermostat

Answer: c

Explanation: This arrangement is called thermocouple. The junction at a higher temperature in thermocouple is termed as measuring junction. The junction at lower temperature in the thermocouple is called the referencetemperature.

276. When two wires of different material are joined together at either end, forming two junctions which are maintained at a differenttemperature, a___force is generated.

- a) thermo-motive
- b) electro-motive
- c) chemical reactive
- d) mechanical

Answer: a

Explanation: When two wires of different material are joined together at either end, forming two junctions which are maintained at a different temperature, a thermo- motive force is generated causing acurrent to flow around the circuit.

This arrangement is called thermocouple. The junction at higher temperature in thermocoupleis termed as measuring junction. Thejunction at lower temperature in the thermocouple is called the referencetemperature.

277. The junction at a lower temperature in the thermocouplecalled measuring junction.

- a) True
- b) False

Answer: b

Explanation: The junction at a lowertemperature in the thermocouple iscalled the reference temperature.

The cold junction is usually kept at0°C. The junction at a higher temperature in thermocouple is termed as measuring junction.

278. The lower temperature junctionin thermocouple is maintained at

- a) -273 K
- b) 0 K
- c) -327 K
- d) 273 K

Answer: d

Explanation: The lower temperaturejunction in thermocouple is maintained at 273 K (0°C). The junction at lower temperature in thethermocouple is called the referencetemperature. The junction at higher

temperature in thermocouple istermed as measuring junction.

279. The resistance R_t of a metallicconductor at any temperature t is given by ___

- a) $R_t = R_o(1+\alpha t)$
- b) $R_t = R_o(1-\alpha t)$
- c) $R_t = R_o(\alpha t-1)$
- d) $R_t = R_o(10+\alpha t)$

Answer: a

Explanation: The resistance R_t of a metallic conductor at any temperature t is given by $R_t = R_o(1+\alpha t)$. R_o is the resistance at 0°C. α is temperature coefficient of resistivity.

280. RTD stands for _____

- a) resistance temperature device
- b) resistance temperature detector
- c) reluctance thermal device
- d) resistive thermal detector

Answer: b

Explanation: RTD stands for Resistance Temperature Device. It is a passive sensor and requires current excitation to produce an output voltage. RTD has very low temperature coefficient. Voltage drop across RTD is much larger than thermocouple output voltage.

281. Thermistor is used to measure

- a) temperature
- b) pressure
- c) height
- d) displacement

Answer: a

Explanation: Thermistor is used to measure temperature. It is a temperature transducer. With a change in temperature its resistance changes. Thus its working principle is variable resistance. Thermistors are the oxides of certain metals like manganese, cobalt and nickel which have large negative temperature coefficient, i.e. resistance decreases with increase in temperature.

282. Doppler velocimetry works on the principle of ____

- a) frequency measurement of fiberoptic sensor
- b) amplitude measurement of fiberoptic sensor
- c) phase measurement of fiber optic sensor
- d) time shift measurement of fiberoptic sensor

Answer: a

Explanation: Doppler velocimetry

works on the principle of frequency measurement of fiber optic sensor. In this method, light from a laser, normally helium/neon, is sent via a fibre onto the skin surface. The moving red blood cells scatter the light and produce a Doppler frequency shift because of their movement.

283. Fluoroptic temperature sensors work on the principle of _____

- a) thermistor
- b) thermocouple
- c) optical fiber
- d) rtd

Answer: c

Explanation: Fluoroptic temperature sensors work on the principle of optical fiber sensors. They contain a rare earth phosphor which is illuminated by a white light along a short length of large core optical fibre. The light excites the phosphor which emits a number of lines. By using filters, two of these lines at 540 and 630 nm are selected, and the ratio of their intensities is a single valued function of the temperature of the phosphor.

284. Monopolar needle electrode have a coating of which material over the stainless steel wires which are bare only at the tips?

- a) carbon
- b) calcium
- c) sodium
- d) teflon Answer: d

Explanation: The monopolar needle electrode consists of a teflon coated stainless steel wire. The wire is bare only at the tip. It is found that after the needle has been used a number of times, the teflon coating will recede, increasing the tip area. The needle should be discarded when this happens.

285. Endoscopic imaging uses

- a) thermal sensors
- b) chemical sensors
- c) optic fiber sensors
- d) pressure sensors Answer: c

Explanation: Optic sensors are used for endoscopic imaging. Optical fibre sensors are non-electrical and hence are free from electrical interference usually associated with electronically based sensors. They are suitable for telemetry applications as the bulk of the instrumentation can be at a reasonable distance from the patient.

286. _____ converts biochemical events into measurable signals.

- a) amplifier
- b) opamp
- c) rectifier
- d) transducer Answer: d

Explanation: Transducers convert biochemical events into measurable signals. They provide the means for detecting the biochemical changes inside the body. Particularly biosensors are employed for this purpose.

287. The biological response of the biosensor is determined by _____

- a) biocatalytic membrane
- b) physio-chemical membrane
- c) chemical membrane
- d) artificial membrane Answer: a

Explanation: The biological response of the biosensor is determined by biocatalytic membrane. The biocatalytic membrane accomplishes the conversion of reactant to product. The product of the reaction diffuses to the transducer. This then causes the electrical response.

288. Home blood glucose sensor works on which principle?

- a) electro-physiological
- b) electrochemical
- c) physio-chemical
- d) chemical Answer: b

Explanation: Home blood glucose detection sensor works on the principle of electrochemical. The biosensor in this instrument relies upon enzymes that recognise and catalyze reactions of glucose with the generation of redox – active species that are detected electrochemically.

289. The chemical reaction of glucose with oxygen is catalyzed in the presence of _____

- a) glucose oxidase
 - b) monoglucose carbodase
 - c) glusoce dioxidase
 - d) biglucose oxidase
- Answer: a

Explanation: The chemical reaction of glucose with oxygen is catalyzed in the presence of glucose oxidase. In the presence of glucose oxidase as a catalyst, the glucose and oxygen react and gluconic acid is produced as by product. Hydrogen peroxide (H_2O_2) is also produced in some amount.

290. Home blood glucose measurement devices measure the glucose level through non-invasive method.

- a) True
 - b) False
- Answer: b

Explanation: Home blood glucose measurement devices measure the glucose level through invasive method. There is a small needle at the tip of the machine that pierces the skin to take blood sample. This blood is then undergoes electrochemical reactions and the glucose level is determined.

291. Blood glucose level measurement device uses a biosensor works on the principle of electrochemical.

- a) True
 - b) False
- Answer: a

Explanation: Home blood glucose detection sensor works on the principle of electrochemical. The biosensor in this instrument relies upon enzymes that recognize and catalyze reactions of glucose with the generation of redox – active species that are detected electrochemically.

292. Which of the following is not a fundamental block in recording systems?

- a) electrodes and transducers
 - b) signal conditioner
 - c) analysis for the output
 - d) writing system
- Answer: c

Explanation: Analysis of the output is not a fundamental block on the recording system. First, the signals are collected from the host. Then they are sent for signal conditioning where they are amplified to the desirable range and then the writing system prints the signals.

293. In medical recorders, the signal of interest is of the order of ____

- a) nanovolts
- b) microvolts
- c) megavolts

d) volts Answer: b

Explanation: The signals of interest in medical recorders are in the range of micro volts. They are captured by the help of sensitive electrodes and transducers and then amplified to a certain higher level. After the amplification further processing is carried out.

294. In medical devices, the amplifiers that are used for the amplification purpose of the input signal must have _____

- a)** low frequency response
- b)** high frequency response
- c)** average frequency response
- d)** frequency response has no role to play in it

Answer: a

Explanation: The bioelectric signals in medical science contains components of extremely low frequency. Thus the amplifiers must also have a low frequency response. The response should be down to less than one hertz which is a very frequent requirement.

295. To achieve the low frequency response for medical applications, the amplifier configuration must contain?

- a)** higher resistance
- b)** higher capacitance
- c)** lower resistance
- d)** lower capacitance Answer: b

Explanation: To achieve the low frequency response required for medical applications, the amplifier must have large values of coupling capacitance. In all RC-coupled amplifiers, low frequency response is limited by the reluctance of the coupling capacitors. The response should be down to less than one hertz which is a very frequent requirement.

296. Filter that amplifies frequency above a certain value is called?

- a)** low pass filter
- b)** high pass filter
- c)** band pass filter
- d)** band stop filter Answer: b

Explanation: High pass filter amplifies signal above a certain frequency. Low pass filter amplifies signals below a certain frequency. Band pass filter amplifies frequencies within a certain band. Band stop filter amplifies all the frequencies except those in a certain band.

297. _____ amplifies all the frequencies except those in a certain band.

- a)** high pass filter
- b)** low pass filter
- c)** band pass filter
- d)** band stop filter Answer: d

Explanation: Band stop filter amplifies all the frequencies except those in a certain band. High pass filter amplifies signal above a certain frequency. Low pass filter amplifies signals below a certain frequency.

Band pass filter amplifies frequencies within a certain band.

298. Active filters use opamps in addition to passive components in order to obtain better performance.

a) True

b) False Answer: a

Explanation: True. Active filters use opamps in addition to passive components in order to obtain better performance. Operational amplifiers are frequently used as the gain blocks in active filters. Passive components are resistors capacitors and inductors.

299. Which of the following component is not a part of the passive filter?

a) resistor

b) operational amplifier

c) capacitor

d) inductor Answer: b

Explanation: Operational amplifier is not a part of passive filters. It is a part of an active filter. Passive components are resistors capacitors and inductors. Active filters use opamps in addition to passive components in order to obtain better performance.

300. Light passing through finger will be adsorbed by _____

(i) Skin Pigments

(ii) Tissue

(iii) Arteries

(iv) Veins

a) (i) & (iii)

b) (ii) & (iv)

c) (i) & (ii)

d) (iii) & (iv) Answer: c

Explanation: The two wavelengths assume that only two absorbers are present; namely oxyhaemoglobin (HbO₂) and reduced haemoglobin (Hb). Light passing through the ear or finger will be absorbed by skin pigments, tissue, cartilage, bone, arterial blood, venous blood.

301. How is the blood flow in arteries and arterioles?

a) plug

b) laminar

c) parabolic

d) pulsatile Answer: d

Explanation: Most of the absorbances are fixed and do not change with time. Even blood in the capillaries and veins under steady state metabolic circumstances is constant in composition and flow, at least over short periods of time. Only the blood flow in the arteries and arterioles is pulsatile.

302. The manufacture of adrenalin and noradrenalin is controlled by:

(a) Nervous system

- (b) Endocrine system
- (c) Regulatory system
- (d) Circulatory system Answer: A

303. Repression is a common mode of resolving:

- (a) Anxieties
- (b) Tensions
- (c) Conflicts
- (d) Motives Answer: C

304. The defense mechanisms are reactions to:

- (a) Frustration
- (b) Psychosexual behaviour
- (c) Aggression
- (d) Goal directed behaviour Answer: A

305. Dynamic psychology is the psychology of:

- (a) Motivation and Emotion
- (b) Perception and Attention
- (c) Learning and Memory
- (d) Personality and Intelligence Answer: A

306. Both the terms "emotion" and "motivation" came from the same Latin root:

- (a) Movement
- (b) Move
- (c) Moment
- (d) "Movere" Answer: D

307. According to Lewin, tensions are emotional states which accompany:

- (a) Needs
- (b) Motives
- (c) Goals
- (d) Anxieties Answer: A

308. In avoidance-avoidance conflict, the individual is compelled to choose between:

- (a) One positive and one negative alternative
- (b) Two negative alternatives
- (c) Two positive alternatives
- (d) Two negative alternatives and two positive alternatives Answer: B

309. A releaser is a highly specific stimulus that "triggers" or initiates:

- (a) Response

- (b) Social Behaviour
- (c) Gregariousness
- (d) Species-specific behaviour aboveAnswer: D

310. Who assumed that human motives are arranged in a hierarchy of potency?

- (a) Neal Miller (1959)
- (b) Janis & Mann (1977)
- (c) Jerome Singer (1962)
- (d) A. H. Maslow (1970) Answer: D

311. Corpus luteum and placenta of pregnant women secrete the hormone:

- (a) Estrogens
- (b) Androgens
- (c) Progestins
- (d) Adrenalin Answer: C

312. According to Maslow, the self-actualizing tendency is:

- (a) Instinct
- (b) Imprinting
- (c) Growth Motivation
- (d) Deficiency motivation Answer: C

313. Need for achievement can be measured by:

- (a) Binnet's scale
- (b) Thurstone's scale
- (c) TAT (Thematic Apperception Test)
- (d) Semantic Differential scale Answer: C

314. The desire to be with one's own kind is termed as:

- (a) Gregariousness
- (b) Consumatory behaviour
- (c) Imprinting
- (d) Coolidge Effect Answer: A

315. The type of conflict in which the goal of the individual has both positive and negative valence of approximate equal intensity is known as:

- (a) Approach-avoidance conflicts
- (b) Avoidance-avoidance conflicts
- (c) Approach-approach conflict
- (d) Multiple approach-avoidance conflicts Answer: A

316. A young woman who turns herself into a religious worker has a strong:

- (a) Approach gradient

- (b) Social Motive
- (c) Hypervigilance
- (d) Encephalization Answer: B

317. The author of the hierarchical theory of motivation is:

- (a) O. H. Mowrer
- (b) McClelland
- (c) J. W. Atkinson
- (d) A. H. Maslow Answer: D

318. When progress towards a goal is blocked and underlying tension is unresolved, we speak of:

- (a) Frustration
- (b) Critical Period
- (c) Goal
- (d) Restriction Answer: A

319. Survival needs activate the organism to:

- (a) Provide for physiological deficits
- (b) Seek pleasure
- (c) Avoid pain
- (d) Gain status and recognition Answer: A

320. Motives can be:

- (a) Inferred from behaviour
- (b) Observed directly
- (c) Used to explain behaviour
- (d) Used to predict behaviour Answer: A

321. A motivated behaviour is directed towards:

- (a) Situation
- (b) Object
- (c) Goal
- (d) Group Answer: C

322. Needs, drives or motives:

- (a) Can be directly observed
- (b) Cannot be directly observed
- (c) Are always dormant
- (d) Are same Answer: B

323. Gregariousness is a/an:

- (a) Social motive
- (d) Biological motive

- (c) Psychological motive
- (d) Personal motive Answer: A

324. Individual's life goal is:

- (a) Social Motive
- (b) Biological Motive
- (c) Personal Motive
- (d) An Instinct Answer: C

325. When the motive has a biological or physiological basis, it is called a/an:

- (a) Drive
- (b) Incentive
- (c) Imprinting
- (d) Libido Answer: A

326. Motives are never observed directly; but they are inferred from:

- (a) Stimulus
- (b) Conflict
- (c) Tension
- (d) Behaviour Answer: D

327. The first stage of motivational cycle is:

- (a) Drive state
- (b) Instrumental behaviour
- (c) Goal
- (d) Frustration Answer: A

328. In studying motivation, we attempt to answer:

- (a) The broadest "why" question of behaviour
- (b) The innate releasing mechanism
- (c) Fixed-action pattern
- (d) Displacement behaviour Answer: A

329. The level of arousal is maintained by a structure in the brain stem called the:

- (a) Pons
- (b) Lymbic system
- (c) Reticular activating system
- (d) Cerebellum Answer: C

330. Motivation can be understood as an interaction between:

- (a) Arousal and Effort
- (b) Vactor and Valence

- (c) Life space and Approach gradient
- (d) Approach gradient and avoidance gradient Answer: A

331. Many years ago, an American Psychologist did a study in Orissa in which he found that achievement needs are higher in the business caste. What is his name?

- (a) Lewis
- (b) Mowerer
- (c) Maslow
- (d) Mc Clelland Answer: D

332. A desire to achieve success and to meet some inner standard of excellence is a good definition of the:

- (a) Achievement Need (n ACH):
- (b) Fixed-Action pattern
- (c) Displacement behaviour
- (d) Encephalization Answer: A

333. The “need for success”, “expectancy for success” and the “incentive value of success” are three motivational factors which determine the strength of:

- (a) Social Motives
- (b) Biological Motives
- (c) Personal Motives
- (d) Achievement Need Answer: D

334. The need to achieve is jointly determined by:

- (a) The expectation of success and the fear of failure
- (b) The blocking of behaviour and fear of failure
- (c) The drive stimulus and approach gradient
- (d) The innate releasing mechanism and frustration Answer: A

335. Social conformity can be described as a reverse:

- (a) J-curve
- (b) S-curve
- (c) U-curve
- (d) T-curve Answer: A

336. F. H. Allport (1935) described social conformity as the:

- (a) S-curve hypothesis
- (b) V-curve hypothesis
- (c) U-curve hypothesis
- (d) J-curve hypothesis Answer: D

337. As motivation is closely related to effort, the emotion is related to:

- (a) Arousal
- (b) Instinct
- (c) Displacement behaviour
- (d) Conflict Answer: A

338. Fritz Heider, an Austrian psychologist, has given us a greatdeal of insight into:

- (a) Imprinting
- (b) Critical period
- (c) Interpersonal relationships
- (d) Coolidge Effect Answer: C

339. A motive ethnologically meansthat

- (a) Which moves
- (b) Which distracts
- (c) Which drives
- (d) Which stimulates Answer: A

340. Since motives activate the organism, they are also known asthe:

- (a) Outer dynamics
- (b) Drive stimulus
- (c) Inner dynamics
- (d) Approach gradient Answer: C

341. The second stage of the motivational cycle is called the:

- (a) Goal
- (b) Instrumental Behaviour
- (c) Driving State
- (d) Relief Answer: B

342. Prolactin, a hormone from theanterior pituitary gland plays an important role in motivating:

- (a) Maternal behaviour
- (b) Imprinting
- (c) Instinct
- (d) Consummatory behaviour Answer: A

343. Behaviour of the mentally illpersons is greatly influenced by their:

- (a) Conscious motives
- (b) Innate Releasing Mechanism
- (c) Unconscious motives
- (d) Fixed-action pattern Answer: C

344. Generally we infer needs anddesires from:

- (a) Covert behaviour
- (b) Approach gradient
- (c) Drive stimulus
- (d) Overt Behaviour Answer: D

345. Physiologists use the term homeostasis to describe the body's tendency to maintain a balance or equilibrium among its:

- (a) External physiological status and environment
- (b) Internal physiological status and the environment
- (c) Displacement behaviour and cephalization
- (d) Approach gradient and avoidance gradient Answer: B

346. The relative strength of the drives of hunger, thirst and sex have been studied experimentally in the white rat by:

- (a) Learning Method
- (b) Obstruction Method
- (c) Activity wheel
- (d) The choice and Preference Method Answer: B

347. The technique by which the strength of need is measured in terms of readiness with which a task is learned under different conditions of motivation is known as:

- (a) Activity wheel
- (b) Obstruction method
- (c) The choice and Preference Method
- (d) Learning Method Answer: D

348. The technique for the measurement of needs by which the strength of a need is measured in terms of the magnitude of an obstacle or the number of times an obstacle of a given magnitude will be overcome in order to obtain a needed object is known as:

- (a) Learning Method
- (b) Obstruction method
- (c) Activity wheel
- (d) The choice and Preference Method Answer: B

349. A tension within an organism which tends to organize the field of the organism with respect to certain incentives or goals and to incite activity directed towards their attainment is called:

- (a) Need
- (b) Imprinting
- (c) Libido
- (d) Valence Answer: A

350. An intraorganic activity or condition of tissue supplying stimulation for a particular type of behaviour is known as:

- (a) Need
- (b) Motive
- (c) Drive
- (d) Conflict Answer: C

351. Maslow viewed that motivated behaviour is:

- (a) Need related
- (b) A vector
- (c) A valence
- (d) An approach gradient Answer: A

UNIT – 5

**ATTENTION,
PERCEPTION, LEARNING,
MEMORY, AND
FORGETTING**

ATTENTION, PERCEPTION, LEARNING, MEMORY AND FORGETTING

WHAT IS ATTENTION: FORMS OF ATTENTION, MODELS OF ATTENTION ?

ATTENTION: FORMS OF ATTENTION, MODELS OF ATTENTION

Understanding attention and its types are critical for improving our ability to live our lives efficiently. In order to fully master the attention mechanism, it is also necessary to learn both the external or internal factors that strengthen and affect it.

Attention can generally be defined as the ability to produce, select, manage and maintain sufficient stimulation at a specific amount of time to process any kind of information. It takes place on the cognitive level and has different types.

Attention is the key to achieve optimum functionality in our lives. The way to do this is to parse the factors or stimuli we encounter as relevant or irrelevant. Actually, this is when we make the most basic choices regarding the topics we are interested in or not.

VISUAL ATTENTION

Generally speaking, visual attention is thought to operate as a two-stage process. In the first stage, attention is distributed uniformly over the external visual scene and the processing of information. In the second stage, attention is concentrated to a specific area of the visual scene; it is focused on a specific stimulus. There are two major models for understanding how visual attention operates, both of which are loose metaphors for the actual neural processes occurring.

SPOTLIGHT MODEL

The term "spotlight" was inspired by the work of William James, who described attention as having a focus, a margin, and a fringe. The focus is the central area that extracts "high-resolution" information from the visual scene where attention is directed. Surrounding the focus is the fringe of attention, which extracts information in a much more crude fashion. This fringe extends out to a specified area, and the cutoff is called the margin.

ZOOM-LENS MODEL

First introduced in 1986, this model inherits all the properties of the spotlight model, but it has the added property of changing in size. This size-change mechanism was inspired by the zoom lens one might find on a camera, and any change in size can be described by a trade-off in the efficiency of processing. The zoom-lens of attention can be described in terms of an inverse trade-off between the size of focus and the efficiency of processing. Because attentional resources are assumed to be fixed, the larger the focus is, the slower processing will be of that region of the visual scene, since this fixed resource will be distributed over a larger area.

COGNITIVE LOAD

Think of a computer with limited memory storage: you can only give it so many tasks before it is unable to process more. Brains work on a similar principle, called the cognitive load theory. "Cognitive load" refers to the total amount of mental effort being used in working memory. Attention requires working memory; therefore devoting attention to something increases cognitive load.

DETERMINING FACTORS THAT INFLUENCE THE FUNCTIONING OF ATTENTION

As we mentioned before, attention is not a one-way process. There are a number of factors for a stimulus to attract our attention. Only a stimulus based on these factors triggers our cognitive functions and can initiate cognitive processing. It is possible to examine these factors that attract our attention and maintain focus in two main groups:

1- Internal Factors

These determinants are personal because they depend on the individual's own cognitive resources and brain functions. Some of them can be listed as follows:

- Mental condition
- Needs
- Emotions
- Mindset
- Interests
- Motivation
- Physical state

2- External Factors

These determinants are usually based on the characteristics of the stimuli or come from our surroundings. Some of them can be listed as follows:

- Intensity
- Uniqueness
- Size
- Color
- Emotional Burden
- Contrast

THE FOUR TYPES OF ATTENTION

There are several types of attention and they are shown in the chart below:

SELECTIVE ATTENTION

When we focus our attention on anything, we actually choose to ignore many things. For example, imagine going to a bookstore. There is a specific book you want to buy and you are walking between the bookshelves to find that book.

Perhaps you are passing through hundreds of books without actually noticing any of them. On the other hand, your eyes actually see all of them and possibly record them deep into your mind, but you don't even realise it. This here is a great selective attention example.

Now that you have an understanding of the concept, let's go over the selective attention definition. If we need to define selective attention we can call it the process of focusing on a particular object in the environment for a certain period of time. Our attention is limited. So to use this limited resource, we need selective attention, which allows us to ignore details that are not important.

HOW DOES SELECTIVE ATTENTION WORK?

The term "cocktail party effect" is also used to describe selective attention psychology, especially in the Memory Selection Model. Because while we're at a party, there are many things that can distract us like music, light, and many other people talking. However, we can still focus on one conversation with a close friend. On the other hand, when our name is called among all the intense stimuli in this background, this will grab our attention.

So which of the following is the reason for human attention being selective? It is proven that the capacity of our brains to take care of everything around us is very limited, so it is impossible for us to pay attention to each of these sensory experiences. Therefore, while our brain focuses our attention on some important elements of our environment, it puts all other stimuli in the background.

THEORIES OF SELECTIVE ATTENTION

In cognitive psychology, there is more than one selective attention theory, which is focused on when our brains react and interact with stimulating information from outside.

This model was defined by **Donald Broadbent in 1958**. He used a filtering metaphor of information processing to describe attention. Broadbent suggested that our filtering of information occurs early on in the **perceptual process**. Physical characteristics like colours, loudness or direction of the stimulants processed before were used to select or reject a stimulus in later operations.

RESOURCE THEORIES OF SELECTIVE ATTENTION

More recent theories suggest that human attention can interact with limited stimuli and tends to explain how these resources are divided among competing stimuli. Hence, source theories appear to be a much more effective metaphor to explain the phenomenon of attention divided into complex stimuli and tasks.

VISUAL SELECTIVE ATTENTION

Perhaps we are exposed to millions of ads every day on the way to work or on the road. We don't even realize that we've seen many of these. But some, on the other hand, manage to attract our attention, especially if they address our current needs or taste. This shows that these advertisements have contacted with us as a stimulus by going through our selective perception.

EXAMPLES OF SELECTIVE ATTENTION COCKTAIL PARTY EFFECT

As we've mentioned before, although there are many stimuli around in crowded and noisy environments such as parties, our brain selects certain stimuli and focuses on them.

DIVIDED ATTENTION

We use divided attention while simultaneously paying attention to two or more tasks. This ability is also called Multitasking. Divided attention uses mental focus on a very large scale. Nonetheless, this does not allow the brain to fully focus on any task. Therefore, this type of attention does not last for long.

ALTERNATING ATTENTION

Alternating attention is the ability to change the focus of your attention and switch between different tasks. In this type of attention, mental flexibility is required so that one task does not limit the performance of others.

SUSTAINED ATTENTION

We often use sustained attention for tasks that take a long time or require intense focus. This type of attention allows one to consistently perform a certain mental activity. For example, when children study for an exam, they need to read and acquire their information in a textbook for several hours.

DIFFERENCES AMONG THE TYPES OF ATTENTION

SelectiveAttention
DIVIDED ATTENTION
Focusingon
TASKS

Unconsciously creating a mental focus on a single task or idea at once while ignoring others

	Increases the amount of attention being directed to a task or idea because of a single focus taking place	Minimizes the amount of attention being placed on any task or idea if there are multiple focuses going on at once
Amount of Attention		
Condition on Distractions & Switching tasks	Successful tuning out of distractions and switching tasks.	Unsuccessful tuning out of distractions and switching tasks
Cognitive Ability	Strengthens cognitive ability	Weakens cognitive ability the most
Amount of Possible Mistakes	Reduces the rate of making mistakes	Drives to make mistakes
Receiving Information	Allows to miss important information	Prevents missing important information

Perception: Approaches to the Study of Perception: Gestalt and physiological approaches

While our sensory receptors are constantly collecting information from the environment, it is ultimately how we interpret that information that affects how we interact with the world. **Perception** refers to the way sensory information is organized, interpreted, and consciously experienced. Perception involves both bottom-up and top-down processing. **Bottom-up processing** refers to the

fact that perceptions are built from sensory input. On the other hand, how we interpret those sensations is influenced by our available knowledge, our experiences, and our thoughts. This is called **top-down processing**.

One way to think of this concept is that sensation is a physical process, whereas perception is psychological. For example, upon walking into a kitchen and smelling the scent of baking cinnamon rolls, the sensation is the scent receptors detecting the odor of cinnamon, but the perception may be "Mmm, this smells like the bread Grandma used to bake when the family gathered for holidays." Although our perceptions are built from sensations, not all sensations result in perception. In fact, we often don't perceive stimuli that remain relatively constant over prolonged periods of time. This is known as **sensory adaptation**. Imagine entering a classroom with an old analog clock. Upon first entering the room, you can hear the ticking of the clock; as you begin to engage in conversation with classmates or listen to your professor greet the class, you are no longer aware of the ticking. The clock is still ticking, and that information is still affecting sensory receptors of the auditory system. The fact that you no longer perceive the sound demonstrates sensory adaptation and shows that while closely associated, sensation and perception are different.

In the beginning of the nineteenth century, two vastly developed areas in psychology, viz. perception and personality came nearer to each other. Numerous researches were carried out to study the relation between perception and personality. Perceptual characteristics have some sort of relation with individual's personality organization. Various journals have published findings of perception personality relationship. While going through this literature, one can find that the relation between perception and personality was studied from different angles. In other words, there are various approaches for studying the relation between these two important fields which have systematically, scientifically and experimentally developed in the last fifty years.

TOPOLOGICAL APPROACH :

As early as 1944, Thurstone described an extensive factorial exploration of various perceptual tasks in order to isolate underlying variables which could be used to account for individual differences. Since that time, there have been many attempts to relate various personality variables to differences in performance on perceptual tasks.

Innumerable perceptual tasks have been studied, and significant correlations have frequently been reported. For example, to mention only a few studies, Johansson⁸ in a study of motion perception and personality, constructed perceptual measures based on the fact that a perceived velocity of a single object moving in a visual field increases considerably when a second object moving with the same speed in the opposite direction is introduced. Ss with extremely slow 'velocity synthesis' (affected little by the A relativity effect introduced by the other object in the ally motion percept) were found to be artistic withdrawn, and to possess self-isolating attitudes. Schumer⁹ found marked differences in the quality of phi-phenomenon experiences reported by 100 college men. These differences were found to be significantly related to productivity of human movement in the Rorschach.

Extensive factor analysis which included 29 simple perceptual measures, such as visual acuity and simple closure, and more complex measures such as after-images, tachistoscopic performance and various automatic tests. The perceptual tasks, as well as a questionnaire which was used, held up well, that is, normal, neurotics and psychotics were differentiated. The author's hypothesis that normality was associated with 'integrative', 'wholistic', 'synthetic' attitudes was, according to them,

generally confirmed. Vandenberg reanalyzing some of Eysenck's results, generally confirmed his findings. It seems strange, however, that in these studies, insufficient attention was paid to the questions of set, attention and motivation which plagued workers in psychopathology.

THE WORK OF ERENKEL-BRUNSWIK

E.F. Brunswik's approach to perception is still another example of perceptual research which is almost entirely personality oriented and which throws light on personality factors as well as social and emotional variables. Brunswik became interested in perceptual variables in connection with the well-known research at the Institute of Child Welfare of the University of California which dealt with prejudiced and nonprejudiced attitudes and their motivational and cognitive correlates. Generally speaking, ethnocentric attitudes were found to be related to authoritarian personality structure. Brunswik soon discovered that many of her Ss were less able to tolerate 'emotional ambiguities' than others. She became interested, in whether or not this intolerance extended also to the more traditional field of perception. As a result of some of her explanations, she was able to offer rich evidence on the basis of interviews, clinical evaluations etc.

DIRECTIVE STATE APPROACH :

In the late 1940's, a 'new look' in perceptual theory emerged. The approach of the workers doing the early studies within this framework can be regarded as the single most important influence in the swing towards the belief that perception is essentially a personality oriented phenomenon. There were innumerable reports of research, some opposing, some defending the conclusions of the original classic and studies; bitterness, criticalness, and deep conviction pervaded the literature.

The 'new look' is a phrase borrowed from the publicity releases from liaison Dior in Paris, which described some startling changes in fashion. The great discovery of the 'new look' was that the perceiver also counts. In some ways, the introduction of the perceiver into the process of perception can be linked to the introduction of the observer into the measurement of velocity in the theory of relativity.

Einstein's great contribution emerges when he introduced the velocity of the observer or his frame of reference into the measurement of the velocity of an object. In the same way, the new look hoped to revolutionize » perception by introducing the characteristics of the perceiver, that is, his personality (drives, needs etc.). Unfortunately, the revolution in psychology did not go off as successfully as the revolution in physics, but fizzled more like the revolution in fashion.

DIRECTIVE STATE THEORY (APPROACH) - THE CONTROVERSY, RE-EVALUATION APPROACH :

McCinnies' study (²) which reported increased thresholds for recognition of emotionally toned, taboo words, was regarded as strongly supportive of perceptual defence, as a special mechanism. This specific study stimulated much controversy. Howes and Solomon (74,75) advanced the notion that McGinnies' results could be explained in other ways.

They noted that McGinnies' taboo words were much less familiar than the neutral words. They demonstrated that the more familiar a word was, the higher was its recognition thresholds; (perceptual defence) for Ss of the taboo words, although McGinnies defended his original interpretation. In general, the concept of perceptual defence began to lose status, even among directive state workers themselves. McGinnies' defence consisted of noting that increased recognition thresholds for neutral words were found when they followed immediately after taboo

words - constituting evidence for 'generalization' of the-avoidance (defensive) reaction. Furthermore, the analysis of pre-recognition responses suggested that for neutral words there was a greater resemblance to the stimulus words than there' was for the (122) taboo words. Postman, Bronson and Gropper strongly contested these explanations, suggesting that uncontrolled variations in familiarity of words could account for most of the perceptual defence effect. Solomon and Postman¹⁵⁵ had already reported a study which showed that recognition thresholds varied inversely with frequency of past usage.

Following are the additional points to be noted.

- Although many correlations between needs and perception have been demonstrated, there is a general failure to explain how and why these take place, that is, the mediation factors are not clear.
- In many studies which have purported to show the relationship of need perception, cognitive and judgmental elements are used as measures of perceptual response. These studies have failed to distinguish between perception and judgment. If motivational states influence perception per se, this should probably be demonstrated in experimental designs which control for factors such as attitude, set, memory, attention and familiarity.
- Most of the effects have been demonstrated with a marginal ambiguous stimulus. Are needs and motivations as powerful and influential in 'everyday' veridical perception as they are under marginal stimulus conditions?
- Perceptual modifications as a result of motivational states should be demonstrated through immediate perception, rather than in more complex, cognitive, and social situations.
- Effects demonstrating the relation between perception and need should probably be studied not only with other means, but with other experimental procedures and other perceptual events and situations.

HYPOTHESIS OR EXPECTANCY THEORY (APPROACH) ;

The directive state approach faces some methodological problems and from that a theory of hypothesis or expectancy was developed. This approach suggests that perceiving is always based on an expectancy or hypothesis on the part of the organism, /V' that is, he is turned to some aspects of his surroundings. (This view of perceiving is of course related to the approach of various set theories.) Bruner and Postman¹⁵⁶ are the original founders of the hypothesis or expectancy theory. Perception involves the input of information from the environment. Input is not specified in terms of stimulus energy, but rather in terms of its signal value, as cue or clue. The next process involves the checking or confirmation of the organism's hypothesis. If there is a confirmation, the hypothesis is strengthened and its arousal will be 'easier' in future when similar 'information' from the environment is received. If the hypothesis is not confirmed, the organism will introduce a new hypothesis, until one of them is confirmed.

Individual Differences as revealed in Perceptual Behaviour! The presence of individual differences in perceptual behaviour was recognised in psychology. Psychologists interested in the field of perception and sensory processes have characteristically taken considerable pains to devise experimental situations that are sufficiently simple and controlled to minimize these individual differences, in the interest of studying more accurately the phenomena with which they are primarily concerned. Any way, little attempt was made to study individual differences in perception systematically in relation to other aspects of behaviour or personality.

Thurstone's extensive factor analysis of perceptual task was predominantly oriented towards

isolating or detecting general factors of perception, but was not particularly concerned with personality correlates of these perceptual factors, There were no personality tests included in the battery that would have made such relationships detectable.

Early investigators used Rorschach ink-blot to relate systematically personality traits and perception. Early in the modern revival of interest in experimentation (84,82) on need in perception, Klein- has drawn attention to the presence of perceptual styles and perceptual modes of handling (82) threatening or emotional material. Klein and his associates have gone on to show the presence of a personality dimension labeled 'leveling1 (versus sharpening) which is revealed not only in perceptual recognition behaviour, but in perceptual judgmental tasks as well.

GESTALT PSYCHOLOGY

school of psychology founded in the 20th century that provided the foundation for the modern study of perception. Gestalt theory emphasizes that the whole of anything is greater than its parts. That is, the attributes of the whole are not deducible from analysis of the parts in isolation.

The word Gestalt is used in modern German to mean the way a thing has been "placed," or "put together." There is no exact equivalent in English. "Form" and "shape" are the usual translations; in psychology the word is often interpreted as "pattern" or "configuration."

Gestalt theory originated in Austria and Germany as a reaction against the associationist and structural schools' atomistic orientation (an approach which fragmented experience into distinct and unrelated elements). Gestalt studies made use instead of phenomenology. This method, with a tradition going back to Johann Wolfgang von Goethe, involves nothing more than the description of direct psychological experience, with no restrictions on what is permissible in the description. Gestalt psychology was in part an attempt to add a humanistic dimension to what was considered a sterile approach to the scientific study of mental life. Gestalt psychology further sought to encompass the qualities of form, meaning, and value that prevailing psychologists had either ignored or presumed to fall outside the boundaries of science.

The publication of Czech-born psychologist Max Wertheimer's "Experimentelle Studien über das Sehen von Bewegung" ("Experimental Studies of the Perception of Movement") in 1912 marks the founding of the Gestalt school. In it Wertheimer reported the result of a study on apparent movement conducted in Frankfurt am Main, Germany, with psychologists Wolfgang Köhler and Kurt Koffka. Together, these three formed the core of the Gestalt school for the next few decades. (By the mid-1930s all had become professors in the United States.)

PERCEPTUAL ORGANIZATION: GESTALT, FIGURE AND GROUND, LAW OF ORGANIZATION

Have you noticed how a series of flashing lights often appears to be moving, such as neon signs or strands of lights? According to Gestalt psychology, this apparent movement happens because our minds fill in missing information. This belief that the whole is greater than the sum of the individual parts led to the discovery of several different phenomena that occur during perception.¹

The law of closure is one example of a Gestalt law of perceptual organization. According to this principle, things in the environment often tend to be seen as part of a whole. In many cases, our minds will even fill in the missing information to create cohesive shapes.

A BRIEF HISTORY OF THE GESTALT LAWS

Gestalt psychology was founded by German thinkers Max Wertheimer, Wolfgang Kohler, and Kurt Koffka and focused on how people interpret the world.² The Gestalt perspective formed partially as a response to the structuralism of Wilhelm Wundt, who focused on breaking down mental events and experiences to the smallest elements.

Max Wertheimer noted that rapid sequences of perceptual events, such as rows of flashing lights, create the illusion of motion even when there is none. This is known as the phi phenomenon. Motion pictures are based on this principle, with a series of still images appearing in rapid succession to form a seamless visual experience.

According to Gestalt psychology, the whole is different from the sum of its parts. Based upon this belief, Gestalt psychologists developed a set of principles to explain perceptual organization, or how smaller objects are grouped to form larger ones.

These principles are often referred to as the "laws of perceptual organization." However, it is important to note that while Gestalt psychologists call these phenomena "laws," a more accurate term would be "principles of perceptual organization." These principles are much like heuristics, which are mental shortcuts for solving problems.

Follow the links below to find more information and examples of the different Gestalt laws of perceptual organization.

Gestalt theory [1] has provided perceptual science with a conceptual framework relating to brain mechanisms that determine the way we see the visual world. This is referred to as "Perceptual Organization" and has inspired researchers in Psychology, Neuroscience and Computational Design ever since. The major Gestalt principles, such as the principle of Prägnanz, and more importantly the Gestalt laws of perceptual organization, have been critically important to our understanding of visual information processing, how the brain detects order in what we see, and derives likely perceptual representations from statistically significant structural regularities. The perceptual integration of contrast information across co-linear space for the organization of objects in the 2D image plane into figure and ground convey the most elementary basis to our understanding of the visual world. Gestalt theory continues to generate powerful concepts and insights for perceptual science even today, where it is to be placed in the context of image-base decision making by human minds and machines.

However, in complex images, some visible stimulus fragments appear clearly aligned, others do not. Specific phenomenal conditions need to be satisfied to enable collinear interpolation in static 2D scenes, and the process of interpolation constrains the spreading of surfaces across unspecified regions in the image [45,46]. Also, not all of perceptual organization is hardwired [47,48], and the contribution of past experience and perceptual learning to early mechanisms of perceptual integration needs to be taken into account given that specific memory data about objects and their most likely spatial configuration may facilitate or interfere with, depending on conditions, ongoing visual processing of ambiguous image data. The question relative to recovery of 'veridical' object properties from image data may be seen as a byproduct of perceptual organization, but was not an issue raised by Gestalt theory. However, the laws of perceptual organization have generated a conceptual framework for addressing this problem space in a

bottom-up approach. The 'veridicality' of perceptual representations our brain may derive from visual stimuli raises deeper philosophical questions. Perceptual organization as such may be seen as resulting from pressure on the perceptual system to actively construct ordered representations of objects in depth in response to intrinsically ambiguous visual data. The biological role of perceptual organization, placed in the context of evolution, would be to ensure behavioral adaptation and success. Perceptual organization becomes mandatory as soon as the visual signals contained in an image or a scene reach our retina [49]. The major part of the necessary information processing then takes place in the visual brain, involving a whole chain of mechanisms well beyond the retina. Perceptual neuroscience has provided us with a diversified account for the many ways in which visual sensitivity to ordered structure and regularities expresses itself in behavior on the basis of cortical mechanisms. Multiple stages of neural processing transform fragmented signals into visual key representations of 3D scenes that can be used to control effective behavior. Since our survival depends on our ability to pick up order in the physical world, and since we conceive the physical world as an ordered one, our brain must be sensitive to structural regularities in the physical world. Neural interactions "beyond the classic receptive field" drive the visual processing of texture dissimilarities, boundary completion, surface filling-in, and figure-ground segregation in the brain genesis of "perceptual order".

FIGURE-GROUND PERCEPTION IN PSYCHOLOGY

Figure-ground perception refers to the tendency of the visual system to simplify a scene into the main object that we are looking at (the figure) and everything else that forms the background (or ground). The concept of figure-ground perception is often illustrated with the classic "faces or vases" illusion, also known as the Rubin vase. Depending on whether you see the black or the white as the figure, you may see either two faces in profile (meaning you perceive the dark color as the figure) or a vase in the center (meaning you see the white color as the figure).

A History of Figure-Ground Perception

The concept of figure-ground perception emerged out of the field of Gestalt psychology. According to the Gestalt approach, the whole is more (or different) than the sum of its parts.¹ The term Gestalt itself comes from the German word meaning "form" or "shape."

During the 1920s, a number of German psychologists including Max Wertheimer and Wolfgang Kohler began studying different principles of perception that govern how people make sense of an often disorderly world. Their work led to what is known as the Gestalt laws of perceptual organization.

The Gestalt theory of perception proposes that people make sense of the world around them by talking separate and distinct elements and combining them into a unified whole.²

For example, if you look at shapes drawn on a piece of paper, your mind will likely group the shapes in terms of things such as similarity or proximity. Objects that are similar to one another tend to be grouped together. Objects that are near each other also tend to be grouped together.

While the concept of figure-ground perception is an important principle in Gestalt psychology, it is usually not identified as one of the laws of perceptual organization.

People Distinguish Between Figure and Ground?

When looking at a visual scene, people tend to look for ways to differentiate between the figure and

the ground. Some ways that people accomplish this include:¹

- **Blurriness:** Objects in the foreground tend to be crisp and distinct while those in the background are blurry or hazy.
- **Contrast:** The high contrast between objects can lead to the perception of figure and ground. The Rubin vase is one example.
- **Size:** Images that appear to be larger will be perceived as closer and part of the figure while those that are smaller will seem further away and part of the background.
- **Separation:** An object isolated from everything else in a visual scene is more likely to be seen as a figure versus background.

Examples

The "faces or vases" illustration is one of the most frequent demonstrations of figure-ground. What you see when you look at the faces or vases illusion depends on whether you see the white as the figure or the black as the figure.

If you see the white as the figure, then you perceive a vase. If you see the black as the figure, then you see two faces in profile.

PERCEPTUAL CONSTANCY: SIZE, SHAPE, AND COLOR; ILLUSIONS

Perceptual constancy is perceiving objects as having constant shape, size, and color regardless of changes in perspective, distance, and lighting.

KEY POINTS

- Perceptual constancy refers to perceiving familiar objects as having standard shape, size, color, and location regardless of changes in the angle of perspective, distance, and lighting.
- Size constancy is when people's perception of a particular object's size does not change regardless of changes in distance from the object, even though distance affects the size of the object as it is projected onto the retina.
- Shape constancy is when people's perception of the shape of an object does not change regardless of changes to the object's orientation.
- Distance constancy refers to the relationship between apparent distance and physical distance: it can cause us to perceive things as closer or farther away than they actually are.
- Color constancy is a feature of the human color perception system that ensures that the color of an object is perceived as similar even under varying conditions.
- Auditory constancy is a phenomenon in music, allowing us to perceive the same instrument over differing pitches, volumes, and timbres, as well as in speech perception, when we perceive the same words regardless of who is speaking them.

VISUAL PERCEPTUAL CONSTANCIES

There are many common visual and perceptual constancies that we experience during the perception process.

Size Constancy

Within a certain range, people's perception of a particular object's size will not change, regardless of changes in distance or size change on the retina. The perception of the image is still based upon the actual size of the perceptual characteristics. The visual perception of size constancy has given rise to many optical illusions.

THE PONZO ILLUSION

This famous optical illusion uses size constancy to trick us into thinking the top yellow line is longer than the bottom; they are actually the exact same length.

SHAPE CONSTANCY

Regardless of changes to an object's orientation, the shape of the object as it is perceived is constant. Or, perhaps more accurately, the actual shape of the object is sensed by the eye as changing but then perceived by the brain as the same. This happens when we watch a door open: the actual image on our retinas is different each time the door swings in either direction, but we perceive it as being the same door made of the same shapes.

SHAPE CONSTANCY

This form of perceptual constancy allows us to perceive that the door is made of the same shapes despite different images being delivered to our retinæ.

DISTANCE CONSTANCY

This refers to the relationship between apparent distance and physical distance. An example of this illusion in daily life is the moon. When it is near the horizon, it is perceived as closer to Earth than when it is directly overhead.

COLOR CONSTANCY

This is a feature of the human color perception system that ensures that the color of an object remains similar under varying conditions. Consider the shade illusion: our perception of how colors are affected by bright light versus shade causes us to perceive the two squares as different colors. In fact, they are the same exact shade of gray.

AUDITORY PERCEPTUAL CONSTANCIES

Our eyes aren't the only sensory organs that "trick" us into perceptual constancy. Our ears do the job as well. In music, we can identify a guitar as a guitar throughout a song, even when its timbre, pitch, loudness, or environment change. In speech perception, vowels and consonants are perceived as constant even if they sound very different due to the speaker's age, sex, or dialect. For example, the word "apple" sounds very different when a two year-old boy and a 30 year-old woman say it, because their voices are at different frequencies and their mouths form the word differently...but we perceive the sounds to be the same. This is thanks to auditory perceptual constancy!

PERCEPTUAL ILLUSION

While the problem of perceptual illusion has not aroused quite the same degree of empirical or theoretical interest among neurophysiologists as among experimental psychologists there has nevertheless been a continuing concern with the neural correlates of illusory phenomena. Both Motokawa¹ and Burns and Pritchard² have recently attempted to establish the neural interactions associated with these distortions. However, the problem has proved extraordinarily intractable and the neural structures and processes associated with illusory effects remain quite obscure.

VISUAL SIZE CONSTANCY AND ILLUSION

As the observer recedes from an object (or vice versa) the retinal image of the latter diminishes but its apparent size is relatively constant. Therefore information for distance must be involved

in the maintenance of constant apparent size. That this is so was made clear in the classic experiments of Holway and Borings in which distance stimuli were progressively reduced. Since then data from three separate experiments⁹⁻¹¹ have shown that when distance stimuli are entirely eliminated an object's apparent size decreases as a linear function of observer-object-distance, i.e., apparent size follows the "law of the visual angle." "Cues" or stimuli for distance fall into five classes:

1. retinal disparity (or binocular parallax);
2. muscular stimuli (convergence and accommodation);
3. monocular parallax;
4. atmospheric stimuli (aerial perspective and the Tyndall effect); and
5. projected stimuli (perspective, texture, overlay, elevation in field, element and interspace size, and element and interspace frequency. Normally all or most of these stimuli for distance are present and visual size constancy is perfect. However, although size constancy falls off as distance stimuli are systematically reduced (e.g., when binocular parallax is eliminated by using one eye and monocular parallax by holding the head stationary⁸) some degree of constancy obtains, i.e., apparent size does not follow the law of the visual angle, as observer-object distance increases.

GEOMETRIC SIZE ILLUSIONS

The projected stimuli for distance, stimuli which derive essentially from the projection of a three-dimensional space on to the two-dimensional retinal surface, are more frequent and subtle than is usually realized. In addition to the well-known stimuli such as perspective, texture, overlay, and elevation, the size and frequency of elements other than the focal object and the size and frequency of interspaces between them vary with distance and provide information for distance.

The trees on the near side of a lake are bigger and fewer per unit visual angle than the smaller and more frequent trees on the far side, as indeed are the interspaces between them. Many geometric optical illusions involve such distance stimuli.

Of two objects one is usually located in the context of larger and less frequent elements or spaces consonant with nearness and the other in the context of smaller and more frequent elements corresponding to greater distance. The former object is judged smaller than the latter.

The Oppel-Kundt, Delboeuf, and Miiller-Lyer illusions are examples of size illusions in which the retinal image of an object, usually a linear simple figure, is invariant but projected stimuli for distance are varied. It should be noted, however, that as had been pointed out elsewhere¹⁵ the Miiller-Lyer illusion as it is classically shown represents two separate effects.

The "short" version with "inboard" elements is probably a different illusion than the "long" version with "outboard" elements. Evidence for this difference has been adduced by Erlebacher and Sekuler.

Visual orientation constancy and illusion When the observer's head is tilted laterally as posture is changed, the retinal orientation of the object's image relative to the normally vertical meridian of the eye changes. When the observer is recumbent this change is nearly 90 degrees.

However, under conditions of normal illumination and when only the object itself is visible in a dark room, its apparent tilt is relatively stable, a phenomena called visual orientation constancy.¹⁷ In normal illumination the bar remains perceptually invariant even for large lateral body tilts.

PERCEPTION OF FORM, DEPTH AND MOVEMENT FORM PERCEPTION

The **Gestalt Psychologists** studied extensively **form perception**, or the perception of objects, shapes and patterns. Gestalt principles may be broken down into two categories: **perceptual organization (grouping)** and **depth perception**.

GESTALT PRINCIPLES OF PERCEPTUAL ORGANIZATION

1. **How objects are grouped together** (Links to an external site.)
2. **CONTINUITY**
We tend to perceive figures or objects as belonging together if they appear to form a continuous pattern
3. **CLOSURE (CONNECTEDNESS)**
We perceive figures with gaps in them to be complete
4. **SIMILARITY**
We perceive figures which look alike as being grouped together
5. **PROXIMITY**
We perceive things close together as being in sets
6. **PRAGNANZ**
We perceive reality in the simplest way rather than inferring complexity

TAKE A MINUTE TO TAKE SOME NOTES: HOW ARE GESTALT GROUPING PRINCIPLES USED IN THE HUMAN CONDITION (ABOVE)

Monocular depth cues

7. **DEPTH CUES THAT CAN BE PERCEIVED BY ONLY ONE EYE**
8. **Interposition**
When one object partly blocks your view of another, you perceive the partially blocked object as farther away
9. **LINEAR PERSPECTIVE**
Parallel lines that are known to be the same distance apart appear to grow closer together, or converge, as they recede into the distance
10. **RELATIVE SIZE**
Larger objects are perceived as being closer to the viewer, and smaller objects as being farther away
11. **TEXTURE GRADIENT**
Near objects appear to have sharply defined textures, while similar objects appear progressively smoother and fuzzier as they recede into the distance
12. **ATMOSPHERIC PERSPECTIVE**
Objects in the distance have a bluish tint and appear more blurred than objects closer to the viewer

TAKE A MINUTE TO TAKE SOME NOTES: HOW ARE DEPTH CUES USED IN THE HUMAN CONDITION (ABOVE)

Gestalt principles help explain how we perceive distance, depth, organization and harmony on a 2 dimensional canvas.

Visual Perception in a nutshell – our visual perceptual system works to heighten differences and impose constancies to help us survive in the big, scary world, often causing disparities between what we see and the physical world.

Or, as Aristotle succinctly put it: “**our senses can be trusted but they can be easily fooled.**”

For example, in the image below both of the orange (middle) circles are exactly the same size. This one of many visual illusions, called the **Ebbinghaus Illusion**, which explore the effect of context on perception. Our visual system compares the circles and exaggerates the differences between them.

Our visual systems allow us to resolve fine detail, track a moving object, perceive depth, and see colors. Somehow, all these components of a visual scene merge so that we have one visual experience; for example, when we see a cat playing with a string, we interpret the scene-paws striking the string, details of claws and whiskers, the cat's paw in front of or behind the string, the colors of the cat-as a unitary visual event, even though we can attend to one or the other of these individually. How do our brains deal with such complex visual information? First, we will consider theories on the processing of motion, form, and color; then we will discuss binocular vision and perceiving depth.

One possibility for how we perceive a visual scene is that a defined series of neurons and their axons handles all information-motion, shape, and color-from a part of the visual field in a hierarchical manner. That is, a defined set of photoreceptors, other retinal cells, lateral geniculate cells, and cortical cells acts as a serial pathway for information from a block of the visual scene. This information arrives at a "master" cell or group of cells, in a visual association area of the cortex, which combines the current information with memories of previous experiences and make sense of it. In this model, pieces of the visual scene are transmitted like sections of a photograph to the brain.

However, evidence does not support this "photographic transmission" or serial pathway theory, but rather a parallel pathways model. This model states that three primary types of information-color, shape, and motion-are individually "pulled out" of the visual scene and sent through three parallel pathways, beginning right in the retina. In this view, one cone receptor receives light from a small area, for example, on the face of a moving calico cat, and signals from this cone go to several intermediate retinal cells and from these to ganglion cells.

Each of the ganglion cells responds to only one of the attributes- color, form, or motion-of the cat's face. The ganglion cells forward their signals to lateral geniculate nucleus (LGN) cells in the thalamus that respond uniquely to that one type of information (color, form, or motion), and so on to the primary visual cortex and further cortical areas. At higher areas, the scene is put back together again, as discussed below.

HIGHER CORTICAL AREAS REASSEMBLE THE VISUAL PUZZLE

Although parallel visual processing seems to fragment what we see, at higher levels the puzzle is reassembled. Further, the immediate visual scene is then interpreted in light of what we know from past visual experiences and what the wiring of our brains allows. While our visual experiences usually make sense to us, we are generally unaware of the cues we are using to interpret scenes until we are challenged with unconventional pictures such as illusions. For example, when we see a friend at some distance, we recognize the person and know that this is a normal adult (or child)

even though the image on the retina is much smaller than that of a person standing right next to us.

PERCEIVING DEPTH DEPENDS ON BOTH MONOCULAR AND BINOCULAR CUES

Along with information on motion, shape, and color, our brains receive input that indicates both depth, the perception that different objects are different distances from us, and the related concept of stereopsis, the solidity of objects. Studies show that people have two ways of judging depth or distance: using monocular (one-eyed) information, and using binocular (two-eyed) data. Monocular cues operate at distances of around 100 feet or greater, where the retinal images seen by both eyes are almost identical. These cues include:

1. Previous familiarity: If we know the range of sizes of people, cats, or trees, we can judge how far away they are.
2. Occlusion: If one object partly hides another, we know that the object in front is closer.
3. Perspective: Parallel lines such as the edges of a road, the intersections of walls and ceilings, and railroad tracks, appear to converge at a distance. The relative distances between objects in a scene with parallel lines are estimated by their positions along the converging lines.
4. Motion parallax: As we move our heads or bodies, nearby objects appear to move more quickly than distant objects; for example, telephone poles beside the road appear to pass by much more quickly when viewed from a moving car than do buildings or trees hundreds of feet back from the road.
5. Shadows and light: Patterns of light and dark can give an impression of depth, and bright colors tend to seem closer than dull colors.

Even though these monocular cues provide some depth vision so that the world does not look "flat" to us when we use just one eye, viewing a scene with two eyes-binocular vision-gives most people a more vivid sense of depth and of stereopsis. This is important when viewing objects closer than about 100 feet. Stereoscopic (three-dimensional) vision depends on the fact that the eyes are separated, on average, by about six centimeters, and thus get slightly different views of the same object. This means that when we fixate an object (place its image on the fovea), we can tell if another object is in front of or behind it by the difference in location of the second object's image on the two retinas. This difference in retinal position is called retinal disparity (Figure 3.) and is essential for stereoscopic vision. Experiments have shown that depth perception occurs at the level of the primary visual cortex or perhaps higher (association cortex), where individual neurons receiving input from the two retinas fire specifically when retinal disparity exists. Although scientists have located such neurons and know they are important for merging or fusing the images from the two eyes, they cannot yet fully explain how the brain accomplishes this.

WE FIRST SCAN A SCENE, AND THEN WE ATTEND TO INDIVIDUAL FEATURES

Finally, what we see depends on what we pay attention to. Sometimes the nature of the visual scene is such that one object or feature "pops out" at us because of distinctive boundaries. If the elements of a scene are not different enough from each other, no one part gets our attention over another. Vision scientists describe two sequential processes that direct our attention: the first is a rapid scanning system that tells us if a simple property is different in one or more parts of a scene. After the initial scan, we direct our attention to individual features of the scene-color, shape, orientation, size-and compare each part with others to detect subtle differences, or we compare each with a previously known version of the scene or object. Our ability to recognize any differences in what appear initially to be two identical objects, or sets of objects, depends on several factors, such as the degree of differences and previous familiarity with the objects.

One illustration of how we can miss differences in scenes when we first rapidly scan them is to make a copy of a photograph of a well-known person and to carefully alter one or two aspects of the picture: make the eyebrows heavier, change the mouth, add bags under the eyes. When the original and the altered copies are viewed side by side and upside down, the changes can be very difficult to identify. If these two pictures are viewed upright, the differences are immediately apparent. Another way to illustrate visual attention is to make a pattern of identical marks or simple objects, such as a sheet of paper with row upon row of X's, with one row containing one or two Z's. See how long it takes to identify the odd letters or objects. Students can devise tests like these in the experimental part of this unit.

ROLE OF MOTIVATION AND LEARNING IN PERCEPTION

In this research, we have examined the characteristics of university students' motivation and its connection with perceptions of the learning environment. Higher education teachers often find it challenging to decide how to organize their lectures and what instructional strategy they should use to be most effective. Therefore, we endeavoured to determine which characteristics of the learning environment best predict the motivational orientation of students and their satisfaction with the course.

The survey included 120 postgraduate students of the Faculty of Arts at the University of Ljubljana. In order to measure their motivation, we employed several scales of the Motivated Strategies for Learning Questionnaire (Pintrich et al., 1991). For the purpose of this research, we created a new questionnaire for their evaluation of the learning environment. The results revealed a high correlation between the intrinsic goal orientation, self-efficacy, and control beliefs. The most important factors of the learning environment that are connected with the formation of intrinsic goal-orientation and the enjoyment of education are the perception of the usefulness of the studied topics, a feeling of autonomy, and teacher support.

To an extent, these findings are supported by the findings of those authors who recommend using those methods of teaching that are in compliance with the student-centred understanding of teaching and learning.

In the previous two decades, the research conducted on achievement goals and achievement goal orientations has become highly prominent in the field of education (e.g. Ames, 1992; Dweck, 1986; Nicholls, 1984; Urdan, 2004). Moreover, certain meta-analyses have shown that this field has become predominant in the research of motivation (Austin & Vancouver, 1996). In psychology, goals are understood as the subject, activity or phenomenon at which our action is directed and with which we satisfy our need (Locke & Latham, 1990), whilst achievement goal orientations are the individuals' general approaches or schemes with which they undertake tasks and evaluate their achievements (Kaplan & Maehr, 2007; Pintrich & Schunk, 2002; Urdan, 2004).

Previous research has shown that, in order to understand the students' approach to studying, it is crucial to know the reasons for their dealing with a particular task and the goals they set for themselves in the process. In this context, the authors predominantly differentiate between mastery goals (i.e. intrinsic goals for which the emphasis is placed on the development of competence) and performance goals (i.e. extrinsic goals that place an emphasis on achievements and comparisons with others).

The positive effects of intrinsic goals have been demonstrated in research on a number of

occasions. They express themselves in higher diligence and assiduity in performing the task (Elliot & Church, 1997; Elliot & McGregor, 1999; Middleton & Midgley, 1997), increased self-efficacy (Pajares, 1997), and using advanced learning strategies (Archer, 1994).

The negative consequences of extrinsic goals are mostly reflected in the use of superficial learning strategies (Elliot et al., 1999), increased perception of stress (Smith, Sinclair, & Chapman, 2002), and self-handicapping (Urdu, 2004).

Achievement goal orientations A review of literature reveals that the research of achievement goals orientations derives predominantly from the work of Nicholls (1984) and Dweck (Dweck, 1985; Elliott & Dweck, 1988). They define motivation as achieving goals, which refer to increasing competences and assessing competence, whilst also defining goals as purposes, which explains why an individual undertakes a particular activity.

Nicholls (1984) was primarily researching how people define success in performance situations, and established that an individual can compare their achievement with their own progress, either self-reflectively (e.g. "I have learned something new", "I have performed better than the last time") or by applying some normative criterion (e.g. "I have performed better than others have").

Although Nicholls pointed out the importance of the situation in setting goals, he principally focused on establishing interpersonal differences in setting goals or motivational orientations. Being task-involved or being ego-involved expresses differences in aspirations in achieving these performance criteria.

These two orientations are supposed to be related to the perception of reasons for success, learning approaches, school evaluation and so on. Explicit differentiation between increasing competences and assessing competence is what led Dweck and Nicholls to define more precisely the two main types of performance goals: the goals that place an emphasis on management and the goals that place an emphasis on achievements.

THE LEARNING ENVIRONMENT

The term "learning environment" most frequently defines the social, psychological, or psychosocial environment in which learning or, as the case may be, teaching takes place (Cleveland & Fisher, 2014). For the most part, research has focused on the different elements of classroom context. Bronfenbrenner (1979) defines the classroom context as a microsystem, "a pattern of activities, roles and interpersonal relations experienced by the developing person in a given setting with particular physical and material characteristics" (Bronfenbrenner, 1979, p. 22), i.e. it contains elements that contribute to the understanding of the happenings in the classroom.

The belief that students and teachers should be researched as a whole prevailed, but researchers have shown a tendency to isolate individual variables instead of attempting to understand the complex integration of thinking, motivation, and feelings. The authors found that teaching never directly affects learning; on the contrary, it operates through intermediary factors that include perceptions of teaching, evaluation, the climate in the classroom, the content of the school subject, structure and similar.

Research has shown that the student's assessment of teaching characteristics or classroom learning environment influences a number of cognitive and affective results (Fraser, 1989; Fraser &

Fisher, 1982; Walberg, 1969). In their meta-analysis, Wang et al. (1990) established that the learning environment is one of the most important factors of learning, which affects both motivation for learning and learning achievements (Wang, Haertel, & Walberg, 1990).

PURPOSE OF THE PRESENT STUDY

To date, research on the influence of learning context on the formation of goal orientations and other factors of learning motivation has primarily focused on classroom settings, specifically on the characteristics of teaching tasks, assessment, and instructional strategies. We believe that goal orientation is among the most important factors of motivation.

The first and most important reason is that goal orientation directly influences many important aspects of student motivation. For example, it is more likely that students with intrinsic goal orientation will have higher self-efficacy, use more complex cognitive learning strategies, be meta-cognitively more active, and achieve better learning outcomes. Previous research shows that goals direct, or at least mediate, the entire process of self-regulation of learning, wherein the use of strategies is only one of the aspects.

METHOD

Participants and procedure The survey was conducted between November and December 2014, and included students who were enrolled in the first year of master studies at the Faculty of Arts at the University of Ljubljana. The sample consisted of 120 students (102 female, 17 male, 1 did not reveal his or her gender) who study in different programs, but are also participating in the common teaching module. This means that than 80% of all the students in this module were included in the research.

Students from foreign language (e.g. English and German Language and Literature), Slovenian, and Comparative Literature study programs prevailed with 76.7% of the whole sample. Females were also predominant in the sample (86%), which accurately reflects the actual participants in the study programs. Students respondents were 21 to 32 years old ($M = 23.3$; $SD = 1.75$). The age category 22 to 25 years represents more than 80% of all students in the research; only 9 students were older than 25 years.

MEASURES

Characteristics of motivation

In order to establish the connection between motivation and perception of the learning environment, we employed motivational scales from the Motivated Strategies for Learning Questionnaire (MSLQ) (Pintrich, Smith, Garcia, & McKeachie, 1991), which is based on a social-cognitive approach to motivation and learning characterized by stressing the interconnection of the cognitive and emotional components of learning.

In the first part of the questionnaire, 20 items was used from the MSLQ, specifically from the "Intrinsic goal-orientation" and "Extrinsic goal-orientation", "Self-efficacy" and "Control beliefs" scales. The respondents replied to the five-point Likert scale questionnaire with the following answer possibilities:

- 1 – Definitely not true of me,
- 2 – Mostly not true of me,
- 3 – Sometimes true and sometimes not true of me,
- 4 – Mostly true of me,

5 – Definitely true of me.

A five-point scale instead of the original seven-point scale was used to unify scales across the questionnaire.

EVALUATION OF THE LEARNING ENVIRONMENT

In addition to the scales from Motivated Strategies for Learning Questionnaire, we also used the Evaluation of the Learning Environment Questionnaire. The questionnaire, developed especially for this survey, is based on Moos' (1974) conceptualization of the learning environment, similar to many other questionnaires that were developed mainly for the use in primary or secondary education. However, the latter instruments are inappropriate for assessing the learning environment in higher education.

In this part of the questionnaire, 42 items were formed, representing the main dimensions of the learning environment: teacher support, student interaction, authentic learning, autonomy, and personal relevance. The respondents assessed their perceptions of learning environment on the course level by using the five-point Likert scale, which represented the frequency of individual "events" in lectures. The following answers were possible: 1 – Never, 2 – Seldom, 3 – Sometimes, 4 – Often, 5 – Always. The number of components was first evaluated with the principal component analysis, and the results of this analysis showed six appropriate dimensions.

CHARACTERISTICS OF THE LEARNING ENVIRONMENT WHICH PREDICT STUDENTS' MOTIVATION AND COURSE SATISFACTION

The theory and empirical findings show that perceptions of learning environment positively influence motivation and course satisfaction. Since correlation only tests for interdependence of the variables, we were also interested in describing the predictive value of learning environment. Correlation analysis (presented in Table 3) showed many moderate to high connections between motivation and evaluation of learning environment. Since learning environment variables were mostly correlated to intrinsic goal-orientation, we were interested to determine which of these variables is the most important in predicting intrinsic motivation.

The regression model is highly statistically significant and explains no less than 43% of the prediction of the dimensions of the learning environment of setting of intrinsic goals during learning ($F = 21.34$; $p < 0.001$). As can be seen in Table 4, two characteristics of the learning environment statistically significant affect the Intrinsic goal-orientation: perception of learning as authentic, connected to practical problems ($\beta = 0.43$) and perceived autonomy during their study ($\beta = 0.20$). These results show that the more that students see their learning as relevant and valuable for their practical experiences, the more intrinsically motivated they feel. Intrinsic orientation was also emphasized with the possibilities of taking control over learning. This means that the more a teacher (according to the opinion of students) encourages and allows the autonomous decisions of students and provides them with opportunities to make co-decisions, the more the students perceive the studied topics as useful and the greater the probability they will be intrinsically motivated during their study.

LEARNING ENVIRONMENT'S EFFECT ON MOTIVATION

The results have shown that students who set themselves intrinsic goals have a greater sense of control of their learning and a feeling of self-efficacy. Furthermore, our study revealed that students who perceive their learning environment as a place that fosters autonomy and self-direction and find their education to be useful and relevant are more intrinsically motivated.

The importance of collaborative learning and teacher support is also underscored. The results of the regression analysis reflect the findings from the correlation analysis and give even more significance to the real-life problems of the studied topics, and support in developing autonomy. The importance of the perceived authenticity of learning have also been proven in the correlation analysis. In this study, the interconnectedness of theoretical knowledge and practical application seems to be among the most important determinants of students' motivation for studying in higher education.

These findings are also supported by the research that has been done on goal-orientations. Ames and Archer (1988) found that goals set on the classroom level also affect the goals set by individual students. Students who believed that their learning environment was performance-oriented and encouraging with regards to good grades and competition set themselves extrinsic goals also with learning.

SIGNAL DETECTION THEORY: ASSUMPTIONS AND APPLICATIONS THE UTILITY OF SIGNAL DETECTION THEORY

Signal detection theory (SDT) is a technique that can be used to evaluate sensitivity in decision-making. Initially developed by radar researchers in the early 1950s (Peterson et al., 1954), the value of SDT was quickly recognized by cognitive scientists and adapted for application in human decision-making (Tanner and Swets, 1954; Green and Swets, 1966). The general premise of SDT is that decisions are made against a background of uncertainty, and the goal of the decision-maker is to tease out the decision signal from background noise. SDT can be applied to any binary decision-making situation where the response of the decision maker can be compared to the actual presence or absence of the target. The advantage of SDT as a measure of decision-making is that it provides a unitless measure of sensitivity, regardless of subject bias, that can be compared to other sensitivities over widely different situations.

INTRODUCTION AND SCOPE

Signal detection theory (SDT) sprouted from World War II research on radar into a probability-based theory in the early 1950s. It specifies the optimal observation and decision processes for detecting electronic signals against a background of random interference or noise. The engineering theory, culminating in the work of Wesley W. Peterson and Theodore G. Birdsall (Peterson et al. 1954), had foundations in mathematical developments for theories of statistical inference, beginning with those advanced by Jerzy Neyman and E. S. Pearson (1933).

SDT was taken into psychophysics, then a century-old branch of psychology, when the human observer's detection of weak signals, or discrimination between similar signals, was seen by psychologists as a problem of inference. In psychology, SDT is a model for a theory of how organisms make fine discriminations and it specifies model-based methods of data collection and analysis. Notably, through its analytical technique called the receiver operating characteristic (ROC), it separates sensory and decision factors and provides independent measures of them. SDT's approach is now used in many areas in which discrimination is studied in psychology, including cognitive as well as sensory processes.

SDT has been applied within a broad range of topics, including memory research (e.g., Banks, 1970), accuracy in radiology diagnostics (e.g., Obuchowski, 2003), and sustained attention in individuals with ADHD (e.g., Huang-Pollock et al., 2012). Further testament to the utility of SDT comes from the

fact that SDT is often discussed in introductory courses and textbooks (e.g., Wade et al., 2013; Lilienfeld et al., 2015). However even with the ubiquity of SDT as an evaluative tool, the mechanics of SDT are not typically discussed in undergraduate textbooks, suggesting that many students are not taught how to practically apply SDT in their university careers. One reason for this is that the procedure itself may appear deceptively complex. Most SDT sources discuss the theory with a rigor that is beyond the mathematical knowledge of most undergraduate students (Fisher, 2014). However, the application of basic SDT principles requires only rudimentary statistical knowledge and can easily be taught at an undergraduate level.

Another reason that SDT may not typically be covered in the undergraduate curriculum is a lack of compelling examples to demonstrate the utility of SDT. Oftentimes, examples are related to sensory performance and the practical application of SDT techniques to more high-level decision-making situations is not immediately apparent to students. For example, Goldstein (2014) and Wolfe et al. (2015), two common introductory textbooks for Sensation and Perception, discuss the theory of SDT in relation to hearing sensitivity in the context of noise.

However, there are more inherently interesting examples that can be used in the classroom to demonstrate the versatility of SDT to learners. Given the importance of active learning through concrete examples when learning inherently abstract statistical principles such as SDT (e.g., Watts, 1991; Garfield and Ben-Zvi, 2007) the onus is on educators to develop compelling examples to capture the interest of undergraduate students. Here, I argue that pseudoscientific “principles” can be used to demonstrate the power of SDT, given that many pseudoscientific results can be explained as the detection of patterns in meaningless noise.

THE MECHANICS OF SIGNAL DETECTION THEORY: A BRIEF OVERVIEW

The basic premise behind SDT is that both signal and noise are represented probabilistically within the decision-maker, and the extent to which those representations overlap can be estimated based on the decision-maker's responses and whether or not the signal is present. The decision-maker bases their decision relative to their criterion (β), where a signal will be reported present when the internal signal is stronger than β and absent when the internal signal is weaker than β . A hit represents the probability that the subject reports the signal present when it is and a false alarm represents the probability that the subject reports the signal present when it is absent.

Alternatively, a miss represents the probability that the subject reports the signal absent when it is present and a correct rejection represents the probability that the subject reports the signal absent when it is absent. All response probabilities are reflected as a part of the area underneath a normal curve. If the probability of each response type is therefore known, both the signal and the noise distributions can be estimated based on simple statistical principles.

Signal detection theory (SDT) is a framework for interpreting data from experiments in which accuracy is measured. In such experiments, two or more stimulus classes (signal and noise in a detection experiment, old and new items in a memory task) are sampled repeatedly, and an observer must select a response corresponding to the class actually presented. According to SDT, performance in such tasks is limited by observer sensitivity, which depends on the degree of overlap between the distributions of a decision variable produced by the stimulus classes.

Within this sensitivity constraint, observers can select from among a range of decision rules in order to satisfy performance goals. Experiments in which appropriate decision rules are manipulated

allow the construction of receiver operating characteristics (ROCs); these functions allow response bias and sensitivity to be distinguished, and can be used to evaluate assumptions about the presumed distributions.

Because it specifies the manner in which accuracy in different discrimination methods depends on sensitivity, SDT allows performance to be predicted across paradigms.

SUBLIMINAL PERCEPTION AND RELATED FACTORS, INFORMATION PROCESSING APPROACH

The meaning of the term subliminal perception has changed over the years, and some prefer to use perception without awareness as an alternative that avoids the sometimes contentious issue of limen (threshold). Generally speaking, "Subliminal perception occurs whenever stimuli presented below the threshold or limen for awareness are found to influence thoughts, feelings, or actions" (Merikle, 2000).

Because an influence on thoughts, feelings, or actions is relatively easy to measure experimentally, the difficult part about the field is evaluating awareness of a stimulus below the subject's threshold. Central to the issue is knowing when a subject is consciously aware of a stimulus, and how this can be reliably ascertained in experiments.

Traditionally, the subjects themselves report awareness. While other areas of psychology may disapprove of introspection as a source of data, in the field of subliminal perception this self-report of "awareness" seems to be unavoidable. The inevitable use of the self-report has also led to much debate over how these self-reports should be interpreted. The dissociation paradigm is the predominant experimental approach used in research on subliminal perception.

The term subliminal is derived from the terms sub (below) and limen (threshold), and it refers to perception so subtle it cannot reach conscious awareness. Most of the research on subliminal perception is done on visual subliminal perception. For instance, one can flash words or pictures so quickly on a computer screen (generally faster than 10-15 milliseconds) that perceivers have the feeling they do not see anything at all.

The first documented findings suggesting an effect that has come to be called "subliminal perception" (or perception without awareness) came from Pierce and Jastrow's (1884) work testing the human response to very similar, barely distinguishable stimuli. Pierce and Jastrow devised an experiment in which they each had to evaluate which of two pressures on skin was greater, along with a reported confidence level. The significant, and surprising, finding was that even when the subject indicated that they were guessing (zero confidence, implied 50% chance), they were actually correct about which pressure was greater more than 60% of the time. The subjects were consistently more accurate than chance, but were not aware of any difference between the two stimuli.

These findings were later confirmed by other researchers, stirring interest about stimuli that were beneath the threshold of conscious awareness. Popular interest in this field was spurred by the claims of a marketing researcher, James Vicary (Merikle, 2000).

In 1957, Vicary claimed that patrons at a movie theatre were exposed to advertising messages Eat Popcorn and Drink Coca-Cola flashed for 3 millisecond durations and repeated throughout a movie.

According to Vicary, patrons were not consciously aware of these hidden messages but responded favourably by significantly increasing their purchases of popcorn and drinks. There has not been any independent evidence to support the claims, and Vicary himself stated that the research was a fabrication (Merikle, 2000).

In other words, they are not consciously aware of the presented words or pictures. However, such visual stimuli are processed unconsciously, and they can have brief and subtle effects on our feeling and thinking. In addition, some research has been done on auditory subliminal perception. No reliable scientific evidence exists, however, for psychological effects of auditory subliminal perception.

The idea of an objective "threshold" is misleading. No objective threshold exists for conscious perception. Whether a briefly presented stimulus reaches conscious awareness depends on many different factors, including individual differences. The threshold is merely subjective.

Effects of subliminal perception are generally small and not easy to establish in controlled laboratory research. However, a few findings are reasonably well established, the most prominent being subliminal mere exposure; Repeated subliminal exposure to a stimulus (for example a picture) leads perceivers to like this picture a little more. Effects of mere exposure have even been obtained for stimuli that were perceived for only one millisecond. Perceivers can to some extent infer the valence (is something good or bad?) from subliminal stimuli. This is shown in research on the subliminal perception of short positive (e.g., sun) and negative (e.g., death) words.

Subliminal perception is controversial mainly because of the notion of subliminal persuasion: The strategy that may be used by marketers or politicians to deliberately influence customers or voters subliminally. In 1957, James Vicary claimed that he increased the sale of cola and popcorn in a New Jersey cinema by subliminally flashing "Drink Coke" and "Eat popcorn" during movies.

This however, turned out to be a myth. Perhaps because of the media attention subliminal perception and persuasion sometimes receives, most of the American population does believe subliminal persuasion to have far reaching consequences. However, although subliminal perception exists, research shows the effects to be minor and usually short-lived. There is no scientific reason to believe it can substantially change consumer behavior.

DEBATE OVER TERMS AND METHODOLOGY

The field of subliminal perception, or perception without awareness, has been marked by continual controversy. In recent years, experts within the field have been debating what qualifies as perception without awareness, and which forms of measurement are valid for experiments. Specifically, researchers question self reports from a subject in an experiment.

While Cheesman and Merikle (1984) have addressed the issue by classifying types of self reports, this controversy is far from resolved. Reingold and Toth (1996) describe one of the fundamental issues: . . . factors unrelated to awareness, such as demand characteristics and preconceived biases, may lead subjects to adopt a conservative response criterion and report null perceptual awareness even under conditions in which conscious perceptual information is available.

Response bias represents a threat not only to the validity of the subjective report measure of awareness, but also to its reliability. In particular, variability in response

criteria makes it difficult to compare reports of null subjective confidence across-subjects, or within-subjects across conditions.

JUST-NOTICEABLE DIFFERENCES (PIERCE AND JASTROW, 1884)

The first documented experiments by Pierce and Jastrow are not only interesting from a historical viewpoint, but also because the experiment alludes to subjective/objective thresholds discussed a century later (Kihlstrom et al., 1992). Pierce set out to research just-noticeable differences when the difference between stimuli was below a physiological threshold.

Two very similar pressures were exerted on the subject's hands, and the subject was forced to choose which of the two pressures was greater. Along with each choice, the subject rated their confidence on a scale of 0-3. Zero confidence denoted "absence of any preference for one answer over its opposite, so that it seemed nonsensical to answer at all" (Pierce and Jastrow, p. 77).

The results indicated a correlation between guesses and the actual proportion of pressures, even when the subjects were guessing (i.e. subliminal). Of the results at zero confidence, subjects guessed the greater pressure correctly in 62%, 70%, and 67% of trials (under different conditions). These results were consistently above 50%, the expected value for guessing.

Therefore, the subjects did perceive the stimuli even though they were not aware of them. A century later, Cheesman and Merikle (1984) defined a subjective versus objective criteria for the threshold which proves to have a major impact on the interpretation of this early experiment and all the others like it.

The subjective threshold would be the point at which subjects in the experiment could no longer report a difference in the stimuli (zero confidence). However, the objective threshold would take into account the successes of the guesses and would rule out subliminal perception in this case (Kihlstrom et al., 1992, p. 20). Visual Masking and Word Recognition (Marcel, 1983) Marcel's famous experiments during the 1970s on visual masking and word recognition exemplify an entire class of experiments on the priming effects of words.

Subjects were shown a masked prime word (or not) and then a target consisting of a string of letters that was sometimes semantically associated to the target. This string of letters sometimes formed a real word, but other times was nonsense. Under one condition, subjects were asked whether the prime word was present. In the other condition, subjects were asked whether the target string was a word.

Subliminal Mere Exposure (Kunst-Wilson and Zajonc, 1980) The "mere exposure" effect refers to the finding that merely being exposed to a stimulus such as an object enhances the subject's attitude toward the stimulus (Zajonc, 1968). This phenomenon is one of affect rather than cognition, and emotional liking or preference after repeated exposure is exhibited both in humans and in animals.

Kunst-Wilson and Zajonc (1980) performed experiments to determine whether the mere exposure effect occurs when the stimulus is presented subliminally, under degraded conditions where subjects indicate no recollection of the stimulus. Their findings are quite surprising, and have since been replicated in many similar experiments. In Kunst-Wilson and Zajonc's (1980) experiment, subjects were exposed to irregular octagons that could easily be discriminated under normal

circumstances.

In the exposure phase, the subjects first saw half of the octagons under “degraded” conditions (1 millisecond duration and poor illumination) which were determined to yield only chance level recognition. In other words, the subjects were later unable to recognize the stimuli they had seen during the exposure phase and so the stimuli were presented subliminally.

In the second phase, subjects had to make comparisons between two octagons under normal viewing conditions. One octagons had been subliminally presented to the subject during the exposure phase, and the other octagon was novel. Subjects were asked to both indicate which octagon they had seen before (recognition), and which octagon they liked better.

EXCLUSION PARADIGM (DEBNER AND JACOBY, 1994)

Recently, Debner and Jacoby (1994) have offered an “exclusion paradigm” which may be able to avoid the disputed aspects of the dissociation paradigm. The word completion experiment illustrates how the exclusion paradigm puts conscious and unconscious processes in conflict with each other. Subjects were first briefly flashed priming words for durations that ranged from subliminal to clearly perceptible. Subjects were then given word stems of partially completed words, and asked to complete the words.

However, subjects were instructed to not use the priming word in order to complete the partial word. If subjects were aware of the priming word, then they should avoid using it in the word completion task. However, if the subjects were not aware of the priming word but had nevertheless perceived it (subliminal perception), then the priming word might influence their word completion task.

Debner and Jacoby (1994) found that indeed, priming words presented for very brief durations – the subliminal stimuli – were much more likely to be used in completing words than the priming words shown for longer durations. This provides an interesting new experimental format in contrast to the usual dissociation, since the exclusion paradigm shows distinct results for consciously versus unconsciously perceived stimuli.

CONCLUSION

While there is much evidence supporting the existence of some kind of perception without awareness, controversy has underscored research in the field. Experts disagree on what should be called subliminal perception, and how such effects can be measured experimentally. Certainly, research has overwhelmingly demonstrated that people can perceive stimuli and act on them without reporting being consciously aware of the stimuli. However, whether or not this qualifies as true subliminal perception is a matter that is hotly debated. The dissociation paradigm, as well as the thresholds for conscious awareness, have been thoroughly criticized.

However, newer findings – those of Kunst-Wilson and Zajonc (1980), and more recently Debner and Jacoby (1994) – tread in new directions that avoid the classical pitfalls of subliminal experiments. While the controversy will no doubt continue, the overwhelming body of evidence from a diverse set of independent experiments is hard to ignore. It seems that subliminal perception, in some form, does exist and can be reliably measured.

INFORMATION PROCESSING

Basic Assumptions

The information processing approach is based on a number of assumptions, including:

1. information made available by the environment is processed by a series of processing systems (e.g. attention, perception, short-term memory);
2. these processing systems transform or alter the information in systematic ways;
3. the aim of research is to specify the processes and structures that underlie cognitive performance;
4. information processing in humans resembles that in computers.

The development of the computer in the 1950s and 1960s had an important influence on psychology and was, in part, responsible for the cognitive approach becoming the dominant approach in modern psychology (taking over from Behaviorism).

The computer gave cognitive psychologists a metaphor, or analogy, to which they could compare human mental processing. The use of the computer as a tool for thinking how the human mind handles information is known as the computer analogy.

Essentially, a computer codes (i.e., changes) information, stores information, uses information, and produces an output (retrieves info). The idea of information processing was adopted by cognitive psychologists as a model of how human thought works.

For example, the eye receives visual information and codes information into electric neural activity which is fed back to the brain where it is "stored" and "coded". This information can be used by other parts of the brain relating to mental activities such as memory, perception and attention. The output (i.e. behavior) might be, for example, to read what you can see on a printed page.

Hence the information processing approach characterizes thinking as the environment providing input of data, which is then transformed by our senses. The information can be stored, retrieved and transformed using "mental programs", with the results being behavioral responses.

Cognitive psychology has influenced and integrated with many other approaches and areas of study to produce, for example, social learning theory, cognitive neuropsychology and artificial intelligence (AI).

INFORMATION PROCESSING AND SELECTIVE ATTENTION

When we are selectively attending to one activity, we tend to ignore other stimulation, although our attention can be distracted by something else, like the telephone ringing or someone using our name.

Psychologists are interested in what makes us attend to one thing rather than another (selective attention); why we sometimes switch our attention to something that was previously unattended (e.g. Cocktail Party Syndrome), and how many things we can attend to at the same time (attentional capacity).

One way of conceptualizing attention is to think of humans as information processors who can only process a limited amount of information at a time without becoming overloaded.

Broadbent and others in the 1950s adopted a model of the brain as a limited capacity information processing system, through which external input is transmitted.

Information processing models consist of a series of stages, or boxes, which represent stages of processing. Arrows indicate the flow of information from one stage to the next.

- **Input** processes are concerned with the analysis of the stimuli.
- **Storage** processes cover everything that happens to stimuli internally in the brain and can include coding and manipulation of the stimuli.
- **Output** processes are responsible for preparing an appropriate response to a stimulus.

CRITICAL EVALUATION

A number of models of attention within the Information Processing framework have been proposed including:

Broadbent's Filter Model (1958), Treisman's Attenuation Model (1964) and Deutsch and Deutsch's Late Selection Model (1963).

However, there are a number of evaluative points to bear in mind when studying these models, and the information processing approach in general. These include:

1. The information processing models assume serial processing of stimulus inputs.
 - **Serial processing** effectively means one process has to be completed before the next starts.
 - **Parallel processing** assumes some or all processes involved in a cognitive task(s) occur at the same time.

There is evidence from dual-task experiments that parallel processing is possible. It is difficult to determine whether a particular task is processed in a serial or parallel fashion as it probably depends (a) on the processes required to solve a task, and (b) the amount of practice on a task. Parallel processing is probably more frequent when someone is highly skilled; for example a skilled typist thinks several letters ahead, a novice focuses on just 1 letter at a time.

2. The analogy between human cognition and computer functioning adopted by the information processing approach is limited.

Computers can be regarded as information processing systems insofar as they:

- combine information presented with stored information to provide solutions to a variety of problems, and
- most computers have a central processor of limited capacity and it is usually assumed that capacity limitations affect the human attentional system.

CULTURE AND PERCEPTION

How much alike, then, are two persons' sensations? Individuals raised in diverse cultures can actually sense the world differently. For example, Marshall Segall and his associates (Segall, Campbell, & Herskovits, 1966) found that people who live in forests or in rural areas can sense crooked and slanted lines more accurately than can people who live in urban areas.

This demonstrates that the rural and urban groups sense the same event differently as a result of their diverse cultural learnings. The term field dependence refers to the degree to which perception of an object is influenced by the background or environment in which it appears.

Some people are less likely than others to separate an object from its surrounding environment. When adults in Japan and the United States are shown an animated underwater scene in which one

large fish swims among small fish and other marine life, the Japanese describe the scene and comment more about the relationships among the objects in the scene.

The Americans were more likely to begin with a description of the big fish and make only half as many comments about the relationships among the objects. Not surprisingly, when showed a second scene with the same big fish, the Americans were more likely to recognize the big fish as the same one as in the first scene (Nisbett, 2003).

More recently, Kitayama, Duffy, Kawamura, and Larsen (2003) showed Japanese and European Americans a picture of a square with a line inside it (see Figure 3.1). They were then given an empty square of a different size and asked to either draw a line the same length as the one they had seen or a line of the same relative length to the one they had seen.

The European Americans were significantly more accurate in drawing the line of the same length while the Japanese were significantly more accurate in drawing the line of relative length. Differences in the environment and culture affected sensation.

The researchers then compared Americans who had been living in Japan and Japanese who had been living in the United States. The time for both was a few years. Given the same picture and task, the Americans who had been living in Japan were close to the Japanese in the original study while the Japanese who had been living in the United States were virtually the same as the native-born Americans.

While other explanations are possible, one strong suggestion is that even living for an extended time in new culture can modify sensation and cognitive processes.

PERCEIVING

Culture also has a great effect on the perception process (Tajfel, 1969; Triandis, 1964). Human perception is usually thought of as a three-step process of selection, organization, and interpretation. Each of these steps is affected by culture.

SELECTION

The first step in the perception process is selection. Within your physiological limitations, you are exposed to more stimuli than you could possibly manage. To use sight as an example, you may feel that you are aware of all stimuli on your retinas, but most of the data from the retinas are handled on a subconscious level by a variety of specialized systems. Parts of our brains produce output from the retinas that we cannot "see." No amount of introspection can make us aware of those processes. In an interesting study by Simons and Chabris (1999), participants viewed videotape of a basketball game. They were told to count the number of passes one team made. In the video, a woman dressed as a gorilla walks into the game, turns to face the camera, and beats her fists on her chest. Fifty percent of all people who watch the video don't see the gorilla. Mack and Rock (1998) argue that we don't consciously see any object unless we are paying direct, focused attention on that object.

PERCEPTUAL STYLES

Perceptual Style is the way you take in information through your five senses and make that information meaningful to you.

Your Perceptual Style acts as a filter between sensation and understanding. It is at the core of who

you are, and it impacts your values, your beliefs, your feelings, and your psychology.

Each of us has one of six unique Perceptual Styles that is innate. Our individual Perceptual Style is literally hard wired and has grown with us as we've aged and developed. The decisions you make, the actions you take, and the directions you choose, are all influenced by your Perceptual Style. This is because our Perceptual Style defines our reality.

We often assume we perceive and respond to the same objective reality and that there is one absolute "right." Research implies that not only is that untrue, but perception is actually a filter applied to objective reality, resulting in natural differences between people.

IT IS BECAUSE OF OUR VARYING PERCEPTUAL STYLES THAT WE ALL EXPERIENCE A DIFFERENT REALITY.

Here is a brief look at the six Perceptual Styles (presented in alphabetical order):

- **Activity:** People with the Activity Perceptual Style jump into life with both feet. They fully engage with the confidence that the details will sort themselves out. Direction, ideas, and pursuits emerge as the result of constant action and involvement with others and their surroundings. They engage until some new possibility or interest emerges to capture their attention. They cultivate extensive networks of friends and associates.
- **Adjustments:** People with the Adjustments Perceptual Style see the world as an objective reality that can be known if they take the time to gather complete information about its intricacies and complexities. They pursue the acquisition and application of knowledge as the basis for their life experience. They enjoy sharing their knowledge with others and gathering new information from research or conversation. They have a strong sense of diplomacy and project a calm certainty.
- **Flow:** People with the Flow Perceptual Style are instinctive advocates for the natural rhythms of life. They see the complex connectivity among seemingly unrelated people, environments, and situations. They intuitively integrate and harmonize their actions within a broadly defined community that provides them and others with a sense of belonging. They honor the continuity between past, present, and future.
- **Goals:** People with the Goals Perceptual Style stride through life focused on the accomplishment of specific results and well-defined objectives. They experience a sense of urgency and clarity of purpose. They believe achievement is primary and method or process secondary – the end justifies the means. They evaluate all activities based on possible contribution towards the achievement of the results they expect. They thrive on competition and believe that life is a constant competition with winners and losers.
- **Methods:** People with the Methods Perceptual Style approach life in a practical, matter-of-fact manner. They focus on how things need to be done. They believe that ordered processes, properly followed, will produce the desired results. They will discern the best processor technique to apply to any specific situation in order to produce reliable, repeatable outcomes. They impose order and they believe that everyone prefers to use well known and proven methods.
- **Vision:** People with the Vision Perceptual Style approach life as a singular experience, a journey toward the future. They face the realities of a situation with serious intent, an optimistic perspective that a solution will be found, and confidence that if one is not, there are always other alternatives to explore. They intuitively see new directions, and actions are taken or dropped opportunistically based on a sense of future possibilities and potential. They are highly

persuasive and easily convince others to follow their vision.

All six Perceptual Styles provide distinctly different experiences of the world. These differences result in a profound psychological and perceptual diversity that is the most important diversity there is because it helps explain the differences between people.

The six Perceptual Styles together describe the total range of perceptual reality. However, individually each Perceptual Style has access to only 1/6 of the total. Everyone has one Perceptual Style that is innate and unchanging. All six Perceptual Styles are evenly distributed in the world, and research confirms there is no difference in regards to culture, race, gender, or age. All six have unique strengths and challenges.

The Perceptual Styles displayed in the circle graph below show the relationships between them. Although all six are psychologically unique, each Perceptual Style shares some similarities with neighboring styles. Each is also attracted and repelled by its opposite style, and each finds the “one-off styles” somewhat puzzling.

NOW LET’S TAKE AN IN-DEPTH LOOK AT EACH PERCEPTUAL STYLE. ACTIVITY

Activity people develop an intense fascination with things that captivate their imagination, and they seek to share the excitement of their experience within their personal network. They are uninterested in things they find tedious or no longer hold their curiosity. They move rapidly from one experience to the next.

Activity people draw on knowledge and previous experience from seemingly unrelated sources to create original and distinctive approaches and results. They find more enjoyment in activities that include members of their personal network. Positive response from their personal network is what drives them, and to that end they pay attention to cultivating and sustaining that network.

Activity people bring energy and vitality to their activities and are often instrumental in getting things started. They believe that life should be fun as well as productive.

Activity people resist details and analysis. They get easily bored with repetitive and routine tasks. They are always ready to jump into something new, and they lose interest in activities that do not deliver attention-grabbing results. They quickly abandon anything they find boring and will wander off in search of other groups or activities that need energizing. Activity people function best in settings that require interaction and allow them to get involved, share insight, tell stories, provide help, and communicate their perspective to others.

ADJUSTMENTS

The actions of Adjustments people reflect their skills in collating, analyzing, and sharing what they know in useful ways. They create intricate systems for the storage and retrieval of their knowledge. The greatest satisfaction for Adjustments people comes from being an information resource for others rather than only applying the information themselves. As such, they are good at explaining and describing complex, detailed, or technical information. Their thoroughness, patience with repetitive tasks, and desire for perfection allow them to spot where information is missing or fuzzy. They edit the written work of others effectively. They actively polish and hone their knowledge, their systems, and their processes to increase elegance and accuracy. They are at their best when given the time to do things carefully and systematically.

Time pressure, competition, and a drive for the bottom-line all violate their view of the world. They believe these conditions lead to a false sense of urgency and impulsive actions that are based on incomplete understanding. They are intrigued by the exploration of ideas when the exploration is characterized by careful and comprehensive analysis that leads to slow evolutionary change.

Because Adjustments people see an effective environment as a complex system that usually requires only incremental alterations and additions rather than wholesale rework, they modify and correct existing processes judiciously.

FLOW

They create and sustain powerful but subtle relationships that form the glue of a community (family, friends, workgroup, social group, etc). They move smoothly and easily between daily events as their awareness emerges and recedes. They attend, in proper proportion, to events and people that require their attention, trusting that what needs to be done will be done.

Flow people facilitate the development of an environment that is comfortable, one that fosters and encourages people. When their environment shifts away from people centered community, they quietly influence its realignment, putting their personal needs aside if necessary to bring it back into harmony.

Flow people welcome new events that support their traditions and values. They use relational communities to gather and transmit informal information, after they have decided what to pass on and what to withhold. Their information sharing is so subtle that others experience the contribution Flow people make to create connection within the community but are often unaware of its source. Flow people provide aid and assistance to the members of a community by serving as a listening post, encouraging development and growth, and empathizing with those who are struggling. They are excellent administrators who interpret policy and procedure for their community.

It is important to them that the value of the community is accurately perceived by outsiders. They are keepers of community history and tradition and provide continuity between the past, present, and future. They use the history of the community to keep it grounded. The activities of Flow people are ultimately focused on support and maintenance of their community.

GOALS

Goals people distrust complexity, subtlety, and solutions that evolve slowly over time. They believe that if a problem needs a solution, there is no time like the present to solve it.

Goals people approach the world with intense energy and have a high level of endurance that allows them to push themselves well after others have given up. They take action with personal intensity and urgency, and they are always anxious to get on to the next task even before the current one is complete. What needs to be done next is obvious to them, so they do not understand why others around them do not see and act on it.

Goals people are very outcome oriented and as such prefer to focus on the accomplishment of goals on which they can see immediate progress. They have no loyalty to current processes or methods and will abandon them quickly if progress towards a solution is slowing down and stagnating. They

make high achievement demands on others but never more than they demand from themselves. Goals people approach life as a competition, and if they find no other worthy competitor they will compete with themselves to see how far they can push themselves in terms of speed, quantity, and endurance.

Goals people are decisive in crises and adept at bringing structure out of chaotic situations. Their single-minded focus allows them to see the fundamental issues in problem situations, to determine the most important task, and to prioritize the steps necessary to accomplish their goal.

METHODS

Methods people follow an ordered set of steps that when performed in a repeatable, logical sequence, inevitably end with the achievement of their objectives. They believe there is a correct method by which each problem, undertaking, or objective can be best handled. Discovering and applying this method is what drives them.

Once the desired result has been determined Methods people do not question it. Instead, they seek to find the steps that will produce the desired outcome with the most efficient use of time, money, and energy. They believe that failure of a solution to work is due to human error in the application of a correctly designed course of action Methods people analyze, manipulate, and apply facts. They use a rational application of facts to make decisions and solve problems, and they are confident that through this method they will arrive at the correct conclusion.

Methods people avoid becoming overly involved on a personal or emotional level and view both as distractions from the objectivity necessary to function effectively Methods people are matter-of-fact and consistent in high-pressure environments. Their ability to see structure and impose order allows them to help others function in the face of chaos and uncertainty.

VISION

Vision people face the realities of a situation with serious intent, an optimistic perspective that a solution will be found, and confidence that if one is not, there are always other alternatives to explore.

Vision people intuitively see new directions that others do not and make the most of this advantage by moving decisively. This ability to intuit new, useful directions and to take swift advantage of opportunities as they arise, gives them a strategic edge over others.

Vision people are unafraid of taking risks and accept that the possibility of high rewards carries with it an equal possibility of failure. However, they view failure as only a temporary setback. They love to play with, explore, and develop new ideas, and they examine all aspects, possible outcomes, and consequences without preconception or judgment Vision people change direction when progress towards achievement of their vision is slow or blocked, and as they move forward, they constantly tinker, experiment, and improvise with their actions in order to increase the likelihood of success. They are strongly committed to achieving their vision but are extremely flexible about the path taken to get there.

Vision people think non-linearly about problems, use their intuition, and try multiple possible solutions as they troubleshoot. When focused on an issue they work it to the exclusion of all else, often until they are exhausted.

Vision people are highly persuasive and easily convince others that the current topic is most important. They enlist others to join them with equal excitement and commitment.

Vision people see multiple successful scenarios, and they coordinate complex information and activities so that all efforts lead towards success.

UNDERSTANDING DIFFERENT PERCEPTUAL STYLES FOR LIFE SUCCESS

The differences between people are often seen as the result of a lack of knowledge, bias, or stubbornness when in truth they are simply a matter of unchangeable biology. Instead of taking a stance that there is a right and wrong way to view things, its best to acknowledge that variations in opinion are due to biologically based perceptual differences.

People literally perceive the world differently, and this differing perception leads to different conclusions about what is important, how things should be done, and what is the “truth” of any situation.

PATTERN RECOGNITION

Pattern recognition is the process of recognizing patterns by using machine learning algorithm. Pattern recognition can be defined as the classification of data based on knowledge already gained or on statistical information extracted from patterns and/or their representation. One of the important aspects of the pattern recognition is its application potential.

Examples: Speech recognition, speaker identification, multimedia document recognition (MDR), automatic medical diagnosis. In a typical pattern recognition application, the raw data is processed and converted into a form that is amenable for a machine to use. Pattern recognition involves classification and cluster of patterns.

- In classification, an appropriate class label is assigned to a pattern based on an abstraction that is generated using a set of training patterns or domain knowledge. Classification is used in supervised learning.
- Clustering generated a partition of the data which helps decision making, the specific decision making activity of interest to us. Clustering is used in an unsupervised learning.

Features may be represented as continuous, discrete or discrete binary variables. A feature is a function of one or more measurements, computed so that it quantifies some-significant characteristics of-the-object.

Example: consider our face then eyes, ears, nose etc are features of the face.

A set of features that are taken together, forms the **features vector**. **Example:** In the above example of face, if all the features (eyes, ears, nose etc) taken together then the sequence is feature vector([eyes, ears, nose]). Feature vector is the sequence of a features represented as a d-dimensional column vector. In case of speech, MFCC (Mel frequency Cepstral Coefficient) is the spectral features of the speech. Sequence of first 13 features forms a feature vector.

Pattern is everything around in this digital world. A pattern can either be seen physically or it can be observed mathematically by applying algorithms.

Example: The colours on the clothes, speech pattern etc. In computer science, a pattern is

represented using vector features values.

PATTERN RECOGNITION POSSESSES THE FOLLOWING FEATURES:

Pattern recognition system should recognise familiar pattern quickly and accurate

- Recognize and classify unfamiliar objects
- Accurately recognize shapes and objects from different angles
- Identify patterns and objects even when partly hidden
- Recognise patterns quickly with ease, and with automaticity.

TRAINING AND LEARNING IN PATTERN RECOGNITION LEARNING

is a phenomena through which a system gets trained and becomes adaptable to give result in an accurate manner. Learning is the most important phase as how well the system performs on the data provided to the system depends on which algorithms used on the data. Entire dataset is divided into two categories, one which is used in training the model i.e. Training set and the other that is used in testing the model after training, i.e. Testing set.

TRAINING

Training set is used to build a model. It consists of the set of images which are used to train the system. Training rules and algorithms used give relevant information on how to associate input data with output decision. The system is trained by applying these algorithms on the dataset, all the relevant information is extracted from the data and results are obtained. Generally, 80% of the data of the dataset is taken for training data.

TESTING

Testing data is used to test the system. It is the set of data which is used to verify whether the system is producing the correct output after being trained or not. Generally, 20% of the data of the dataset is used for testing. Testing data is used to measure the accuracy of the system. Example: a system which identifies which category a particular flower belongs to, is able to identify seven category of flowers correctly out of ten and rest others wrong, then the accuracy is 70 %

Real-time Examples and Explanations: A pattern is a physical object or an abstract notion. While talking about the classes of animals, a description of an animal would be a pattern. While talking about various types of balls, then a description of a ball is a pattern. In the case balls considered as pattern, the classes could be football, cricket ball, table tennis ball etc. Given a new pattern, the class of the pattern is to be determined. The choice of attributes and representation of patterns is a very important step in pattern classification. A good representation is one which makes use of discriminating attributes and also reduces the computational burden in pattern classification. An obvious representation of a pattern will be a **vector**.

Each element of the vector can represent one attribute of the pattern. The first element of the vector will contain the value of the first attribute for the pattern being considered. **Example:** While representing spherical objects, (25, 1) may be represented as an spherical object with 25 units of weight and 1 unit diameter. The class label can form a part of the vector. If spherical objects belong to class 1, the vector would be (25, 1, 1), where the first element represents the weight of the object, the second element, the diameter of the object and the third element represents the class of the object.

ADVANTAGES:

- Pattern recognition solves classification problems

- Pattern recognition solves the problem of fake bio metric detection.
- It is useful for cloth pattern recognition for visually impaired blind people.
- It helps in speaker diarization.
- We can recognise particular object from different angle.

DISADVANTAGES:

- Syntactic Pattern recognition approach is complex to implement and it is very slow process.
- Sometime to get better accuracy, larger dataset is required.
- It cannot explain why a particular object is recognized. Example: my face vs my friend's face.

APPLICATIONS:

- **Image processing, segmentation and analysis** Pattern recognition is used to give human recognition intelligence to machine which is required in image processing.
- **COMPUTER VISION**
Pattern recognition is used to extract meaningful features from given image/video samples and is used in computer vision for various applications like biological and biomedical imaging.
- **SEISMIC ANALYSIS**
Pattern recognition approach is used for the discovery, imaging and interpretation of temporal patterns in seismic array recordings. Statistical pattern recognition is implemented and used in different types of seismic analysis models.
- **Radar signal classification/analysis** Pattern recognition and Signal processing methods are used in various applications of radar signal classifications like AP mine detection and identification.
- **SPEECH RECOGNITION**
The greatest success in speech recognition has been obtained using pattern recognition paradigms. It is used in various algorithms of speech recognition which tries to avoid the problems of using a phoneme level of description and treats larger units such as words as pattern
- **Finger print identification** The fingerprint recognition technique is a dominant technology in the biometric market. A number of recognition methods have been used to perform fingerprint matching out of which pattern recognition approaches is widely used.

ECOLOGICAL THEORY OF PERCEPTION

During World War II, difficulties had been encountered in the flying of aircraft, particularly landing, and in the training of pilots (Gibson, 1979/1986). Tests had been given for depth perception using the static, frozen-in-time, stimulus presentations in two dimensions that are intended to assess perception of monocular and binocular depth cues. Tests might be for linear perspective or apparent size, or other monocular or binocular cues of depth. None of these tests, as it turned out, were able to predict how well a student pilot would perform. The traditional theory of depth perception was not working; it failed to apply where it should have. Gibson puzzled over this and came to realize that the traditional theory of depth perception was wrong.

Helmholtz (1866, in F. H. Allport, 1955) had struggled with the fact that visual perception of three dimensions was based upon a two-dimensional structure—the retina (the retina was flat and visual sensations without depth; Gibson, 1966). It was not possible, given that barrier, to perceive the three dimensions immediately. Helmholtz proposed that cues, which were signs of distance, provided

the basis for making unconscious inferences regarding size and distance (Hilgard, 1987).

Based upon his research Gibson (1979/1986) began to suspect that the traditional list of depth cues was simply not sufficient. Pondering the situation, he theorized that light provided information and that the changes taking place in the surrounding field of light (an array of reflections from objects) provided a form of information that the static displays did not. In the "optic array," an "optic flow pattern" was provided, by the changes in the structure of surrounding light, with information about one's position relative to environmental objects, and changes in that relation as one moves through time and space.

It was clear to Gibson that each approach—the classical approach and his—had a very different conception regarding the stimulus of perception.

Gibson was of the view that visual perception is due to the fact that ambient (surrounding) light conveys visual information that is accessible directly rather than being based upon visual cues (or clues) from the retina which have to be interpreted. Regarding his work prior to this realization, Gibson wrote: I failed to distinguish between stimulation proper and stimulus information, between what happens at passive receptors and what is available to active perceptual systems.

Traditional psychophysics is a laboratory discipline in which physical stimuli are applied to an observer. He is prodded with controlled and systematically varied bits of energy so as to discover how his experience varies correspondingly.

Gibson was working from the assumption that humans actively extract information from the environment that they use to guide their deliberations regarding how to act next. More than that, Gibson was putting forward an "ecological theory" that proposed that there was no absolute division between subject and object, perceiver and perceived (analogous to the assumed division into the stimulus–response sequences of discrete events).

There was a symbiosis between the perceptual apparatus and the environment that it evolved to perceive; perceiver and thing perceived were a system in which there was a constant, ongoing provision of feedback that served as information for the purposeful regulation of continuing activities.

Based upon his recent revelations, regarding the apparent, direct access to the real environment for perception, Gibson, between 1957 and 1961, worked toward developing a new theory of perception that would be consistent with direct realism – an ecological theory of perception (Lombardo, 1987). Up to that point, the person was seen as an individual who was isolated from the environment and that resulted in a metaphysical dichotomy (in the sense that two divisible and completely separate entities confronted and opposed each other). There was the subject (the individual who perceived the world) and the object (that which was perceived).

The result of such conceptual dichotomization was the puzzle of how an individual could perceive the world and to what degree phenomenological experience reflects the true nature of that objective world. This was the difficulty that Gibson would struggle with.

Psychology has long paid homage to evolutionary theory without appreciating the full implication of that theory for psychology. Darwin, on the other hand, was completely aware of the possible

contribution of his theory to psychology: In the distant future I see open fields for far more important researches. Psychology will be based on a new foundation, that of the necessary acquirement of each mental power and capacity by gradation. Light will be thrown on the origin of man and his history.

Mental powers evolved. They are not of a separate realm called mind nor are they apart from the world of nature; they are processes of nature, natural and material. Humans do not gaze upon the world from some distant, non-organic, supra-natural, plateau, separate from and independent of the remainder of living forms. We are of nature, bound to nature, its product. Mental processes are material processes (not of some separate substance called mind) that evolved because they were serviceable to continued existence in a material world.

Darwin's theory was that nature provides obstacles to survival, e.g., drought, famine, pestilence, changing climate, and so on, and that those individuals that were suited to these changed conditions would thrive and survive. This meant that variability of characteristics, within a species, would enhance chances for the survival of the species (not particular individuals). Those individuals, from the species as a whole, that could adapt to changing conditions would be the ones that would carry the species forward (in terms of evolutionary development).

The adapting individuals were selected by nature (a purely random, nonconscious, unintentional process) to continue to exist and have offspring. The adaptive characteristics were passed on to offspring through reproduction. By these means adaptive characteristics would be passed throughout the surviving members of the species and, through a very gradual process, could result in alterations of the species characteristics (morphologically or behaviorally). Darwin surmised that mental processes, upon appearing, were serviceable to continued existence and would therefore be favored by random selection processes.

GIBSON'S ECOLOGICAL THEORY IN HIS ECOLOGICAL THEORY,

Gibson (1966, 1979/1986) emphasizes the inseparable relation between perceptual systems and the physical world in which they evolved. The words animal and environment, from this perspective, imply each other; they cannot be disconnected. Reciprocity exists between animal and environment and, while they are distinguishable, they are mutually supportive (Lombardo, 1987). The ecological approach takes as its unit of study the animal in its environment, considered as an interactive system.

The relations within this system are reciprocal, with the reciprocity including a species evolving in an environment to which it becomes adapted, and an individual acting in its own niche, developing and learning. (Gibson and Pick, 2000, p. 14) In this reciprocal interaction the environment makes available resources, opportunities and information for action.

Actions themselves result in feedback (more information) that can lead to alterations in action. When chasing down prey, for instance, if it begins to pull away from one, speed can either be increased to compensate and overtake, or the chase broken off if that is not possible. In progressing toward some end, whatever that may be, one can continuously monitor one's progress and make adjustments as required.

Perception can be conceived of as an evolved adaptation to lawful relations between the environment and the energy arrays, e.g., optic, acoustic, chemical, that surround individuals and act

upon their sensory receptors. It is through the ecological reciprocity that Gibson transcends the barrier of the senses and discovers the basis for direct realism. This was not a position, however, that Gibson arrived at easily or without a great deal of thought and experimentation. In order to get to that point Gibson, who had originally been aligned with the constructionists, had to realize that problems existed for that perspective.

Gibson's discontent was not simply with the stimulus materials and experimental methods of the constructionists. With Helmholtz the place of commencement for the study of vision was at the retina, with sense impressions and receptor reactions. Up to 1950 this had been Gibson's focus, i.e., the retinal image as the stimulus for the eye (Gibson, 1966). With a change in perspective, he proposed that Newton had misled us when he suggested that light rays painted a picture of the visible object on the back of the eye. The retinal image, contrary to this, is not a picture. That is misleading since it suggests something looked at. The retinal image is a scintillation—a flash or a trace—because the retina jerks about (saccadic movement) and it has a gap called the blind spot where the optic nerve leaves the eye. It was a further misconception, argued Gibson, to think that a retinal sensory pattern can be impressed on the brain neural tissue since the neural pattern never existed in the retinal mosaic. A further reason for discounting the retina as the basis for visual perception was what was found through cross-species comparisons.

The visual organs of octopi, rabbits, bees, spiders, flies, and humans differ widely but all suggest visual perception of those conditions in the environment that are essential to surviving.

VERBAL LEARNING AND DISCRIMINATION LEARNING RECENT TRENDS IN LEARNING: NEUROPHYSIOLOGY OF LEARNING

Learning Process: Fundamental theories: Thorndike, Guthrie, Hull Classical

The underlying ability a teacher must have to orchestrate differentiated instruction day after day, hour after hour, by assessing his/her students and adjusting strategies and tactics moment by moment, requires sophisticated knowledge and skills.

To successfully use differentiated instruction, a teacher must first have a firm understanding of each of the cognitive components of the learning process, what they look like when they are working, and what the specific subcomponents of each look like when they are breaking down. Next, a teacher must develop a rich repertoire of strategies and tactics from which to pull the exact

strategy or tactic that will address a specific breakdown for a specific task, at the right moment. Using a great strategy at the wrong time, or mismatching a strategy with breakdown for which the strategy will yield no gains, will frustrate students and teachers alike when the strategy fails to produce the desired result.

There are six interactive components of the learning process: attention, memory, language, processing and organizing, graphomotor (writing) and higher order thinking. These processes interact not only with each other, but also with emotions, classroom climate, behavior, social skills, teachers and family.

In order to engage, motivate and teach all learners at optimal levels, teachers must understand the learning process in general, understand and respond to students' individual emotional and cognitive profiles and select instructional strategies and tactics that are effective for diverse learners.

ATTENTION

Paying attention is the first step in learning anything. It is easy for most of us to pay attention to things that are interesting or exciting to us. It is difficult for most of us to pay attention to things that are not. When something is not interesting to us, it is easier to become distracted, to move to a more stimulating topic or activity, or to tune out.

The teacher's job is to construct lessons that connect to the learner. Relating what is to be taught to the students' lives can accomplish this. Relate Romeo and Juliet, for example, to the realities in our communities of prejudice, unfounded hatred and gang wars. Or relate today's discrimination to The Diary of Anne Frank, and hold class discussions of discrimination that students have personally experienced or witnessed.

Physical movement can help to "wake up" a mind. When a student shows signs of inattentiveness and/or restlessness, teachers can provide the student with opportunities to move around. Many students with attention challenges actually need to move in order to remain alert. It is wise to find acceptable, non-destructive ways for these students to be active. Responsibilities such as erasing the board, taking a message to the office, and collecting papers can offer appropriate outlets for activity.

MEMORY

Memory is the complex process that uses three systems to help a person receive, use, store, and retrieve information. The three memory systems are (1) short-term memory (e.g., remembering a phone number you got from information just long enough to dial it), (2) working memory (e.g., keeping the necessary information "files" out on the mind's "desktop" while performing a task such as writing a paragraph or working a long division problem), and (3) long-term memory (a mind's ever expanding file cabinet for important information we want to retrieve over time).

Children in school have to remember much more information every day than most adults do. Adults generally have more specialized days – mechanics use and remember mechanical information, dentists use and remember information about dentistry, and so on. On the other hand, school expects that children become experts in several subjects – e.g., math, language, science, social studies, a foreign language, the arts.

It is important to remember that when a student understands something, it does not guarantee that he will remember it. For example, a person may understand a joke that he heard at a party on Saturday night, but he may have trouble remembering it when he tries to tell it to his friends on Monday.

In order to enhance the likelihood that all students will elaborate on new information, teachers should activate their prior knowledge and make new information meaningful to them. For example, a teacher may ask second graders how to divide a pan of brownies evenly among the 20 students in the class, and then connect their solution to the concept of equivalent fractions. Relating how algebraic equations need to be equal or balanced on both sides to the benefits of dividing candy or cookies evenly between friends also connects to prior knowledge.

Students who have difficulty with both short-term and working memory may need directions repeated to them. Giving directions both orally and in written form, and giving examples of what is expected will help all students. All students will benefit from self-testing. Students should be asked to identify the important information, formulate test questions and then answer them. This tactic is also effective in cooperative learning groups and has been shown by evidence-based research to increase reading comprehension (NICHD, 2000).

LANGUAGE

Language is the primary means by which we give and receive information in school. The two language processing systems are expressive and receptive. We use expressive language when we speak and write, and we use receptive language when we read and listen. Students with good language processing skills usually do well in school. Problems with language, on the other hand, can affect a student's ability to communicate effectively, understand and store verbal and written information, understand what others say, and maintain relationships with others.

Most students, especially those with weaknesses in written language, will benefit from using a staging procedure for both expository and creative writing. With this procedure, students first generate ideas. Next they may organize their ideas. Third, they may look at sentence structure. Then they examine their spelling. Finally, they attend to mechanical and grammatical rules. It is also helpful for students to list their most frequently occurring errors in a notebook and refer to this list when self-correcting.

All students will benefit from systematic, cumulative, and explicit teaching of reading and writing. Students who have receptive language challenges such as a slower processing speed must use a lot of mental energy to listen, and, therefore, may tire easily. Consequently, short, highly structured lectures or group discussion times should be balanced with frequent breaks or quiet periods. Oral instructions may also need to be repeated and/or provided in written form.

Cooperative Strategic Reading (Klinger, Vaughan, Hughes, Schumm, and Elbaum as referenced in Marzola 2006) is another way to engage students in reading and at the same time increase oral language skills. This tactic is ideal for promoting intellectual discussion and improving reading comprehension of expository text in mixed-level classrooms across disciplines. Using this tactic, students are placed into cooperative learning groups of four to six students of mixed abilities. The students work together to accomplish four main tasks: (1) preview (skim over the material, determine what they know and what they want to learn), (2) identify clicks and clunks (clicks = we get it; clunks = we don't understand this concept, idea or word), (3) get the gist (main idea) and (4)

wrap up (summarize important ideas and generate questions (think of questions the teacher might ask on a test). Each student in the group is assigned a role such as the leader/involver/taskmaster, the clunk expert, the gist expert, and the timekeeper/pacer (positive interdependence). Each student should be prepared to report the onthe group's conclusions (individual accountability).

Broadening the way we communicate information in the classroom can connect all students more to the topic at hand, and especially students with language challenges. Using visual communication such as pictures and videos to reinforce verbal communication is helpful to all students, and especially to students with receptive language challenges. Challenge students to invent ways to communicate with pictures and other visuals, drama, sculpture, dance and music, and watch memory of key concepts increase and classrooms come alive.

ORGANIZATION

We process and organize information in two main ways: simultaneous (spatial) and successive (sequential). Simultaneous processing is the process we use to order or organize information in space. Having a good sense of direction and being able to "see" how puzzle pieces fit together are two examples of simultaneous processing. Successive processing is what we use to order or organize information in time and sequence. Concepts of time, dates, and order – yesterday, today, and tomorrow, months of the year, mathematical procedures such as division and multiplication, word order in sentences, and sentence order in paragraphs are examples of sequential processing. Students who are good at successive organization usually have little or no trouble with time management and usually find it easy to organize an essay in a sequence that is logical.

Students who have trouble with understanding spatial or geographical problems may need successive verbal explanations given to them. They may benefit from writing written explanations and descriptions of the information contained in charts, graphs or diagrams. Teachers should model this process for all students.

Students who have trouble remembering sequences of information but who are strong in simultaneous processing should benefit from graphic organizers, and making diagrams or flow charts of sequential information such as events in history rather than the standard timeline. They may benefit from software programs such as Inspiration that organize concepts and information into visual maps.

Practicing cooperative learning allows each student's processing and organizing strengths to be utilized to the benefit of the group. For example, those who are strong in simultaneous organization may create the group's chart, visual, or map, and those strong in successive organization may be the task step organizers, the taskmasters, timekeepers and pace setters.

GRAPHOMOTOR

The writing process requires neural, visual, and muscular coordination to produce written work. It is not an act of will but rather an act of coordination among those functions. Often the student who seems unmotivated to complete written work is the student whose writing coordination is klutzy. We have long accepted that students may fall on a continuum from very athletic to clumsy when it comes to sports, but we have not known until recently that some students are writing "athletes" while others writing klutzes. Just as practice, practice, practice will not make a football all-star out of an absolute klutz, practice and acts of will not make a writing all-star out of someone whose neurological wiring does not allow her to be a high performing graphomotor athlete.

Students with handwriting difficulties may benefit from the opportunity to provide oral answers to exercises, quizzes, and tests. Having computers in place for all children helps level the playing field for the graphomotor klutz. Parents and teachers should be aware, however, that many children with graphomotor challenges may also have difficulty with the quick muscular coordination required by the keyboard.

Higher Order Thinking Higher order thinking (HOT) is more than memorizing facts or relating information in exactly the same words as the teacher or book expresses it. Higher order thinking requires that we do something with the facts. We must understand and manipulate the information. HOT includes concept formation; concept connection; problem solving; grasping the “big picture”; visualizing; creativity; questioning; inferring; creative, analytical and practical thinking; and metacognition. Metacognition is thinking about thinking, knowing about knowing, and knowing how you think, process information, and learn.

All students will benefit from advance organizers that relate the big picture and the main concepts to be covered. Also, all students should be explicitly taught how to build concept maps (graphic organizers that connect all components of a concept, and may also connect one concept to another concept).

Give choices for projects and exams that include analytical, practical and creative thinking options. For example, an analytical choice might be to compare and contrast the events of the Holocaust to events in Rwanda. A practical choice might be to show how we can apply the lessons learned from the Holocaust to how we treat one another in our schools. A creative choice might be to write a play about tolerance, create a dance that communicates the emotions of the Holocaust, or write a poem or paint a picture that tells a story about how you feel about the conditions in Darfur.

Providing ample opportunities in the classroom for self-evaluation and self-reflection helps students develop self-understanding. Self-Evaluation... Helping Students Get Better At It! By Carol Rolheiser is listed in the reference section following this article and is a helpful resource for teachers who want to incorporate more student self-evaluation in their classrooms.

A student with metacognition can answer the question, “How am I smart?” The first part of metacognition is thinking about thinking. If a person has metacognition, he understands the way he thinks, and he understands his strengths and challenges in specific skill areas, subjects and activities.

A person with metacognition also monitors and regulates how he learns. He can take a task and decide how best to accomplish it by using his strategies and skills effectively. He knows how he would best learn a new math procedure and which strategies he would use to understand and remember a science concept. He understands the best way for him to organize an essay – whether he would be more successful by using an outline, a graphic organizer or a mind map. He has mental self-management.

Psychologist Robert Sternberg lists six components of mental self-management:

- Know your strengths and weaknesses.
- Capitalize on your strengths and compensate for your weaknesses.-

- Defy--negative-expectations.
- Believe-in-yourself-(self-efficacy).
- Seek--out role-models.
- Seek out an environment where you can make a difference.

Ultimately, this is where we hope students who attend our schools will be upon graduation. As adults, we should model our own metacognition, talk about metacognition, and give meaningful examples of metacognition often and well.

Teaching students about the six components of the learning process – attention, memory, language, processing and organizing, graphomotor (writing) and higher order thinking, then, demystifies learning and provides an opportunity to increase their metacognition. It also enhances their sense of self-worth. A student who understands that she may need to use a particular strategy to help her working memory function better or that taking frequent breaks will help her stay more focused on her homework assignments is much better off than thinking that she is stupid or lazy.

EMOTIONS

Emotions control the on-off switch to learning. When we are relaxed and calm, our learning processes have a green light. When we are uptight, anxious, or afraid, our learning processes have a red light. In the classroom, tension slams the steel door of the mind shut. Creating a non-threatening classroom environment or climate where mistakes are welcomed as learning opportunities reduces tension, opens the mind and increases the opportunity for learning.

The more teachers know about how learning takes place – how information is processed, manipulated and created, the more we will know about what it looks like when it's working and what it looks like when it starts to break down. Then, rather than thinking a student isn't motivated, teachers will look to see if it is attention, memory, language, organizing, graphomotor or higher order thinking that needs an intervention.

MOTIVATION

It is every teacher's job to motivate every student. Learning more about the brain and the development of the mind, studying new information on learning, making learning meaningful and learning about learning, watching the learning process, monitoring closely for breakdowns, and celebrating the successes of every student – these are our challenges as we create schools that honor diversity – the schools all children deserve.

FUNDAMENTAL THEORIES: THORNDIKE

Edward Thorndike (1898) is famous in psychology for his work on learning theory that led to the development of operant conditioning within Behaviorism.

Whereas classical conditioning depends on developing associations between events, operant conditioning involves learning from the consequences of our behavior.

Skinner wasn't the first psychologist to study learning by consequences. Indeed, Skinner's theory of operant conditioning is built on the ideas of Edward Thorndike.

Thorndike studied learning in animals (usually cats). He devised a classic experiment in which he used a puzzle box (see fig. 1) to empirically test the laws of learning.

He placed a cat in the puzzle box, which was encourage to escape to reach a scrap of fish placed outside. Thorndike would put a cat into the box and time how long it took to escape. The cats experimented with different ways to escape the puzzle box and reach the fish.

Eventually they would stumble upon the lever which opened the cage. When it had escaped it was put in again, and once more the time it took to escape was noted. In successive trials the cats would learn that pressing the lever would have favorable consequences and they would adopt this behavior, becoming increasingly quick at pressing the lever.

Edward Thorndike put forward a “**Law of effect**” which stated that any behavior that is followed by pleasant consequences is likely to be repeated, and any behavior followed by unpleasant consequences is likely to be stopped.

CRITICAL EVALUATION

Thorndike (1905) introduced the concept of reinforcement and was the first to apply psychological principles to the area of learning.

His research led to many theories and laws of learning, such as operant conditioning. Skinner (1938), like Thorndike, put animals in boxes and observed them to see what they were able to learn. The learning theories of Thorndike and Pavlov were later synthesized by Hull (1935). Thorndike's research drove comparative psychology for fifty years, and influenced countless psychologists over that period of time, and even still today.

The theory suggests that transfer of learning depends upon the presence of identical elements in the original and new learningsituations; i.e., transfer is always specific, never general. In later versions of the theory, the concept of “belongingness” was introduced; connections are more readily established if the person perceives that stimuli or responses go together (c.f. Gestalt principles). Another concept introduced was “polarity” which specifies that connections occur more easily in the direction in which they were originally formed than the opposite. Thorndike also introduced the “spread of effect” idea, i.e., rewards affect not only the connection that produced them but temporally adjacent connections as well.

APPLICATION

Connectionism was meant to be a general theory of learning for animals and humans. Thorndike was especially interested in the application of his theory to education including mathematics (Thorndike, 1922), spelling and reading (Thorndike, 1921), measurement of intelligence (Thorndike et al., 1927) and adultlearning (Thorndike at al., 1928).

EXAMPLE

The classic example of Thorndike’s S-R theory was a cat learning toescape from a “puzzle box” by pressing a lever inside the box. After much trial and error behavior, the cat learns to associate pressing the lever (S) with opening the door (R). This S-R connection is established because it results in a satisfying state of affairs (escape from the box). The law of exercise specifies that the connection wasestablished because the S-R pairing occurred many times (the law of effect) and was rewarded (law of effect) as well as forming a single sequence (law of readiness).

FUNDAMENTAL THEORIES: GUTHRIE

Guthrie attempted to explain learning through **association** of stimuli with responses. Learning, in terms of behavior is a function of the environment. According to Guthrie, learning is associating a particular stimulus with a particular response. This association, however, will only occur if **stimuli and responses occur soon enough** one after another (**the contiguity law**). The association is established on the **first experienced instance of the stimulus (one trial learning)**. Repetitions or **reinforcements** in terms of reward or punishment do not influence the strength of this connection. Still, every stimulus is a bit different, which results in many trials in order to form a general response. This was according to Guthrie the only type of learning identifying him not as reinforcement theorist, but contiguity theorist.

More complex behaviors are composed of a **series of movements** (habits where each movement is a small stimulus-response combination. These movements or are actually what is being learned in each one trial learning rather than behaviors. Learning a number of moves forms an act (incremental learning). Unsuccessful acts remain not learned because they are replaced by later successfully learned acts.

Other researchers like John Watson studied whole acts just because it was easier, but movements are, according to Guthrie what should actually be studied.

Forgetting occurs not due to time passage, but due to interference. As time passes, stimulus can become associated with new responses. Three different methods can help in forgetting an undesirable old habit and help replacing it

- **Fatigue method** - using numerous repetitions, an animal becomes so fatigued that it is unable to reproduce the old response, and introduces a new response (or simply doesn't react).
- **Threshold method** - first, a very mild version of the stimulus below the threshold level is introduced. Its intensity is then slowly increased until the full stimulus can be tolerated without causing the undesirable response
- **Incompatible stimuli method** - the response is "unlearned" by placing the animal in a situation where it cannot exhibit the undesirable response.

Although it was intended to be a general theory of learning, Guthrie's theory was tested mostly on animals.

WHAT IS THE PRACTICAL MEANING OF CONTIGUITY THEORY AND ONE TRIAL LEARNING?

In Guthrie's own words, "we learn only what we ourselves do".

Learning must be active, but as such must involve both **teacher's and students' activity** in order to relate stimulus with a response within a time limit. Guthrie also applied his ideas to treatment of **personality disorders**.

CRITICISMS

Guthrie's theory was first preferred, due to its **simplicity**, but later criticized for the same reason. Its simplicity was later turned into **incompleteness**. It was also based on too little experimental data and criticized for being unable to explain why people often behave differently in same situations. Guthrie's contiguity theory specifies that "a combination of stimuli which has accompanied a movement will on its recurrence tend to be followed by that movement". According to Guthrie, all learning was a consequence of association between a particular stimulus and response. Furthermore, Guthrie argued that stimuli and responses affect specific sensory-motor patterns; what is learned are movements, not behaviors.

In contiguity theory, rewards or punishment play no significant role in learning since they occur after the association between stimulus and response has been made. Learning takes place in a single trial (all or none). However, since each stimulus pattern is slightly different, many trials may be necessary to produce a general response. One interesting principle that arises from this position is called “postremity” which specifies that we always learn the last thing we do in response to a specific stimulus situation.

Contiguity theory suggests that forgetting is due to interference rather than the passage of time; stimuli become associated with new responses. Previous conditioning can also be changed by being associated with inhibiting responses such as fear or fatigue. The role of motivation is to create a state of arousal and activity which produces responses that can be conditioned.

APPLICATION

Contiguity theory is intended to be a general theory of learning, although most of the research supporting the theory was done with animals. Guthrie did apply his framework to personality disorders (e.g. Guthrie, 1938).

EXAMPLE

The classic experimental paradigm for Contiguity theory is cats learning to escape from a puzzle box (Guthrie & Horton, 1946). Guthrie used a glass paneled box that allowed him to photograph the exact movements of cats. These photographs showed that cats learned to repeat the same sequence of movements associated with the preceding escape from the box. Improvement comes about because irrelevant movements are unlearned or not included in successive associations.

PRINCIPLES

- In order for conditioning to occur, the organism must actively respond (i.e., do things).
- Since learning involves the conditioning of specific movements, instruction must present very specific tasks.
- Exposure to many variations in stimulus patterns is desirable in order to produce a generalized response.
- The last response in a learning situation should be correct since it is the one that will be associated.

HULL - LEARNING THEORY INTRODUCTION

Learning is one of the most important topics in present-day psychology, yet it is an extremely difficult concept to define. Learning occupies a very important place in our life. Most of what we do or do not do is influenced by what we learnt it. Learning therefore provides a key to the structure of our personality and behavior. An individual starts to learning immediately after his birth or in a strict sense even in womb of the mother. Experience direct or indirect is found to play a dominant role in molding and shaping our behavior of the individual from the very beginning. The change in behavior brought about by experience is commonly known as learning. In this way, the term learning broadly speaking, stands for all those changes and modifications in the behavior of the individual which he undergoes during his life time.

DEFINITION

Gardner Murphy (1968)

The term learning covers every modification in behavior to meet environmental requirements.

Henry P. Smith (1962)

Learning is the acquisition of new behavior or the strengthening or weakening of old behavior as the result of experience.

Crow and Crow (1973)

Learning is the acquisition of habits, knowledge and attitudes. It involves new ways of doing things, and it operates in an individual's attempts to overcome obstacles or to adjust to new situation. It represents progressive changes in behavior. It enables him to satisfy interests to attain goals.

Kimble (1961)

Learning is a relatively permanent change in behavioral potentiality that occurs as a result of reinforced practice.

The above definition reveals the following facts:

1. Learning is a process and not a product.
2. It involves all those experience and training of an individual (right from birth) which help him to produce changes in his behavior
3. Learning leads to changes in behavior but this does not necessarily mean that these changes always bring about improvement or positive development. One has an equal chance to drift to the negative side of human personality.
4. Learning prepares an individual for any adjustment and adaptation that may be necessary

Clark Hull grew up handicapped and contracted polio at the age of 24, yet he became one of the great contributors to psychology. His family was not well off so his education had to be stopped at times. Clark earned extra money through teaching. Originally Clark aspired to be a great engineer, but that was before he fell in love with the field of Psychology.

By the age of 29 he graduated from Michigan University. When Clark was 34 when he received his Ph.D. in Psychology at the University of Wisconsin in 1918.

Soon after graduation he became a member of the faculty at the University of Wisconsin, where he served for 10 years. Although one of his first experiments was an analytical study of the effects of tobacco on behavioral efficiency, his lifelong emphasis was on the development of objective methods for psychological studies designed to determine the underlying principles of behavior.

Hull devoted the next 10 years to the study of hypnosis and suggestibility, and in 1933 he published *Hypnosis and Suggestibility*, while employed as a research professor at Yale University. This is where he developed his major contribution, an elaborate theory of behavior based on Pavlov's laws of conditioning. Pavlov provoked Hull to become greatly interested in the problem of conditioned reflexes and learning. In 1943 Hull published, *Principles of Behavior*, which presented a number of constructs in a detailed Theory of Behavior. Soon he became the most cited psychologist. For his effort, Hull received the Warren medal in 1945 from the society of Experimental Psychology. Hull was physically disabled most of his life. In 1948 he had coronary attack, and four years later he died. In his last book he wrote (*A behavior system*), he expressed regret that the third book that he had intended to write on learning would never be written.

HULL LEARNING THEORY

1. DERIVE REDUCTION THEORY

Drive Reduction Theory - the notion that behavior occurs in response to "drives" such as hunger, thirst, sexual interest, feeling cold, etc. When the goal of the drive is attained (food, water, mating, warmth) the drive is reduced, and this constitutes reinforcement of the behaviors that lead to the drive reduction, and ultimately learning.

Hull viewed the drive as a stimulus, arising from a tissue need, which in turn stimulates behavior. The strength of the drive is determined upon the length of the deprivation, or the intensity / strength of the resulting behavior. He believed the drive to be non-specific, which means that the drive does not direct behavior rather it functions to energize it. In addition this drive reduction is the reinforcement.

Hull's learning theory focuses mainly on the principle of reinforcement; when an S-R relationship is followed by a reduction of the need, the probability increases that in future similar situations the same stimulus will create the same prior response. Reinforcement can be defined in terms of reduction of a primary need. Just as Hull believed that there were secondary drives, he also felt that there were secondary reinforcements - "If the intensity of the stimulus is reduced as the result of a secondary or learned drive, it will act as a secondary reinforcement" (Schultz & Schultz, 1987, p 241). The way to strengthen the S-R response is to increase the number of reinforcements, habit strength.

2. CHANGE IN THE TRADITIONAL S-R NOTION

Hull introduced concept of intervening variables between S and R. Accordingly, when a stimulus(S) impinges on the organism, it results in a sensory neural impulse(s) a kind of stimulus trace. This stimulus trace ultimately causes a motor neural reaction(r) those results in an overt response (R). Thus we may have the formula S- s-r-R instead of the traditional S-R. However, there are so many other things within the inner mechanism of the organism like his interest, needs and drives also the reinforcing mechanism that may influence his response or behavior.

The link between the S-R relationships could be anything that might affect how an organism responds; learning, fatigue, disease, injury, motivation, etc. He labeled this relationship as "E", a reaction potential, or as **sEr**. Clark goal was to make a science out of all of these intervening factors. He classified his formula.

THE CONCEPT OF DRIVE STIMULI REDUCTION

Originally, Hull had a drive reduction theory of learning, but later he revised it to a Drive Stimuli Reduction theory of learning. One reason for the change was the realization that if a thirsty animal is given water as a reinforce for performing some act, it takes a considerable amount of time for the thirst drive to be satisfied by the water. The water goes into the mouth, the throat, the stomach, and eventually the blood. The effects of ingestion of water must ultimately reach the brain, and finally the thirst drive will be reduced.

Hull concluded that the drive reduction was too far removed from the presentation of the reinforce to explain how learning could take place. What was needed to explain learning was something that occurred soon after the presentation of a reinforce, and that something was the reduction of drive stimuli (SD).

REASONS

- Drive stimuli for thirst include dryness in the mouth and parched lips. Water almost immediately reduces such stimulation thus Hull had the mechanism he needed for explaining learning.
- It was provided by Sheffield and Roby (1950), who found that hungry rats were reinforced by non-nutritive saccharine, which could not possibly have reduced the hunger drive.

INCENTIVE MOTIVATION (K)

Results found by Creps and Zeaman led Hull to reach the conclusion that organisms learn as rapidly for a small incentive as they do for a large one, but they perform differently as size of the incentive (K) varies. The rapid change in performance following a change in reinforcement size is referred to as the **Creps effect**, after the man who first observed it.

STIMULUS-INTENSITY DYNAMISM

According to Hull, Stimulus-Intensity Dynamism (V) is an intervening variable that varies along with the intensity of the external stimulus (S). Stated simply, Stimulus-Intensity Dynamism indicates that the greater the intensity of a stimulus, the greater the probability that a learned response will be elicited. Thus we must revise Hull's earlier formula as follows

$$SER = (SHR \times D \times K \times V) - (SIR + IR) - SOR$$

It is interesting to note that because **sHr**, **D**, **K** and **V** are multiplied together, if any one had a value of zero, reaction potential would be zero. For example there could have been many pairings between S and R (sHr), but if drive is zero, reinforcement is zero or the organism cannot detect the stimulus, a learned response will not occur.

HULL'S FINAL SYSTEM SUMMARIZED

There are three kinds of variable in Hull's theory:

1. **Independent variable** – which are stimulus events systematically manipulated by the experimenter.
2. **Intervening variables** – which are process thought to be taking place within the organism but directly observable.
3. **Dependent variables** – which are some aspect of behavior that is measured by the experimenter in order to determine whether the independent variables had any effect.

EDUCATIONAL IMPLICATION

- The development of curriculum
In this reference Hull emphasized the importance of needs in learning process and accordingly the needs of all categories of children should be incorporated in the curriculum learning becomes meaningful only when it satisfies the needs of children.
- The know actual needs of the students by teacher and parents
Hull is felt that teachers and parents of the student should also share their responsibility in teaching the actual needs of the student through various means proper guidance is must for their attitude and aptitudes.
- Emphasized anxiety as a drive in human learning
From this line of reasoning, it follows that encouraging some anxiety in students that could subsequently be reduced by success is a necessary condition for classroom learning. Too little anxiety results in no learning (because there is no drive to be reduced), and too much anxiety is disruptive. Therefore, students who are mildly anxious are in the best position to learn and are therefore easiest to teach.

Hull's system of learning advocated the following chain sequence for improved results in the teaching-learning process:

- a) Drive – This is something which is needed by the learner in order to behave or respond.
- b) Cue – There must be something to which the learner must respond.
- c) Response – The learner must be made to respond in order to learn some act.
- d) Reward – The learner's response must be reinforced or rewarded, thus enabling him to learn what he wants to learn.

Hull developed a version of behaviorism in which the stimulus (S) affects the organism (O) and the resulting response (R) depends upon characteristics of both O and S. In other words, Hull was interested in studying intervening variables that affected behavior such as initial drive, incentives, inhibitors, and prior training (habit strength). Like other forms of behavior theory, reinforcement is the primary factor that determines learning. However, in Hull's theory, drive reduction or need satisfaction plays a much more important role in behavior than in other frameworks (i.e., connectionism, operant conditioning).

Hull's theoretical framework consisted of many postulates stated in mathematical form; They include:

- organisms possess a hierarchy of needs which are aroused under conditions of stimulation and drive,
- habit strength increases with activities that are associated with primary or secondary reinforcement,
- habit strength aroused by a stimulus other than the one originally conditioned depends upon the closeness of the second stimulus in terms of discrimination thresholds,
- stimuli associated with the cessation of a response become conditioned inhibitors,
- the more the effective reaction potential exceeds the reaction threshold, the shorter the latency of response. As these postulates indicate, Hull proposed many types of variables that accounted for generalization, motivation, and variability (oscillation) in learning.

One of the most important concepts in Hull's theory was the habit strength hierarchy: for a given stimulus, an organism can respond in a number of ways. The likelihood of a specific response has a probability which can be changed by reward and is affected by various other variables (e.g. inhibition). In some respects, habit strength hierarchies resemble components of cognitive theories such as schema and production systems.

APPLICATION

Hull's theory is meant to be a general theory of learning. Most of the research underlying the theory was done with animals, except for Hull et al. (1940) which focused on verbal learning. Miller & Dollard (1941) represents an attempt to apply the theory to a broader range of learning phenomena. As an interesting aside, Hull began his career researching hypnosis – an area that landed him in some controversy at Yale (Hull, 1933).

EXAMPLE

Here is an example described by Miller & Dollard (1941): A six year old girl who is hungry and wants candy is told that there is candy hidden under one of the books in a bookcase. The girl begins to pull out books in a random manner until she finally finds the correct book (210 seconds). She is sent out of the room and a new piece of candy is hidden under the same book. In her next search, she is much more directed and finds the candy in 86 seconds. By the ninth repetition of this

experiment, the girl finds the candy immediately (2 seconds). The girl exhibited a drive for the candy and looking under books represented her responses to reduce this drive. When she eventually found the correct book, this particular response was rewarded, forming a habit. On subsequent trials, the strength of this habit was increased until it became a single stimulus-response connection in this setting.

PRINCIPLES

- (1) Drive is essential in order for responses to occur (i.e., the student must want to learn).
- (2) Stimuli and responses must be detected by the organism in order for conditioning to occur (i.e., the student must be attentive).
- (3) Response must be made in order for conditioning to occur (i.e., the student must be active).
- (4) Conditioning only occurs if the reinforcement satisfied a need (i.e., the learning must satisfy the learner's wants).

CONCLUSION

Hull's system of learning is acclaimed and remembered for putting forward a most systematic, scientific and mathematical theory of learning. Hull was able to popularize a very innovative and objective behavioristic approach to learning which was more effective in comparison to the approach of his predecessors. The greatest contribution of Hull's theory lies in its emphasis on linking the learning to the needs of the children.

He says that it is the need, drive or drive stimuli that energize an individual to act or learn or behave. Therefore, he advocated the need-based goals of education, including need-based curricula and methods of teaching. Whereas needs start the process of learning, reinforcement and incentives act as catalytic agents for increasing one's efforts towards achieving the goals of learning. Therefore in any education process we must involve sufficient possibilities of proper motivation and reinforcement incentives.

CLASSICAL CONDITIONING: PROCEDURE, PHENOMENA AND RELATED ISSUES

Classical conditioning (also known as Pavlovian conditioning) is learning through association and was discovered by Pavlov, a Russian physiologist. In simple terms, two stimuli are linked together to produce a new learned response in a person or animal.

John Watson proposed that the process of classical conditioning (based on Pavlov's observations) was able to explain all aspects of human psychology.

Everything from speech to emotional responses was simply patterns of stimulus and response. Watson denied completely the existence of the mind or consciousness. Watson believed that all individual differences in behavior were due to different experiences of learning.

STAGE 1: BEFORE CONDITIONING:

In this stage, the unconditioned stimulus (UCS) produces an unconditioned response (UCR) in an organism.

In basic terms, this means that a stimulus in the environment has produced a behavior / response which is unlearned (i.e., unconditioned) and therefore is a natural response which has not been taught. In this respect, no new behavior has been learned yet.

This stage also involves another stimulus which has no effect on a person and is called the neutral stimulus (NS). The NS could be a person, object, place, etc.

The neutral stimulus in classical conditioning does not produce a response until it is paired with the unconditioned stimulus.

DURING CONDITIONING:

During this stage, a stimulus which produces no response (i.e., neutral) is associated with the unconditioned stimulus at which point it now becomes known as the conditioned stimulus (CS).

For example, a stomach virus (UCS) might be associated with eating a certain food such as chocolate (CS). Also, perfume (UCS) might be associated with a specific person (CS).

For classical conditioning to be effective, the conditioned stimulus should occur before the unconditioned stimulus, rather than after it, or during the same time. Thus, the conditioned stimulus acts as a type of signal or cue for the unconditioned stimulus.

AFTER CONDITIONING:

Now the conditioned stimulus (CS) has been associated with the unconditioned stimulus (UCS) to create a new conditioned response (CR).

For example, a person (CS) who has been associated with nice perfume (UCS) is now found attractive (CR). Also, chocolate (CS) which was eaten before a person was sick with a virus (UCS) now produces a response of nausea (CR).

CLASSICAL CONDITIONING IN THE CLASSROOM

The implications of classical conditioning in the classroom are less important than those of operant conditioning, but there is still a need for teachers to try to make sure that students associate positive emotional experiences with learning.

If a student associates negative emotional experiences with school, then this can obviously have bad results, such as creating a school phobia.

For example, if a student is bullied at school they may learn to associate the school with fear. It could also explain why some students show a particular dislike of certain subjects that continue throughout their academic career. This could happen if a student is humiliated or punished in class by a teacher.

Critical Evaluation

Classical conditioning emphasizes the importance of learning from the environment, and supports nurture over nature. However, it is limiting to describe behavior solely in terms of either nature or nurture, and attempts to do this underestimate the complexity of human behavior. It is more likely that behavior is due to an interaction between nature (biology) and nurture (environment).

A strength of classical conditioning theory is that it is scientific. This is because it's based on empirical evidence carried out by controlled experiments. For example, Pavlov (1902) showed how classical conditioning could be used to make a dog salivate to the sound of a bell.

Classical conditioning is also a reductionist explanation of behavior. This is because a complex

behavior is broken down into smaller stimulus-response units of behavior.

Supporters of a reductionist approach say that it is scientific. Breaking complicated behaviors down to small parts means that they can be scientifically tested. However, some would argue that the reductionist view lacks validity. Thus, while reductionism is useful, it can lead to incomplete explanations.

A final criticism of classical conditioning theory is that it is deterministic. This means that it does not allow for any degree of free will in the individual. Accordingly, a person has no control over the reactions they have learned from classical conditioning, such as a phobia.

BASIC PRINCIPLES OF CLASSICAL CONDITIONING

Classical conditioning is a form of learning whereby a conditioned stimulus (CS) becomes associated with an unrelated unconditioned stimulus (US) in order to produce a behavioral response known as a conditioned response (CR). The conditioned response is the learned response to the previously neutral stimulus. The unconditioned stimulus is usually a biologically significant stimulus such as food or pain that elicits an unconditioned response (UR) from the start. The conditioned stimulus is usually neutral and produces no particular response at first, but after conditioning it elicits the conditioned response.

Extinction is the decrease in the conditioned response when the unconditioned stimulus is no longer presented with the conditioned stimulus. When presented with the conditioned stimulus alone, the individual would show a weaker and weaker response, and finally no response. In classical-conditioning terms, there is a gradual weakening and disappearance of the conditioned response. Related to this, spontaneous recovery refers to the return of a previously extinguished conditioned response following a rest period. Research has found that with repeated extinction/recovery cycles, the conditioned response tends to be less intense with each period of recovery.

PAVLOV'S FAMOUS STUDY

The best-known of Pavlov's experiments involves the study of the salivation of dogs. Pavlov was originally studying the saliva of dogs as it related to digestion, but as he conducted his research, he noticed that the dogs would begin to salivate every time he entered the room—even if he had no food. The dogs were associating his entrance into the room with being fed. This led Pavlov to design a series of experiments in which he used various sound objects, such as a buzzer, to condition the salivation response in dogs.

He started by sounding a buzzer each time food was given to the dogs and found that the dogs would start salivating immediately after hearing the buzzer—even before seeing the food. After a period of time, Pavlov began sounding the buzzer without giving any food at all and found that the dogs continued to salivate at the sound of the buzzer even in the absence of food. They had learned to associate the sound of the buzzer with being fed.

If we look at Pavlov's experiment, we can identify the four factors of classical conditioning at work:

- The unconditioned response was the dogs' natural salivation in response to seeing or smelling their food.
- The unconditioned stimulus was the sight or smell of the food itself.
- The conditioned stimulus was the ringing of the bell, which previously had no association with food.

- The conditioned response, therefore, was the salivation of the dogs in response to the ringing of the bell, even when no food was present.

Pavlov had successfully associated an unconditioned response (natural salivation in response to food) with a conditioned stimulus (a buzzer), eventually creating a conditioned response (salivation in response to a buzzer). With these results, Pavlov established his theory of classical conditioning.

NEUROLOGICAL RESPONSE TO CONDITIONING

Consider how the conditioned response occurs in the brain. When a dog sees food, the visual and olfactory stimuli send information to the brain through their respective neural pathways, ultimately activating the salivation glands to secrete saliva. This reaction is a natural biological process as saliva aids in the digestion of food. When a dog hears a buzzer and at the same time sees food, the auditory stimulus activates the associated neural pathways. However, because these pathways are being activated at the same time as the other neural pathways, there are weak synapse reactions that occur between the auditory stimulus and the behavioral response. Over time, these synapses are strengthened so that it only takes the sound of a buzzer (or a bell) to activate the pathway leading to salivation.

BEHAVIORISM AND OTHER RESEARCH

Pavlov's research contributed to other studies and theories in behaviorism, which is an approach to psychology interested in observable behaviors rather than the inner workings of the mind. The philosopher Bertrand Russell argued that Pavlov's work was an important contribution to a philosophy of mind. Pavlov's research also contributed to Hans Eysenck's personality theory of introversion and extroversion. Eysenck built upon Pavlov's research on dogs, hypothesizing that the differences in arousal that the dogs displayed was due to inborn genetic differences. Eysenck then extended the research to human personality traits.

Pavlov's research further led to the development of important behavior-therapy techniques, such as flooding and desensitizing, for individuals who struggle with fear and anxiety. Desensitizing is a kind of reverse conditioning in which an individual is repeatedly exposed to the thing that is causing the anxiety. Flooding is similar in that it exposes an individual to the thing causing the anxiety, but it does so in a more intense and prolonged way.

CLASSICAL CONDITIONING IN HUMANS

The influence of classical conditioning can be seen in responses such as phobias, disgust, nausea, anger, and sexual arousal. A familiar example is conditioned nausea, in which the sight or smell of a particular food causes nausea because it caused stomach upset in the past. Similarly, when the sight of a dog has been associated with a memory of being bitten, the result may be a conditioned fear of dogs.

As an adaptive mechanism, conditioning helps shield an individual from harm or prepare them for important biological events, such as sexual activity. Thus, a stimulus that has occurred before sexual interaction comes to cause sexual arousal, which prepares the individual for sexual contact. For example, sexual arousal has been conditioned in human subjects by pairing a stimulus like a picture of a jar of pennies with views of an erotic film clip. Similar experiments involving blue gourami fish and domesticated quail have shown that such conditioning can increase the number of offspring. These results suggest that conditioning techniques might help to increase fertility rates in infertile individuals and endangered species.

ISSUES

Classical conditioning is one of those introductory psychology terms that gets thrown around. Many people have a general idea that it is one of the most basic forms of associative learning, and people often know that Ivan Pavlov's 1927 experiment with dogs has something to do with it, but that is often where it ends.

CLASSICAL CONDITIONING, EXPLAINED

The most important thing to remember is that classical conditioning involves automatic or reflexive responses, and not voluntary behavior (that's operant conditioning, and that is a different post). What does this mean? For one thing, that means that the only responses that can be elicited out of a classical conditioning paradigm are ones that rely on responses that are naturally made by the animal (or human) that is being trained. Also, it means that the response you hope to elicit must occur below the level of conscious awareness - for example, salivation, nausea, increased or decreased heart rate, pupil dilation or constriction, or even a reflexive motor response (such as recoiling from a painful stimulus). In other words, these sorts of responses are involuntary.

The basic classical conditioning procedure goes like this: a neutral stimulus is paired with an unconditional stimulus (UCS). The neutral stimulus can be anything, as long as it does not provoke any sort of response in the organism. On the other hand, the unconditional stimulus is something that reliably results in a natural response. For example, if you shine a light into a human eye, the pupil will automatically constrict (you can actually see this happen if you watch your eyes in a mirror as you turn on and off a light). Pavlov called this the "unconditional response." (UCR)

As soon as the neutral stimulus is presented with the UCS, it becomes a conditional stimulus (CS). If the CS and UCS always occur together, then the two stimuli would become associated over time. The response that was initially produced in response to the UCS would also be produced in response to the CS, even if it was presented alone. Pavlov called this the "conditional response." (CR)

To make this a bit more concrete, we'll use Pavlov's dogs as an example. Before learning took place, the dogs would reliably salivate (UCR) when given meat powder (UCS), but they gave no response to the ringing of a bell (neutral). Then Pavlov would always ring a bell just before he would present the dogs with some meat powder. Pretty soon, the dogs began to associate the sound of the bell with the impending presence of meat powder. As a result, they would begin to salivate (CR) as soon as they heard the bell (CS), even if it was not immediately followed by the meat powder (UCS). In other words, they learned that the bell was a reliable predictor of meat powder. In this way, Pavlov was able to elicit an involuntary, automatic, reflexive response to a previously neutral stimulus.

Classical conditioning can help us understand how some forms of **addiction**, or drug dependence, work. For example, the repeated use of a drug could cause the body to compensate for it, in an effort to counterbalance the effects of the drug. This causes the user to require more of the substance in order to get the equivalent effect (this is called tolerance). However, the development of tolerance also takes into account other environmental variables (the conditional variables) - this is called the situational specificity of tolerance. For example, alcohol tends to taste a certain way, and when alcohol is consumed in the usual way, the body responds in an effort to counteract the effect. But, if the alcohol is delivered in a novel way (such as in Four Loko), the individual could overdose. This effect has also been observed among those who have become tolerant to otherwise lethal amounts of opiates: they may experience an overdose if they take their typical dose in an

atypical setting. These results have been found in species ranging from rats and mice to humans. In these examples, it's the environmental context (conditional stimuli) that prompts the body to prepare for the drug (the conditional response). But if the conditional stimuli are absent, the body is not able to adequately prepare itself for the drug, and bad things could happen.

Another example of classical conditioning is known as the **appetizereffect**. If there are otherwise neutral stimuli that consistently predict a meal, they could cause people to become hungry, because those stimuli induce involuntary changes in the body, as a preparation for digestion. There's a reason it's called the "dinner bell," after all.

Classical conditioning is also being used in **wildlife conservation efforts**! At Extinction Countdown, John Platt pointed out last month that taste aversion, which is a form of classical conditioning, is being used to keep lions from preying on cattle. This should, in turn, prevent farmers from killing the lions.

INSTRUMENTAL LEARNING: PHENOMENA, PARADIGMS AND THEORETICAL ISSUES; **Introduction To Instrumental Conditioning**

We now shift from the topic of classical conditioning to that of **instrumental** (or as Skinner terms it, **operant**) **conditioning**. This topic will prove a bit more complex in its findings. As you will see, however, many of the ideas that were important in classical conditioning will prove relevant here. Indeed, there has long been a debate over whether classical and operant conditioning ought to be regarded as truly different forms of learning. They appear to differ in the sense that classical conditioning generally involves the presence of **reflex actions**, whereas instrumental conditioning generally involves modifications of **voluntary behavior** contingent on presence of **reinforcers** or **punishers**. Whether that is a sufficient reason to distinguish them is arguable, as we will see later. My sense of the field today is that most theorists would like to see similar theories explain the results in both. Thus, it will not surprise you, for example, that a modified version of the Rescorla-Wagner model has also been proposed for instrumental conditioning.

TWO EARLY VIEWS OF INSTRUMENTAL CONDITIONING

We will look at two quite different claims about the nature of instrumental conditioning. One comes from **Watson**, the author of the 1913 behaviorist manifesto, *Psychology as the behaviorist views it*, and the second comes from **Thorndike**, who can probably safely be credited with conducting the first truly sophisticated and careful observations of complex animal learning. Their accounts differ in ways that prefigured an important debate about what was needed for learning to occur.

First, however, let us distinguish instrumental conditioning from classical conditioning. In instrumental conditioning, an animal makes one of a number of possible responses in the presence of some stimulus complex or context. That response may lead to some outcome. We typically define learning in this circumstance as an alteration in some observed characteristic of the response such as its frequency, latency, or amplitude. We will revisit this definition in more detail later, once we have examined several theories of what gets acquired, and why.

For now, we can talk about instrumental conditioning as the type of learning involved in navigating a maze, choosing the correct one of several doors to run to, or even performing some response that will be successful in avoiding a future shock. In instrumental conditioning, **new** responses may be taught that differ from any reflexive response already in the animal's behavioral repertoire.

BASIC PARADIGMS

We have already introduced two general paradigms involving acquisition and extinction. In acquisition, an outcome is typically paired with making a response in the presence of a stimulus; in extinction, that pairing typically ceases. Within this broad framework (particularly with respect to acquisition), we may distinguish several additional paradigms.

In **appetitive** or **approach learning**, the animal makes a response that results in a desired reward. This is the type of learning involving reinforcement that we have implicitly and explicitly discussed so far. But it is not the only paradigm based on reinforcement. Another that deserves particular note is **omission training**, in which an animal has to suppress or withhold a response in order to get its reward. **Sheffield**, for example, trained dogs to salivate in the presence of a tone associated with food, and then shifted them to omission training. In this latter phase, the dogs had to avoid salivating to the tone for several seconds to get the food. Omission training is initially typically difficult, and displays a relatively slow learning curve. However, there are several studies suggesting that in the long run, it will be as effective as extinction in decreasing the frequency of a response. Omission training is sometimes referred to as negative punishment to indicate that making the response is associated with removal of a reinforcer (which thus acts as a punishment).

Another paradigm based on reinforcement is **escape learning**. In escape learning, the animal learns a response that gets it away from punishment, either by turning off the punisher, or by allowing the animal to leave the area where the punishment was administered. Escape learning is closely associated with another paradigm, **avoidance learning**. In avoidance learning, the punishment is intermittent rather than continuous. If the animal makes the proper response before the punishment comes on, it will succeed in canceling that punishment. In avoidance learning, animals typically start out by escaping the aversive stimulation (making a response during the punishment that stops it), and then come to make the response early enough that they subsequently successfully avoid the aversive stimulation.

Punishment training (or **aversive learning**), of course, involves the administration of an unpleasant, aversive outcome following a response. Thus, punishment training, omission training, and extinction all have in common reducing the level of a given response, whereas appetitive learning, escape learning, and avoidance learning attempt to increase response level. There are some obvious interplays in paradigms here, depending on which response you focus on. Often, aspects of several different paradigms combine: One response may be punished while another is reinforced. We may also distinguish between **signaled** and **unsignaled learning**. A discrete, distinct stimulus is present in signaled learning, but not in unsignaled learning. Thus, for example, in unsignaled avoidance, shocks can occur at regular intervals that could be avoided if the animal responds shortly before the shock's onset. There is no physical stimulus signaling the shock; the animal in this case needs to rely on an internal sense of time. In unsignaled conditions, features such as time or the contextual cues presumably act as stimuli.

Another paradigm, **transfer training** will prove important, especially when we focus on discrimination in a later chapter. In transfer training, we look at the effects of learning one task on another. Transfer might be **nonexistent (zero)**, **positive (facilitation)**: the learning is faster), or **negative (inhibition)**: there is interference). In addition, transfer effects might be **proactive** (in which we look at the effect of an earlier task on the learning or performance of a later task), or **retroactive** (in which we saw how the later task influences performance on the earlier one).

A final paradigm involves **shaping**. Normally, approach learning applies to responses that are not especially frequent to start with, since we want to track an increase in frequency as one of our measures of learning. Thus, we find ourselves in the following situation: We sit in the lab, watching our animal subject, waiting for it to make the desired response so that we can administer the reinforcer.

Such a procedure will obviously be inefficient. In some cases (such as a pig rolling a coin), the wait may be very long indeed! Hence, a technology has developed that involves increasing the probability of having the animal emit that response so that we can then train it further through reinforcement. This technology, called shaping, requires **reinforcing successive approximations to the desired response**.

Shaping works as follows. We start out by identifying a high-frequency component of the response we want, and we reinforce that. So, if we want our rat to press a bar on the left side of an experimental chamber, then a high-frequency component would involve having the rat be in the left half of the chamber. While it is exploring its environment, we reinforce for crossing over to the left.

Then, as it increases its time on the left, we drop the reinforcer. That will cause the behavior to become more variable. We await some response yet closer to what we want to train (such as being near the bar), and when that occurs we reintroduce the reinforcer. And then, of course, we cycle the process through again in order to obtain yet a closer approximation (such as touching the bar). Shaping is a very powerful technique, not only because of its ability to 'coax' low frequency responses out of an animal, but also -- and especially -- because of **its ability to mold a response that is not normally part of the animal's repertoire!** Thus, by combining shaping and chaining, instrumental conditioning allows us to train **totally new responses**, rather than just transfer stimulus control of an old response to a new stimulus.

Operant behavior involves adaptation to the consequences of responding; it is the prototype of adaptive behavior during the life of the individual -- the ontogenetic equivalent of Darwinian natural selection in phylogeny. Techniques for exploring operant behavior exploded with the invention of the Skinner box and the discovery of the orderly and powerful effects of schedules of reinforcement. In the 1950s and 1960s, much research addressed the limits of operant conditioning and in particular the intimate relationship between the processes underlying operant and classical conditioning. In recent decades, two research areas, interval timing and choice, have dominated the field. We have reviewed these topics and, in addition, discussed post-Skinner developments in the economics of operant behavior. We hope, with this chapter, to have aroused the interest of the reader for this fascinating and lively field of behavioral science.

Instrumental Conditioning of Avoidance. Another important model of learning and stress reactivity derived from research with animals was pioneered by B. F. Skinner (1938; Ferster & Skinner, 1957) in landmark works on "contingencies of reinforcement" affecting the behaviors of animals such as rats and pigeons. Skinner observed that animals tend to increase the rate of behaviors that are followed by certain changes in their environment.

He called this phenomenon "reinforcement" that occurs due to the animal's learning that there is a "contingent" relationship between doing that behavior (e.g., pecking or pushing a lever in the cage) and receiving a desired outcome (the reinforce—for example, a pellet of food). Behavior that

might previously have been rare or sporadic can become regular and frequent if the contingency of reinforcement is set up to teach the animal that the behavior seems to produce the reinforcer. This is another form of conditioned learning, which is called instrumental conditioning because the animal learns that a behavior is “instrumental” in increasing the likelihood that a reinforcer will occur.

“Operant conditioning” does not refer to a single therapeutic technique. Instead, the term refers to an important form of learning, or conditioning, in which behavior is primarily controlled by its consequences. The consequences of a particular kind of behavior in one setting can either increase or decrease the probability of such behavior occurring in similar settings in the future. Descriptions of the consequences of behavior, called rules, can have similar effects. A great deal is known concerning how consequences affect behavior, and this knowledge has been put to good use in designing interventions shown to be effective across a wide range of client populations, behavior problems, and settings.

THE MAJOR PHENOMENA OF INSTRUMENTAL CONDITIONING

As Skinner noted, classical and instrumental conditioning are different in important ways: Classical conditioning builds on a response (UR) that’s automatically triggered by a stimulus (US); instrumental conditioning involves behaviors that appear to be voluntary. Classical conditioning involves learning about the relation between two stimuli (US and CS); instrumental conditioning involves learning about the relation between a response and a stimulus (the operant and a reward). Even with these differences, modern theorists have argued that the two forms of conditioning have a lot in common. This makes sense because both involve learning about relationships among simple events (stimuli or responses).

It’s perhaps inevitable, then, that many of the central phenomena of instrumental learning parallel those of classical conditioning. For example, in classical conditioning, learning trials typically involve the presentation of a CS followed by a US. In instrumental conditioning, learning trials typically involve a response by the organism followed by a reward or **reinforcer**. The reinforcement often involves the presentation of something good, such as grain to a hungry pigeon. Alternatively, reinforcement may involve the termination or prevention of something bad, such as the cessation of a loud noise.

In both forms of conditioning, the more such pairings there are, the stronger the learning. And if we discontinue these pairings so that the CS is no longer followed by the US or the response by a reinforcer, the result is extinction.

GENERALIZATION AND DISCRIMINATION

An instrumental response is not directly triggered by an external stimulus, the way a CR or UR is. But that doesn’t mean external stimuli have no role here. In instrumental conditioning, external events serve as discriminative stimuli, signaling for an animal what sorts of behaviors will be rewarded in a given situation. For example, suppose a pigeon is trained to hop onto a platform to get some grain. When a green light is on, hopping on the platform pays off. But when a red light is on, hopping gains no reward. Under these circumstances, the green light becomes a positive discriminative stimulus and the red light a negative one (usually labeled S^+ and S^- , respectively). The pigeon swiftly learns this pattern and so will hop in the presence of the first and not in the presence of the second.

Other examples are easy to find. A child learns that pinching her sister leads to punishment when her parents are on the scene but may have no consequences otherwise. In this situation, the child may learn to behave well in the presence of the S^+ (i.e., when her parents are there) but not in other circumstances. A hypochondriac may learn that loud groans will garner sympathy and support from others but may bring no benefits when others are not around. As a result, he may learn to groan in social settings but not when alone.

Let's be clear, though, about the comparison between these stimuli and the stimuli central to classical conditioning. A CS^+ tells the animal about events in the world: "No matter what you do, the US is coming." The S^+ , on the other hand, tells the animal about the impact of its own behavior: "If you respond now, you'll get rewarded." The CS^- indicates that no matter what the animal does, no US is coming. The S^- , in contrast, tells the animal something about its behavior—namely, that there's no point in responding right now.

Despite these differences, generalization in instrumental conditioning functions much the way it does in classical conditioning, and likewise for discrimination. One illustration of these parallels lies in the generalization gradient. We saw earlier that if an organism is trained with one CS (perhaps a high tone) but then tested with a different one (a low tone), the CR will be diminished. The greater the change in the CS, the greater the drop in the CR's strength. The same pattern emerges in instrumental conditioning. In one experiment, pigeons were trained to peck at a key illuminated with yellow light. Later, they were tested with light of varying wavelengths, and the results showed an orderly generalization gradient (Figure 7.22). As the test light became less similar to the original S^+ , the pigeons were less inclined to peck at it (Guttman & Kalish, 1956).

BEHAVIOR MOTIVATION

Once we've identified a stimulus as a reinforcer, what determines how effective the reinforcer will be? We know that some reinforcers are more powerful than others—and so an animal will respond more strongly for a large reward than for a small one. However, what counts as large or small depends on the context. If a rat is used to getting 60 food pellets for a response, then 16 pellets will seem measly and the animal will respond only weakly for this puny reward. But if a rat is used to getting only 4 pellets for a response, then 16 pellets will seem like a feast and the rat's response will be fast and strong (for the classic demonstration of this point, see Crespi, 1942). Thus, the effectiveness of a reinforcer depends largely on what other rewards are available (or have recently been available); this effect is known as **behavioral contrast**.

Contrast effects are important for their own sake, but they may also help explain another (somewhat controversial) group of findings. In one study, for example, nursery-school children were given an opportunity to draw pictures. The children seemed to enjoy this activity and produced a steady stream of drawings. The experimenters then changed the situation: They introduced an additional reward so that the children now earned an attractive "Good Player" certificate for producing their pictures. Then, later on, the children were again given the opportunity to draw pictures—but this time with no provision for "Good Player" rewards. Remarkably, these children showed considerably less interest in drawing than they had at the start and chose instead to spend their time on other activities (see, for example, Lepper, Greene, & Nisbett, 1973; also Kohn, 1993).

Some theorists say these data illustrate the power of behavioral contrast. At the start of the study, the activity of drawing was presumably maintained by certain reinforcements in the situation—perhaps encouragement from the teachers or comments by other children. Whatever the

reinforcements were, they were strong enough to maintain the behavior; we know this because the children were producing drawings at a steady pace. Later on, though, an additional reinforcement (the “Good Player” certificate) was added and then removed. At that point the children were back to the same rewards they’d been getting at the start, but now these rewards seemed puny in comparison to the greater prize they’d been earning during the time when the “Good Player” award was available. As a consequence, the initial set of rewards was no longer enough to motivate continued drawing.

Other theorists interpret these findings differently. In their view, results like this one suggest that there are actually two different types of reward. One type is merely tacked onto a behavior and is under the experimenter’s control; it’s the sort of reward that’s in play when we give a pigeon a bit of food for pecking a key, or hand a factory worker a paycheck for completing a day’s work. The other type of reward is intrinsic to the behavior and independent of the experimenter’s intentions; these rewards are in play when someone is engaging in an activity just for the pleasure of the activity itself.

In addition, these two forms of reward can interfere with each other. Thus, in the study with the “Good Player” certificates, the children were initially drawing pictures for an intrinsic reward. Drawing, in other words, was a form of play engaged in for its own sake. However, once the external rewards (the certificates) entered the situation, the same activity became a form of work—something you do for a payoff. And once the activity was redefined in this way, then the absence of a payoff meant there was no longer any point in drawing.

Debate continues about which of these interpretations is preferable—the one based on behavioral contrast or the one based on intrinsic motivation. (It also seems plausible that both interpretations may capture aspects of what’s going on here.) Clearly, there’s more to be learned about reinforcement and the nature of motivation. (For further exploration, see Bowles, 2008; Deci, Koestner, & Ryan, 1999a, 1999b; Eisenberger, Pierce, & Cameron, 1999; Henderlong & Lepper, 2002.)

REINFORCEMENT-BASED LEARNING

Rewards and punishers, in contrast, played a pivotal role in the work of Thorndike, who is often credited with founding the field of instrumental conditioning. Thorndike published a monograph in 1898 on his studies with animals such as cats. He set up an experimental apparatus termed a **puzzle box**: a cage in which the animal was placed, and which could be escaped through the performance of a simple response such as pulling on a rope attached to a door. These studies really involved the first careful, detailed observations of what animals in general learned, as opposed to anecdotal stories collected of amazing things animals did that obviously proved their intelligence. (Television still plays into that sort of approach, needless to say!)

Thorndike asked a very simple question: Would escape from a puzzle box exhibit any signs of intelligence? Would it display evidence of **insight**, in which the animal would be able to glance about its environment, understand that the rope was attached to the door, and realize that it needed only to pull on the rope to get out? To answer this question, Thorndike repeatedly placed animals in the same puzzle box, and measured how long it took them to escape. And what he found was that **the time to escape decreased only gradually**. By the end of the experiment, after 20 or so trials, cats would easily leave the box by performing the appropriate response as soon as they were placed in it. But, their history clearly demonstrated that this had to have been a learned response. In particular, Thorndike pointed out that an animal making the correct response on a given trial early

in training would not necessarily choose that same response as its first response on the next trial. So, rather than insight, he concluded that learning involved **trial- and-error**.

Trial-and-error refers to the gradual accumulation of correct responses through a slow process of trying out all sorts of possibilities, and slowly weeding out the ones that do not work. As did Watson, Thorndike thought animals were acquiring associations between stimulus configurations (such as the puzzle box) and certain responses. But unlike Watson, he claimed that an additional factor was important in the acquisition of these associations: They would depend on the outcome of the animal's actions. This involved a principle Thorndike termed the **Law of Effect**. Put briefly, this law claimed that an association between a stimulus and a response would strengthen if the response were followed by a **satisfactory state of affairs**, and would weaken if the response were followed by an **unsatisfactory state of affairs**. Thus, Thorndike deliberately included Bentham's notion of hedonistic value as a principle governing the formation of an association, in contrast to Watson. Rather than being a simple contiguity theory, this was a **reinforcement theory**: In modern terms, learning of an association will occur when there is a reinforcer following a response.

There are, of course, a number of interpretations available to account for how a reinforcer might operate according to the law of effect. One of the first to come to most people's minds is a **teleological** or **purposive** explanation: The animal performs a response because it desires the outcome. But of course, desiring an outcome is a mental state that involves an object not present at the time the animal is performing the response. That type of an explanation would violate the positivist program Watson insisted everyone follow. Thus, as an alternative, we might propose that a positive outcome has an automatic effect of strengthening the association: The animal does not perform the response because it wants the outcome, but rather because the response is strongly associated to the stimulus that is present.

Here is what Thorndike actually said regarding satisfying and unsatisfying states (1913, p. 2):
By a satisfying state of affairs is meant one which the animal does nothing to avoid, often doing things which maintain or renew it. By an annoying state of affairs is meant one which the animal does nothing to preserve, often doing things which put an end to it.

Although he was accused of using hopelessly mentalistic terms in describing learning as depending on satisfactory or unsatisfactory states, his actual definition provided a clear behavioral test for determining when one or the other state was present. In that sense, it ought to have troubled people no more than Watson's use of the term "emotional."

Note too that Thorndike did not include the outcome in the association. As we will see, other theorists have claimed that associations to the outcome may also form, so that we can have S-R associations, R-O associations, and even S-O associations. To anticipate how such a model might differ from Thorndike's, a strong S-R association may exist despite a highly unpleasant or unsatisfying outcome: The presence of an R-O association in that event may serve to inhibit the R excited by presence of an associated stimulus.

Thorndike also proposed another principle, the **Law of Exercise** (sometimes called the **Law of Use**). This was essentially a principle of practice, somewhat similar to Watson's notion of frequency: An association would strengthen if practiced. Both laws were revised in his later work: the Law of Effect was essentially restricted to satisfactory outcomes, and the Law of Use was modified to include outcomes rather than simple exercise.

Thorndike also spoke of the value of different satisfactory states, so that strong satisfiers would do a better job of strengthening an association than weak satisfiers. And as an interesting historical footnote, he actually contradicted one of the major principles of strict contiguity by proposing an early version of belongingness by which some things would be more likely to associate together than others.

In some sense, **Skinner** may be regarded as Thorndike's intellectual successor. Skinner proposed similar ideas involving the **law of reinforcement** and the **law of punishment**. According to Skinner, a **reinforcer** was any event that, following a response, made that response more likely, whereas a punisher was any event that had the opposite effect. To try to identify reinforcers and punishers in a way that wasn't completely circular (and also wasn't mentalistic), Skinner imposed a condition of **transituationality**: A reinforcer or punisher, once identified in terms of its effects on one response, also has to be shown capable of having a similar effect in other situations, on other responses. Otherwise, we find ourselves defining a response as that which, when followed by a reinforcer, increases in frequency. And that type of definition, of course, reciprocally defines responses and reinforcers in terms of one another in an uninteresting, circular fashion.

With this as background, let us look at some of the basic findings in instrumental conditioning.

REINFORCEMENT: BASIC VARIABLES

One of the most critical challenges in applied empirical research is to draw causal inference from observational data. Empirical marketing research, which often involves causal analysis of the impact of marketing strategy, is no exception. A central difficulty is endogeneity of variables entering the causal relationship, arising from either omitted variable bias, simultaneity bias, sample selection bias, or measurement errors. According to recent research, mentions of endogeneity and procedures to address it have risen 5x across the field's top four journals (Rutz and Watson (2019)). Instrumental Variable (IV) methods are among the most frequently used techniques to address such endogeneity issues. Instruments that are correlated with the endogenous variable but are otherwise not associated with the outcome variable can be used to partition the variance of the endogenous variable into endogenous and exogenous components.

The method of instrumental variables is based on using the variation in the exogenous component of the endogenous variable induced by the variation in the instrumental variable to make inference of causal effects. In recent years, use of the IV method has come under criticism in Marketing (e.g. Rossi (2014)) and multiple other disciplines (e.g. Bound et al. (1995) and Young (2017) in Economics; Yogo (2004), Stock and Yogo (2002), and Hausman et al. (2005) in Finance). This is because IVs used in practice are often weakly correlated with the endogenous variables, e.g. the instruments used in practice induce limited variation in the endogenous variables leading to impractically large imprecision of estimates of causal effects.

In the extreme case when the correlation becomes sufficiently weak, this leads to a formal "weak instruments" problem whereby standard asymptotics break down, and the estimated parameters are no longer even consistent and have a non-standard asymptotic distribution (see Stock and Wright (2000) and Staiger and Stock (1994)). The bias becomes worse (Hausman et al. (2005)) when the researcher adds more weak instruments.

The problem can be acute for industrial organization models (e.g., Berry et al. (1995), Arellano and

Bond (1991), Arellano and Bover (1995), Blundell and Bond (1998), Hendel and Nevo (2006)), which involve estimating parameters from highly nonlinear functions and makes even the detection of weak IV's more challenging.

Such models have been widely used in marketing literature and remain the workhorse models for studying many marketing problems (see Goldfarb et al. (2009), Chintagunta and Nair (2011) and many others) Constructing strong and valid instruments is, therefore, an important endeavor for causal inference from observational data. In this paper, we approach the problem of constructing strong instrumental variables from exogenous information in causal models as a (supervised) machine learning problem. We first formulate the choice of construction of instruments in a causal model as a decision problem that is amenable to the learning approach. The key empirical problem which arises for the econometrician that is distinct from the machine learner is that, in the typical applied context, the econometrician does not have the luxury of treating the sample in-hand as the training sample for the decision problem. Instead, the sample in-hand is typically the only information from which instruments must be constructed and causal inference must simultaneously be derived. We extend the standard learning framework to develop an algorithm we term "MLIV Algorithm", which allows training of instruments and causal inference to be simultaneously performed from sample data.

RELATED LITERATURE

As discussed above, the standard existing approach to weak IV concerns is approached through approximation of optimal instruments. Most work on optimal instrument variables in linear models casts the problem as a selection problem among the available exogenous variables (and their transformations e.g., b- splines). Early work on instrument selection goes back to ((Kloek and Mennes 1960) and Amemiya (1966)) where they studied using "selected" principal components of the many available instruments to counter inference issues due to many instruments. Further work by (Kapetanios and Marcellino (2010)) proposed using factor analysis for decomposing the high-dimensional instruments onto a lowdimensional space.

Both principal component analysis and factor analysis are not targeted at approximating the optimal instruments, but rather at coming up with a low dimensional vector that summarizes the high- dimensional instruments, which could potentially yield (Amemiya (1966)) better performance in terms of bias and mean squared error. Recent work on instrument selection assumes strong sparsity of the optimal instruments structure (i.e. a small set of the available IVs are valid and sufficient for first stage).

Work by (Bai and Ng (2009)) demonstrate how boosting can be used for recovering the sparse structure but do not provide any formal proof. (Belloni et al. (2012)) explicitly shows how Lasso can be used for instrument selection among a large set of candidate instruments under the strong sparsity assumption. Further they are also able to prove theoretical consistency and other inference results for their IV estimator.

Their proposed approach does not work as well when sparsity is violated, i.e. most instruments are weak, as it selects all of the weak IVs or drops them all. Unlike the extant literature, our learning approach to instrumental variables still exhibits asymptotic guarantees and does not rely on any sparsity assumption on the optimal instrument structure. Further, our approach allows the researcher to apply a broad arsenal of machine learning methods in constructing the instrumental variables.

REINFORCEMENT SCHEDULES

Remember, the best way to teach a person or animal a behavior is to use positive reinforcement. For example, Skinner used positive reinforcement to teach rats to press a lever in a Skinner box. At first, the rat might randomly hit the lever while exploring the box, and out would come a pellet of food. After eating the pellet, what do you think the hungry rat did next? It hit the lever again, and received another pellet of food. Each time the rat hit the lever, a pellet of food came out. When an organism receives a reinforcer each time it displays a behavior, it is called **continuous reinforcement**. This reinforcement schedule is the quickest way to teach someone a behavior, and it is especially effective in training a new behavior. Let's look back at the dog that was learning to sit earlier in the module. Now, each time he sits, you give him a treat. Timing is important here: you will be most successful if you present the reinforcer immediately after he sits, so that he can make an association between the target behavior (sitting) and the consequence (getting a treat).

Once a behavior is trained, researchers and trainers often turn to another type of reinforcement schedule—partial reinforcement. In **partial reinforcement**, also referred to as intermittent reinforcement, the person or animal does not get reinforced every time they perform the desired behavior. There are several different types of partial reinforcement schedules (Table 1). These schedules are described as either fixed or variable, and as either interval or ratio. Fixed refers to the number of responses between reinforcements, or the amount of time between reinforcements, which is set and unchanging. Variable refers to the number of responses or amount of time between reinforcements, which varies or changes. Interval means the schedule is based on the time between reinforcements, and ratio means the schedule is based on the number of responses between reinforcements.

Reinforcement Schedule	Description	Result
Fixed interval	Reinforcement is delivered at predictable time intervals (e.g., after 5, 10, 15, and 20 minutes).	Moderate response rate with significant pauses after reinforcement
Variable interval	Reinforcement is delivered at unpredictable time intervals (e.g., after 5, 7, 10, and 20 minutes).	Moderate yet steady response rate
Fixed ratio	Reinforcement is delivered after a predictable number of responses	High response rate with pauses after reinforcement

(pain relief) only occurs on a fixed interval, there is no point in exhibiting the behavior when it will not be rewarded.

With a **variable interval reinforcement schedule**, the person or animal gets the reinforcement based on varying amounts of time, which are unpredictable. Say that Manuel is the manager at a fast-food restaurant. Every once in a while someone from the quality control division comes to Manuel's restaurant. If the restaurant is clean and the service is fast, everyone on that shift earns a \$20 bonus. Manuel never knows when the quality control person will show up, so he always tries to keep the

restaurant clean and ensures that his employees provide prompt and courteous service. His productivity regarding prompt service and keeping a clean restaurant are steady because he wants his crew to earn the bonus.

With a **fixed ratio reinforcement schedule**, there are a set number of responses that must occur before the behavior is rewarded. Carla sells glasses at an eyeglass store, and she earns a commission every time she sells a pair of glasses. She always tries to sell people more pairs of glasses, including prescription sunglasses or a backup pair, so she can increase her commission. She does not care if the person really needs the prescription sunglasses, Carla just wants her bonus. The quality of what Carla sells does not matter because her commission is not based on quality; it's only based on the number of pairs sold. This distinction in the quality of performance can help determine which reinforcement method is most appropriate for a particular situation. Fixed ratios are better suited to optimize the quantity of output, whereas a fixed interval, in which the reward is not quantity based, can lead to a higher quality of output.

In a **variable ratio reinforcement schedule**, the number of responses needed for a reward varies. This is the most powerful partial reinforcement schedule. An example of the variable ratio reinforcement schedule is gambling. Imagine that Sarah—generally a smart, thrifty woman—visits Las Vegas for the first time. She is not a gambler, but out of curiosity she puts a quarter into the slot machine, and then another, and another. Nothing happens. Two dollars in quarters later, her curiosity is fading, and she is just about to quit. But then, the machine lights up, bells go off, and Sarah gets 50 quarters back. That's more like it! Sarah gets back to inserting quarters with renewed interest, and a few minutes later she has used up all her gains and is \$10 in the hole. Now might be a sensible time to quit. And yet, she keeps putting money into the slot machine because she never knows when the next reinforcement is coming. She keeps thinking that with the next quarter she could win \$50, or \$100, or even more. Because the reinforcement schedule in most types of gambling has a variable ratio schedule, people keep trying and hoping that the next time they will win big. This is one of the reasons that gambling is so addictive—and so resistant to extinction.

TYPES OF REINFORCEMENT SCHEDULES

The two foundational forms of reinforcement schedules are referred to as continuous reinforcement and partial reinforcement.

CONTINUOUS REINFORCEMENT

In continuous reinforcement, the desired behavior is reinforced every single time it occurs.¹ This schedule is best used during the initial stages of learning to create a strong association between the behavior and response.

Imagine, for example, that you are trying to teach a dog to shake your hand. During the initial stages of learning, you would stick to a continuous reinforcement schedule to teach and establish the behavior. This might involve grabbing the dog's paw, shaking it, saying "shake," and then offering a reward each and every time you perform these steps. Eventually, the dog will start to perform the action on its own.

Continuous reinforcement schedules are most effective when trying to teach a new behavior. It denotes a pattern to which every narrowly-defined response is followed by a narrowly-defined consequence.

PARTIAL REINFORCEMENT

Once the response is firmly established, a continuous reinforcement schedule is usually switched to a partial reinforcement schedule.¹ In partial (or intermittent) reinforcement, the response is reinforced only part of the time. Learned behaviors are acquired more slowly with partial reinforcement, but the response is more resistant to extinction.

Think of the earlier example in which you were training a dog to shake and. While you initially used continuous reinforcement, reinforcing the behavior every time is simply unrealistic. In time, you would switch to a partial schedule to provide additional reinforcement once the behavior has been established or after considerable time has passed.

THERE ARE FOUR SCHEDULES OF PARTIAL REINFORCEMENT: FIXED-RATIO SCHEDULES

Fixed-ratio schedules are those in which a response is reinforced only after a specified number of responses. This schedule produces a high, steady rate of responding with only a brief pause after the delivery of the reinforcer. An example of a fixed-ratio schedule would be delivering a food pellet to a rat after it presses a bar five times.

VARIABLE-RATIO SCHEDULES

Variable-ratio schedules occur when a response is reinforced after an unpredictable number of responses. This schedule creates a high steady rate of responding. Gambling and lottery games are good examples of a reward based on a variable ratio schedule. In a lab setting, this might involve delivering food pellets to a rat after one bar press, again after four bar presses, and then again after two bar presses.

FIXED-INTERVAL SCHEDULES

Fixed-interval schedules are those where the first response is rewarded only after a specified amount of time has elapsed. This schedule causes high amounts of responding near the end of the interval but slower responding immediately after the delivery of the reinforcer. An example of this in a lab setting would be reinforcing a rat with a lab pellet for the first bar press after a 30-second interval has elapsed.

VARIABLE-INTERVAL SCHEDULES

Variable-interval schedules occur when a response is rewarded after an unpredictable amount of time has passed. This schedule produces a slow, steady rate of response.

An example of this would be delivering a food pellet to a rat after the first bar press following a one-minute interval; a second pellet for the first response following a five-minute interval; and a third pellet for the first response following a three-minute interval.

USING THE APPROPRIATE SCHEDULE

Deciding when to reinforce a behavior can depend on a number of factors. In cases where you are specifically trying to teach a new behavior, a continuous schedule is often a good choice. Once the behavior has been learned, switching to a partial schedule is often preferable.

In daily life, partial schedules of reinforcement occur much more frequently than do continuous ones. For example, imagine if you received a reward every time you showed up to work on time. Over time, instead of the reward being a positive reinforcement, the denial of the reward could be regarded as negative reinforcement.

Instead, rewards like these are usually doled out on a much less predictable partial reinforcement schedule. Not only are these much more realistic, but they also tend to produce higher response rates while being less susceptible to extinction.¹

Partial schedules reduce the risk of satiation once a behavior has been established. If a reward is given without end, the subject may stop performing the behavior if the reward is no longer wanted or needed.

For example, imagine that you are trying to teach a dog to sit. If you use food as a reward every time, the dog might stop performing once it is full. In such instances, something like praise or attention may be more effective in reinforcing an already-established behavior.

Behaviours by reinforcement

HIGHLIGHTS

- Developmental differences in acquiring and adapting behaviours by reinforcement were examined.
- Children and adults acquired simple new behaviours by feedback comparably.
- Children's performance was more disrupted than adults' when adapting behaviours.
- P3 ERP changes indicated children consolidated adapted behaviours less than adults.
- FRN ERP changes showed children relied more on feedback than adults in adaptation.

REINFORCEMENT LEARNING IN DEVELOPMENT

The ability to learn and modify behaviours based on the positive and negative outcomes of our actions is an important skill used throughout the lifespan. This skill, known as reinforcement learning (Holroyd and Coles, 2002, Thorndike and Bruce, 1911), may be particularly valuable in the first two decades of life, affording the naïve developing child an effective method of identifying advantageous behaviours and discerning when and how learned actions should be adapted for changing contexts. Indeed, impaired reinforcement learning has been implicated in the pathology of several neurodevelopmental disorders, including Tourette syndrome and ADHD (Marsh et al., 2004, Sagvolden et al., 2005), although the precise deficits in these conditions are unclear. A thorough understanding of the typical development of reinforcement learning may help clarify these deficits, but few studies have examined this aspect of cognitive development.

DIFFERENCES IN REINFORCEMENT LEARNING ACROSS TYPICAL DEVELOPMENT

Previous studies have consistently reported performance differences between children and adults in reinforcement learning. Younger children are less accurate when learning associations between stimuli and responses (S–R associations) by positive and negative feedback than older children and adults (Baldwin et al., 2012, Crone et al., 2004). Children learn at a slower rate than adults (Crone et al., 2004) and show particular difficulties when reinforcements are inconsistent. Specifically, performance differences between children and adults increase when feedback is probabilistic and does not correctly reinforce performance 100% of the time (Eppinger et al., 2009, Hämmerer et al., 2010).

Neural processes underlying these developmental differences have been examined using EEG, particularly the feedback-related negativity (FRN) event-related potential (ERP). The FRN is a negative deflection in the waveform at ~250 ms following feedback (Miltner et al., 1997). FRN

amplitude is larger following negative than positive feedback, and in some studies positive feedback elicits a positive-going deflection in the FRN time-range, the feedback-positivity (FP) (Holroyd et al., 2008). Evidence suggests the FRN/FP is generated by prefrontal cortical regions associated with performance monitoring, and reflects the processing of dopaminergic reinforcement learning signals triggered by feedback indicating behaviour was better or worse than expected (Bellebaum and Daum, 2008, Luque et al., 2012, Oliveira et al., 2007). FRN/FP amplitudes decrease during a reinforcement learning episode, likely reflecting decreased reliance on external feedback with increasing knowledge of the to-be-learned behaviours (Eppinger et al., 2009, Holroyd and Coles, 2002).

Children show less enhancement of the FRN for negative compared with positive feedback, suggesting children are poorer at differentiating between types of feedback than adults (Hämmerer et al., 2010). The authors suggest this may explain why learning is more disrupted in children when feedback is probabilistic and difficult to discriminate. FP amplitude decreases less across learning in children than adults and ERP correlates of monitoring errors in performance differentiate less between correct and error responses in children than in adults (Eppinger et al., 2009). Based on these differences between children and adults, Eppinger et al. (2009) suggested that children have weaker internal representations of whether a response is correct or erroneous, resulting in a greater reliance on feedback processing to achieve successful performance. In a recent review of this literature, Hämmerer and Eppinger (2012) proposed that increasing reinforcement learning ability reflects developing efficiency in processing feedback, using reinforcements effectively to guide goal-directed behaviour, and building internal representations of correct behaviours, as prefrontal cortical regions mature.

However, due to the scarcity of research in this area further studies are needed (Hämmerer and Eppinger, 2012). Furthermore, previous research has not addressed an important aspect of reinforcement learning, that is, the ability to alter and re-learn behaviours following changes in reinforcements. A robust finding in the executive function literature is that children are poorer than adults in switching to new behaviours when prompted by cues (Koolschijn et al., 2011). This suggests that children will have particular difficulty with learning when reinforcement contingencies change. Furthermore, the learning tasks used previously have been complicated, with multiple feedback conditions presented for different S-R associations within task blocks, creating considerable working memory demands (Crone et al., 2004, Eppinger et al., 2009, Hämmerer et al., 2010). Crone et al. (2004) and Eppinger et al. (2009) controlled for this problem by allocating children extra response time, but nevertheless the difficulty of these tasks may have enhanced developmental differences.

THE CURRENT STUDY

The study aims were firstly to further investigate neurocognitive differences in the typical development of reinforcement learning using a simple task designed to reduce the influence of age-related performance differences on ERP correlates of learning. The intention was to ensure all participants could perform the task adequately regardless of age so that any ERP differences are more likely to reflect differences in the recruitment of neural networks underlying task performance, rather than floor or ceiling effects in one age group. Secondly, to assess developmental differences in the ability to change and re-learn acquired behaviour in response to altered reinforcement contingencies we compared children aged 9–11 years with adults aged 21 years and over. Our aim was to establish whether children differ from adults in behavioural and

brain correlates of learning before they undergo the significant maturational changes that take place during adolescence. During EEG recording typically developing children and adults performed a task in which they learned four S–R associations by positive and negative feedback and then reversed the associations after an unexpected change in reinforcement contingencies. Changes in performance and feedback processing, indexed by the FRN, related to learning and reversal were examined across the task and between age groups. Additionally, changes in the P3 ERP, a positive deflection at ~300 ms post-stimulus, were examined. P3 amplitude increases with progressing reinforcement learning in adults, which is thought to reflect increasing consolidation of to-be-learned behaviours). The P3 may further elucidate neurocognitive differences between children and adults, for example, children may show weaker consolidation of associations than adults reflected by smaller P3 amplitude increases with learning. We predicted children would show smaller learning-related changes in performance and ERP amplitudes during the initial acquisition of S–R mappings than adults, reflecting poorer learning ability at this age. Further, we expected children to show greater disruptions to performance and greater reliance on feedback, indexed by smaller FRN amplitude changes, when the reversal occurred.

• **METHOD**

Participants

Fourteen 9–11 year olds (12 male, mean age: 10.2 years) and 15 adults (5 male, mean age: 25.5 years) were recruited from local primary schools and the University of Nottingham, UK to take part in this study. Participants were typically developing with no known neurological or psychiatric problems which may have affected brain function, right-handed (determined by the dominant hand for writing) and had normal or corrected-to-normal vision. Participants were tested in accordance with procedures approved by the University of Nottingham Medical School Ethics Committee and/or the East Midlands NHS Research Ethics Committee. Monetary reimbursement (£10) was provided for taking part.

REINFORCEMENT LEARNING TASK AND TESTING PROCEDURE

The reinforcement learning task required participants to learn by trial-and-error, using deterministic (always valid) performance feedback, to associate a set of two visual stimuli with a right hand button-press and another two stimuli with a left hand button-press. Three blocks of trials were presented for participants to learn the stimulus–response (S–R) associations. The S–R mappings reversed unexpectedly in a fourth block, requiring participants to re-learn the correct response for each stimulus. In a fifth block, the mappings remained reversed. Every block contained 48 trials, with each stimulus presented 12 times in random order in each block. Particular S–R associations were counterbalanced across participants. Stimuli were four cartoon characters from a popular animated film, presented in colour and surrounded by a rectangular 3 mm thick green frame. Stimuli measured 60 mm × 57 mm including the frame. Circular yellow happy-face images and blue sad-face images (both 60 mm in diameter) were used as positive and negative feedback. The words 'Too slow!' (10 mm × 90 mm) were displayed in green for late responses.

ACQUISITION OF SIMPLE NEW BEHAVIOURS BY REINFORCEMENT

Children and adults showed equivalent increases in accuracy and P3 amplitude and decreases in FRN amplitude as they learned the S–R associations. Therefore, in contrast to previous research children in this study acquired and consolidated new behaviours and gradually decreased their use of external feedback at the same rate as adults. Accuracy significantly correlated with FRN amplitude during the first task block in children, indicating that feedback processing was related to the correct production of S–R associations in children in this study. This extends previous

research by indicating that feedback processing and guidance of goal-directed behaviour by reinforcement information is not deficient in children compared with adults, as has previously been proposed.

Our findings indicate that when reinforcement learning is non-probabilistic the neural mechanisms underlying this basic form of learning work as efficiently in children as in adults. Problems with acquiring new behaviours may only appear in children when reinforcement learning becomes more complicated, for instance when reinforcements are unclear, for example probabilistic, and demands on other maturing cognitive functions such as working memory or executive function are high. As such, our findings highlight the importance of ensuring task difficulty is appropriate for children in developmental investigations of reinforcement learning.

4.2. DEVELOPMENTAL DIFFERENCES IN ALTERING LEARNED BEHAVIOURS BY REINFORCEMENT

Performance was significantly more impaired in children than adults when reinforcements changed and the reversal of S–R associations was required in block 4 of the task. Nevertheless, following the reversal children improved their performance at the same rate as adults (task block 5). These findings suggest that children have specific performance difficulties when unexpected changes in reinforcements occur, but are eventually able to re-acquire simple behaviours in a similar manner to adults. Analysis of the P3 and FRN revealed further developmental differences in neurocognitive processes underlying performance.

The magnitude of P3 amplitude changes during learning can be considered to index the strength of internal representation of correct S–R associations in working memory (Barceló et al., 2000, Rose et al., 2001). P3 amplitude changes were significantly greater in adults than children, decreasing more during reversal of associations and increasing more with re-acquisition of reversed mappings, indicating that internal representations of the S–R associations underwent less adaptation and re-consolidation in children than adults. In contrast, FRN amplitude changes were greatest in children, decreasing more with re-learning of the associations in block 5 than in adults. Indeed, FRN amplitude showed little variation after the first task block in adults while a prominent increase with reversal and decrease with re-acquisition was observed in children, indicating that feedback processing varied more with reversal and re-learning in children than adults. Previous authors have emphasised that difficulties with feedback processing, resulting from immature performance monitoring functions of the developing prefrontal cortex, underlie children's poorer reinforcement learning performance (Hämmerer and Eppinger, 2012, Hämmerer et al., 2010). It has been suggested that children are less successful than adults in integrating feedback information with motor action plans, or that children use feedback in a less goal-directed manner than adults (Hämmerer and Eppinger, 2012, Hämmerer et al., 2010). In contrast to the latter proposal, our findings suggest that children do use feedback to drive goal-directed learning behaviour. Changes in FRN amplitude were associated with changes in performance accuracy in children when most re-learning was occurring (block 4). Furthermore, FRN changes were largest in children, indicating children were using feedback more than adults to guide behaviour. However, as children performed more poorly than adults, children may have had greater difficulty in integrating feedback information to consolidate S–R associations and so produce the correct behaviours, consistent with other work using a probabilistic learning task (Van Duijvenvoorde et al., 2013).

Errors were not sufficiently numerous to allow analysis of the ERN in this study. However, the profile of P3 and FRN effects here are similar to the ERN and FP findings reported by Eppinger et

al.(2009), and support the proposal put forward by those authors that children build weaker internal representations of to-be-learned behaviours and engage in greater processing of external feedback than adults when alterations in reinforcement learning are required. This may be due to interference arising from the extra cognitive processing demands of reversing the S–R associations, such as the requirement to suppress the previously correct behaviours and produce new responses that conflict with the original S–R associations. A wealth of evidence demonstrates that such executive functions are poorer in children than adults (Johnstone et al., 2005, Ladouceur et al., 2007, Rueda et al., 2004). Therefore, it may be that these additional processing requirements reduce children's cognitive capacity for learning, decreasing the efficiency of the processes of consolidating the reversed S–R associations and integrating new feedback information with behaviour plans. Children may exercise greater feedback processing to compensate for these difficulties. Alternatively, the enhanced FRN in children may reflect a greater affective or motivational response to correct responses during the more challenging phases of the task. Amplitude of the FRN to negative feedback has been related to individual differences in punishment sensitivity in adolescence and adults (Santesso et al., 2011) and may reflect evaluation of good versus bad outcomes based on motivational as well as cognitive goals (Hajcak et al., 2006). It is possible therefore that the children in the present study invoked this evaluative process more strongly than adults having encountered greater difficulty during the reversal phase of the task. However, the present task was not designed with this question in mind and further research is needed to investigate the role of the FRN in children in this age range.

Another possible explanation for our findings is that children learn in a different manner from adults. Research in adults has shown that providing information about reward likelihood enhances the reinforcement learning process. For example, Li et al. (2011) and Walsh and Anderson (2011) compared adults' performance on a probabilistic S–R learning task when no information about reinforcement probabilities was given and adults were required to learn the S–R associations solely by feedback, with a separate condition in which participants were instructed as to the probability that each S–R pair would be followed by valid feedback, for example that one S–R association would be correctly reinforced on 30% of trials. Adults' performance increased gradually in the no-instruction learning condition, but began and remained at asymptote in the instruction condition. The enhancing effect of instruction on learning is suggested to reflect the top-down influence of rules for learning represented in prefrontal regions on striatal reinforcement learning mechanisms (Li et al., 2011).

In the current study, a rule for how the S–R associations should be re-learned would have been acquired easily after only a few trials in block 4 based on knowledge of what the original S–R mappings were and identifying that the mappings simply had to be reversed. If implemented, this rule would facilitate faster re-learning of the associations. Adults verbally reported that they realised the S–R combinations in block 4 were simply the opposite of those in blocks 1–3. Adults' rapid increase in consolidation of the new S–R associations, improvement in performance and minimal variation of the FRN suggests that they used this inferred rule to guide re-learning rather than relied on external feedback. Children's slower consolidation of reversed S–R associations, more disrupted performance, and greater feedback processing suggests that they were relying on external reinforcement information rather than the internally derived rule for re-learning that adults appeared to employ. Therefore, a possible explanation for the developmental difference in performance and neurocognitive processing in the reversal phase is that unlike adults, children do not infer and use rules for learning, and instead rely on slower feedback-based learning. It is unclear whether this reflects an inability of children to infer learning rules and use them to drive performance due to

under-developed prefrontal regions, or a strategic preference for experience-based learning in children. Future studies comparing instruction-based and experience-based learning in children and adults would be useful in clarifying this issue.

One final observation to discuss is the prolonged negativity following the FRN observed in the feedback-locked waveforms in all learning blocks in children but not in adults. A detailed analysis of this component was beyond the scope of this article, but would be worthy of future research. It is likely that this second negative peak in the children reflects a second oscillation of the same ongoing physiological process (feedback-processing), and may occur due to additional or more effortful processing of the feedback information in children to compensate for their greater difficulty in learning the S-R associations. Alternatively, this negativity might index different learning strategies used in children compared with adults. A recent study comparing feedback-locked potentials between groups of adults using different learning strategies to acquire new behaviours reported strategy-related differences in the morphology of positive feedback components.

BEHAVIOUR MODIFICATION AND ITS APPLICATIONS OF REINFORCEMENT:

- **Agent:** It is an assumed entity which performs actions in an environment to gain some reward.
- **Environment (e):** A scenario that an agent has to face.
- **Reward (R):** An immediate return given to an agent when he or she performs specific action or task.
- **State (s):** State refers to the current situation returned by the environment.
- **Policy (π):** It is a strategy which applies by the agent to decide the next action based on the current state.
- **Value (V):** It is expected long-term return with discount, as compared to the short-term reward.
- **Value Function:** It specifies the value of a state that is the total amount of reward. It is an agent which should be expected beginning from that state.
- **Model of the environment:** This mimics the behavior of the environment. It helps you to make inferences to be made and also determine how the environment will behave.
- **Model based methods:** It is a method for solving reinforcement learning problems which use model-based methods.
- **Q value or action value (Q):** Q value is quite similar to value. The only difference between the two is that it takes an additional parameter as a current action.

REINFORCEMENT LEARNING WORKS

Let's see some simple example which helps you to illustrate the reinforcement learning mechanism.

Consider the scenario of teaching new tricks to your cat

- As cat doesn't understand English or any other human language, we can't tell her directly what to do. Instead, we follow a different strategy.
- We emulate a situation, and the cat tries to respond in many different ways. If the cat's response is the desired way, we will give her fish.
- Now whenever the cat is exposed to the same situation, the cat executes a similar action with even more enthusiastically in expectation of getting more reward (food).
- That's like learning that cat gets from "what to do" from positive experiences.
- At the same time, the cat also learns what not to do when faced with negative experiences.

MODEL-BASED:

In this Reinforcement Learning method, you need to create a virtual model for each environment. The agent learns to perform in that specific environment.

CHARACTERISTICS OF REINFORCEMENT LEARNING

Here are important characteristics of reinforcement learning

- There is no supervisor, only a real number or reward signal
- Sequential decision making
- Time plays a crucial role in Reinforcement problems
- Feedback is always delayed, not instantaneous
- Agent's actions determine the subsequent data it receives

TYPES OF REINFORCEMENT LEARNING

Two kinds of reinforcement learning methods are:

POSITIVE:

It is defined as an event, that occurs because of specific behavior. It increases the strength and the frequency of the behavior and impacts positively on the action taken by the agent.

This type of Reinforcement helps you to maximize performance and sustain change for a more extended period. However, too much Reinforcement may lead to over-optimization of state, which can affect the results.

NEGATIVE:

Negative Reinforcement is defined as strengthening of behavior that occurs because of a negative condition which should have stopped or avoided. It helps you to define the minimum stand of performance. However, the drawback of this method is that it provides enough to meet up the minimum behavior.

LEARNING MODELS OF REINFORCEMENT

There are two important learning models in reinforcement learning: Markov Decision Process and Q learning Markov Decision Process

The following parameters are used to get a solution:

- Set of actions- A
- Set of states -S
- Reward- R
- Policy- π
- Value- V

The mathematical approach for mapping a solution in reinforcement Learning is recon as a Markov Decision Process or (MDP).

Reinforcement Learning vs. Supervised Learning

Parameters	Reinforcement Learning
Decision style	reinforcement learning helps you to take your decisions sequentially.
Works on	Works on interacting with the environment.

Dependency on decision	In RL method learning decision is dependent. Therefore, you should give labels to all the dependent decisions.

Best suited Supports and work better in AI, where human interaction is prevalent. Example Chess game

APPLICATIONS OF REINFORCEMENT LEARNING

Here are applications of Reinforcement Learning:

- Robotics for industrial automation.
- Business strategy planning
- Machine learning and data processing
- It helps you to create training systems that provide custom instruction students.
- and materials according to the requirement of
- Aircraft control and robot motion control

WHY USE REINFORCEMENT LEARNING?

Here are prime reasons for using Reinforcement Learning:

- It helps you to find which situation needs an action
- Helps you to discover which action yields the highest reward over the longer period.
- Reinforcement Learning also provides the learning agent with a reward function.
- It also allows it to figure out the best method for obtaining larger rewards.

WHEN NOT TO USE REINFORCEMENT LEARNING?

You can't apply reinforcement learning model in all the situation. Here are some conditions when you should not use reinforcement learning model.

- When you have enough data to solve the problem with a supervised learning method
- You need to remember that Reinforcement Learning is computing-heavy and time-consuming, in particular when the action space is large.

CHALLENGES OF REINFORCEMENT LEARNING

Here are the major challenges you will face while doing Reinforcement learning:

- Feature/reward design which should be very involved
- Parameters may affect the speed of learning.
- Realistic environments can have partial observability.
- Too much Reinforcement may lead to an overload of states which can diminish the results.
- Realistic environments can be non-stationary.

SUMMARY:

- Reinforcement Learning is a Machine Learning method
- Helps you to discover which action yields the highest reward over the longer period.
- Three methods for reinforcement learning are 1) Value-based 2) Policy-based and Model based

learning.

- Agent, State, Reward, Environment, Value function Model of the environment, Model based methods, are some important terms using in RL learning method
- The example of reinforcement learning is your cat is an agent that is exposed to the environment.
- The biggest characteristic of this method is that there is no supervisor, only a real number or reward signal
- Two types of reinforcement learning are 1) Positive 2) Negative
- Two widely used learning model are 1) Markov Decision Process 2) Q learning
- Reinforcement Learning method works on interacting with the environment, whereas the supervised learning method works on given sample data or example.
- Application or reinforcement learning methods are: Robotics for industrial automation and business strategy planning
- You should not use this method when you have enough data to solve the problem
- The biggest challenge of this method is that parameters may affect the speed of learning

COGNITIVE APPROACHES IN LEARNING: LATENT LEARNING, OBSERVATIONAL LEARNING

Cognitive approaches to learning are concerned with how information is processed by learners. Cognitive theories view students as active in “an internal learning process that involves memory, thinking, reflection, abstraction, motivation, and meta-cognition” (Ally, 2008). Students organize old knowledge, scripts, and schema, find relationships, and link new information to old (Cognitive Theories of Learning, n.d.). Ertmer and Newby (1993) note that “learning is a change in the state of knowledge, and is a mental activity where an active learner internally codes and structures knowledge” (p. 58). They believe that “the real focus of the cognitive approach is on changing the learner by encouraging him/her to use appropriate learning strategies” (Ertmer & Newby, 1993, p. 59).

Cognition refers to mental activity including thinking, remembering, learning and using language. When we apply a cognitive approach to learning and teaching, we focus on the understanding of information and concepts. If we are able to understand the connections between concepts, break down information and rebuild with logical connections, then our retention of material and understanding will increase.

When we are aware of these mental actions, monitor them and control our learning processes it is called metacognition

CLASSIFYING COGNITIVIST THEORIES

Behaviorist, cognitivist, and constructivist ideas and principles overlap in many areas (Ally, 2008). Therefore, classifying theories is challenging; some theories fit in more than one classification and different sources classify the theories in different ways. For example, in some sources Jerome Bruner’s Discovery Learning Theory is classified as cognitive (Using the Web for Learning: Background, n.d.) and not developmental (Cognitive Theories of Learning, n.d.). In other sources, Bruner is deemed developmental (Driscoll, 2005/2007). In still other sources, Bruner is considered constructivist (Learning Theories Knowledgebase, 2009). In addition, Albert Bandura is often classified as a behaviorist; however, Bandura, himself, claimed that he was never a behaviorist (From Behaviorism to Social Cognition??, n.d.).

CLASSIFICATIONS

Course materials in ETEC 512 classified theorists as follows:

COGNITIVE

- Social Cognitive Theory (Social Learning Theory) by Bandura
- Bandura focused on observational learning and self- efficacy (Zeldin, Britner, & Pajares, 2008).
- Information Processing Theories by various theorists
- The computer was seen as a metaphor for the mind(Schunk 2004/2007a).
- Information was input and the mind processed the information, creating output (Information Processing,n.d.).
- Assimilation Theory (Meaningful Learning) by Ausubel
- Ausubel focused on reception learning; he noted that the learner was active and thus he differentiated betweenrote and meaningful learning (Novak, 1998/2007).
- Ausubel stressed the importance of the advance organizer.

DEVELOPMENTAL

- Genetic Epistemology by Piaget
- Piaget believed that experience with the environmentaffected knowledge acquisition.
- His four stages of development detail how humansdevelop cognitively.
- Sociocultural Theory by Vygotsky
- Vygotsky's Zone of Proximal Development (ZPD) details the difference between what a learner can do independently and what the learner can do with help; independent learning may not take place, but scaffolded learning can.
- Discovery Learning by Bruner
- Bruner describes representational stages, andemphasizes exploring the environment.

CONCEPT MAP OF COGNITIVE AND DEVELOPMENTAL THEORIES

Using the computer metaphor of input and output, this concept map of the theories organizes the main principles. The component referring to an individual is shown on the left hand side of each theory diagram, while the social contribution is shown on the right hand side.

COMPONENTS OF COGNITIVE LEARNING APPROACHES

Ertmer and Newby (1993) describe the commonalities that exist between the many different cognitive theories:

HOW LEARNING OCCURS

- mental activity: internal coding and structuring by the learner
- change occurs in state of knowledge

FACTORS INFLUENCING LEARNING

- environmental conditions
- practice with corrective feedback
- processes of mental planning, goal-setting, and organizationalstrategies
- way learners attend to, code, transform, rehearse, store andretrieve information
- learners' thoughts, beliefs, attitudes, and values

ROLE OF MEMORY

- information is stored in an organized, meaningful manner; need to relate new information to prior knowledge

TRANSFER

- function of how information is stored in memory
- occurs when learner understands how to apply knowledge in different contexts

TYPES OF LEARNING BEST EXPLAINED

- complex forms of learning (reasoning, problem-solving, information-processing)
- communicate/transfer knowledge in an efficient effective manner: simplification, standardization (knowledge analyzed, decomposed, simplified into basic building blocks; irrelevant information eliminated)

INSTRUCTIONAL DESIGN

- feedback to help create accurate mental representations and connections
- learner and task analysis: determine learner's predisposition to learning; look at existing mental structures to design instruction so it can be readily assimilated

MAJOR TASKS OF TEACHER/DESIGNER

- understand that learners have different backgrounds/experiences which can impact learning outcomes
- determine the most effective manner in which to organize and structure new information to work with these backgrounds/experiences
- arrange practice with feedback so that the new information is effectively and efficiently assimilated and /or accommodated with the learner's cognitive structure

RELEVANCE OF COGNITIVIST APPROACHES

Cognitivist approaches to learning are relevant to today's educators. Pratt (n.d.) cautions "while I do not argue with the basic tenets of constructivism, I do resist the rush to adopt any single, dominant view of learning or teaching" (p. 1). Hung (2001) advises that "instead of regarding the different learning theories as discordant, we rather adopt the instructional approaches derived from each of the learning theories and situate them in the appropriate instructional context based on the learning objectives" (Conclusion). Ertmer and Newby (1993) suggest that the best theoretical approach depends on the learner's experience with the knowledge, and the level of cognitive processing required by the task; behaviourist approaches can allow the learner to master content (know what), cognitivist approaches are better for problem-solving with facts and rules applied in unfamiliar situations (know how), and constructivist approaches are better for ill-defined problems (reflection-in-action).

DISTRIBUTED LEARNING

In a Distributed Learning (DL) program, parents are very involved in helping their children learn. The parents are not trained teachers, and have difficulty with using pedagogy to inform their practices at home. The parents find value in the efficient delivery method inherent in cognitivist approaches. DL students in programs that have social/interactive components (face-to-face classes or online discussions) can use the knowledge and skills learned from a cognitivist approach, from content to critical thinking and problem-solving strategies, to engage in knowledge construction. Pratt (n.d.) states "that teachers are 'pedagogical engineers' with the responsibility to plan a lesson(s) with the most relevant instructional approaches and technologies at his or her disposal" (Conclusion). In a DL program, it is the teacher's responsibility to understand the needs of parents and learners; this makes it even more important that teachers understand and choose the most relevant approach.

LATENT LEARNING

Strict behaviorists like Watson and Skinner focused exclusively on studying behavior rather than cognition (such as thoughts and expectations). In fact, Skinner was such a staunch believer that cognition didn't matter that his ideas were considered **radical behaviorism**. Skinner considered the mind a "black box"—something completely unknowable—and, therefore, something not to be studied. However, another behaviorist, Edward C. Tolman, had a different opinion. Tolman's experiments with rats demonstrated that organisms can learn even if they do not receive immediate reinforcement (Tolman & Honzik, 1930; Tolman, Ritchie, & Kalish, 1946). This finding was in conflict with the prevailing idea at the time that reinforcement must be immediate in order for learning to occur, thus suggesting a cognitive aspect to learning.

Latent learning is a form of learning that is not immediately expressed in an overt response. It occurs without any obvious reinforcement of the behavior or associations that are learned.

Latent learning is not readily apparent to the researcher because it is not shown behaviorally until there is sufficient motivation. This type of learning broke the constraints of behaviorism, which stated that processes must be directly observable and that learning was the direct consequence of conditioning to stimuli.

In the experiments, Tolman placed hungry rats in a maze with no reward for finding their way through it. He also studied a comparison group that was rewarded with food at the end of the maze. As the unreinforced rats explored the maze, they developed a **cognitive map**: a mental picture of the layout of the maze (Figure 1).

After 10 sessions in the maze without reinforcement, food was placed in a goal box at the end of the maze. As soon as the rats became aware of the food, they were able to find their way through the maze quickly, just as quickly as the comparison group, which had been rewarded with food all along. This is known as latent learning: learning that occurs but is not observable in behavior until there is a reason to demonstrate it.

Latent learning also occurs in humans. Children may learn by watching the actions of their parents but only demonstrate it at a later date, when the learned material is needed. For example, suppose that Ravi's dad drives him to school every day. In this way, Ravi learns the route from his house to his school, but he's never driven there himself, so he has not had a chance to demonstrate that he's learned the way. One morning Ravi's dad has to leave early for a meeting, so he can't drive Ravi to school. Instead, Ravi follows the same route on his bike that his dad would have taken in the car. This demonstrates latent learning. Ravi had learned the route to school, but had no need to demonstrate this knowledge earlier.

EVERYDAY CONNECTION: THIS PLACE IS LIKE A MAZE

Have you ever gotten lost in a building and couldn't find your way back out? While that can be frustrating, you're not alone. At one time or another we've all gotten lost in places like a museum, hospital, or university library. Whenever we go someplace new, we build a mental representation—or cognitive map—of the location, as Tolman's rats built a cognitive map of their maze. However, some buildings are confusing because they include many areas that look alike or have short lines of sight. Because of this, it's often difficult to predict what's around a corner or decide whether to turn left or right to get out of a building.

Psychologist Laura Carlson (2010) suggests that what we place in our cognitive map can impact our success in navigating through the environment. She suggests that paying attention to specific features upon entering a building, such as a picture on the wall, a fountain, a statue, or an escalator, adds information to our cognitive map that can be used later to help find our way out of the building.

OBSERVATIONAL LEARNING

Observational learning, method of learning that consists of observing and modeling another individual's behavior, attitudes, or emotional expressions. Although it is commonly believed that the observer will copy the model, American psychologist Albert Bandura stressed that individuals may simply learn from the behavior rather than imitate it. Observational learning is a major component of Bandura's social learning theory. He also emphasized that four conditions were necessary in any form of observing and modeling behavior: attention, retention, reproduction, and motivation.

CONDITIONS FOR OBSERVATIONAL LEARNING ATTENTION

If an organism is going to learn anything from a model, he or she must be paying attention to it and the behavior it exhibits. Many conditions can affect the observer's attention. For instance, if the observer is sleepy, ill, or distracted, he or she will be less likely to learn the modeled behavior and imitate it at a later date. In addition, the characteristics of the model have an influence on the observer's attention. Bandura and others have shown that humans pay more attention to models that are attractive, similar to them, or prestigious and are rewarded for their behaviors. This explains the appeal that athletes have on the behavior of young children and that successful adults have on college students. Unfortunately, this aspect of modeling can also be used in detrimental ways. For example, if young children witness gang members gaining status or money, they may imitate those behaviors in an effort to gain similar rewards.

RETENTION

The second requirement of observational learning is being able to remember the behavior that was witnessed. If the human or animal does not remember the behavior, there is a less than probable chance that they will imitate it.

REPRODUCTION

This requisite of behavior concerns the physical and mental ability of the individual to copy the behavior he or she observed. For instance, a young child may observe a college basketball player dunk a ball. Later, when the child has a basketball, he or she may attempt to dunk a ball just like the college player. However, the young child is not nearly as physically developed as the older college player and, no matter how many times he or she tries, will not be able to reach the basket to dunk the ball.

An older child or an adult might be able to dunk the ball but likely only after quite a bit of practice. Similarly, a young colt observes another horse in the herd jump over the creek while running in the pasture. After observing the model's jumping behavior, the colt attempts to do the same only to land in the middle of the creek. He simply was not big enough or did not have long enough legs to clear the water. He could, however, after physical growth and some practice, eventually be able to replicate the other horse's jump.

MOTIVATION

Perhaps the most important aspect of observational learning involves motivation. If the human or animal does not have a reason for imitating the behavior, then no amount of attention, retention, or reproduction will overcome the lack of motivation. Bandura identified several motivating factors for imitation. These include knowing that the model was previously reinforced for the behavior, being offered an incentive to perform, or observing the model receiving reinforcement for the behavior. These factors can also be negative motivations. For instance, if the observer knew that the model was punished for the behavior, was threatened for exhibiting the behavior, or observed the model being punished for the behavior, then the probability of mimicking the behavior is less.

APPLICATIONS OF OBSERVATIONAL LEARNING

Modeling has been used successfully in many therapeutic conditions. Many therapists have used forms of modeling to assist their patients to overcome phobias. For example, adults with claustrophobia may observe a model in a video as they move closer and closer to an enclosed area before entering it. Once the model reaches the enclosed area, for instance a closet, he or she will open the door, enter it, and then close the door. The observer will be taught relaxation techniques and be told to practice them anytime he or she becomes anxious while watching the film. The end result is to continue observing the model until the person can enter the closet himself or herself. Bandura's findings in the Bobo doll experiments have greatly influenced children's television programming. Bandura filmed his students physically attacking the Bobo doll, an inflatable doll with a rounded bottom that pops back up when knocked down. A student was placed in the room with the Bobo doll. The student punched the doll, yelled "sockeroo" at it, kicked it, hit it with hammers, and sat on it. Bandura then showed this film to young children. Their behavior was taped when in the room with the doll. The children imitated the behaviors of the student and at times even became more aggressive toward the doll than what they had observed. Another group of young children observed a student being nice to the doll. Ironically, this group of children did not imitate the positive interaction of the model. Bandura conducted a large number of varied scenarios of this study and found similar events even when the doll was a live clown. These findings have prompted many parents to monitor the television shows their children watch and the friends or peers with which they associate. Unfortunately, the parental saying "Do as I say, not as I do" does not hold true for children. Children are more likely to imitate the behaviors versus the instructions of their parents. One of the most famous instances of observational learning in animals involves the blue jay, a small European bird. During the 1920s and through the 1940s, many people reported that the cream from the top of the milk being delivered to their homes was being stolen. The cream-stealing incidents spread all over Great Britain. After much speculation about the missing cream, it was discovered that the blue tit was the culprit. Specifically, one bird had learned to peck through the foil top of the milk container and suck the cream out of the bottle. It did not take long before other blue tit birds imitated the behavior and spread it through the country.

VERBAL LEARNING

Verbal learning is the process of acquiring, retaining and recalling of verbal material. At its most elementary level, it can be defined as a process of building associations between a stimulus and a response, with both of them being verbal. At a broader level, verbal learning includes the processes of organizing the stimulus material by the learner and the related changes in the learner's behavior. At different stages of the development of the verbal learning studies, a variety of aspects of this phenomenon were highlighted. For example, German psychologist Hermann Ebbinghaus (1850-1909) in his book *On Memory* (1885), focused on the processes of association building and recall, which shaped his experiments with verbal material. Ebbinghaus's work, albeit not dealing explicitly with verbal learning, is considered as the first seminal work in the field, due to the material and the

methods used.

Verbal learning can be based on different processes and can be classified in several types. The first process is serial verbal learning. People engage in it when they learn a list of verbal items (for example, words or syllables) while maintaining the order of the items. Psychologists test this type of learning by asking subjects to read a list of verbal stimuli and then reproduce this list while keeping the original order of the items. Such experiments have been widely used in tests of short- and long-term memory.

A useful strategy that can be used while remembering such lists of words is to build associations between them. Thus, the first word "anticipates" the second, and, analogically, every word points to the one after it. Ebbinghaus called this learning strategy the serial anticipation method. Studies of this type of learning have also discovered the serial position effect, which says that different parts of the list are learned with different difficulty. Usually, the first few items are the easiest to learn, then come those at the end of the list. The hardest to learn are the items just after the middle.

Another type of verbal learning is referred to paired associate learning. It happens when people read pairs of words, or other verbal stimuli, then get to see just one item of a pair and have to say what the other is. This type of learning is largely used in education, especially in learning foreign languages. Pupils learn vocabularies as pairs of known English words and words from another language, building associations between the items of a pair. Then, when presented with a foreign word (stimulus), the pupil has to name the corresponding English word (response).

Free verbal learning is a type of learning, which people use when they learn lists of items regardless of their order. A task used to test this type of learning is free recall. The subject is asked to recall as many items from a list as possible, regardless of their sequence. Such tests are often used to establish organizational patterns of learning and memory. For example, the subject may use a clustering strategy - grouping items according to their similarity or the number of letters in them. Another kind of verbal learning is verbal discrimination (or recognition) learning. It is studied by a task which requires of the subject, after reading a list of items, to read another one and to say which items of the second list were present in the first. Verbal learning theorists use different materials in their tests. Ebbinghaus used nonsense syllables - syllables of the type consonant-vowel-consonant, such as GOC, TER, and BIV. He argued that these stimuli were easily controlled and thus had an advantage for being used in the studies of memory compared to meaningful words.

In 1932, British psychologist Frederic Bartlett (1886-1969) challenged Ebbinghaus's view that nonsense syllables were easily controlled and that they eliminated meaning as a factor in learning. Another influential perspective and perhaps the most important contribution to this field was *The Psychology of Human Learning: An Introduction* (1942) by John McGeoch (1897-1942), a book which summarized many of the trends in verbal learning.

In the 1950s, the verbal learning studies focused on verbal behavior - the characteristics of language and its use. In the 1960s through to the 1980s, psycholinguists developed models of word acquisition, verbal information processing and lexicon building. Examples of such models are the logogen model of John Morton (1969), which was considered to be an important theory, along with the PDP (parallel distributed processing) model of Mark Seidenberg and James Lloyd McClelland (1989).

DISCRIMINATION LEARNING

Learning Set and Learning by Exclusion

Discrimination learning can be generalized. The point is illustrated by experiments with monkeys on learning set. In the typical procedure, a monkey is presented with two objects; under one is a piece of food. When it learns the discrimination, two new objects are presented, and so on. Learning proceeds more rapidly after each problem until it learns new discriminations in a single trial. Learning set has also been demonstrated in other species and with other tasks.

Learning set is evident in a word-learning discrimination called learning by exclusion. In typical experiments employing nonverbal humans with mental retardation, subjects are first taught names for several foods. Then a new food is placed among foods with known names. Without any further training or prompts, subjects are asked to point to the new food that is given a never before heard name. Experienced subjects correctly select the novel food on the first test, and in subsequent tests with that food and new foods they demonstrate retention of the new name. These experiments show that after learning several names, individuals learn the contingency that exists between new names and new objects.

Discrimination Learning

Discrimination learning can be used as a part of training for more difficult tasks, including the judgement bias tasks and Iowa gambling task described earlier in the chapter. It can, however, also be used as a task in and of itself, to determine the ability of animals to discriminate between two stimuli and the capacity of animals to learn and perform tasks based on discrimination in different modalities.

Visual discrimination is frequently used in discrimination learning in various species. This can entail the use of lights, including discrimination between light color, intensity, or frequency of flashing lights. Visual stimuli can also include the use of pictures or patterns. Pigs have visual acuity which is inferior to humans, sheep, and cattle (Entsu et al., 1992; Tanaka et al., 1995; Zonderland et al., 2008) but which should, in theory, be quite sufficient for learning visual discriminations. In practice, however, discrimination based on visual stimuli in pigs has proven quite difficult, requiring lengthy training to show operant responses to distinct 2D shapes (Gielsing et al., 2012a; Graf, 1976; Haagensen et al., 2013). Discrimination of conspecifics based on photographs, which has been demonstrated in domestic sheep (Ferreira et al., 2004) and cows (Coulon et al., 2009) did not seem to be possible in pigs (Gielsing et al., 2012a).

Discrimination tasks based on auditory stimuli have been more successful, with pigs showing distinct operant responses to auditory stimuli of different frequencies (Murphy et al., 2013a). Other modalities, such as odor cues or tactile cues, have yet to be tested in pigs. Given their strong olfactory and tactile abilities (the snout is particularly sensitive), this may be an interesting avenue to explore to improve discrimination learning.

Neural Basis

The different forms of discrimination learning and reversal tasks seem to have distinct neural bases. Rapid acquisition of object discrimination problems seems to involve the inferotemporal cortex and ventral prefrontal cortex, as well as the mediodorsal thalamus (Gaffan and Murray, 1990; Gaffan et al., 1993; Baxter and Murray, 2000). The entorhinal and perirhinal cortices seem to be required for rapid learning of visual discrimination problems only to the extent that these cortical areas are involved in identification of the stimuli to be discriminated (see discussion in Baxter et al.,

1999). Other medial temporal lobe structures may be involved in retention of these rapidly learned discrimination problems (Zola-Morgan et al., 1994; Alvarez et al., 1995). In contrast, slow learning of object discrimination problems (e.g., in the "24-hr ITI" task) is independent of limbic structures (amygdala and hippocampus) but does require inferior temporal cortical area TE (Phillips et al., 1988) and again the entorhinal and perirhinal cortices only to the extent that object identification is taxed (Buckley and Gaffan, 1997; Thornton et al., 1998); as well as the ventral and orbital frontal cortices (Murray and Wise, 1997) and the tail of the caudate nucleus (Wang et al., 1990). The commonality between cortical systems required for learning of visual discrimination problems and visual recognition memory is notable (see Section II,B). Interestingly, individual monkeys who are impaired on DNMS performance also appear to demonstrate an impairment in object discrimination learning (Rapp, 1993), suggesting a common neural substrate for these deficits, likely inferior temporal-prefrontal connections (see Section II,B).

Spatial discrimination learning appears to involve hippocampal formation and dorsolateral prefrontal cortex. Monkeys with dorsolateral prefrontal cortex lesions are markedly impaired on acquisition of a spatial discrimination problem (Pohl, 1973), as are monkeys with aspiration lesions of the hippocampus that include the overlying parahippocampal cortex (Jones and Mishkin, 1972). The contribution of the hippocampus proper to spatial discrimination learning is unclear, as monkeys with neurotoxic hippocampal lesions (sparing the parahippocampal cortex) are not impaired on this particular spatial discrimination learning task (Murray et al., 1998).

Reversal learning appears to recruit additional neural systems. Lesions that impair the initial discrimination also produce impairment in subsequent reversals of that discrimination. However, lesions of the orbitofrontal cortex, which produce no impairment in initial acquisition of a spatial discrimination, produce a marked impairment in reversal of that discrimination (Jones and Mishkin, 1972). Similarly, rhinal cortex lesions, which have little effect on object discriminations, produce an impairment in subsequent reversals of that discrimination (Murray et al., 1998).

Lesions restricted to the hippocampus also appear to produce an impairment in object reversals, milder than that produced by rhinal cortex lesions (Mahut, 1971; Murray et al., 1998). Of note is the pattern of errors made during reversal learning: Jones and Mishkin (1972) analyzed errors in reversal learning based on whether the monkey was performing below chance (stage 1), at chance (stage 2), or above chance but not yet at criterion (stage 3).

Damage to the orbitofrontal cortex is characterized by a marked increase in stage 1 errors, suggestive of perseverative behavior (Jones and Mishkin, 1972). Rhinal cortex lesions produce similar perseverative behavior (Murray et al., 1998).

Hence, perseverative behavior on reversals may suggest damage to the prefrontal cortex, rhinal cortex, or both. It is also worth noting that impairments in reversal learning may be limited to the first time a particular type of reversal problem is encountered (Dias et al., 1997); this may explain why a lack of impairment on reversal learning is observed when the monkeys have previously performed reversals in a different stimulus domain (e.g., testing on spatial reversals after having performed object reversals).

RECENT TRENDS IN LEARNING: NEUROPHYSIOLOGY OF LEARNING

Each new year brings with it new learning and development trends, and a few key themes are already shining through in 2019. Organisations are placing a strong emphasis on learning, while

employees want more control of what, where and when they learn. They're also adopting both conventional and unconventional approaches to maximise their learning. This blog will uncover the latest trends in learning for 2019 including:

- Continuous learning culture
- Employee led learning
- People leaders as coaches
- Social learning
- Employee-curated content
- Mobile (aka on-demand)
- Microlearning
- Data and analytics
- Learning Experience Platform (LXP)
- Gamification, Augmented and Virtual Reality
- People data

The learning landscape is shifting. With continuous advances in technology, employees are taking control of their own education and development. Organisations are stepping up to help shape the future of learning. They're focusing on providing coaching, ongoing feedback and resources for learning opportunities.

Technologies which focus on usability and experience are helping improve learner engagement. Unsurprisingly, mobile and social learning are gaining traction and feature heavily in a modern learning environment. Learners are demanding just-in-time learning, where and when they want it. Explore the shifts in learning with our updated learning trends for 2019.

1. CONTINUOUS LEARNING CULTURE

The shelf-life of skills is diminishing. The need for ongoing learning and development is greater than at any previous point in history. 38% of CEOs believe a shortage of key skills is the top people-related threat to growth. That's up from 31% in 2017. With this in mind, it's no surprise that building a culture of continuous learning is currently a priority for L&D leaders. This encompasses just-in-time learning designed to close a specific knowledge gap in a current role, right through to development of competencies and behaviours needed for future roles.

Today's learner expects (and is expected to) continually learn and develop. This culture of continual learning is simultaneously driving and being reinforced by the shifting attitude to performance management. As everyday performance and ongoing feedback approaches gain momentum, the desire to upskill, develop and close skill gaps reinforces the symbiotic relationship between performance and development.

2. EMPLOYEE-LED LEARNING

Organisations are moving away from top-down driven development frameworks and empowering employees to lead their own learning. Some examples of employee-led learning include:

- moving away from a one-size-fits-all' approach
- creating personalised learning paths to help develop employees in their current role, next role and future roles;
- basing content on both development needs and interests.
- 68% of employees prefer to learn at work, according to recent research by LinkedIn, but they don't always have time to complete learning activities. In fact, the same research found that

the #1 challenge for talent development is getting employees to make time for learning.

As the above diagram suggests, over half of employees (58%) want to learn at their own pace depending on their requirements, development needs and interests. But employees still want their manager's input on how to improve, with 56% saying they would spend more time learning if their manager suggested activities.

Instead of a 'one-size-fits-all' approach, organisations are creating personalised learning paths that develop employees in their current role, next role and future career paths."

3. PEOPLE LEADERS AS COACHES

Finding the time for learning is the number one development challenge employees face. The second-largest challenge is getting people leaders to take an active role in employee development. It's no longer only the responsibility of the L&D department to ensure employees get the training they need. Learning professionals are now looking to people managers to own and develop their teams. Empowering people leaders to help employees on their continuous learning journey is becoming a priority. When it's done well, it's highly successful. Nearly three-quarters (74%) of employees who felt empowered to drive their own career say that their manager provides coaching and supports their development.

4. SOCIAL LEARNING

In addition to social collaborative tools, organisations are also experimenting with cross-functional project-based learning, creating online learning marketplaces and structured mentoring forums. At the very minimum, employees expect workplace technologies that allow:

- social networking
- instant messaging,
- online collaboration;
- video conferencing.

Humans are social by nature: 87% of employees say that sharing knowledge with their team is critical for learning. 34% of organisations are already investing in social learning tools and over the next few years we anticipate the uptake will accelerate. The increasing complexity of work, rise of the contingent and freelance workforce, and the desire to work 'anywhere, anytime' will drive the adoption of social collaboration and knowledge-sharing tools.

5. EMPLOYEE-CURATED CONTENT

Relevant content is what matters most to employees. Yet less than half (46%) of employees are satisfied with the relevance of the content provided by their organisation. How can we help employees cut through the clutter? Employees want the ability to create their own online content and share learning resources. It's no surprise that peer-to-peer learning continues to gain traction – empowering people to share relevant content with their colleagues.

Organisations are also supporting apps which curate, publish and share content to keep peers, teammates and managers across the latest and most relevant content. Crowdsourcing means content is constantly refreshed, removing the barrier of irrelevant information which can deter time-poor learners.

6. MOBILE (AKA ON-DEMAND)

Employees expect to access content anytime, anywhere via a mobile device. Although this trend isn't new, corporate adoption levels have lagged behind employee expectations. Over three-quarters of employees do at least some of their learning on a mobile device and 99% of mobile learners believe the mobile format enhanced their learning. Despite this, mobile access is ranked as the second-largest challenge to learning from an employee's perspective. Tellingly, access to mobile learning doesn't register within the top three perceived challenges L&D professionals face. Looking to the future, 23% plan to purchase mobile learning solutions and this trend is expected to accelerate. Organisations that want to improve the learning experience of their employees need to ensure mobile is part of the solution.

7. Microlearning

Making time for learning isn't easy. Our constantly-connected lifestyles also means that attention spans are shrinking. A solution could lie in Microlearning: this is bite-sized chunks of learning content, completed in three to five minutes, that makes learning easily digestible. Some examples of successful microlearning can be found on popular mediums including:

- podcasts
- blogs
- eLearning
- videos

As a medium, videos are still a popular way to learn. More organisations are turning to mobile devices to create quick, inexpensive, easily uploadable content. According to Training Journal (TJ) "In 2019, we can expect to see even more of this 'guerilla' film production with high-end features with interactivity that will be distributed on mobile devices and applications for easy accessibility." Online content can be parceled into smaller components, so employees can learn where and when it suits them.

This trend has been driven not only by a better understanding of how we learn, but also by advances in technology. The uptake of mobile and cloud technologies means content can be accessed as needed. This can have a positive impact on a company's bottom line. Organisations that empower their employees with microlearning experience a 63% increase in revenue compared to their peers.

NEURO-PHYSIOLOGY OF LEARNING

Many seem to be the points of contact that relate the analysis of studies on the neuro-phenomenological vision of knowledge (and the occurrence of states of consciousness in relation to the act of knowing) and further studies phenomena related to bio physical and neuro-logical that govern and influence the physiology of learning.

A study conducted by several parties on the subject show that individual neurons are able to recognize people, landscapes, objects and even written and names. The finding suggests the existence of a consistent and explicit code that could play a role in the transformation of complex visual representations into long-term memories.

This conception of individual neurons as 'thinking cells' - says the neuro-surgeon Itzhak Fried - represents an important step toward deciphering the code of the cognitive brain. If we can understand this process, maybe one day we will be able to build cognitive prostheses to replace

functions lost due to brain injury or disease, and perhaps even to improve memory Angeles is based on a new conception of the mode of storage of memories, stating that encode memories are small sets of neurons located in specific regions of the brain. These small clusters of neural cells simultaneously represent many aspects of the same thing.

This statement leads to the conclusion that each neuron has its own memory and that groups of neurons fire selectively to images of faces, animals, objects or scenes. In this perspective are here analyzed two different areas of research that are based on two different approaches: one referring to the neuro-phenomenological studies (total embodiment of Varela and Thompson), and the other in reference to the neuro-physiological and bio-medical studies (neurophysiology of learning of Zhuo Joseph Tsien).

But as you can remember the mental states activated by past perceptions and refer back to an object in the world, even when it is not present or does not exist? How is it that a model of external reality emerges in the physical system, which is the brain? What role has the intentionality and the emergence of consciousness in this process?

The answers to these problems are numerous and controversial and detection of connection points difficult and problematic (hampered by the differentiation of the areas of inquiry: Philosophy of mind, Philosophy of language, Cognitive science, Neuroscience, etc.). This basically means that "Philosophy" speaks little of "Biology" and "Biology" of "Philosophy" speaks even less.

Tsien founded the Shanghai Institute of Brain Functional Genomics at East China Normal University and is now director of the Center for Systems Neurobiology at Boston University. His studies are focused on the search for a neural code that can explain the experience phenomenologically lived through the observation of specific biological processes.

For a long time research of the neural mechanisms by which memories are stored in the brain has been studied by neuroscientists. Learning and memory are very important in the structuring of knowledge: learning is the process by which one acquires knowledge and memory is the process by which knowledge is preserved in time. For many years we have tried, therefore, to investigate the intricacies of cellular memory and to understand the functional basis for action at the neural level. Tsien and his team, in a biomedical field and through combined and complex experiments, have developed an interesting theory on the basic mechanism by which the brain would be able to transform experience into memory. Clans of neurons involved in coding, they say, make a selection of experiences stored, giving a sense of the experience and transforming it into knowledge. This extraordinary research could allow, in the near future, to decipher the neural universal code allowing the reading of the memories of a human being by monitoring brain activity. Interesting observations are: a) the nature of the mechanisms of action and the behavior of neural cells, b) the sophisticated mechanism of action research (covering the area CA1 of the hippocampus). In this theoretical model each event is represented by a group of neuronal clans that encode different characteristics; a clan is represented by a set of neurons that responds in a similar manner to each stimulus, working in harmony in the encoding of events. It is believed, therefore, that it is the clan to generate neural memories, acting in unison on the information conveyed phenomenal experience. Does this mean that behavior is also the derivation of genetic relational nature of man and his predisposition to the "lineage"? (Maturana Dávila, 2006) The brain is, in this perspective, the clan for neural discrimination of events encoded in memory. In a three-dimensional view, each experience is represented on a pyramid at various levels; each pyramid is considered

an integral part of a polyhedron which, in turn, represents the category common to all the pyramids. This model represents a consolidation of memories in a clear and inconceivable way and demonstrate the dynamic nature of the human brain and its extraordinary ability.

Organization and on the categorization as universal principles of the functioning of our brain. In the case of memory these properties allow you to create an unlimited number of patterns of neuronal activation (corresponding to the number of experiences that an organism can live). In this perspective, Tsien and his research team in a recent article say “The ability to learn and remember conspecifics is essential for the establishment and maintenance of social groups. Many animals, including humans, primates and rodents, depend on stable social relationships for survival. Social learning and social recognition have become emerging areas of interest for neuroscientists but are still not well understood. It has been established that several hormones play a role in the modulation of social recognition including estrogen, oxytocin and arginine vasopression. Relatively few studies have investigated how social recognition might be improved or enhanced. In this study, we investigate the role of the NMDA receptor in social recognition memory, specifically the consequences of altering the ratio of the NR2B:NR2A subunits in the forebrain regions in social behavior. We reproduced transgenic mice in which the NR2B subunit of the NMDA receptor was overexpressed postnatally in the excitatory neurons of the forebrain areas including the cortex, amygdala and hippocampus. We investigated the ability of both our transgenic animals and their wild-type littermate to learn and remember juvenile conspecifics using both 1-hr and 24-hr memory tests.

Our experiments show that the wild-type animals and NR2B transgenic mice performed similarly in the 1-hr test. However, transgenic mice showed better performances in 24-hr tests of recognizing animals of a different strain or animals of a different species. We conclude that NR2B overexpression in the forebrain enhances social recognition memory for different strains and animalspecies”(Jacobs,Tsien, 2012).

CONCLUSION

That having been said, the paideia-society interrelation stands within a paradigmatic vision of contemporary pedagogy like the double-faced Janus, from which a new dimension of man and citizen arises along with a new way of understanding education//educability of the subject-person (Pastena 2011). It is all about suggesting a new way of interpreting pedagogy where the teaching-learning interaction becomes alternative teaching methodology to the many current practices.

No doubt so much uneasiness and failure to achieve success in the schools are caused by the nature and the way of teaching approaches, by an agency that is often too prone to hyperdidacticisms that bring about confusion and disconcert rather than self-orientating enaction. In fact, enaction means understanding learning as the creation of worlds, where the student experiences the didactic action in structural coupling with the teacher. In short, it is a Paideia that is seen in its atropo-ethical dimension as the hard core that allows interaction (in an enactive circuit) between “sense”, “logic” and “evolution”

WHAT IS MEMORY AND FORGETTING MEMORY PROCESSES: ENCODING, STORAGE, RETRIEVAL STAGES OF MEMORY: SENSORY MEMORY, SHORT-TERM MEMORY (WORKING MEMORY), LONG-TERM MEMORY (DECLARATIVE – EPISODIC AND SEMANTIC; PROCEDURAL)

Theories of Forgetting: Interference, Retrieval Failure, Decay, Motivated forgetting?

MEMORY AND FORGETTING MEMORY PROCESSES: ENCODING, STORAGE, RETRIEVAL STAGES OF MEMORY: SENSORY MEMORY, SHORT-TERM MEMORY (WORKING MEMORY), LONG-TERM MEMORY (DECLARATIVE – EPISODIC AND SEMANTIC; PROCEDURAL) THEORIES OF FORGETTING: INTERFERENCE, RETRIEVAL FAILURE, DECAY, MOTIVATED FORGETTING

Memory and Forgetting Memory processes: Encoding, Storage Human Memory

Human memory, like memory in a computer, allows us to store information for later use. In order to do this, however, both the computer and we need to master three processes involved in memory. The first is called encoding; the process we use to transform information so that it can be stored. For a computer this means transferring data into 1's and 0's. For us, it means transforming the data into a meaningful form such as an association with an existing memory, an image, or a sound.

Next is the actual storage, which simply means holding onto the information. For this to take place, the computer must physically write the 1's and 0's onto the hard drive. It is very similar for us because it means that a physiological change must occur for the memory to be stored. The final process is called retrieval, which is bringing the memory out of storage and reversing the process of encoding. In other words, return the information to a form similar to what we stored.

The major difference between humans and computers in terms of memory has to do with how the information is stored. For the most part, computers have only two types; permanent storage and permanent deletion. Humans, on the other hand are more complex in that we have three distinct memory storage capabilities (not including permanent deletion). The first is Sensory memory, referring to the information we receive through the senses. This memory is very brief lasting only as much as a few seconds.

Short Term Memory (STM) takes over when the information in our sensory memory is transferred to our consciousness or our awareness (Engle, Cantor, & Carullo, 1993; Laming, 1992). This is the information that is currently active such as reading this page, talking to a friend, or writing a paper. Short term memory can definitely last longer than sensory memory (up to 30 seconds or so), but it still has a very limited capacity. According to research, we can remember approximately 5 to 9 (7 +/- 2) bits of information in our short term memory at any given time (Miller, 1956) If STM lasts only up to 30 seconds, how do we ever get any work done? Wouldn't we start to lose focus or concentrate about twice every minute? This argument prompted researchers to look at a second phase of STM that is now referred to as Working Memory. Working Memory is the process that takes place when we continually focus on material for longer than STM alone will allow (Baddeley, 1992).

What happens when our short term memory is full and another bit of information enters? Displacement means that the new information will push out part of the old information. Suddenly someone says the area code for that phone number and almost instantly you forget the last two digits of the number. We can further sharpen our short term memory skills, however, by mastering chunking and using rehearsal (which allows us to visualize, hear, say, or even see the information repeatedly and through different senses).

Finally, there is long term memory (LTM), which is most similar to the permanent storage of a computer. Unlike the other two types, LTM is relatively permanent and practically unlimited in terms

of its storage capacity. It's been argued that we have enough space in our LTM to memorize every phone number in the U.S. and still function normally in terms of remembering what we do now. Obviously we don't use even a fraction of this storage space.

There are several subcategories of LTM. First, memories for facts, life events, and information about our environment are stored in declarative memory. This includes semantic memory, factual knowledge like the meaning of words, concepts, and our ability to do math (Lesch & Pollatsek, 1993, Rohrer et al., 1995) and episodic memory, memories for events and situations (Goldring, 1996; Kliegel & Lindberger, 1993). The second subcategory is often not thought of as memory because it refers to internal, rather than external information. When you brush your teeth, write your name, or scratch your eye, you do this with ease because you previously stored these movements and can recall them with ease. This is referred to as nondeclarative (or implicit) memory. These are memories we have stored due to extensive practice, conditioning, or habits.

WHY WE REMEMBER WHAT WE REMEMBER

Short Term Memory. There are typically six reasons why information is stored in our short term memory.

primacy effect – information that occurs first is typically remembered better than information occurring later. When given a list of words or numbers, the first word or number is usually remembered due to rehearsing this more than other information.

recency effect – often the last bit of information is remembered better because not as much time has passed; time which results in forgetting. **distinctiveness** – if something stands out from information around it, it is often remembered better. Any distinctive information is easier to remember than that which is similar, usual, or mundane.

frequency effect – rehearsal, as stated in the first example, results in better memory. Remember trying to memorize a formula for your math class. The more you went over it, the better you knew it.

associations – when we associate or attach information to other information it becomes easier to remember. Many of us use this strategy in our professions and everyday life in the form of acronyms.

reconstruction – sometimes we actually fill in the blanks in our memory. In other words, when trying to get a complete picture in our minds, we will make up the missing parts, often without any realization that this is occurring.

Long Term Memory. Information that passes from our short term to our long term memory is typically that which has some significance attached to it. Imagine how difficult it would be to forget the day you graduated, or your first kiss. Now think about how easy it is to forget information that has no significance; the color of the car you parked next to at the store or what shirt you wore last Thursday. When we process information, we attach significance to it and information deemed important is transferred to our long term memory.

There are other reasons information is transferred. As we all know, sometimes our brains seem full of insignificant facts. Repetition plays a role in this, as we tend to remember things more

the more they are rehearsed. Other times, information is transferred because it is somehow attached to something significant. You may remember that it was a warm day when you bought your first car. The temperature really plays no important role, but is attached to the memory of buying your first car.

FORGETTING

You can't talk about remembering without mentioning its counterpart. It seems that as much as we do remember, we forget even more. Forgetting isn't really all that bad, and is in actuality, a pretty natural phenomenon. Imagine if you remembered every minute detail of every minute or every hour, of every day during your entire life, no matter how good, bad, or insignificant. Now imagine trying to sift through it all for the important stuff like where you left your keys.

There are many reasons we forget things and often these reasons overlap. Like in the example above, some information never makes it to LTM. Other times, the information gets there, but is lost before it can attach itself to our LTM. Other reasons include decay, which means that information that is not used for an extended period of time decays or fades away over time. It is possible that we are physiologically preprogrammed to eventually erase data that no longer appears pertinent to us.

Failing to remember something doesn't mean the information is gone forever though. Sometimes the information is there but for various reasons we can't access it. This could be caused by distractions going on around us or possibly due to an error of association (e.g., believing something about the data which is not correct causing you to attempt to retrieve information that is not there). There is also the phenomenon of repression, which means that we purposefully (albeit subconsciously) push a memory out of reach because we do not want to remember the associated feelings. This is often cited in cases where adults 'forget' incidences of sexual abuse when they were children. And finally, amnesia, which can be psychological or physiological in origin.

Forgetting is an all too common part of daily life. Sometimes these memory slips are simple and fairly innocuous, such as forgetting to return a phone call. Other times, forgetting can be much more dire and even have serious consequences, such as an eyewitness forgetting important details about a crime.

Memory failures are an almost daily occurrence. Forgetting is so common that you probably rely on numerous methods to help you remember important information, such as jotting down notes in a daily planner or scheduling important events on your phone's calendar.

As you are frantically searching for your missing car keys, it may seem that the information about where you left them is permanently gone from your memory. However, forgetting is generally not about actually losing or erasing this information from your long-term memory.

TIME PLAYS A KEY ROLE IN FORGETTING

Psychologist Hermann Ebbinghaus was one of the first to scientifically study forgetting. In experiments where he used himself as the subject, Ebbinghaus tested his memory using three-letter nonsense syllables. He relied on such nonsense words because using previously known words would have involved drawing on his existing knowledge and associations in his memory.²

In order to test for new information, Ebbinghaus tested his memory for periods of time ranging from 20 minutes to 31 days. He then published his findings in 1885 in *Memory: A Contribution to*

Experimental Psychology.

His results, plotted in what is known as the Ebbinghaus forgetting curve, revealed a relationship between forgetting and time. Initially, information is often lost very quickly after it is learned. Factors such as how the information was learned and how frequently it was rehearsed play a role in how quickly these memories are lost. Information stored in long-term memory is surprisingly stable. The forgetting curve also showed that forgetting does not continue to decline until all of the information is lost.² At a certain point, the amount of forgetting levels off.

HOW TO MEASURE FORGETTING

Sometimes it might seem that information has been forgotten, but even a subtle cue can help trigger the memory. Imagine the last time you took an exam for school. While you might have initially felt forgetful and unprepared, seeing the information presented on the test probably helped cue the retrieval of information you might not have known you even remembered.

So how do we know when something has been forgotten? There are a few different ways to measure this:³

- **Recall:** People who have been asked to memorize something, such as a list of terms, might be asked to recall the list from memory. By seeing how many items are remembered, researchers are able to identify how much information has been forgotten. This method might involve the use of free recall (recalling items without hints) or prompted recall (utilizing hints to trigger memories).
- **Recognition:** This method involves identifying information that was previously learned. On a test, for example, students might have to recognize which terms they learned about in a chapter of their assigned reading.

Theories About Why We Forget

Of course, many factors can contribute to forgetting. Sometimes you might be distracted when you learn new information, which might mean that you never truly retain the information long enough to remember it later. Well-known memory researcher Elizabeth Loftus has proposed four key explanations for why forgetting occurs. These have led to some major theories of forgetting.

MEMORY PROCESSES: ENCODING, STORAGE, RETRIEVAL

“Memory” is a single term that reflects a number of different abilities: holding information briefly while working with it (working memory), remembering episodes of one’s life (episodic memory), and our general knowledge of facts of the world (semantic memory), among other types.

Remembering episodes involves three processes: encoding information (learning it, by perceiving it and relating it to past knowledge), storing it (maintaining it over time), and then retrieving it (accessing the information when needed). Failures can occur at any stage, leading to forgetting or to having false memories. The key to improving one’s memory is to improve processes of encoding and to use techniques that guarantee effective retrieval.

Good encoding techniques include relating new information to what one already knows, forming mental images, and creating associations among information that needs to be remembered. The key to good retrieval is developing effective cues that will lead the rememberer back to the encoded information. Classic mnemonic systems, known since the time of the ancient Greeks and still used by some today, can greatly improve one’s memory abilities.

KEY POINTS

- The three main stages of memory are encoding, storage, and retrieval. Problems can occur at any of these stages.
- The three main forms of memory storage are sensory memory, short-term memory, and long-term memory.
- Sensory memory is not consciously controlled; it allows individuals to retain impressions of sensory information after the original stimulus has ceased.
- Short-term memory lasts for a very brief time and can only hold 7 +/- 2 pieces of information at once.
- Long-term storage can hold an indefinitely large amount of information and can last for a very long time.
- Implicit and explicit memories are two different types of long-term memory. Implicit memories are of sensory and automatized behaviors, and explicit memories are of information, episodes, or events.

KEY TERMS

- **memory:** The ability of an organism to record information about things or events with the facility of recalling them later at will.
- **rehearsal:** Repetition of an item in short-term memory in order to store it in long-term memory.
- Memory is the ability to take in information, store it, and recall it at a later time. In psychology, memory is broken into three stages: encoding, storage, and retrieval.

The Memory Process

1. Encoding (or registration): the process of receiving, processing, and combining information. Encoding allows information from the outside world to reach our senses in the forms of chemical and physical stimuli. In this first stage we must change the information so that we may put the memory into the encoding process.
2. Storage: the creation of a permanent record of the encoded information. Storage is the second memory stage or process in which we maintain information over periods of time.
3. Retrieval (or recall, or recognition): the calling back of stored information in response to some cue for use in a process or activity. The third process is the retrieval of information that we have stored. We must locate it and return it to our consciousness. Some retrieval attempts may be effortless due to the type of information.

Problems can occur at any stage of the process, leading to anything from forgetfulness to amnesia. Distraction can prevent us from encoding information initially; information might not be stored properly, or might not move from short-term to long-term storage; and/or we might not be able to retrieve the information once it's stored.

MEMORY ENCODING

Our memory has three basic functions: encoding, storing, and retrieving information. Encoding is the act of getting information into our memory system through automatic or effortful processing. Storage is retention of the information, and retrieval is the act of getting information out of storage and into conscious awareness through recall, recognition, and relearning. There are various models that aim to explain how we utilize our memory. In this section, you'll learn about some of these models as well as the importance of recall, recognition, and relearning.

ENCODING

We get information into our brains through a process called **encoding**, which is the input of information into the memory system. Once we receive sensory information from the environment, our brains label or code it. We organize the information with other similar information and connect new concepts to existing concepts. Encoding information occurs through automatic processing and effortful processing. If someone asks you what you ate for lunch today, more than likely you could recall this information quite easily. This is known as **automatic processing**, or the encoding of details like time, space, frequency, and the meaning of words. Automatic processing is usually done without any conscious awareness. Recalling the last time you studied for a test is another example of automatic processing. But what about the actual test material you studied? It probably required a lot of work and attention on your part in order to encode that information.

What are the most effective ways to ensure that important memories are well encoded? Even a simple sentence is easier to recall when it is meaningful (Anderson, 1984). Read the following sentences (Bransford & McCarrell, 1974), then look away and count backwards from 30 by threes to zero, and then try to write down the sentences (no peeking back at this page!).

- The notes were sour because the seams split.
- The voyage wasn't delayed because the bottle shattered.
- The haystack was important because the cloth ripped.

How well did you do? By themselves, the statements that you wrote down were most likely confusing and difficult for you to recall. Now, try writing them again, using the following prompts: bagpipe, ship christening (shattering a bottle over the bow of the ship is a symbol of good luck), and parachutist. Next count backwards from 40 by fours, then check yourself to see how well you recalled the sentences this time. You can see that the sentences are now much more memorable because each of the sentences was placed in context. Material is far better encoded when you make it meaningful.

There are three types of encoding. The encoding of words and their meaning is known as **semantic encoding**. It was first demonstrated by William Bousfield (1935) in an experiment in which he asked people to memorize words. The 60 words were actually divided into 4 categories of meaning, although the participants did not know this because the words were randomly presented. When they were asked to remember the words, they tended to recall them in categories, showing that they paid attention to the meanings of the words as they learned them.

Visual encoding is the encoding of images, and **acoustic encoding** is the encoding of sounds, words in particular. To see how visual encoding works, read over this list of words: car, level, dog, truth, book, value. If you were asked later to recall the words from this list, which ones do you think you'd most likely remember? You would probably have an easier time recalling the words car, dog, and book, and a more difficult time recalling the words level, truth, and value. Why is this? Because you can recall images (mental pictures) more easily than words alone. When you read the words car, dog, and book you created images of these things in your mind. These are concrete, high-imagery words. On the other hand, abstract words like level, truth, and value are low-imagery words. High-imagery words are encoded both visually and semantically (Paivio, 1986), thus building a stronger memory.

Now let's turn our attention to acoustic encoding. You are driving in your car and a song comes on the radio that you haven't heard in at least 10 years, but you sing along, recalling every word. In the United States, children often learn the alphabet through song, and they learn the number of days in each month through rhyme: "Thirty days hath September, / April, June, and November; / All the rest have thirty-one, / Save February, with twenty-eight days clear, / And twenty-nine each leap year." These lessons are easy to remember because of acoustic encoding. We encode the sounds the words make. This is one of the reasons why much of what we teach young children is done through song, rhyme, and rhythm.

Which of the three types of encoding do you think would give you the best memory of verbal information? Some years ago, psychologists Fergus Craik and Endel Tulving (1975) conducted a series of experiments to find out. Participants were given words along with questions about them. The questions required the participants to process the words at one of the three levels. The visual processing questions included such things as asking the participants about the font of the letters. The acoustic processing questions asked the participants about the sound or rhyming of the words, and the semantic processing questions asked the participants about the meaning of the words. After participants were presented with the words and questions, they were given an unexpected recall or recognition task.

Words that had been encoded semantically were better remembered than those encoded visually or acoustically. Semantic encoding involves a deeper level of processing than the shallower visual or acoustic encoding. Craik and Tulving concluded that we process verbal information best through semantic encoding, especially if we apply what is called the self-reference effect. The self-reference effect is the tendency for an individual to have better memory for information that relates to oneself in comparison to material that has less personal relevance (Rogers, Kuiper & Kirker, 1977).

RECODING

The process of encoding is selective, and in complex situations, relatively few of many possible details are noticed and encoded. The process of encoding always involves **recoding**—that is, taking the information from the form it is delivered to us and then converting it in a way that we can make sense of it. For example, you might try to remember the colors of a rainbow by using the acronym ROY G BIV (red, orange, yellow, green, blue, indigo, violet). The process of recoding the colors into a name can help us to remember. However, recoding can also introduce errors—when we accidentally add information during encoding, then remember that new material as if it had been part of the actual experience (as discussed below).

VARIETIES OF MEMORY

To be a good chess player you have to learn to increase working memory so you can plan ahead for several offensive moves while simultaneously anticipating - through use of memory - how the other player could counter each of your planned moves. [Image: karpidis, <https://goo.gl/EhzMKM>, CC BY-SA 2.0, <https://goo.gl/jSSrc0>]

For most of us, remembering digits relies on short-term memory, or working memory—the ability to hold information in our minds for a brief time and work with it (e.g., multiplying 24×17 without using paper would rely on working memory). Another type of memory is **episodic memory**—the ability to remember the episodes of our lives. If you were given the task of recalling everything you did 2 days ago, that would be a test of episodic memory; you would be required to mentally

travel through the day in your mind and note the main events.

SEMANTIC MEMORY

Is our storehouse of more-or-less permanent knowledge, such as the meanings of words in a language (e.g., the meaning of “parasol”) and the huge collection of facts about the world (e.g., there are 196 countries in the world, and 206 bones in your body). Collective memory refers to the kind of memory that people in a group share (whether family, community, schoolmates, or citizens of a state or a country). For example, residents of small towns often strongly identify with those towns, remembering the local customs and historical events in a unique way. That is, the community’s collective memory passes stories and recollections between neighbors and to future generations, forming a memory system unto itself.

Psychologists continue to debate the classification of types of memory, as well as which types rely on others (Tulving, 2007), but for this module we will focus on episodic memory. Episodic memory is usually what people think of when they hear the word “memory.” For example, when people say that an older relative is “losing her memory” due to Alzheimer’s disease, the type of memory-loss they are referring to is the inability to recall events, or episodic memory. (Semantic memory is actually preserved in early-stage Alzheimer’s disease.) Although remembering specific events that have happened over the course of one’s entire life (e.g., your experiences in sixth grade) can be referred to as **autobiographical memory**, we will focus primarily on the episodic memories of more recent events.

STORAGE MEMORY

Every experience we have changes our brains. That may seem like a bold, even strange, claim at first, but it’s true. We encode each of our experiences within the structures of the nervous system, making new impressions in the process—and each of those impressions involves changes in the brain. Psychologists (and neurobiologists) say that experiences leave **memory traces**, or **engrams** (the two terms are synonyms).

Memories have to be stored somewhere in the brain, so in order to do so, the brain biochemically alters itself and its neural tissue. Just like you might write yourself a note to remind you of something, the brain “writes” a memory trace, changing its own physical composition to do so. The basic idea is that events (occurrences in our environment) create engrams through a process of **consolidation**: the neural changes that occur after learning to create the memory trace of an experience. Although neurobiologists are concerned with exactly what neural processes change when memories are created, for psychologists, the term memory trace simply refers to the physical change in the nervous system (whatever that may be, exactly) that represents our experience.

Although the concept of engram or memory trace is extremely useful, we shouldn’t take the term too literally. It is important to understand that memory traces are not perfect little packets of information that lie dormant in the brain, waiting to be called forward to give an accurate report of past experience. Memory traces are not like video or audio recordings, capturing experience with great accuracy; as discussed earlier, we often have errors in our memory, which would not exist if memory traces were perfect packets of information.

Thus, it is wrong to think that remembering involves simply “reading out” a faithful record of past experience. Rather, when we remember past events, we reconstruct them with the aid of our

memory traces—but also with our current belief of what happened. For example, if you were trying to recall for the police who started a fight at a bar, you may not have a memory trace of who pushed whom first. However, let's say you remember that one of the guys held the door open for you. When thinking back to the start of the fight, this knowledge (of how one guy was friendly to you) may unconsciously influence your memory of what happened in favor of the nice guy. Thus, memory is a construction of what you actually recall and what you believe happened. In a phrase, remembering is reconstructive (we reconstruct our past with the aid of memory traces) not reproductive (a perfect reproduction or recreation of the past).

Psychologists refer to the time between learning and testing as the retention interval. Memories can consolidate during that time, aiding retention. However, experiences can also occur that undermine the memory. For example, think of what you had for lunch yesterday—a pretty easy task. However, if you had to recall what you had for lunch 17 days ago, you may well fail (assuming you don't eat the same thing every day). The 16 lunches you've had since that one have created **retroactive interference**. Retroactive interference refers to new activities (i.e., the subsequent lunches) during the retention interval (i.e., the time between the lunch 17 days ago and now) that interfere with retrieving the specific, older memory (i.e., the lunch details from 17 days ago). But just as newer things can interfere with remembering older things, so can the opposite happen. Proactive interference is when past memories interfere with the encoding of new ones. For example, if you have ever studied a second language, often times the grammar and vocabulary of your native language will pop into your head, impairing your fluency in the foreign language.

in which she shows how memory for an event can be changed via misinformation supplied during the retention interval. For example, if you witnessed a car crash but subsequently heard people describing it from their own perspective, this new information may interfere with or disrupt your own personal recollection of the crash. In fact, you may even come to remember the event happening exactly as the others described it! This **misinformation effect** in eyewitness memory represents a type of retroactive interference that can occur during the retention interval (see Loftus [2005] for a review). Of course, if correct information is given during the retention interval, the witness's memory will usually be improved.

RETRIEVAL MEMORY

Endel Tulving argued that “the key process in memory is retrieval” (1991, p. 91). Why should retrieval be given more prominence than encoding or storage? For one thing, if information were encoded and stored but could not be retrieved, it would be useless. As discussed previously in this module, we encode and store thousands of events—conversations, sights and sounds—every day, creating memory traces. However, we later access only a tiny portion of what we've taken in. Most of our memories will never be used—in the sense of being brought back to mind, consciously. This fact seems so obvious that we rarely reflect on it. All those events that happened to you in the fourth grade that seemed so important then? Now, many years later, you would struggle to remember even a few. You may wonder if the traces of those memories still exist in some latent form. Unfortunately, with currently available methods, it is impossible to know.

Psychologists distinguish information that is available in memory from that which is accessible (Tulving & Pearlstone, 1966). Available information is the information that is stored in memory—but precisely how much and what types are stored cannot be known. That is, all we can know is what information we can retrieve—accessible information. The assumption is that accessible information represents only a tiny slice of the information available in our brains. Most of us have

had the experience of trying to remember some fact or event, giving up, and then—all of a sudden!—it comes to us at a later time, even after we've stopped trying to remember it. Similarly, we all know the experience of failing to recall a fact, but then, if we are given several choices (as in a multiple-choice test), we are easily able to recognize it.

What factors determine what information can be retrieved from memory? One critical factor is the type of hints, or cues, in the environment. You may hear a song on the radio that suddenly evokes memories of an earlier time in your life, even if you were not trying to remember it when the song came on. Nevertheless, the song is closely associated with that time, so it brings the experience to mind.

The general principle that underlies the effectiveness of retrieval cues is the **encoding specificity principle** (Tulving & Thomson, 1973): when people encode information, they do so in specific ways. For example, take the song on the radio: perhaps you heard it while you were at a terrific party, having a great, philosophical conversation with a friend. Thus, the song became part of that whole complex experience. Years later, even though you haven't thought about that party in ages, when you hear the song on the radio, the whole experience rushes back to you. In general, the encoding specificity principle states that, to the extent a retrieval cue (the song) matches or overlaps the memory trace of an experience (the party, the conversation), it will be effective in evoking the memory. A classic experiment on the encoding specificity principle had participants memorize a set of words in a unique setting. Later, the participants were tested on the word sets, either in the same location they learned the words or a different one. As a result of encoding specificity, the students who took the test in the same place they learned the words were actually able to recall more words (Godden & Baddeley, 1975) than the students who took the test in a new setting.

One caution with this principle, though, is that, for the cue to work, it can't match too many other experiences (Nairne, 2002; Watkins, 1975). Consider a lab experiment. Suppose you study 100 items; 99 are words, and one is a picture—of a penguin, item 50 in the list. Afterwards, the cue "recall the picture" would evoke "penguin" perfectly. No one would miss it. However, if the word "penguin" were placed in the same spot among the other 99 words, its memorability would be exceptionally worse. This outcome shows the power of distinctiveness that we discussed in the section on encoding: one picture is perfectly recalled from among 99 words because it stands out. Now consider what would happen if the experiment were repeated, but there were 25 pictures distributed within the 100-item list. Although the picture of the penguin would still be there, the probability that the cue "recall the picture" (at item 50) would be useful for the penguin would drop correspondingly. Watkins (1975) referred to this outcome as demonstrating the **cue overload principle**. That is, to be effective, a retrieval cue cannot be overloaded with too many memories. For the cue "recall the picture" to be effective, it should only match one item in the target set (as in the one-picture, 99-word case).

To sum up how memory cues function: for a retrieval cue to be effective, a match must exist between the cue and the desired target memory; furthermore, to produce the best retrieval, the cue-target relationship should be distinctive. Next, we will see how the encoding specificity principle can work in practice.

Psychologists measure memory performance by using production tests (involving recall) or recognition tests (involving the selection of correct from incorrect information, e.g., a multiple-choice test). For example, with our list of 100 words, one group of people might be asked to recall

the list in any order (a free recall test), while a different group might be asked to circle the 100 studied words out of a mix with another 100, unstudied words (a recognition test). In this situation, the recognition test would likely produce better performance from participants than the recall test. We usually think of recognition tests as being quite easy, because the cue for retrieval is a copy of the actual event that was presented for study. After all, what could be a better cue than the exact target (memory) the person is trying to access? In most cases, this line of reasoning is true; nevertheless, recognition tests do not provide perfect indexes of what is stored in memory. That is, you can fail to recognize a target staring you right in the face, yet be able to recall it later with a different set of cues (Watkins & Tulving, 1975). For example, suppose you had the task of recognizing the surnames of famous authors. At first, you might think that being given the actual last name would always be the best cue. However, research has shown this not necessarily to be true (Muter, 1984). When given names such as Tolstoy, Shaw, Shakespeare, and Lee, subjects might well say that Tolstoy and Shakespeare are famous authors, whereas Shaw and Lee are not. But, when given a cued recall test using first names, people often recall items (produce them) that they had failed to recognize before. For example, in this instance, a cue like George Bernard often leads to a recall of "Shaw," even though people initially failed to recognize Shaw as a famous author's name. Yet, when given the cue "William," people may not come up with Shakespeare, because William is a common name that matches many people (the cue overload principle at work). This strange fact—that recall can sometimes lead to better performance than recognition—can be explained by the encoding specificity principle. As a cue, George Bernard matches the way the famous writer is stored in memory better than does his surname, Shaw, does (even though it is the target). Further, the match is quite distinctive with George Bernard, but the cue William is much more overloaded (Prince William, William Yeats, William Faulkner, will.i.am).

The phenomenon we have been describing is called the recognition failure of recallable words, which highlights the point that a cue will be most effective depending on how the information has been encoded (Tulving & Thomson, 1973). The point is, the cues that work best to evoke retrieval are those that recreate the event or name to be remembered, whereas sometimes even the target itself, such as Shaw in the above example, is not the best cue. Which cue will be most effective depends on how the information has been encoded.

Whenever we think about our past, we engage in the act of retrieval. We usually think that retrieval is an objective act because we tend to imagine that retrieving a memory is like pulling a book from a shelf, and after we are done with it, we return the book to the shelf just as it was. However, research shows this assumption to be false; far from being a static repository of data, the memory is constantly changing. In fact, every time we retrieve a memory, it is altered. For example, the act of retrieval itself (of a fact, concept, or event) makes the retrieved memory much more likely to be retrieved again, a phenomenon called the testing effect or the retrieval practice effect (Pyc & Rawson, 2009; Roediger & Karpicke, 2006). However, retrieving some information can actually cause us to forget other information related to it, a phenomenon called retrieval-induced forgetting (Anderson, Bjork, & Bjork, 1994). Thus the act of retrieval can be a double-edged sword—strengthening the memory just retrieved (usually by a large amount) but harming related information (though this effect is often relatively small).

As discussed earlier, retrieval of distant memories is reconstructive. We weave the concrete bits and pieces of events in with assumptions and preferences to form a coherent story (Bartlett, 1932). For example, if during your 10th birthday, your dog got to your cake before you did, you would likely tell that story for years afterward. Say, then, in later years you misremember where the dog

actually found the cake, but repeat that error over and over during subsequent retellings of the story. Over time, that inaccuracy would become a basic fact of the event in your mind. Just as retrieval practice (repetition) enhances accurate memories, so will it strengthen errors or false memories (McDermott, 2006). Sometimes memories can even be manufactured just from hearing a vivid story. Consider the following episode, recounted by Jean Piaget, the famous developmental psychologist, from his childhood:

One of my first memories would date, if it were true, from my second year. I can still see, most clearly, the following scene, in which I believed until I was about 15. I was sitting in my pram . . . when a man tried to kidnap me. I was held in by the strap fastened round me while my nurse bravely tried to stand between me and the thief. She received various scratches, and I can still vaguely see those on her face. . . . When I was about 15, my parents received a letter from my former nurse saying that she had been converted to the Salvation Army. She wanted to confess her past faults, and in particular to return the watch she had been given as a reward on this occasion. She had made up the whole story, faking the scratches. I therefore must have heard, as a child, this story, which my parents believed, and projected it into the past in the form of a visual memory. . . . Many real memories are doubtless of the same order. (Norman & Schacter, 1997, pp. 187–188)

Piaget's vivid account represents a case of a pure reconstructive memory. He heard the tale told repeatedly, and doubtless told it (and thought about it) himself. The repeated telling cemented the events as though they had really happened, just as we are all open to the possibility of having "many real memories ... of the same order." The fact that one can remember precise details (the location, the scratches) does not necessarily indicate that the memory is true, a point that has been confirmed in laboratory studies, too (e.g., Norman & Schacter, 1997).

PUTTING IT ALL TOGETHER: IMPROVING YOUR MEMORY

A central theme of this module has been the importance of the encoding and retrieval processes, and their interaction. To recap: to improve learning and memory, we need to encode information in conjunction with excellent cues that will bring back the remembered events when we need them. But how do we do this? Keep in mind the two critical principles we have discussed: to maximize retrieval, we should construct meaningful cues that remind us of the original experience, and those cues should be distinctive and not associated with other memories. These two conditions are critical in maximizing cue effectiveness (Nairne, 2002).

So, how can these principles be adapted for use in many situations? Let's go back to how we started the module, with Simon Reinhard's ability to memorize huge numbers of digits. Although it was not obvious, he applied these same general memory principles, but in a more deliberate way. In fact, all **mnemonic devices**, or memory aids/tricks, rely on these fundamental principles. In a typical case, the person learns a set of cues and then applies these cues to learn and remember information. Consider the set of 20 items below that are easy to learn and remember (Bower & Reitman, 1972).

1. is a gun. 11 is penny-one, hot dog bun.
2. is a shoe. 12 is penny-two, airplane glue.
3. is a tree. 13 is penny-three, bumble bee.
4. is a door. 14 is penny-four, grocery store.
5. is knives. 15 is penny-five, big beehive.
6. is sticks. 16 is penny-six, magic tricks.
7. is oven. 17 is penny-seven, go to heaven.
8. is plate. 18 is penny-eight, golden gate.
9. is wine. 19 is penny-nine, ball of twine.

10. is hen. 20 is penny-ten, ballpoint pen.

It would probably take you less than 10 minutes to learn this list and practice recalling it several times (remember to use retrieval practice!). If you were to do so, you would have a set of peg words on which you could “hang” memories. In fact, this mnemonic device is called the peg word technique. If you then needed to remember some discrete items—say a grocery list, or points you wanted to make in a speech—this method would let you do so in a very precise yet flexible way. Suppose you had to remember bread, peanut butter, bananas, lettuce, and so on. The way to use the method is to form a vivid image of what you want to remember and imagine it interacting with your peg words (as many as you need). For example, for these items, you might imagine a large gun (the first peg word) shooting a loaf of bread, then a jar of peanut butter inside a shoe, then large bunches of bananas hanging from a tree, then a door slamming on a head of lettuce with leaves flying everywhere. The idea is to provide good, distinctive cues (the weirder the better!) for the information you need to remember while you are learning it. If you do this, then retrieving it later is relatively easy. You know your cues perfectly (one is gun, etc.), so you simply go through your cue word list and “look” in your mind’s eye at the image stored there (bread, in this case).

This peg word method may sound strange at first, but it works quite well, even with little training (Roediger, 1980). One word of warning, though, is that the items to be remembered need to be presented relatively slowly at first, until you have practice associating each with its cue word. People get faster with time. Another interesting aspect of this technique is that it’s just as easy to recall the items in backwards order as forwards. This is because the peg words provide direct access to the memorized items, regardless of order.

How did Simon Reinhard remember those digits? Essentially he has a much more complex system based on these same principles. In his case, he uses “memory palaces” (elaborate scenes with discrete places) combined with huge sets of images for digits. For example, imagine mentally walking through the home where you grew up and identifying as many distinct areas and objects as possible. Simon has hundreds of such memory palaces that he uses. Next, for remembering digits, he has memorized a set of 10,000 images. Every four-digit number for him immediately brings forth a mental image. So, for example, 6187 might recall Michael Jackson. When Simon hears all the numbers coming at him, he places an image for every four digits into locations in his memory palace. He can do this at an incredibly rapid rate, faster than 4 digits per 4 seconds when they are flashed visually, as in the demonstration at the beginning of the module. As noted, his record is 240 digits, recalled in exact order. Simon also holds the world record in an event called “speed cards,” which involves memorizing the precise order of a shuffled deck of cards. Simon was able to do this in 21.19 seconds! Again, he uses his memory palaces, and he encodes groups of cards as single images.

Many books exist on how to improve memory using mnemonic devices, but all involve forming distinctive encoding operations and then having an infallible set of memory cues. We should add that to develop and use these memory systems beyond the basic peg system outlined above takes a great amount of time and concentration. The World Memory Championships are held every year and the records keep improving. However, for most common purposes, just keep in mind that to remember well you need to encode information in a distinctive way and to have good cues for retrieval. You can adapt a system that will meet most any purpose.

STAGES OF MEMORY: SENSORY MEMORY, SHORT-TERM MEMORY (WORKING

MEMORY), LONG-TERM MEMORY (DECLARATIVE – EPISODIC AND SEMANTIC; PROCEDURAL)

Types of Memory Sensory Memory

Sensory memory allows individuals to retain impressions of sensory information after the original stimulus has ceased. One of the most common examples of sensory memory is fast-moving lights in darkness: if you've ever lit a sparkler on the Fourth of July or watched traffic rush by at night, the light appears to leave a trail. This is because of "iconic memory," the visual sensory store. Two other types of sensory memory have been extensively studied: echoic memory (the auditory sensory store) and haptic memory (the tactile sensory store). Sensory memory is not involved in higher cognitive functions like short- and long-term memory; it is not consciously controlled. The role of sensory memory is to provide a detailed representation of our entire sensory experience for which relevant pieces of information are extracted by short-term memory and processed by working memory.

KEY TAKEAWAYS

Key Points

- Sensory memory allows individuals to recall great detail about a complex stimulus immediately following its presentation.
- There are different types of sensory memory, including iconic memory, echoic memory, and haptic memory.
- In sensory memory, no manipulation of the incoming information occurs, and the input is quickly transferred to the working memory.

KEY TERMS

- **sensory memory:** The brief storage (in memory) of information experienced by the senses; typically only lasts up to a few seconds.
- **iconic:** Visually representative.
- **echoic:** Imitative of a sound; onomatopoeic.

Sensory memory allows individuals to retain impressions of sensory information for a brief time after the original stimulus has ceased. It allows individuals to remember great sensory detail about a complex stimulus immediately following its presentation. Sensory memory is an automatic response considered to be outside of cognitive control. The information represented in this type of memory is the "raw data" which provides a snapshot of a person's overall sensory experience. Information from sensory memory has the shortest retention time, ranging from mere milliseconds to five seconds. It is retained just long enough for it to be transferred to short-term (working) memory.

In sensory memory, no manipulation of the incoming information occurs as it is transferred quickly to working memory. The amount of information is greatly reduced during this transfer because the capacity of working memory is not large enough to cope with all the input coming from our sense organs.

TYPES OF SENSORY MEMORY

It is assumed that there is a subtype of sensory memory for each of the five major senses (touch, taste, sight, hearing, and smell); however, only three of these types have been extensively studied: echoic memory, iconic memory, and haptic memory.

ICONIC MEMORY

Sensory input to the visual system goes into iconic memory, so named because the mental representations of visual stimuli are referred to as icons. Iconic memory has a duration of about 100 ms. One of the times that iconic memory is noticeable is when we see “light trails.” This is the phenomenon when bright lights move rapidly at night and you perceive them as forming a trail; this is the image that is represented in iconic memory.

Light trails: In iconic memory, you perceive a moving bright light as forming a continuous line because of the images retained in sensory memory for milliseconds.

ECHOIC MEMORY

Echoic memory is the branch of sensory memory used by the auditory system. Echoic memory is capable of holding a large amount of auditory information, but only for 3–4 seconds. This echoic sound is replayed in the mind for this brief amount of time immediately after the presentation of the auditory stimulus.

HAPTIC MEMORY

Haptic memory is the branch of sensory memory used by the sense of touch. Sensory receptors all over the body detect sensations like pressure, itching, and pain, which are briefly held in haptic memory before vanishing or being transported to short-term memory. This type of memory seems to be used when assessing the necessary forces for gripping and interacting with familiar objects. Haptic memory seems to decay after about two seconds. Evidence of haptic memory has only recently been identified and not as much is known about its characteristics compared to iconic memory.

SHORT-TERM MEMORY

Short-term memory is also known as working memory. It holds only a few items (research shows a range of 7 +/- 2 items) and only lasts for about 20 seconds. However, items can be moved from short-term memory to long-term memory via processes like rehearsal. An example of rehearsal is when someone gives you a phone number verbally and you say it to yourself repeatedly until you can write it down. If someone interrupts your rehearsal by asking a question, you can easily forget the number, since it is only being held in your short-term memory.

KEY TAKEAWAYS

Key Points

- Short-term memory acts as a scratchpad for temporary recall of information being processed. It decays rapidly and has a limited capacity.
- Rehearsal and chunking are two ways to make information more likely to be held in short-term memory.
- Working memory is related to short-term memory. It contains a phonological loop that preserves verbal and auditory data, a visuospatial scratchpad that preserves visual data, and a central manager that controls attention to the data.

KEY TERMS

- **chunking:** The splitting of information into smaller pieces to make reading and understanding faster and easier.

- **encoding:** The process of converting information into a construct that can be stored within the brain.
- **consolidation:** A process that stabilizes a memory trace after its initial acquisition.

Short-term memory is the capacity for holding a small amount of information in an active, readily available state for a brief period of time. It is separate from our long-term memory, where lots of information is stored for us to recall at a later time. Unlike sensory memory, it is capable of temporary storage. How long this storage lasts depends on conscious effort from the individual; without rehearsal or active maintenance, the duration of short-term memory is believed to be on the order of seconds.

CAPACITY OF SHORT-TERM MEMORY

Short-term memory acts as a scratchpad for temporary recall of information. For instance, in order to understand this sentence you need to hold in your mind the beginning of the sentence as you read the rest. Short-term memory decays rapidly and has a limited capacity.

The psychologist George Miller suggested that human short-term memory has a forward memory span of approximately seven items plus or minus two. More recent research has shown that this number is roughly accurate for college students recalling lists of digits, but memory span varies widely with populations tested and with material used.

For example, the ability to recall words in order depends on a number of characteristics of these words: fewer words can be recalled when the words have longer spoken duration (this is known as the word-length effect) or when their speech sounds are similar to each other (this is called the phonological similarity effect). More words can be recalled when the words are highly familiar or occur frequently in the language. Chunking of information can also lead to an increase in short-term memory capacity. For example, it is easier to remember a hyphenated phone number than a single long number because it is broken into three chunks instead of existing as ten digits.

Rehearsal is the process in which information is kept in short-term memory by mentally repeating it. When the information is repeated each time, that information is re-entered into the short-term memory, thus keeping that information for another 10 to 20 seconds, the average storage time for short-term memory. Distractions from rehearsal often cause disturbances in short-term memory retention. This accounts for the desire to complete a task held in short-term memory as soon as possible.

WORKING MEMORY

Though the term “working memory” is often used synonymously with “short-term memory,” working memory is related to but actually distinct from short-term memory. It holds temporary data in the mind where it can be manipulated. Baddeley and Hitch’s 1974 model of working memory is the most commonly accepted theory of working memory today. According to Baddeley, working memory has a phonological loop to preserve verbal data, a visuospatial scratchpad to control visual data, and a central executive to disperse attention between them.

PHONOLOGICAL LOOP

The phonological loop is responsible for dealing with auditory and verbal information, such as phone numbers, people’s names, or general understanding of what other people are talking about. We could roughly say that it is a system specialized for language. It consists of two parts: a

short-term phonological store with auditory memory traces that are subject to rapid decay, and an articulatory loop that can revive these memory traces. The phonological store can only store sounds for about two seconds without rehearsal, but the auditory loop can “replay them” internally to keep them in working memory. The repetition of information deepens the memory.

VISUOSPATIAL SKETCHPAD

Visual and spatial information is handled in the visuospatial sketchpad. This means that information about the position and properties of objects can be stored. The phonological loop and visuospatial sketchpad are semi-independent systems; because of this, you can increase the amount you can remember by engaging both systems at once. For instance, you might be better able to remember an entire phone number if you visualize part of it (using the visuospatial sketchpad) and then say the rest of it out loud (using the phonological loop).

CENTRAL EXECUTIVE

The central executive connects the phonological loop and the visuospatial sketchpad and coordinates their activities. It also links the working memory to the long-term memory, controls the storage of long-term memory, and manages memory retrieval from storage. The process of storage is influenced by the duration in which information is held in working memory and the amount that the information is manipulated. Information is stored for a longer time if it is semantically interpreted and viewed with relation to other information already stored in long-term memory.

TRANSPORT TO LONG-TERM MEMORY

The process of transferring information from short-term to long-term memory involves encoding and consolidation of information. This is a function of time; that is, the longer the memory stays in the short-term memory the more likely it is to be placed in the long-term memory. In this process, the meaningfulness or emotional content of an item may play a greater role in its retention in the long-term memory.

This greater retention is owed to an enhanced synaptic response within the hippocampus, which is essential for memory storage. The limbic system of the brain (including the hippocampus and amygdala) is not necessarily directly involved in long-term memory, but it selects particular information from short-term memory and consolidates these memories by playing them like a continuous tape.

LONG-TERM MEMORY

Long-term memories are all the memories we hold for periods of time longer than a few seconds; long-term memory encompasses everything from what we learned in first grade to our old addresses to what we wore to work yesterday. Long-term memory has an incredibly vast storage capacity, and some memories can last from the time they are created until we die.

There are many types of long-term memory. Explicit or declarative memory requires conscious recall; it consists of information that is consciously stored or retrieved. Explicit memory can be further subdivided into semantic memory (facts taken out of context, such as “Paris is the capital of France”) and episodic memory (personal experiences, such as “When I was in Paris, I saw the Mona Lisa”).

In contrast to explicit/declarative memory, there is also a system for procedural/implicit memory. These memories are not based on consciously storing and retrieving information, but on implicit

learning. Often this type of memory is employed in learning new motor skills. An example of implicit learning is learning to ride a bike: you do not need to consciously remember how to ride a bike, you simply do. This is because of implicit memory.

KEY TAKEAWAYS

Key Points

- Long-term memory is the final, semi-permanent stage of memory; it has a theoretically infinite capacity, and information can remain there indefinitely.
- Long-term memories can be categorized as either explicit or implicit memories.
- Explicit memories involve facts, concepts, and events, and must be recalled consciously.
- Explicit memories can be either semantic (abstract, fact-based) or episodic (based on a specific event).
- Implicit memories are procedures for completing motor actions.

KEY TERMS

- **long-term memory:** Memory in which associations among items are stored indefinitely; part of the theory of a dual-store memory model.
- **script:** A “blueprint” or routine for dealing with a specific situation.

If we want to remember something tomorrow, we have to consolidate it into long-term memory today. Long-term memory is the final, semi-permanent stage of memory. Unlike sensory and short-term memory, long-term memory has a theoretically infinite capacity, and information can remain there indefinitely. Long-term memory has also been called reference memory, because an individual must refer to the information in long-term memory when performing almost any task. Long-term memory can be broken down into two categories: explicit and implicit memory.

EXPLICIT MEMORY

Explicit memory, also known as conscious or declarative memory, involves memory of facts, concepts, and events that require conscious recall of the information. In other words, the individual must actively think about retrieving the information from memory. This type of information is explicitly stored and retrieved—hence its name. Explicit memory can be further subdivided into semantic memory, which concerns facts, and episodic memory, which concerns primarily personal or autobiographical information.

SEMANTIC MEMORY

Semantic memory involves abstract factual knowledge, such as “Albany is the capital of New York.” It is for the type of information that we learn from books and school: faces, places, facts, and concepts. You use semantic memory when you take a test. Another type of semantic memory is called a script. Scripts are like blueprints of what tends to happen in certain situations. For example, what usually happens if you visit a restaurant? You get the menu, you order your meal, you eat it, and then you pay the bill. Through practice, you learn these scripts and encode them into semantic memory.

EPISODIC MEMORY

Episodic memory is used for more contextualized memories. They are generally memories of specific moments, or episodes, in one’s life. As such, they include sensations and emotions associated with the event, in addition to the who, what, where, and when of what happened. An example of an episodic memory would be recalling your family’s trip to the beach.

Autobiographical memory (memory for particular events in one's own life) is generally viewed as either equivalent to, or a subset of, episodic memory. One specific type of autobiographical memory is a flashbulb memory, which is a highly detailed, exceptionally vivid "snapshot" of the moment and circumstances in which a piece of surprising and consequential (or emotionally arousing) news was heard. For example, many people remember exactly where they were and what they were doing when they heard of the terrorist attacks on September 11, 2001. This is because it is a flashbulb memory.

Semantic and episodic memory are closely related; memory for facts can be enhanced with episodic memories associated with the fact, and vice versa. For example, the answer to the factual question "Are all apples red?" might be recalled by remembering the time you saw someone eating a green apple. Likewise, semantic memories about certain topics, such as football, can contribute to more detailed episodic memories of a particular personal event, like watching a football game. A person that barely knows the rules of football will remember the various plays and outcomes of the game in much less detail than a football expert.

IMPLICIT MEMORY

In contrast to explicit (conscious) memory, implicit (also called "unconscious" or "procedural") memory involves procedures for completing actions. These actions develop with practice over time. Athletic skills are one example of implicit memory. You learn the fundamentals of a sport, practice them over and over, and then they flow naturally during a game. Rehearsing for a dance or musical performance is another example of implicit memory. Everyday examples include remembering how to tie your shoes, drive a car, or ride a bicycle. These memories are accessed without conscious awareness—they are automatically translated into actions without us even realizing it. As such, they can often be difficult to teach or explain to other people. Implicit memories differ from the semantic scripts described above in that they are usually actions that involve movement and motor coordination, whereas scripts tend to emphasize social norms or behaviors.

WORKING MEMORY FROM THE PSYCHOLOGICAL

Since the concept of working memory was introduced over 50 years ago, different schools of thought have offered different definitions for working memory based on the various cognitive domains that it encompasses.

The general consensus regarding working memory supports the idea that working memory is extensively involved in goal-directed behaviors in which information must be retained and manipulated to ensure successful task execution. Before the emergence of other competing models, the concept of working memory was described by the multicomponent working memory model proposed by Baddeley and Hitch. In the present article, the authors provide an overview of several working memory-relevant studies in order to harmonize the findings of working memory from the neurosciences and psychological standpoints, especially after citing evidence from past studies of healthy, aging, diseased, and/or lesioned brains.

In particular, the theoretical framework behind working memory, in which the related domains that are considered to play a part in different frameworks (such as memory's capacity limit and temporary storage) are presented and discussed.

From the neuroscience perspective, it has been established that working memory activates the fronto-parietal brain regions, including the prefrontal, cingulate, and parietal cortices. Recent

studies have subsequently implicated the roles of subcortical regions (such as the midbrain and cerebellum) in working memory.

Aging also appears to have modulatory effects on working memory; age interactions with emotion, caffeine and hormones appear to affect working memory performances at the neurobiological level. Moreover, working memory deficits are apparent in older individuals, who are susceptible to cognitive deterioration. Another younger population with working memory impairment consists of those with mental, developmental, and/or neurological disorders such as major depressive disorder and others.

A less coherent and organized neural pattern has been consistently reported in these disadvantaged groups. Working memory of patients with traumatic brain injury was similarly affected and shown to have unusual neural activity (hyper- or hypoactivation) as a general observation. Decoding the underlying neural mechanisms of working memory helps support the current theoretical understandings concerning working memory, and at the same time provides insights into rehabilitation programs that target working memory impairments from neurophysiological or psychological aspects.

Working memory has fascinated scholars since its inception in the 1960's (Baddeley, 2010; D'Esposito and Postle, 2015). Indeed, more than a century of scientific studies revolving around memory in the fields of psychology, biology, or neuroscience have not completely agreed upon a unified categorization of memory, especially in terms of its functions and mechanisms (Cowan, 2005, 2008; Baddeley, 2010).

From the coining of the term "memory" in the 1880's by Hermann Ebbinghaus, to the distinction made between primary and secondary memory by William James in 1890, and to the now widely accepted and used categorizations of memory that include: short-term, long-term, and working memories, studies that have tried to decode and understand this abstract concept called memory have been extensive (Cowan, 2005, 2008).

Short and long-term memory suggest that the difference between the two lies in the period that the encoded information is retained. Other than that, long-term memory has been unanimously understood as a huge reserve of knowledge about past events, and its existence in a functioning human being is without dispute (Cowan, 2008). Further categorizations of long-term memory include several categories:

1. episodic;
2. semantic;
3. Pavlovian; and
4. procedural memory (Humphreys et al., 1989). For example, understanding and using language in reading and writing demonstrates long-term storage of semantics. Meanwhile, short-term memory was defined as temporarily accessible information that has a limited storage time (Cowan, 2008).

Holding a string of meaningless numbers in the mind for brief delays reflects this short-term component of memory.

Thus, the concept of working memory that shares similarities with short-term memory but attempts to address the oversimplification of short-term memory by introducing the role of information

manipulation has emerged (Baddeley, 2012). This article seeks to present an up-to-date introductory overview of the realm of working memory by outlining several working memory studies from the psychological and neurosciences perspectives in an effort to refine and unite the scientific knowledge concerning working memory.

EPISODIC MEMORY

Episodic memory refers to any events that can be reported from a person's life.

This covers information such as any times, places involved – for example, when you went to the zoo with a friend last week. It is a type of 'declarative' memory, i.e. it can be explicitly inspected and recalled consciously. Episodic memory can be split further into autobiographical episodic memory (memories of specific episodes of one's life) and experimental episodic memory (where learning a fact [a semantic memory, below] has been associated with memory of the specific life episode when it was learned). Flashbulb memories are detailed autobiographical episodic memories that are stored permanently in LTM when they are first learned, often because they were of emotional or historical importance in that person's life (e.g. a birth or a death).

SEMANTIC MEMORY

Like episodic memory, semantic memory is also a type of 'declarative' (explicit, consciously recalled) memory.

However, the conscious recall here is of facts that have meaning, as opposed to the recall of past life events associated with episodic memory. For instance, recalling that you listen to music using your ears does not require knowing when or where you first learned this fact.

PROCEDURAL MEMORY

Procedural memory describes our implicit knowledge of tasks that usually do not require conscious recall to perform them. One example would be riding a bike – you might struggle to consciously recall how to manage the task, but we can [unconsciously] perform it with relative ease.

THEORIES OF FORGETTING: INTERFERENCE, RETRIEVAL FAILURE, DECAY, MOTIVATED FORGETTING

The Interference Theory

What did you have for dinner Tuesday night of last week? Is that difficult to recall? If someone had asked you that question Wednesday morning, you probably would have had no problem recalling what you had for dinner the night before.

But as intervening days pass, the memories of all the other meals you have eaten since then start to interfere with your memory of that one particular meal. This is a good example of what psychologists call the interference theory of forgetting.⁴

According to interference theory, forgetting is the result of different memories interfering with one another. The more similar two or more events are to one another, the more likely interference will occur.

It is difficult to remember what happened on an average school day two months ago because so many other days have occurred since then. Unique and distinctive events, however, are less likely

to suffer from interference. Your high school graduation, wedding, and the birth of your first child are much more likely to be recalled because they are singular events—days like no other.

Interference also plays a role in what is known as the **serial position effect**, or the tendency to recall the first and last items of a list.⁵ For example, imagine that you wrote down a shopping list but forgot to take it with you to the store. In all likelihood, you will probably be able to easily recall the first and last items on your list, but you might forget many of the items that were in the middle.

The first thing you wrote down and the last thing you wrote down stand out as being more distinct, while the fourth item and seventh item might seem so similar that they interfere with each other. There are two basic types of interference that can occur:⁴

- **Retroactive interference** happens when newly acquired information interferes with old memories. For example, a teacher learning the names of her new class of students at the start of a school year might find it more difficult to recall the names of the students in her class last year. The new information interferes with the old information.
- **Proactive interference** occurs when previously learned information makes it more difficult to form new memories. Learning a new phone number or locker combination might be more difficult, for example, because your memories of your old phone number and combination interfere with the new information.

Eliminating interference altogether is impossible, but there are a few things you can do to minimize its effects. One of the best things you can do is rehearse new information in order to better commit it to memory. In fact, many experts recommend overlearning important information, which involves rehearsing the material over and over again until it can be reproduced perfectly with no errors.⁶

Another tactic to fight interference is to switch up your routine and avoid studying similar material back to back. For example, don't try to study vocabulary terms for your Spanish language class right after studying terms for your German class. Break up the material and switch to a completely different subject each study session.

Sleep also plays an essential role in memory formation. Researchers suggest that sleeping after you learn something new is one of the best ways to turn new memories into lasting ones.

THE DECAY THEORY OF FORGETTING

According to the trace theory of memory, physical and chemical changes in the brain result in a memory "trace." Information in short-term memory lasts several seconds and if it is not rehearsed, the neurochemical memory trace quickly fades.⁸ According to the trace decay theory of forgetting, the events that happen between the formation of a memory and the recall of the memory have no impact on recall.⁹

Trace theory proposes that the length of time between the memory and recalling that information determines whether the information will be retained or forgotten. If the time interval is short, more information will be recalled. If a longer period of time passes, more information will be forgotten and memory will be poorer.

The idea that memories fade over time is hardly new. The Greek philosopher Plato suggested such a thing more than 2,500 years ago. Later, experimental research by psychologists such as Ebbinghaus bolstered this theory.²

One of the problems with this theory is that it is difficult to demonstrate that time alone is responsible for declines in recall. In real-world situations, many things happen between the formation of a memory and the recall of that information. A student who learns something in class, for example, might have hundreds of unique and individual experiences between learning that information and having to recall it on an exam.

Was forgetting the date that the American Revolutionary War began due to the length of time between learning the date in your American History class and being tested on it? Or did the multitude of information acquired during that interval of time play a role? Testing this can be exceedingly difficult. It is nearly impossible to eliminate all the information that might have an influence on the creation of the memory and the recall of the memory.

Another problem with decay theory is it does not account for why some memories fade quickly while others linger. Novelty is one factor that plays a role. For example, you are more likely to remember your very first day of college than all of the intervening days between it and graduation. That first day was new and exciting, but all the following days probably seem quite similar to each other.

RETRIEVAL FAILURE THEORY

Retrieval failure is where the information is in long term memory, but cannot be accessed. Such information is said to be available (i.e. it is still stored) but not accessible (i.e. it cannot be retrieved). It cannot be accessed because the retrieval cues are not present.

When we store a new memory we also store information about the situation and these are known as retrieval cues. When we come into the same situation again, these retrieval cues can trigger the memory of the situation. Retrieval cues can be: **External / Context** - in the environment, e.g. smell, place etc. **Internal / State** - inside of us, e.g. physical, emotional, mood, drunk etc.

There is considerable evidence that information is more likely to be retrieved from long-term memory if appropriate retrieval cues are present. This evidence comes from both laboratory experiments and everyday experience. A retrieval cue is a hint or clue that can help retrieval.

Tulving (1974) argued that information would be more readily retrieved if the cues present when the information was encoded were also present when its retrieval is required. For example, if you proposed to your partner when a certain song was playing on the radio, you will be more likely to remember the details of the proposal when you hear the same song again. The song is a retrieval cue - it was present when the information was encoded and retrieved.

Tulving suggested that information about the physical surroundings (external context) and about the physical or psychological state of the learner (internal context) is stored at the same time as information is learned. Reinstating the state or context makes recall easier by providing relevant information, while retrieval failure occurs when appropriate cues are not present. For example, when we are in a different context (i.e. situation) or state.

CONTEXT (EXTERNAL) CUES

Retrieval cues may be based on context - the setting or situation in which information is encoded and retrieved. Examples include a particular room, driving along a motorway, a certain group of people, a rainy day and so on.

Context also refers to the way information is presented. For example, words may be printed, spoken or sung, they may be presented in meaningful groups - in categories such as lists of animals or furniture - or as a random collection without any link between them. Evidence indicates that retrieval is more likely when the context at encoding matches the context at retrieval.

You may have experienced the effect of context on memory if you have ever visited a place where you once lived (or an old school). Often such a visit helps people recall lots of experiences about the time they spent there which they did not realize were stored in their memory.

A number of experiments have indicated the importance of context-based cues for retrieval. An experiment conducted by **Tulving and Pearlstone (1966)** asked participants to learn lists of words belonging to different categories, for example names of animals, clothing and sports.

Participants were then asked to recall the words. Those who were given the category names recalled substantially more words than those who were not. The categories provided a context, and naming the categories provided retrieval cues. Tulving and Pearlstone argued that cue-dependent forgetting explains the difference between the two groups of participants. Those who recalled fewer words lacked appropriate retrieval cues.

An interesting experiment conducted by **Baddeley (1975)** indicates the importance of setting for retrieval. Baddeley (1975) asked deep-sea divers to memorize a list of words. One group did this on the beach and the other group underwater. When they were asked to remember the words half of the beach learners remained on the beach, the rest had to recall underwater.

Half of the underwater group remained there and the others had to recall on the beach. The results show that those who had recalled in the same environment (i.e. context) which they had learned recalled 40% more words than those recalling in a different environment. This suggests that the retrieval of information is improved if it occurs in the context in which it was learned.

State (internal) Dependent Cues The basic idea behind state-dependent retrieval is that memory will be best when a person's physical or psychological state is similar at encoding and retrieval.

For example, if someone tells you a joke on Saturday night after a few drinks, you'll be more likely to remember it when you're in a similar state - at a later date after a few more drinks. Stone cold sober on Monday morning, you'll be more likely to forget the joke.

State retrieval clues may be based on the physical or psychological state of the person when information is encoded and retrieved. For example, a person may be alert, tired, happy, sad, drunk or sober when the information was encoded. They will be more likely to retrieve the information when they are in a similar state.

Tulving and Pearlstone's (1966) study involved **external cues** (e.g. presenting category names). However, cue-dependent forgetting has also been shown with **internal cues** (e.g. mood state). Information about current mood state is often stored in the memory trace, and there is more forgetting if the mood state at the time of retrieval is different. The notion that there should be less forgetting when the mood state at learning and at retrieval is the same is generally known as **mood-state-dependent memory**.

A study by **Goodwin et al. (1969)** investigated the effect of alcohol on state-dependent retrieval.

They found that when people encoded information when drunk, they were more likely to recall it in the same state. For example, when they hid money and alcohol when drunk, they were unlikely to find them when sober. However, when they were drunk again, they often discovered the hiding place.

Other studies found similar state-dependent effects when participants were given drugs such as marijuana.

People tend to remember material better when there is a match between their mood at learning and at retrieval. The effects are stronger when the participants are in a positive mood than a negative mood. They are also greater when people try to remember events having personal relevance.

EVALUATION

According to retrieval-failure theory, forgetting occurs when information is available in LTM but is not accessible. Accessibility depends in large part on retrieval cues. Forgetting is greatest when context and state are very different at encoding and retrieval. In this situation, retrieval cues are absent and the likely result is cue-dependent forgetting.

There is considerable evidence to support this theory of forgetting from laboratory experiments. The ecological validity of these experiments can be questioned, but their findings are supported by evidence from outside the laboratory.

For example, many people say they can't remember much about their childhood or their school days. But returning to the house in which they spent their childhood or attending a school reunion often provides retrieval cues which trigger a flood of memories.

MOTIVATED FORGETTING IN EARLY

Educators assume that students are motivated to retain what they are taught. Yet, students commonly report that they forget most of what they learn, especially in mathematics. In the current study I ask whether students may be motivated to forget mathematics because of academic experiences threaten the self-perceptions they are committed to maintaining. Using a large dataset of 1st and 2nd grade children (N = 812), I hypothesize that math anxiety creates negative experiences in the classroom that threaten children's positive math self-perceptions, which in turn spurs a motivation to forget mathematics.

I argue that this motivation to forget is activated during the winter break, which in turn reduces the extent to which children grow in achievement across the school year. Children were assessed for math self-perceptions, math anxiety and math achievement in the fall before going into winter break. During the spring, children's math achievement was measured once again.

A math achievement growth score was devised from a regression model of fall math achievement predicting spring achievement. Results show that children with higher math self-perceptions showed reduced growth in math achievement across the school year as a function of math anxiety. Children with lower math interest self-perceptions did not show this relationship. Results serve as a proof-of-concept for a scientific account of motivated forgetting within the context of education.

INTRODUCTION

Despite all of the effort that students put into studying, they commonly report that knowledge is

rapidly lost once a course is over. While the belief in a total loss of formally acquired knowledge is false (Bahrlick, 1979), it is true that students experience a significant amount of forgetting soon after the completion of a course (Conway et al., 1991; Kamuche and Ledman, 2011). Research on long-term retention of classroom knowledge reports that forgetting arises because of blocked learning schedules (Landauer and Bjork, 1978; Dempster, 1992), a lack of subsequent relearning (Bahrlick and Phelps, 1987; Bahrlick and Hall, 1991; Cooper et al., 2000; Deslauriers and Wieman, 2011), poor initial knowledge structures and shallow levels of understanding gained during the course itself (Conway et al., 1991). In this article, I consider an alternative explanation. I draw on the suppression and threat based coping literature to argue that students themselves may be motivated to forget due to negative academic experiences that threaten their self-perceptions.

MOTIVATED FORGETTING
